Organisation

CONGRESS PRESIDENTS

- Samuele Marcora - Congress President (ITA)
- Marco Narici - Congress Vice President (ITA)

ECSS EXECUTIVE BOARD

- Alexander Ferrauti - President (GER)
- Janice L. Thompson - President Elect (UK)
- Jørn Wulff Helge - Past President (DEN)
- Elke Grimminger-Seidensticker (GER)
- Andrew Jones (UK)
- Truls Raastad (NOR)

ECSS SCIENTIFIC BOARD

- Maria Francesca Piacentini - Chair (ITA)
- Markus Gruber - Co-Chair (GER)
- Maurizio Bertollo (ITA)
- Jafin Burniston (UK)
- Tim Cable (UK)
- Christian Couppé (DEN)
- Anne-Marie Elbe (GER)
- Peter Federolf (AUT)
- José González-Alonso (UK)
- Amelia Guadalupe Grau (ESP)
- Robert Lamberts (NED)
- Olivier Seynnes (NOR)
- Johannes Van Lieshout (NED)

ECSS SCIENTIFIC COMMITTEE

- Per Aagaard (DEN)
- Ignacio Ara (ESP)
- Leigh Breen (UK)
- Aaron Coutts (AUS)
- Sally Fenton (UK)
- Martino Franchi (ITA)
- Keith George (UK)
- Andrew Lane (UK)
- Pierre-Nicolas Lemyre (CAN)
- Uros Marusic (SVN)
- Ryoichi Nagatomi (JPN)
- Fernando Pareja Blanco (ESP)
- Dace Reihmane (LVA)
- Ramona Ritzmann (GER)
- Bart Roelands (BEL)
- Wolfgang Taube (SUI)
- Lex Verdijk (NED)
- Tobias Vogt (GER)

ECSS REVIEWING PANEL

- Julian Alcazar (ESP)
- Stephen Bailey (UK)
- Nick Ball (AUS)
- Bill Baltzopoulos (UK)
- Marco Beato (UK)
- Gregory Bogdanis (GRE)
- Matteo Bonato (ITA)
- Ulrike Burrmann (GER)
- Neil Cronin (FIN)
- Christopher Gaffney (UK)
- Dominic Gehring (GER)
- Daniel Green (AUS)
- Sidney Grospretre (FRA)
- Mette Hansen (DEN)
- Ilkka Heinonen (FIN)
- Kristin Jonvik (NOR)
- Jaak Jürimäe (EST)
- Pascale Kippelen (UK)
- Benedikt Lauber (SUI)
- Stefan Josef Lindinger (SWE)
- Jamie McPhee (UK)
- Fabian Möller (USA)
- David Morales-Álamo (ESP)
- Hannah Rice (NOR)
- Miriam Seyda (GER)
- Christopher Shaw (AUS)
- Ana Sousa (POR)
- Mike Stembridge (UK)
- Ian Taylor (UK)

ECSS ADMINISTRATION

- Thomas Giel - Managing Director (GER)
- Elena Jacobi - Vice Managing Director (GER)
- Elias Tsolakidis - Technical Director (GRE)
- Vinisha Prashant - Communications Manager (IND)
- Nicolas Puhe - Office Manager (GER)
- Pablo García González - Office Manager (ESP)
- Konstantina Patera - Congress Secretariat (GRE)

LOCAL SCIENTIFIC COMMITTEE

- Antonio Paoli - Co-Chair (ITA)
- Giuseppe De Vito - Co-Chair (ITA)
- Elena Barbieri (ITA)
- Laura Bragonzoni (ITA)
- Tatiana Moro (ITA)
- Ivan Malagoli Lanzoni (ITA)
- Silvia Fantozzi (ITA)
- Andrea Casolo (ITA)
- Marta Ghisi (ITA)
- Athanasios Pappous (ITA)

LOCAL ORGANISING COMMITTEE

- Rocco Di Michele - Chair (ITA)
- Martino Franchi - Head of Volunteers (ITA)
- Sandro Bartolomei - Head of Social Events (ITA)
- Ricardo Barbieri - Head of Media/Marketing (ITA)
- Matteo Cortesi – Head of Sponsorship (ITA)
- Erica Gobbi (ITA)
- Erika Ercolani (ITA)
- Shara Cattarozzi (ITA)
- Giovanni Martino (ITA)
- Silvia Pertegato (ITA)

Welcome to ECSS Rimini 2025

It is with great pleasure that we announce our hosting of the 30th ECSS Annual Congress in 2025 in the charming city of Rimini, through a collaboration between the Universities of Bologna and Padova. Above all, we are thrilled to bring the ECSS Annual Congress back to Italy after a span of 26 years, following the ECSS Congress held in Rome in 1999. At that time, there were no sport and exercise science programmes in Italian universities. Since then, sport science has developed quickly in Italy and we look forward to promoting it further by welcoming our colleagues across Europe and the rest of the world.

ECSS Rimini 2025 will take place at the Palacongressi di Rimini, a modern and attractive convention centre capable of accommodating over 9,000 attendees. This venue is conveniently located within walking distance of the city centre, hotels and the picturesque Adriatic seafront.

Rimini, with its origins dating back to 268 BC as the Roman Ariminum, boasts a captivating historic centre adorned with ancient Roman monuments, renaissance squares and architectural wonders. The city is home to churches embellished with treasures and works of art, allowing visitors to immerse themselves in its rich history. Additionally, Rimini proudly hosts the Federico Fellini Museum, dedicated to the world-famous film director who was born in the city.

The city's seafront stretches over 15 kilometres, offering access to 250 seaside resorts, cycle paths and sports facilities. Rimini is also renowned for its vibrant nightlife, featuring some of Italy's most famous venues. Rimini also serves as the nucleus of the Wellness Valley, established in 2003. This initiative aims to transform the Romagna region into a leading hub for knowledge and culture related to wellness and the quality of life. This mission aligns seamlessly with the ECSS's objective of disseminating high-quality, innovative science that makes a meaningful impact within the sports science community and society at large.

The Universities of Bologna and Padova have collaborated closely with the ECSS Scientific Board to deliver an outstanding scientific programme. This programme will encompass recent advancements in muscle biology, physiology and biophysics, as well as topics such as inactivity and aging, motor control, nutrition, physical activity and health, performance in extreme environments, exercise and sports medicine, psychology and social sciences. In addition, applied sports sciences, including Olympic winter sports, motorsports, football, cycling and other endurance sports, will also be addressed, along with physical performance of military personnel. A particular emphasis will be given to promote a multidisciplinary and interdisciplinary approach within sport science to break the barriers that often divide the biomedical and the psychosocial sciences applied to sport and physical activity.

We eagerly anticipate welcoming you to Rimini, where we can exchange knowledge within the ECSS scientific community in the vibrant, joyful and lively backdrop of this beautiful city along the Adriatic riviera.

Yours in Sport Science,

The ECSS Rimini 2025 Organising Team
Prof Samuele Marcora (Congress President)
University of Bologna

Prof Marco Narici (Congress Vice President)
University of Padova

Table of Contents

ORGANISATION.....	3
WELCOME TO ECSS RIMINI 2025	6
TABLE OF CONTENTS	7
TUESDAY, 1 JULY 2025.....	18
12:00 - 13:15	18
OP-PN17 PHYSIOLOGY AND METHODOLOGY OF MUSCLE ADAPTATION TO EXERCISE	18
IS-BM01 NEUROMOTOR STABILITY CONTROL AND INTER-TASK GENERALISATION IN IRREGULAR HUMAN GAIT	20
IS-MH01 REDS PREVENTION: NAVIGATING BARRIERS AND HARNESSING OPPORTUNITIES	22
IS-EX01 ECSS-ECSS EXCHANGE SYMPOSIUM – TECHNOLOGY SUPPORT IN FOOTBALL YOUTH PERFORMANCE PROGRESSION IN THE MILLENNIUM ERA	23
GSSI	24
OP-AP01 CYCLING I	26
OP-BM13 SPORTS TECHNOLOGY MARKER LESS	29
OP-MH01 HIT	32
OP-MH20 AEROBIC EXERCISE AND CANCER.....	35
OP-PN11 NUTRITION I - AMINO ACIDS AND PROTEIN II	38
OP-SH01 ATHLETE PSYCHOLOGY	41
OP-PN16 RESPIRATORY / PULMONARY PHYSIOLOGY	43
OP-MH19 PHYSIOTHERAPY	46
OP-MH37 LIFESTYLE.....	49
13:30 - 14:45	51
IS-SH01 ECSS-FEPSAC INVITED SYMPOSIA-PSYCHOLOGICAL FIRST AID: WELFARE STRATEGIES AT MAJOR SPORTS EVENTS	51
OP-PN19 EXERCISE AND ENERGY INTAKE.....	52
IS-MH02 INTERNATIONAL PERSPECTIVE ON HOW PA IMPACTS MOTHER, CORD, & BABY METABOLOME & INFLAMMATION.....	54
OP-PN01 PHYSIOLOGY OF FATIGUE I	56
IS-PN01 HUMAN SKELETAL MUSCLE PLASTICITY STUDIED WITH SINGLE-NUCLEI RNA SEQUENCING AND NOVEL SPATIAL PROTEOMIC APPROACHES.....	59
OP-AP02 RUNNING I	60
OP-BM01 MOTOR CONTROL	63
OP-BM21 NEUROMUSCULAR FATIGUE	66
OP-MH21 PHYSICAL TRAINING IN CANCER PATIENTS.....	68
OP-PN12 METABOLOMICS AND HEALTH	71
OP-PN18 NUTRITION II - CAFFEINE	74
OP-MH39 CARDIOVASCULAR DISEASE	77
OP-MH38 METABOLIC FLEXIBILITY	79

OP-MH36 RESPIRATORY DISEASE	81
WEDNESDAY, 2 JULY 2025	84
08:00 - 09:15	84
IS-EX02 JSPFSM-ECSS EXCHANGE SYMPOSIUM: NEW PERSPECTIVE OF EXERCISE-COGNITION INTERACTION	84
OP-AP09 TRAINING AND TESTING I - RUNNING.....	85
IS-MH03 RECENT EFFORTS BY THE INTERNATIONAL SKI AND SNOWBOARD FEDERATION (FIS) TO REDUCE THE RISK OF INJURY IN COMPETITIVE SNOW SPORTS FOR THE WINTER OLYMPIC GAMES IN MILANO CORTINA, ITALY.....	87
OP-PN02 RESISTANCE TRAINING AND NUTRITION	88
IS-PN02 POWER, BREATH, AND BEAT: EXPLORING FEMALE MUSCULAR, PULMONARY, AND CARDIOVASCULAR PHYSIOLOGY	91
OP-AP03 TEAM SPORTS I.....	92
OP-BM02 NEUROMUSCULAR PHYSIOLOGY I	95
OP-MH02 CLINICAL POPULATION GROUPS	98
OP-PN13 MOLECULAR BIOLOGY OF EXERCISE AND DISEASES.....	101
OP-MH04 WEIGHT LOSS I	103
OP-SH12 MENTAL HEALTH AND WELL-BEING IN ATHLETES.....	106
OP-PN22 CARDIOVASCULAR PHYSIOLOGY I	108
OP-PN21 GUT AND MICROBIOME	111
OP-MH40 EXERCISE THERAPY / BEDREST.....	114
09:30 - 10:45	116
OP-AP10 TEAM SPORTS II - FATIGUE AND RECOVERY	116
IS-BM02 THE POWER OF ECCENTRIC CONTRACTIONS ON MUSCLE ADAPTATION, REMODELING, AND FUNCTION IN OLD AGE: THE POSITIVES OF NEGATIVES.....	119
IS-MH04 WHY IS ELITE ATHLETE ORAL HEALTH SO POOR AND WHAT CAN WE DO TO REVERSE THE PERFORMANCE IMPACTS?	121
OP-PN03 ENDURANCE PHYSIOLOGY I	122
OP-AP06 TALENT IDENTIFICATION	125
OP-AP04 WINTER SPORTS	127
OP-BM03 SPORTS INJURY	130
OP-BM14 GAIT.....	133
OP-PN20 HYPOXIA AND BRAIN	136
OP-MH05 WEIGHT LOSS II	139
OP-SH02 PSYCHOLOGY I - MENTAL FATIGUE	141
OP-MH42 SEDENTARY BEHAVIOUR	144
OP-PN23 IMMOBILISATION AND BED REST	146
OP-SH03 PHILOSOPHY AND ETHICS	149
11:00 - 12:15	152
IS-EX03 ACSM-ECSS EXCHANGE SYMPOSIUM: LACTATE METABOLISM	152
IS-BM03 BIOMECHANICAL AND PHYSIOLOGICAL TRADE-OFFS IN SPRINT AND ENDURANCE PERFORMANCE: LESSONS FROM THE ANIMAL KINGDOM TO HUMAN ATHLETES	153
OP-PN25 THERMOREGULATION	154

OP-PN04 FEMALE PHYSIOLOGY	157
OP-AP12 TRAINING AND TESTING II - MATURITY, RELATIVE AGE AND PERFORMANCE	160
OP-AP05 RESISTANCE TRAINING	163
OP-AP11 TEAM SPORTS III - BASKETBALL	165
OP-MH03 SPORTS MEDICINE AND ORTHOPEDICS I	168
OP-BM15 CORTICOSPINAL RESPONSES	170
OP-SH11 MENTAL HEALTH	173
OP-MH18 HEALTH AND FITNESS - CHILDREN	176
OP-PN14 MOLECULAR BIOLOGY AND BIOCHEMISTRY I - OMICS AND TRAINING	179
OP-MH35 ANKLE INJURIES	181
OP-SH13 PHYSICAL EDUCATION I	184
13:15 - 14:30	187
OP-PN15 ENDURANCE PHYSIOLOGY II	187
OP-PN27 MUSCLE DAMAGE AND REPAIR	190
IS-AP02 FEMALE HEALTH AND MENSTRUAL CYCLE RESEARCH; DO WE NEED TO CHANGE OUR APPROACH? A CALL FOR ACTION	192
IS-BM07 THE AGING BRAIN IN MOTOR CONTROL AND BALANCE LEARNING: FROM MOLECULES TO NEURONS AND NETWORKS	194
IS-PN03 FROM SEA TO SPACE - HUMAN PHYSIOLOGY AND PERFORMANCE IN THE EXTREME ENVIRONMENTS UNDERWATER, HIGH-ALTITUDE, AND WEIGHTLESSNESS	195
OP-AP13 TRAINING AND TESTING III - INTERVAL / SPRINT TRAINING	197
OP-BM04 NEUROMUSCULAR PHYSIOLOGY II	199
OP-AP08 MACHINE LEARNING IN TEAM SPORTS	202
OP-AP07 COMBAT SPORTS	205
OP-PN26 MIXED PHYSIOLOGY - SLEEP, BRAIN AND BLOOD BIOMARKERS	208
OP-SH14 DECISION MAKING	210
OP-AP43 RUNNING II - ULTRA AND LONG DISTANCE	213
OP-PN24 MOLECULAR BIOLOGY AND BIOCHEMISTRY II	216
OP-SH22 SOCIOLOGY I	219
14:45 - 16:00	221
IS-AP01 NAVIGATING THE PERCEPTION OF TIME IN SPORT: PSYCHOLOGICAL AND PHYSIOLOGICAL INSIGHTS	221
OP-PN28 PHYSIOLOGY OF FATIGUE II	222
OP-PN05 PHYSIOLOGY	225
IS-BM04 NEURAL MODULES IN THE CONTROL OF MOVEMENT: ASSESSING THE UTILITY OF EMG RECORDINGS	228
OP-AP14 TEAM SPORTS IV - RUGBY AND AUSTRALIAN FOOTBALL	229
OP-MH22 RESISTANCE TRAINING IN OLDER ADULTS	231
OP-BM16 SPORTS BIOMECHANICS	233
OP-PN06 NUTRITION III - AMINO ACIDS AND PROTEIN I	236
OP-PN29 CARDIOVASCULAR PHYSIOLOGY II	239
OP-AP44 SPORTS EQUIPMENT	242
OP-SH10 PHYSICAL ACTIVITY PROMOTION IN CHILDREN	244
OP-SH21 FEMALE SPORT AND PHYSICAL ACTIVITY	247

OP-SH20 PSYCHOLOGY II - MIXED SESSION I	249
OP-MH41 INTERVENTIONS I	252
16:30 - 17:30	255
CP-AP01 TRAINING AND TESTING I - MIXED	255
CP-AP02 STATISTICS AND ANALYSES I - TEAM SPORTS.....	260
CP-AP04 SPORTS EQUIPMENT	263
CP-AP05 SPORTS TECHNOLOGY / MONITORING I	268
CP-AP10 COACHING I - TEAM SPORTS.....	272
CP-AP13 COACHING II - MIXED	275
CP-AP15 INDIVIDUAL SPORTS.....	280
CP-AP16 COMBAT SPORTS AND STRENGTH	284
CP-AP17 HANDBALL, VOLLEYBALL AND FOOTBALL.....	289
CP-AP18 POWER AND STRENGTH I	293
CP-AP21 FOOTBALL	298
CP-AP24 SWIMMING.....	302
CP-AP30 TRAINING AND TESTING II - MIXED.....	306
CP-BM01 BIOMECHANICS AND MOTOR CONTROL - MIXED.....	309
CP-BM04 MUSCLE AND TENDON MECHANICS	314
CP-BM10 JUMPING AND SQUATING I.....	319
CP-BM14 KINEMATICS	324
CP-BM16 BIOMECHANICS - MIXED	327
CP-MH01 HEALTH AND FITNESS I - MIXED	332
CP-MH02 SPORTS MEDICINE AND REHABILITATION - MIXED	338
CP-MH03 SPORTS MEDICINE	342
CP-MH04 AGEING I	346
CP-MH05 CANCER I.....	350
CP-MH06 CARDIOVASCULAR HEALTH.....	355
CP-MH08 EXERCISE DURING PREGNANCY / OBESITY.....	360
CP-SH05 PHYSICAL ACTIVITY PROMOTION I.....	365
CP-PN01 MUSCLE METABOLISM	367
CP-PN02 SEX DIFFERENCES AND THE FEMALE ATHLETE.....	373
CP-PN03 PHYSIOLOGY AND NUTRITION - MIXED	377
CP-PN11 HYPOXIA, PHYSIOLOGY AND HIGH ALTITUDE	380
CP-PN12 MOLECULAR SIGNALING.....	386
CP-SH01 SOCIAL SCIENCES - MIXED	390
CP-SH09 PHYSICAL EDUCATION I.....	396
CP-SH18 MENTORING / COACHING I - MIXED	401
CP-SH20 PSYCHOLOGY I - MIXED	405
CP-SH21 PSYCHOLOGY II - MIXED	410
17:45 - 19:00	413
PS-PL01 DSD- AND TRANS-ATHLETES IN THE FEMALE CATEGORY: SCIENTIFIC AND ETHICAL CONTROVERSIES.....	413

THURSDAY, 3 JULY 2025	416
08:30 - 09:45	416
IS-SH02 FROM THE PITCH TO THE LAB AND BACK AGAIN: IDENTIFYING, UNDERSTANDING AND DEALING WITH THE VARIOUS EFFECTS OF FATIGUE ON SPORT AND EXERCISE PERFORMANCE	416
OP-AP15 TEAM SPORTS V - CHANGE OF DIRECTION AND JUMPING	417
IS-PN04 DIGITAL HEALTH EXERCISE INTERVENTIONS FOR PRIMARY AND SECONDARY CARDIOVASCULAR DISEASE PREVENTION: INNOVATIONS FROM 3 EUROPEAN COUNTRIES	419
OP-AP16 TRAINING AND TESTING IV - POWER AND STRENGTH: SPORT-SPECIFIC ASPECTS	420
OP-BM17 RUNNING III	423
OP-BM05 MUSCLE TENDON FUNCTION	426
OP-MH23 ENDURANCE TRAINING IN OLDER ADULTS	429
OP-PN30 HYPOXIA AND TRAINING	431
OP-PN07 NUTRITION IV - VITAMIN D AND OTHER SUPPLEMENTS	434
OP-MH06 WEIGHT LOSS III	437
OP-AP17 SWIMMING I - STRENGTH TRAINING	439
OP-AP18 COACHING I - PSYCHOLOGY	441
OP-MH44 CARDIOVASCULAR DISEASE AND DISFUNCTION	443
OP-MH07 ORTHOPEDICS	446
10:00 - 11:15	448
OP-PN31 PHYSIOLOGY OF FATIGUE III	448
OP-AP22 POWER AND STRENGTH I - POST-ACTIVATION PERFORMANCE ENHANCEMENT	451
IS-MH06 DIVERSITY IN MECHANISMS UNDERLYING IMPAIRMENTS TO EXERCISE AND RECOVERY IN TYPE 1 DIABETES	454
IS-BM05 CYCLIC PROPULSION IN SPORTS	455
OP-AP23 TEAM SPORTS VI - FEMALE FOOTBALL	456
IS-AP03 OPTIMISING THE WARFIGHTER: APPLYING SPORT SCIENCE IN THE MILITARY CONTEXT	458
OP-MH24 FITNESS AND COGNITION IN OLDER ADULTS	459
OP-BM18 MUSCLE DISUSE AND AGEING	462
OP-PN08 NUTRITION V - SUPPLEMENTS AND SUPERFOODS	464
OP-AP21 TRAINING AND TESTING VI - COGNITIVE PERFORMANCE AND COORDINATION	467
OP-AP19 TRAINING AND TESTING V - HYROX, CROSSFIT AND ROWING	470
OP-MH11 MENTAL DISABILITIES	473
OP-SH04 SOCIOLOGY II - GENDER	475
OP-SH15 PHYSICAL EDUCATION II	478
11:30 - 12:45	481
PS-PL02 MECHANISMS OF HUMAN SKELETAL MUSCLE HYPERTROPHY: SORTING THE WHEAT FROM THE CHAFF ...	481
13:45 - 15:00	482
OP-PN33 PHYSIOLOGY OF FATIGUE IV	482
OP-PN34 CARBOHYDRATES	485
OP-AP24 SWIMMING II - RECOVERY AND SLEEP	487
IS-BM06 EXERCISE AND THE CENTRAL NERVOUS SYSTEM: MECHANISMS, PERFORMANCE, AND THERAPY	490

OP-AP20 TRAINING AND TESTING VII - MIDDLE AGE AND OLDER ADULTS	491
OP-PN32 HYPOXIA AND ENVIRONMENT.....	494
OP-MH26 PHYSICAL ACTIVITY AND BODY COMPOSITION IN CHILDREN	497
OP-AP42 STATISTICS AND ANALYSES I - ENDURANCE SPORTS	499
OP-PN09 NUTRITION VI - MIXED	502
OP-SH16 MENTORING / COACHING	505
OP-MH13 SPORTS CARDIOLOGY.....	508
OP-MH12 EPIDEMIOLOGY I.....	510
OP-SH05 PHYSICAL EDUCATION III.....	513
OP-SH23 SOCIOLOGY III	515
15:15 - 16:30	518
IS-MH05 EFFORT AND ITS PERCEPTION: CURRENT KNOWLEDGE AND PERSPECTIVES	518
OP-PN35 ENERGY METABOLISM.....	519
IS-PN05 EFFECTS OF ENVIRONMENTAL HEAT STRESS ON HUMAN PERFORMANCE AND HEALTH ACROSS THE LIFECOURSE	522
OP-AP26 CYCLING II	523
OP-BM06 RATE OF FORCE DEVELOPMENT	526
OP-PN10 NUTRITION VII - KETOGENIC.....	529
OP-MH27 MIXED SLEEP / PHYSICAL ACTIVITY PERFORMANCE ACROSS THE LIFESPAN.....	530
OP-BM19 MOTOR LEARNING AND VARIABILITY.....	533
OP-AP27 SPORTS TECHNOLOGY IN RUNNING	536
OP-MH45 PHYSICAL ACTIVITY PROMOTION I.....	538
OP-MH14 DISABILITIES AND REHABILITATION	541
OP-SH17 PHYSICAL ACTIVITY PROMOTION II.....	544
OP-AP25 PERFORMANCE ANALYSIS IN INDIVIDUAL SPORTS.....	546
OP-SH06 SPORT MANAGEMENT AND LAW I.....	549
17:00 - 18:15	552
OP-AP31 TEAM SPORTS VII - TALENT SUPPORT AND YOUTH TRAINING	552
OP-AP30 RUNNING III - APPLIED PHYSIOLOGY	555
IS-MH07 EMERGING PERSPECTIVES IN EXERCISE ONCOLOGY: INSIGHTS FROM EXERCISE-INDUCED CANCER SUPPRESSION TO PRAGMATIC IMPLEMENTATION EXERCISE ONCOLOGY: NEW INSIGHTS	557
OP-BM07 NEUROMUSCULAR PHYSIOLOGY III - AGEING.....	559
IS-PN06 SEX DIFFERENCES IN HEMODYNAMICS AND OXYGEN TRANSPORT DURING MAXIMAL, SUPRAMAXIMAL, AND TIME-TRIAL EXERCISES: INSIGHTS FROM NORMALIZATION STRATEGIES AND THERMODILUTION MEASUREMENTS	561
OP-AP29 POWER AND STRENGTH II - CLUSTER SETS AND LOWER LIMBS.....	562
OP-BM20 CORTICAL ACTIVITY.....	565
OP-MH29 METABOLIC SYNDROME AND DIABETES I.....	568
OP-MH28 PARKINSONS DISEASE	570
OP-SH18 PSYCHOLOGY III - MOTIVATION	573
OP-MH15 AGEING I.....	576
OP-AP28 STATISTICS AND ANALYSES II - TEAM SPORTS	578

OP-SH19 IDENTITY AND GENDER	581
OP-SH07 SPORT MANAGEMENT AND LAW II	582
18:30 - 19:30	585
CP-AP03 STATISTICS AND ANALYSES II - FOOTBALL	585
CP-AP06 SPORTS TECHNOLOGY / MONITORING II	590
CP-AP11 COACHING III - RUNNING AND BIATHLON	594
CP-AP14 COACHING AND TRAINING IN YOUTH ATHLETES	597
CP-AP19 POWER AND STRENGTH II	601
CP-AP22 BASKETBALL	605
CP-AP26 RUNNING	608
CP-AP28 HIIT, AGILITY AND FATIGUE	614
CP-AP31 TRAINING AND TESTING III - MIXED	618
CP-BM02 MOTOR LEARNING AND MOTOR CONTROL I	623
CP-BM06 GAIT	627
CP-BM08 SPORTS BIOMECHANICS	631
CP-BM09 UPPER LIMB BIOMECHANICS	634
CP-BM11 JUMPING AND SQUATING II	639
CP-BM15 FATIGUE	643
CP-MH11 CARDIOVASCULAR AND NEUROLOGICAL DISEASES	648
CP-MH12 CANCER II	653
CP-MH13 AGEING II	656
CP-SH08 PHYSICAL EDUCATION II	661
CP-MH15 PARALYMPIC ATHLETES	665
CP-MH16 AGEING III - COVID-19	669
CP-MH17 PHYSICAL ACTIVITY / INACTIVITY AND MENTAL DISABILITIES	672
CP-MH18 ADOLESCENTS / CHILDREN	677
CP-SH11 PSYCHOLOGY III - COGNITION	682
CP-PN04 EXERCISE BIOMARKERS	686
CP-PN05 ENERGY RESTRICTION	691
CP-PN06 SUPPLEMENTS	696
CP-PN07 RESPIRATION AND GAS EXCHANGE	700
CP-PN08 ENDURANCE, INTERVAL TRAINING AND CAFFEINE	706
CP-PN09 SLEEP, FATIGUE AND EXTREME EXERTION	710
CP-PN10 NUTRITION AND PERFORMANCE	715
CP-SH13 PSYCHOLOGY IV - INTERVENTION	720
CP-PN14 CARDIOVASCULAR PHYSIOLOGY TRAINING	724
CP-PN15 OMICS	729
CP-PN16 MUSCLE AND BONE	733
CP-PN17 THERMOREGULATION TRAINING AND PERFORMANCE	739
CP-SH06 PHYSICAL ACTIVITY PROMOTION II	744
CP-SH16 PSYCHOLOGICAL WELL-BEING	748

CP-SH19 PSYCHOLOGY V - MENTAL HEALTH.....	752
CP-SH22 PSYCHOLOGY AND SOCIOLOGY - MIXED	755
FRIDAY, 4 JULY 2025.....	760
08:00 - 09:15	760
IS-AP04 ADVANCING PERFORMANCE: THE APPLIED USE OF WEARABLE TECHNOLOGIES IN SPORTS SCIENCE	760
IS-BM08 BRAIN & BODY BOOTCAMP: REVOLUTIONIZING FITNESS WITH EXERGAMES!.....	761
OP-AP33 CYCLING III	762
OP-AP36 RECOVERY AND PERFORMANCE ENHANCEMENT	765
OP-AP32 POWER AND STRENGTH III - LOAD VELOCITY APPROACHES	768
OP-AP34 COACHING II - TEAM SPORTS.....	771
OP-AP35 RUNNING IV - TRAIL.....	773
OP-BM08 AGEING II.....	776
OP-MH30 METABOLIC SYNDROME AND DIABETES II.....	779
OP-MH08 INJURY PREVENTION	782
OP-SH08 PSYCHOBIOLOGY.....	784
OP-MH17 POST-SURGICAL RECOVERY	787
OP-SH24 CHILDREN AND BODY IMAGE.....	789
OP-MH09 SPORTS MEDICINE AND ORTHOPEDICS II.....	791
09:30 - 10:45	794
IS-AP05 INVESTIGATING THE CAUSES OF FATIGUE IN ENDURANCE ACTIVITIES: SOCIETAL BENEFITS, PHYSIOLOGICAL MARKERS, AND INTERDISCIPLINARY APPROACHES.....	794
OP-AP37 BLOOD FLOW RESTRICTIONS	795
OP-AP38 WEARABLE TECHNOLOGIES	798
OP-BM09 NEUROMUSCULAR ADAPTATIONS TO EXERCISE	800
IS-PN08 UNRAVELING DIETARY PROTEIN SOURCES FOR SKELETAL MUSCLE HEALTH AND PERFORMANCE: FROM WORKOUTS TO WELLNESS	803
OP-BM12 BALANCE.....	805
OP-AP39 SWIMMING III - PERFORMANCE TESTING.....	808
OP-MH25 SARCOPENIA / DYNAPENIA / POWERPENIA	811
OP-AP40 MIXED SESSION - FROM POWERLIFTING TO HRV	813
OP-MH32 EPIDEMIOLOGY II.....	816
OP-MH31 NEUROLOGICAL DISEASES.....	819
OP-MH10 SPORTS MEDICINE AND ORTHOPEDICS III.....	821
OP-SH25 ANXIETY AND STRESS	824
OP-SH09 SOCIOLOGY IV - AGEING.....	826
11:00 - 12:00	829
CP-AP07 SPORTS TECHNOLOGY - MIXED	829
CP-AP08 STATISTICS AND ANALYSES III - PERFORMANCE	832
CP-AP09 STATISTICS AND ANALYSES IV - MIXED	837
CP-API2 COACHING IV - ELITE ATHLETES.....	841

CP-AP20 POWER AND STRENGTH III.....	845
CP-AP23 CYCLING	850
CP-AP27 BODY COMPOSITION AND AGEING	855
CP-AP29 YOUTH FOOTBALL	860
CP-AP32 TRAINING AND TESTING IV - MIXED	864
CP-AP33 HOCKEY, ICE HOCKEY AND WARM-UP	869
CP-BM03 MOTOR LEARNING AND MOTOR CONTROL II.....	873
CP-BM12 RUNNING BIOMECHANICS	878
CP-BM13 NEUROMUSCULAR PHYSIOLOGY	882
CP-BM17 PERCEPTION AND BALANCE - MIXED.....	888
CP-BM18 MUSCLE / TENDON AND EXERCISE - MIXED.....	891

OP-PN17 Physiology and Methodology of Muscle Adaptation to Exercise

HISTAMINE MEDIATES FOOD INTAKE, BUT NOT MUSCLE ADAPTATIONS, FOLLOWING 10 WEEKS OF RESISTANCE TRAINING IN HUMANS

VAN DE LOOCK, A., VANDECAUTER, J., LIEVENS, E., SCHROË, H., MORENO JUSTICIA, R., WEYNS, A., VAN THIENEN, R., DESHMUKH ATUL, S., BLEMKER, S., VAN DER STEDE, T., DERAWE, W.

GHENT UNIVERSITY

INTRODUCTION: Antihistamine medication blocks the functioning of the histamine system and is widely used to treat allergies. Intake of antihistamines during a six-week cycling training period results in marked impairments in training adaptations (1), likely due to an impaired intercellular histaminergic cross-talk initiated by mast cells in muscle (2). However, it remains unclear whether this is a universal mechanism of muscle adaptation. Therefore, we investigated the impact of antihistamine medication on resistance training adaptations.

METHODS: Eighteen men were randomly assigned to either a placebo (n=9) or antihistamine (n=9, 180mg fexofenadine) group and performed 10 weeks of resistance training. Dietary intake was monitored using self-reported three-day food diaries (baseline, week 4, and week 6) and a dietitian ensured sufficient protein intake. Before and after the training program, maximal strength, muscle volume, fat mass, fat free mass, whole-body insulin sensitivity and vascular function were determined. Training-induced changes between groups were evaluated with two-way ANOVA tests or linear mixed models.

RESULTS: Both the placebo and antihistamine groups showed similar increases in muscle volume (+6% and +7%, p=0.316) and maximal strength (+14% and +20%, p=0.083). Unexpectedly, the antihistamine group gained fat mass (+0.6kg), while the placebo group did not (-0.3kg, p=0.011). This result is reflected by the rise in total caloric and carbohydrate intake in the antihistamine, but not the placebo group (+34% vs +7%, p=0.064 and +29% vs -7%, p=0.005). Both groups showed reductions in mean arterial blood pressure (-2.5 mmHg, p=0.047) and diastolic blood pressure (-4.4 mmHg, p=0.004), as well as a decrease in total glucose level during the oral glucose tolerance test (-81 mM, p=0.001). Surprisingly, fasting glucose and insulin concentrations increased following training (+4%, p=0.041 and +25%, p=0.013, respectively), in both groups.

CONCLUSION: Antihistamine intake did not alter resistance training adaptations, indicating that the intercellular histaminergic cross-talk initiated by mast cells is not a universal mechanism across training modalities. Unexpectedly, antihistamine intake led to increased food intake and fat mass following 10 weeks of resistance training, likely linked to the well-known role of histamine in appetite regulation.

REGIONAL DIFFERENCES IN INTRAMUSCULAR BLOOD FLOW AND MUSCLE DEOXYGENATION OF THE QUADRICEPS FEMORIS DURING INCREMENTAL ISOMETRIC KNEE EXTENSION

IZUMI, K., KATAYAMA, K., TANAKA, N., KANO, Y., AKIMA, H.

NAGOYA UNIVERSITY, UNIVERSITY OF ELECTRO-COMMUNICATIONS

INTRODUCTION: Blood flow plays an important role in supplying oxygen to the exercising muscles. The impairment of oxygen supply via blood flow profoundly impacts exercise performance. Previous studies have shown a heterogeneity of the metabolic responses among the quadriceps muscle. For example, intramuscular blood flow measured by positron emission tomography is heterogeneous within the quadriceps muscle. Moreover, the kinetics of muscle deoxygenation during incremental exercise differ among muscles in the quadriceps. However, it is unknown the dynamics of intramuscular blood flow and its relationship to muscle deoxygenation within the quadriceps femoris. Therefore, the purpose of this study was to evaluate the changes in intramuscular blood flow, muscle deoxygenation, and their relationship in different muscles of the quadriceps femoris.

METHODS: Thirteen healthy young men (19.4 ± 1.0 years) performed intermittent (5-second contraction, 5-second relaxation) and incremental isometric knee extensions. The exercise began at 30% of maximal voluntary contraction (MVC) and increased by 10% for every five contractions to 70% of MVC until task failure. Intramuscular blood flow using power Doppler ultrasonography and muscle deoxygenation using near-infrared spectroscopy (NIRS) were simultaneously measured from the vastus lateralis (VL), rectus femoris (RF) and vastus medialis (VM) in randomized order over 3 days. All variables were measured up to 5 minutes after task failure and averaged every 30 seconds. NIRS measurement provided muscle oxygen saturation (StO₂) and deoxy-hemoglobin/myoglobin (deoxy-Hb/Mb).

RESULTS: There were no significant differences in Δ Intramuscular blood flow, Δ StO₂, and the ratio between intramuscular blood flow and deoxy-Hb/Mb among three muscles during exercise. However, significant regional differences were observed for all parameters after exercise. Δ Intramuscular blood flow was significantly higher in the RF (3 minutes; 1698.5 ± 1038.1 a.u., 4 minutes; 1573.9 ± 950.0 a.u.) than in the VL after 3 minutes post-exercise (824.6 ± 855.5 a.u., $P = 0.009$) and in the VM after 4 minutes post-exercise (713.7 ± 529.3 a.u., $P = 0.037$). Δ StO₂ was significantly higher in the RF (3 minutes; 12.08 ± 5.36 %, 3.5 minutes; 11.78 ± 5.70 %) than in the VL after 3 minutes post-exercise (6.87 ± 3.11 %, $P = 0.025$) and in the VM after 3.5 minutes post-exercise (7.18 ± 5.88 %, $P = 0.044$). The ratio between intramuscular blood flow and deoxy-Hb/Mb was significantly higher in the RF (1.5 minutes; 15.10 ± 7.77 a.u. $\times 10^4$, 3.5 minutes; 15.31 ± 9.74 a.u. $\times 10^4$) than in the VL after 1.5 minutes post-exercise (9.31 ± 6.45 a.u. $\times 10^4$, $P = 0.044$) and in the VM after 3.5 minutes post-exercise (4.94 ± 4.15 a.u. $\times 10^4$, $P = 0.016$).

CONCLUSION: These results suggest that the metabolic requirements in the RF are different from other quadriceps femoris during fatiguing knee extension.

THE HIGHEST POWER OUTPUT AT WHICH THERE IS A PREDOMINANTLY AEROBIC CONTRIBUTION REPRESENTS THE UPPER BOUNDARY OF THE SEVERE EXERCISE INTENSITY DOMAIN

PEKER, A., AS, H., JONES, A.M., OZKAYA, O.

FACULTY OF SPORTS SCIENCES

INTRODUCTION: It has recently been identified that the highest power output at which energy supply is derived predominantly from the aerobic energy system, i.e., aerobic limit power (ALP), coincides with the upper boundary of the severe exercise intensity domain, defined as the highest power output that elicits maximal VO₂ (i.e., PUPPERBOUND) (1). ALP is assessed based on VO₂ dynamics during exercise, peak blood lactate concentration, and the fast phase of recovery VO₂ kinetics, representing the contributions of aerobic, lactic, and phosphagen energy systems, respectively. A non-invasive alternative for estimating relative energy contribution rates is the maximal accumulated oxygen deficit (MAOD), which is defined as the difference between the estimated total oxygen cost of exercise and the accumulated oxygen uptake (2). Since the energy contribution rates derived from these two methodologies are often considered interchangeable (3), it is important to indicate that ALP as derived from MAOD still represents PUPPERBOUND. The aim of this study was to evaluate whether ALP, as determined by MAOD, coincides with PUPPERBOUND.

METHODS: Thirteen physically active male individuals underwent a ramp incremental exercise test, followed by four sub-maximal, 6-7 maximal and at least one supramaximal constant-work-rate test to estimate PUPPERBOUND and MAOD-derived ALP. A linear regression line was plotted using data points from the relationship between VO₂ responses and power outputs obtained from submaximal exercise tests and then extrapolated to target power outputs to calculate MAOD. The PUPPERBOUND was estimated based on the linear relationship between the time to achieve VO₂max and the time to task failure. The ALP was estimated by MAOD, based on the difference between the predicted VO₂ demand and the accumulated O₂ uptake.

RESULTS: The ALP derived from MAOD and PUPPERBOUND were not significantly different ($p = 0.16$; ES: 0.42) and they were interchangeable (r : 0.99; Bias: 3 ± 7 W; SEE: 7 W; LoA: -11 to 17 W). Pulmonary VO₂ just above ALP was significantly different from VO₂max (Δ : 4 ± 3 mL/min/kg; $p < 0.001$). When ALP was exceeded, relative contribution rates obtained from the energy systems shifted and anaerobic contribution rate above ALP was significantly higher than that of ALP (51% vs 46%; $p < 0.001$).

CONCLUSION: This study demonstrated that ALP, as derived from the MAOD method, provides a simple, cost-effective, and non-invasive approach to accurately determine the PUPPERBOUND.

DOES HUMAN MUSCLE VOLUME HOMEOSTATICALLY ADAPT TO BONE VOLUME?

DHOE, B., VAN DE LOOCK, A., VAN VOSSEL, K., BLEMKER, S., LIEVENS, E., DERAIVE, W.

GHENT UNIVERSITY

INTRODUCTION: The 'adipostat' is a homeostatic framework that keeps fat storage levels around an internal setpoint. Similarly, the 'myostat' would encompass homeostatic mechanisms that maintain muscle volume in a dynamic equilibrium around an optimal bone-scaled setpoint (myostatic setpoint). The primary function of skeletal muscles is to move bones. Therefore, one might expect a relationship between a particular muscle volume and the associated bone volume (e.g., biceps brachii vs. humerus), as a larger bone could support more muscle. The current study explores whether there is a normative ratio of muscle volume relative to its associated bone volume, indicating a setpoint, independent of human stature. Moreover, we hypothesize that resistance training (RT) would increase muscle volume more and easier when starting below the myostatic setpoint and increasing muscle volume towards the setpoint, as opposed to increasing muscle volume beyond the myostatic setpoint.

METHODS: Previously untrained males ($n=29$) and females ($n=10$), aged 23 ± 4 years, underwent whole-body MRI scanning before and after 12 weeks of whole-body RT. An extensive set of individual skeletal muscle volumes ($n=57$) and their anatomically associated bone volumes were determined through AI-based automated segmentation analysis (Springbok

Analytics) and height-corrected, followed by Z-score extraction. The linear relationship between the mean Z-score across all muscle volumes and their associated bone volumes was assessed at baseline using linear regression, and residuals were derived from subject positioning relative to the corresponding regression line (myostatic setpoint). Positive residuals indicate a muscle volume above the setpoint relative to bone volume, and vice versa. Mean muscle volume Z-score changes from baseline were calculated after 12 weeks of RT.

RESULTS: At baseline, mean muscle volume Z-scores across all muscles showed a strong positive correlation with the mean associated bone volume Z-scores ($R^2=0.58$, $p=2.59 \times 10^{-8}$). This means that a major portion of the inter-individual variation in muscle volume can be explained by the volume of their associated bones. The RT-induced increase in mean muscle volume Z-scores exhibits a negative correlation with the baseline residual Z-scores ($R^2=0.11$, $p=0.0067$). This indicates that individuals who start below the myostatic setpoint experience greater hypertrophy than those who are already above the myostatic setpoint before RT.

CONCLUSION: In untrained individuals, muscle volume is strongly associated with bone volume, after adjusting for height. The resulting linear regression line could be considered a myostatic setpoint. RT-induced increases in muscle volume tend to be inversely related to initial bone-scaled muscle volume in previously untrained males and females, supporting the myostat theory. This model could be used to predict normative muscle volume and RT effects based on bone volume, potentially defining upper and lower limits of muscle volume.

NO PERFECT FIT: EVALUATING THE ACCURACY OF RMR PREDICTION EQUATIONS IN MASTERS ENDURANCE ATHLETES

DEVIRIM LANPIR, A., DEVENNEY, S., EGAN, B.

DUBLIN CITY UNIVERSITY

INTRODUCTION: Accurate RMR assessment is crucial for evaluating energy balance in masters endurance athletes, who experience age-related metabolic changes (1). While indirect calorimetry is the gold standard, its limited practicality makes predictive equations a common alternative (2). This study evaluates the validity of existing RMR equations and develops a new regression model tailored for masters endurance athletes.

METHODS: One hundred masters endurance athletes (70 males; 46.2 ± 7.1 years (40–65), 30 females; 48.5 ± 8.3 years (40–72)) underwent RMR assessment via indirect calorimetry. The accuracy of nine commonly used RMR prediction equations was evaluated using mean bias, limits of agreement, intraclass correlation coefficients (ICC), and root mean square error (RMSE). Additionally, a multiple regression model incorporating fat-free mass (FFM), age, and sex was developed to enhance predictive accuracy.

RESULTS: Among male athletes, the De Lorenzo (3) and Cunningham (1991) (4) equations demonstrated the highest accuracy, with ICC values of 0.557 and 0.607, respectively. In females, Cunningham (1991) showed the best predictive performance (ICC = 0.557), but substantial under- and overpredictions were observed across equations. Regression analysis identified FFM as the strongest predictor of RMR, explaining 63% of the variance. The newly developed regression model, which included FFM, age, and sex as predictors, demonstrated improved predictive power, explaining 74% of the variance in measured RMR ($R^2 = 0.74$). The model exhibited moderate agreement with measured RMR (ICC = 0.531 for males, 0.612 for females), with lower RMSE values (184 kcal/day for males, 168 kcal/day for females) compared to commonly used equations. However, it still displayed wide limits of agreement, suggesting variability in individual predictions.

CONCLUSION: No single predictive equation demonstrated consistently high accuracy in masters endurance athletes. While Cunningham (1991) and De Lorenzo provided moderate agreement with measured RMR, their errors remain significant for individual assessments. The newly developed regression model outperformed existing equations in predictive accuracy but requires further refinement to improve individual-level precision. Future research may integrate additional physiological parameters, such as somatotype and metabolic adaptations, to enhance RMR estimation in endurance athletes.

Invited Symposium

STABILITY REGULATION MECHANISMS OF THE WHOLE-BODY DURING GAIT ON UNEVEN GROUND

NIKOLAIDOU, M.

NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS

Leg posture and muscle activation patterns are important mechanisms that control two important measures of stability, namely margin of stability (MoS) and whole-body angular momentum, for maintaining dynamic balance during stable and unstable locomotion (1,2). Leg posture adjustments and muscle activation influence the base of support and the moment arm from the centre of mass (CoM) to the ground reaction force (GRF) vector, affecting stance phase dynamics. Experience-based and visually guided anticipatory adjustments in leg posture and activation patterns provide the opportunity to proactively plan movement initiation and modify subsequent responses, facilitating robust and stable gait on uneven ground. Therefore, understanding the neuromuscular and biomechanical mechanisms that control the translational and rotational behaviour of the whole-body during movement on uneven ground will provide important knowledge for effec-

tive stability control and fall prevention. During hole negotiation, we found a decrease in MoS and an increase in the peak-to-peak range of the whole-body angular momentum compared to level walking, especially in the frontal plane, indicating an increased challenge to body stability. As a result, the rate of the angular momentum, which is similar to the external moment of the GRF around the CoM, was increased during the negotiation of the hole predicting a higher demand in the muscles of the ipsilateral leg to control body stability. On the other hand, the decrease in the medio-lateral moment arm of the GRF at touchdown indicated an anticipatory foot displacement strategy to control the angular momentum towards the contralateral leg. Furthermore, the muscle activation patterns and the resulting kinematics of the contralateral leg before touchdown also showed proactive adjustments to regulate the kinetic CoM energy and to reduce the contribution of gravity to the angular momentum rate. Nevertheless, the high activation of the soleus, gastrocnemii and vastii muscles of the ipsilateral leg required to manage the total CoM energy during hole negotiation dominated the aforementioned anticipatory adaptations and resulted in the increased range and rate of angular momentum. We argue that the high activation of the plantar flexors and knee extensors during the stance phase in the hole suggests that the regulation of total CoM energy at the expense of an increase in whole-body angular momentum is a reasonable trade-off in the regulatory stability mechanisms, and demonstrates the challenge of moving on uneven ground. The presentation will address (i) the translational and rotational behaviour of the whole-body, (ii) the functional diversity in activation between the ipsilateral and contralateral leg muscles and (iii) how humans regulate MoS and whole-body angular momentum to maintain stability during hole negotiation. REFERENCES: 1) Hof et al. 2010, J Exp Biol 213, 2655-2664 2) Neptune and Vistamehr 2019, J Biomech Eng 141, 0708011-07080

GENERALIZABILITY OF BALANCE RECOVERY RESPONSE ADAPTATIONS FROM MECHANICAL- AND VIRTUAL-BASED GAIT PERTURBATION EXERCISES

KARAMANIDIS, K.

LONDON SOUTH BANK UNIVERSITY

Human bipedal locomotion faces various perturbations to stability that require neuromotor adjustments and adaptations to maintain postural integrity and avoid falls. Previous research suggests that the central nervous system monitors and corrects motor responses by predicting sensory consequences of perturbations (1). However, these predictions must accurately reflect the nature of the perturbation, and hence, motor control is continuously refined based on error-feedback information. This ability of the neuromotor system to adapt suggests that enhanced balance recovery responses developed through exposure to specific perturbations may improve coping with altered forms of the exercised task (2). Understanding the factors that enable the neuromotor system to improve and transfer balance recovery mechanisms across diverse perturbation tasks and environmental conditions is essential for enhancing fall resilience in both healthy and pathological conditions. Using unpredictable mechanical-based perturbations during walking, our recent findings support the hypothesis that the neuromotor system can facilitate improved reactive balance responses by enhancing neuromuscular coordination, along with retaining balance improvements over several years, potentially reducing fall risk. Acquiring and retaining fall-resistance skills appear to rely more on neural rather than muscle-tendon capacities, emphasizing the neural system's critical role in maintaining stability under challenging conditions. In addition to perturbations in physical environments, visual-based gait perturbations in virtual environments stimulate motor skill learning that can be retained for several weeks. Our data further indicate that the neuromotor system can partly transfer those balance recovery adaptations from virtual to physical environments. However, the generalizability and transfer of stability recovery mechanisms from one task to another and from the virtual to physical environments seem to depend on perturbation direction and the degree of similarity in neuromuscular control patterns between tasks. Furthermore, balance recovery performance of an individual affects the responsiveness to perturbation exercises and therefore task demand should be considered when accessing transfer potential, particularly for studies on populations with varying locomotor capacities. The current presentation will focus on our recent findings about (i) how gait stability and adaptability during unpredictable mechanical-based gait perturbations are affected by age, and (ii) whether transfer of enhanced stability recovery responses to novel perturbation tasks is impacted by neuromuscular function, and (iii) whether visual-based gait perturbation exercises in a virtual environment benefit dynamic stability in physically challenging environments. ACTIVATION PATTERNS AND BIARTICULAR MECHANISMS OF POWER SHARING BETWEEN THE SYNERGISTIC MUSCLES OF THE TRICEPS SURAE DURING HUMAN GAIT PERTURBATIONS

ARAMPATZIS, A.

HUMBOLDT-UNIVERSITY BERLIN

There is evidence for a critical role of the ankle joint in human locomotion and indications for muscle-specific functional relevance of the plantar flexors during perturbations (1). The soleus (Sol), gastrocnemius medialis (GM) and gastrocnemius lateralis (GL) form the triceps surae muscle and operate together as ankle extensors to generate moments and perform power at the ankle joint. Although the three muscles work synergistically, they have important differences in function, geometry and size. The Sol, as monoarticular muscle, acts around the ankle joint, while the GM and GL are biarticular and act across the ankle and knee joints. The biarticular gastrocnemii may transfer power and energy between the two joints (2) increasing intrinsic stability by reducing the effort required for neural control. Recently, we found a significant increase in the energy transfer potential between the ankle and knee joint via the biarticular gastrocnemii in both trip-like (1.6-fold) and drop-like (2.5-fold) perturbations compared to unperturbed walking. This modulation was consistent during the un-

predictable and adapted walking perturbations and was accompanied by a high activation of the gastrocnemii, indicating a crucial involvement of biarticular mechanisms to counteract locomotor disturbances. Subsequently, Achilles tendon (AT) force and AT elastic energy storage and recoil were quantified during drop-like perturbations. Based on the AT force as a proxy for triceps surae muscle force, the generated moment and the performed power and work of the monoarticular Sol at the ankle joint and the biarticular gastrocnemii at the ankle and knee joints were calculated. We found that the biarticular mechanisms of the gastrocnemii significantly affect the mechanical power and work through an ankle-to-knee joint in the first part and a knee-to-ankle joint energy transfer in the second part of the stance phase after the perturbations. The transfer of energy from the ankle to the knee joint via the biarticular gastrocnemii provides evidence of an important contribution of biarticular mechanisms to the absorption of body energy during unpredictable trials, where beneficial mechanisms to control stability modulated by prediction are not available. The presentation will focus on (i) the consequences of unpredictable and predictable gait perturbations on the translational and rotational behaviour of the whole-body, (ii) the functional diversity of activation and power sharing between the synergistic Sol, GM and GL muscles with a special focus on biarticular mechanisms to control gait stability, and (iii) how improvements in gait stability through prior experience and motor learning are related to the interplay between activation and biarticular mechanisms for power and energy transfer between the ankle and knee joints. REFERENCES: 1) Dick et al. 2021, Proc Biol Sci, 31, 288(1947):20210201 2) van Ingen Schenau 1989, Hum Mov Sci 8, 301-337

Invited Symposium

IS-MH01 REDs Prevention: Navigating Barriers and Harnessing Opportunities

NAVIGATING BODY COMPOSITION AND WEIGHT ISSUES IN REDS MANAGEMENT

MELIN, A.

SPORTS SCIENCE

A higher power-to-weight ratio can enhance performance outcomes across various sports disciplines and is typically achieved through modifications in body composition, such as increased lean mass and/or reduced fat mass. Additionally, there is a widespread belief within the sports community that reduced body weight or maintaining a low body weight contributes to improved athletic performance. However, an excessive focus on maintaining a low body weight and specific body composition for performance, coupled with frequent anthropometric assessments, can lead to body dissatisfaction, body image disturbances, and disordered eating and training behaviors. These behaviors can result in problematic low energy availability (LEA) and Relative Energy Deficiency in Sport (REDs). Moreover, the fear of undesired weight gain may deter athletes experiencing REDs symptoms from optimizing their energy availability. This presentation will address strategies for managing body composition and weight issues within the sporting environment to prevent REDs and eating disorders.

TRANSLATING REDS BIOMARKERS: ENHANCING PRACTITIONER UNDERSTANDING AND INTERPRETATION

HACKNEY, A.

UNIVERSITY OF NORTH CAROLINA

The 2023 IOC Consensus statement on REDs presented a revision of the clinical assessment tool (CAT) to appraise the severity/risk of REDs syndrome development. The new tool is referred to as the 'REDs CAT2' which utilizes a number of primary and secondary indicators (biomarkers) to assess athlete severity and risk status using a stoplight model – green = none, yellow = mild, orange = moderate to high, red = very high/extreme (i.e., with multiple levels of biomarkers used for classification). These biomarkers are essential for secondary prevention strategies. However, assessing and interpreting the various biomarkers can be challenging for the practitioner as many of these markers require research or clinical backgrounds to understand fully. To that end, this presentation will: 1) provide an overview of what are the biomarkers utilized in the REDs CAT2, 2) discuss the importance of standardized methodology for measuring the biomarkers, and 3) explain translationally what changes in such biomarkers mean or denote for the athlete relative to performance and health. The overarching theme herein will be to focus on discussing these topics in a clear and useful approach for the practitioners.

THE MIND AND REDS. OVERCOMING PSYCHOLOGICAL HURDLES IN PREVENTION

TORSTVEIT, M.

UNIVERSITY OF AGDER

Although the physical harm caused by problematic low energy availability (LEA) in athletes has been extensively researched and documented, the psychological risk factors and the subsequent consequences related to psychological problems and psychological health are less understood. In order to prevent REDs, it is crucial to understand the different attitudes, habits, and behaviours associated with problematic LEA, and whether they are intentional or unintentional. The psychological indicators associated with problematic LEA and REDs include cognitive dietary restraint, perfectionistic tendencies, drive for thinness, mood disturbances, and reduced sleep quality. Other adverse psychological health outcomes associated with problematic LEA and REDs are affective disorders, depressive symptoms, reduced well-being,

anxiety related to injury and/or recovery, exercise dependence or addiction, and sport-specific issues such as coping with weight requirements and developing eating disorders. Moreover, under-fuelling may be driven by distorted thoughts, cognitive restraint, perfectionism, disordered body image, body dysmorphia, unregulated emotions, compulsive drive for thinness, and/or compulsive exercise. Thus, it is of utmost importance to increase our understanding of these psychological factors in order to prevent and manage athletes with problematic LEA and REDs. This presentation will therefore focus on 1) How to reduce psychological risk factors and improve psychological protective factors in order to prevent REDs from developing (primary prevention), 2) How to early identify symptoms of psychological problems related to REDs and prevent them from evolving to more serious psychological health problems (secondary prevention), and 3) How to manage athletes with more severe psychological health problems related to REDs (tertiary prevention).

Invited Symposium

IS-EX01 CSSS-ECSS Exchange Symposium – Technology support in Football youth performance progression in the Millennium Era

FROM THE PAST TO THE MILLENNIUM ERA - REFINED INNOVATION PROCESS OF THE PERFORMANCE EVALUATION OF FOOTBALL YOUTH TRAINING

LI, H.

CHINA INSTITUTE OF SPORT SCIENCE

The football youth training system has undergone profound changes from being extensive to refined, and this has been especially notable in aspects like physical fitness, technical and tactical skills, and the evaluation of comprehensive sports performance. In the past, football youth training was still in its initial stage. Physical training mainly encompassed simple running and strength training, while technical and tactical skills depended on the traditional method of being passed down from masters to apprentices. After entering the 20th century, more scientific physical training methods started to be incorporated into football youth training as the sports science developed. For instance, interval training, strength training, and aerobic training were integrated organically, and technical and tactical training also gradually became systematic, emphasizing team cooperation and tactical implementation. By the Millennium Era, the evaluation of physical fitness, technical and tactical skills, and comprehensive sports performance in football youth training had reached a climax of refined innovation, and there are also a growing number of relevant research papers. Physical training emphasizes analyzing the physical characteristics of different ages and on-field positions. Scientific and reasonable training plans are designed by combining these physical characteristics with athletes' physiological features and competition requirements. High-tech means such as big data analysis and video analysis also increase their investment in football youth training. Consequently, precisely evaluating and adjusting footballers' technical movements and competition performance has gradually become a hot research topic. This refined training innovation process has not only enhanced the sports performance of young footballers but also energized the development of the global football youth training system. For example, it has cultivated many young talents such as Kylian Mbappé, Jude Bellingham, and Lamine Yamal. In the future, as technology and training theories continuously progress, the evaluation of physical fitness, technical and tactical skills, and comprehensive sports performance in football youth training will be further deepened, contributing more wisdom and strength to the prosperous development of the global football industry.

DATA-INFORMED DIAGNOSTIC AND TRAINING PROCEDURES OF YOUTH FOOTBALL PLAYERS IN THE MILLENNIUM ERA

DÜKING, P.

TECHNICAL UNIVERSITY OF BRAUNSCHWEIG

In the Millennium Era, different technologies which promise to support coaches regarding personalization of training procedures with the aim to enhance performance and/or reduce the likelihood of injuries in football youth training are increasingly available. Technological developments can be rapid, and among the most currently discussed technologies are wearable technologies and forms of Artificial Intelligence (AI). While it can be argued that technologies provide benefits to coaches and (youth) football players, not all available technologies are equally beneficial. Stakeholders must cautiously evaluate if, when, and how to employ different technologies (and by whom), in order to select and deploy them effectively to achieve desired, and avoid undesired outcomes. In this presentation, an overview of various technologies and their applications in sports, with a particular focus on youth football players, including selected examples of how wearable technologies and forms of AI can inform diagnostics and training procedures will be given. For example, the talk will focus on using wearable technologies in diagnostic procedures for youth football players, specifically comparing the assessment of VO₂max with smartwatches or portable seismographic devices to established methodologies. Additionally, this talk will provide an example of how machine learning can be employed to reveal relationships between internal and external load parameters and its potential for planning of training procedures. The contribution will conclude by highlighting key factors needed to enhance the development and implementation of scientifically trustworthy technologies, partly derived from a global survey, for youth football players and stimulate future (interdisciplinary) ideas for research in this field.

DOES DEHYDRATION IMPAIR EXOGENOUS CARBOHYDRATE OXIDATION DURING PROLONGED RUNNING IN A HOT ENVIRONMENT?

MOUGIN, L., INGRAM, C., CHAIZE, C., KNOWLES, H., TAYLOR, L., JAMES, L.J., MEARS, S.A.

LOUGHBOROUGH UNIVERSITY

INTRODUCTION: Exogenous carbohydrate oxidation (i.e., from drinks) is reduced in hot conditions (1,2). Increased thermal and cardiovascular strain and reduced gastrointestinal (GI) integrity (3) may impair glucose uptake and transport, gastric emptying, and intestinal absorption. However, dehydration, often resulting from heat exposure, may also contribute to these impairments by reducing blood volume and altering blood flow distribution. As previous studies in hot conditions have not controlled hydration status, the impact of dehydration on reduced exogenous carbohydrate oxidation is unclear. Therefore, this study aimed to investigate the effect of hydration status on exogenous carbohydrate oxidation during running in a hot environment.

METHODS: Ten trained male runners (21 ± 2 y; 68.9 ± 7.6 kg; $\text{VO}_{2\text{peak}}$: 67 ± 6 mL/kg/min) completed a preliminary session ($\text{VO}_{2\text{peak}}$ and sweat rate testing) and two experimental trials [100 min of steady state running at $\sim 65\%$ $\text{VO}_{2\text{peak}}$ in hot conditions (32°C) with hydration (water intake to replace 90% of mass losses; HYD) or to induce dehydration (minimal fluid provided; DEH)]. In each trial, participants consumed 60 g/h (bolus every 20 min) of a 35% dextrose solution enriched with [U- ^{13}C] glucose (145 ± 2 ‰ enrichment). Expired breath (analysed for $^{13}\text{C}:^{12}\text{C}$ ratio using GC-IRMS), venous blood samples and subjective scales of GI comfort were collected at rest and every 20 min during exercise. Data were analysed using linear mixed models with significance at $P < 0.05$. Results presented as mean $\pm$ SD.

RESULTS: Average (40-100 min) and peak exogenous carbohydrate oxidation rates were 29% (DEH: 0.35 ± 0.15 vs. HYD: 0.50 ± 0.13 g/min; $P = 0.016$) and 24% (DEH: 0.54 ± 0.19 vs. HYD: 0.71 ± 0.13 g/min; $P = 0.017$) lower in DEH than HYD, respectively. Total (DEH: 2.52 ± 0.47 vs. HYD: 2.56 ± 0.26 g/min; $P = 0.737$) and endogenous carbohydrate oxidation (DEH: 2.17 ± 0.36 vs. HYD: 2.06 ± 0.30 g/min; $P = 0.188$) were not different between trials. GI temperature (DEH: $39.4 \pm 0.5^\circ\text{C}$; HYD: $39.2 \pm 0.4^\circ\text{C}$; $P = 0.380$) and heart rate (DEH: 173 ± 11 bpm; HYD: 169 ± 12 bpm; $P = 0.124$) at the end of trials were not different between conditions. Body mass loss ($-2.7 \pm 0.5\%$ vs. $-0.4 \pm 0.5\%$; $P < 0.001$) and changes in plasma volume from baseline ($-9.3 \pm 4.1\%$ vs. $-2.5 \pm 5.1\%$; $P < 0.001$) were greater in DEH. No differences in GI symptoms, including stomach bloatedness, were observed between conditions ($P > 0.05$).

CONCLUSION: Prolonged exercise in the heat, with minimal fluid intake leading to dehydration, impaired exogenous carbohydrate oxidation. These findings underscore the importance of hydration and fluid delivery for optimising exogenous carbohydrate utilisation, particularly for athletes aiming to sustain endurance performance in hot conditions.

CO-INGESTING WHEY PROTEIN WITH DUAL SOURCE CARBOHYDRATE ENHANCES AMINO ACID AVAILABILITY WITHOUT COMPROMISING POST-EXERCISE LIVER GLYCOGEN RESYNTHESIS

HANNON, S., MCSTRAVICK, J., HENTHORN, L., BAWDEN, S., TANG, J., DUNN, R., MAKINO, R., SMITH, K., GONZALEZ, J., HODSON, N., MORTON, J., KENNERLEY, A., HEARRIS, M.

MANCHESTER METROPOLITAN UNIVERSITY

INTRODUCTION: Carbohydrates (CHO) are crucial for prolonged moderate- to high-intensity exercise, although storage within the liver and skeletal muscle is relatively limited. The development of practical strategies to optimize glycogen resynthesis with athletes is thereby essential for enhancing recovery and performance. In addition to CHO, protein consumption during recovery supports muscle protein synthesis and enhances muscle glycogen storage, particularly when carbohydrate intake is suboptimal. While protein may aid liver glycogen repletion by promoting hepatic glucose storage and providing glucogenic amino acids, protein stimulates glucagon secretion - potentially impairing liver glycogen synthesis. Therefore, the present study examined the effects of co-ingesting whey protein with dual source carbohydrates on post-exercise liver and muscle glycogen resynthesis.

METHODS: Following glycogen-depleting exercise, ten well-trained male cyclists (mean $\pm$ SD: age 29 ± 7 years; body mass 78.5 ± 6.4 kg; stature 181.9 ± 4.7 cm; $\text{VO}_{2\text{max}}$ 57.5 ± 5.8 mL·kg $^{-1}$ ·min $^{-1}$) ingested 60 g·h $^{-1}$ CHO from either maltodextrin (MAL), fructose (FRU), maltodextrin + fructose (MF) or maltodextrin + fructose plus 30 g whey protein (PRO) at 0 and 180 min during a 5-h recovery period. ^{13}C magnetic resonance spectroscopy and imaging were performed at 0-, 120- and 300-min post-exercise to determine liver and muscle glycogen concentrations and liver volume.

RESULTS: Protein co-ingestion resulted in elevated serum insulin and plasma glucagon compared with FRU and MF ($P < 0.001$ for all). Similarly, serum insulin and plasma glucagon concentrations were markedly higher with MAL when compared with both FRU and MF ($P < 0.05$ for all), although plasma glucagon concentrations were also higher when com-

pared with PRO ($P < 0.001$). Liver glycogen concentrations were significantly higher with FRU (276 ± 70 mmol-L⁻¹), MF (257 ± 65 mmol-L⁻¹) and PRO (285 ± 49 mmol-L⁻¹) compared with MAL (198 ± 41 mmol-L⁻¹) ($P < 0.05$ for all) following 5 hours of recovery. However, muscle glycogen concentrations (MAL, 166 ± 39 ; FRU, 145 ± 51 ; MF, 153 ± 39 ; PRO 154 ± 36 , mmol-L⁻¹) were not different between trials ($P > 0.05$).

CONCLUSION: In summary, ingesting dual-source carbohydrates enhances liver glycogen repletion whilst maintaining comparable rates of muscle glycogen resynthesis when compared to maltodextrin only. Notably, despite enhancing glucagonemia, co-ingestion of whey protein (with a 1:1 combination of maltodextrin and fructose) does not compromise post-exercise liver glycogen resynthesis, allowing for increased aminoacidemia alongside rapid glycogen resynthesis. Considering the importance of post-exercise protein intake for muscle reconditioning and the dietary habits of elite endurance athletes, our findings suggest that combining dual-source carbohydrates (a 1:1 ratio of maltodextrin and fructose) with whey protein offers a practical strategy to optimize both amino acid availability and endogenous glycogen resynthesis.

THE IMPACT OF SEX, MENSTRUAL PHASE, AND ORAL CONTRACEPTIVE USE ON THE ANABOLIC SENSITIVITY TO DIETARY LEUCINE AT REST AND AFTER RESISTANCE EXERCISE

POURHASHEMI, N., AGUILERA, J.A., FUNG, H.J.W., IDRISOVA, D., WEST, D.W.D., MOORE, D.R.

UNIVERSITY OF TORONTO

INTRODUCTION: Dietary amino acids (AA), such as the essential AA leucine (Leu), are used for building new body proteins (i.e. protein synthesis) or as a source of energy (i.e., oxidation). Our laboratory has developed an oral [¹³C]Leu 'breath-test' that measures the leucine retention (Leu Ret) for protein synthesis as a marker of the body's 'anabolic sensitivity' to dietary AAs. However, the effect of biological sex (i.e., males vs. females) or female hormonal milieu (i.e., naturally cycling eumenorrheic females vs. oral contraceptive (OC) use) on whole-body dietary Leu Ret at rest and following resistance exercise (RE) remains unknown. Thus, the purpose of the study was to determine Leu Ret (i.e., 'anabolic sensitivity') in equal groups of $n=8$ males (26.4 ± 4.8 y, 78.3 ± 7.7 kg body mass (BM), $13.8 \pm 5.9\%$ body fat (BF)), eumenorrheic females in the follicular (21.4 ± 3.1 y, 65.1 ± 0.5 kg BM, $26.4 \pm 6.9\%$ BF) and luteal (24.4 ± 4.3 y, 64.7 ± 10.2 kg BM, $28.2 \pm 5.1\%$ BF) phases and monophasic OC users (23.3 ± 2.4 y, 59.3 ± 10.0 kg BM, $24.9 \pm 4.9\%$ BF) during the active pill phase (days 10-21) upon consuming a [¹³C]Leu-enriched beverage at rest (FED) and after a bout of full-body RE (EXFED).

METHODS: Using a counterbalanced, crossover design, participants ingested a mixed macronutrient beverage containing carbohydrate and crystalline AAs (0.75 and 0.25 g/kg BM, respectively) in both FED and EXFED, enriched to ~5% with [¹³C]Leu, which is preferentially metabolized in peripheral (e.g. muscle) lean tissues. The oxidation of ingested Leu (Exo Ox) was assessed using ¹³CO₂ enrichment (via isotope ratio mass spectrometry) and CO₂ production (via indirect calorimetry) over 6 h. Leu Ret relative to fat-free mass (FFM) was determined by the algebraic difference between total Leu intake and the area-under-the-curve for Exo Ox.

RESULTS: Over the 6 h post-prandial period, Leu Ret at rest was greater ($p < 0.01$) in males (16.27 mg/kg FFM) compared to females in the follicular (12.70 mg/kg FFM) but not luteal (14.39 mg/kg FFM) phase or active pill OC users (14.08 mg/kg FFM), with no further group differences ($p \geq 0.05$). Although Leu Ret after exercise was ~11.2% greater in males than females in the follicular phase, there were no significant differences between groups ($F(3, 28) = 2.65$, $p = 0.07$, $f^2 = 0.39$).

CONCLUSION: The greater anabolic sensitivity to dietary leucine in males compared to females during the follicular phase at rest is attenuated during recovery from RE. The impact of these differences in whole-body leucine retention on muscle protein metabolism and/or dietary protein requirements at rest or during recovery from RE warrants further investigation. This study is supported by a New Frontiers in Research Fund Grant to D.R.M.

CO-INGESTION OF A KETONE ESTER SUPPRESSES EXOGENOUS CARBOHYDRATE OXIDATION IN MALE CYCLISTS WHEN FEEDING 120 G.H-1 CARBOHYDRATE COMPARED WITH CARBOHYDRATE ALONE.

MARTYN, H., PUGH, J., OWENS, D., SHEPHERD, S., GONZALEZ, J., MORTON, J.

LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: Ketone esters are purported to improve endurance exercise performance via alterations in substrate metabolism, including a sparing of muscle glycogen (1). However, recent evidence suggests ketone ester ingestion could alter glucose metabolism, which in turn could impair exercise performance (2). Such studies have not been completed under conditions of best nutritional practice, including CHO loading, pre-exercise feeding and high rates of CHO ingestion during exercise. In this regard, it is unclear whether ketone esters are ergogenic to performance when consumed with optimal CHO. Accordingly, we aimed to test the hypothesis that co-ingestion of ketone esters during exercise suppresses exogenous CHO oxidation rates without affecting exercise capacity when compared to CHO alone.

METHODS: In a randomised, crossover design seven male trained cyclists ($\text{VO}_{2\text{max}} 64.6 \pm 6.1$ ml.kg⁻¹.min⁻¹) completed four 180-min cycling experimental trials at 95% of lactate threshold (LT) followed by an exercise capacity test to exhaustion at 150% LT. Each trial was commenced following 36 h of high CHO loading (11.6 g.kg⁻¹) and 2 h after a high CHO breakfast (2 g.kg⁻¹). Participants consumed 0 g.h⁻¹ during a familiarisation trial (FAM), 0 g.h⁻¹ (PLA), 120 g.h⁻¹ CHO (CHO) or 120 g.h⁻¹ CHO co-ingested with 75 g of ketone monoester (CHO + KE) ((R)-3-hydroxybutyl (R)-3-hydroxybutyrate) delivered in 3 boluses (25 g) at -60, 0 and 90 min during the protocol. Carbohydrate (exogenous and whole body) and lipid oxidation, subjective GI symptoms, blood lactate, glucose and β -hydroxybutyrate (β HB) were measured throughout exercise.

RESULTS: KE ingestion increased blood β HB to a peak concentration of 2.8 ± 0.8 mM at 30 min during exercise and mean concentrations were higher following KE ingestion vs CHO and PLA (both $P = 0.002$). There was no difference in mean whole body CHO oxidation rates between CHO + KE and CHO (2.40 ± 0.11 , 2.31 ± 0.13 g.min⁻¹, $P > 0.99$). However, whole body CHO oxidation rates in PLA (1.78 ± 0.12 g.min⁻¹) were lower than CHO + KE ($P = 0.008$) and CHO ($P = 0.013$). Mean rates of exogenous CHO oxidation were significantly reduced during exercise in CHO + KE vs CHO alone (1.37 ± 0.05 , 1.51 ± 0.05 g.min⁻¹, $P = 0.029$) (assessed via stable isotope methodology). Exercise capacity was not increased by CHO + KE compared with CHO (334 ± 239 , 365 ± 198 s, $P = 0.986$), though both trials (CHO + KE vs FAM, $P = 0.034$, CHO + KE vs PLA, $P = 0.053$, CHO vs FAM, $P = 0.016$, CHO vs PLA, $P = 0.025$) resulted in greater exercise capacity than PLA (85 ± 109 s) and FAM (67 ± 89 s).

CONCLUSION: Data demonstrate that ketone ester and CHO co-ingestion suppresses exogenous CHO oxidation during exercise and does not enhance exercise capacity when compared to CHO ingestion alone. Such data provide further evidence that ketone esters are unlikely ergogenic for exercise performance.

INGESTION OF A VARIETY OF PROTEIN-RICH WHOLE-FOODS RESULTS IN SIMILAR POST-EXERCISE WHOLE-BODY AND MYOFIBRILLAR PROTEIN SYNTHESIS RATES COMPARED WITH A PROTEIN ISOLATED FROM WHOLE-FOOD IN YOUNG ADULTS

HAIGH, F., MONTEYNE, A., ABDELRAHMAN, D., MURTON, A., FINNIGAN, T., THEOBALD, H., STEPHENS, F., WALL, B.
UNIVERSITY OF EXETER

INTRODUCTION: The ingestion of protein-rich whole-foods may stimulate (post-exercise) whole-body (WB) and myofibrillar protein synthesis (MyoPS) rates to a greater extent than protein isolated from whole-foods. However, to date, few (mostly animal-derived) foods have been investigated with regard to their potential to augment post-exercise anabolism. We assessed WB phenylalanine kinetics (to calculate indices of WB protein turnover) and MyoPS rates following a single bout of resistance exercise and ingestion of a variety of protein-rich whole-foods (from animal and non-animal derived sources) and egg whites (protein isolated from whole-food) in resistance trained young adults.

METHODS: In a randomised parallel design, sixty-five healthy young males and females received primed, continuous infusions of L-[ring-2H5]phenylalanine and L-[3,3-2H2]tyrosine and completed a bout of bilateral lower body resistance exercise before ingesting 0.25g protein per kg body mass[bm] from: egg whites (n=11; 7f, age 22 ± 2 y, bm 77.4 ± 4.7 kg), whole egg (n=11; 7f, age 24 ± 2 y, bm 77.0 ± 2.7 kg), salmon (n=10; 6f, age 24 ± 2 y, bm 75.2 ± 3.8 kg), pork (n=11; 7f, age 24 ± 2 y, bm 74.7 ± 3.6 kg) lentils (n=11; 7f, age 26 ± 2 y, bm 77.9 ± 3.0 kg) or mycoprotein (n=11; 7f, age 24 ± 2 y, bm 77.4 ± 3.5 kg). Blood and muscle samples (vastus lateralis) were taken pre- and (2 and 5 h) post-exercise/protein ingestion to assess postabsorptive and postprandial WB phenylalanine kinetics and MyoPS rates (as fractional synthetic rates; FSRs). Calculated WB protein metabolism parameters and FSRs were analysed using 2-way (condition x time) ANOVAs.

RESULTS: WB protein synthesis and breakdown rates increased and decreased, respectively, post-exercise/food ingestion in all conditions, with both effects being most pronounced following egg white ingestion. This resulted in the shift from postabsorptive negative to post-exercise postprandial positive WB net protein balance being most pronounced following egg white ingestion (postprandial net balance [0-5h]; egg whites, 256.6 ± 15.4 vs; whole egg, 161.0 ± 6.1 ; pork, 166.8 ± 7.2 ; salmon, 195.4 ± 7.1 ; lentils, 175.8 ± 8.1 ; mycoprotein, 189.7 ± 8.4 μ mol.kg⁻¹.min⁻¹ [$P < 0.0001$, all]). FSRs increased following exercise/food ingestion with no (temporal) differences between conditions despite divergent plasma amino acid responses (Δ change in FSRs [0-5 h]; egg whites, 0.050 ± 0.013 ; whole egg, 0.051 ± 0.009 ; pork, 0.008 ± 0.008 ; salmon, 0.021 ± 0.014 ; lentils, 0.029 ± 0.012 ; mycoprotein, 0.041 ± 0.012 %·h⁻¹ [$P = 0.077$]).

CONCLUSION: The ingestion of a variety of protein-rich whole-foods or a protein isolated from whole-foods (egg whites) immediately following lower body exercise results in comparable MyoPS rates, though a greater WB net protein anabolism was achieved with egg whites. These data demonstrate that a variety of commonly consumed protein-rich foods from different origins may be selected to support acute post-exercise reconditioning, though a potentiation due to consuming protein within its whole-food form does not necessarily occur.

Oral Presentations

RELAXATION TECHNIQUES TO IMPROVE SLEEP AND TIME-TO-EXHAUSTION TASK: PRELIMINARY FINDINGS

DI PINTO, G., ROSITO, S.A., POMPA, D., BERTOLLO, M., DI FRONSO, S., CURZI, D.
UNIVERSITÀ DEGLI STUDI GABRIELE DANNUNZIO CHIETI - PESCARA

INTRODUCTION: Relaxation techniques have been shown to improve both sleep quality and quantity, potentially playing a critical role in increasing the individual coping ability when facing high stressor (1). However, their role in performance improvement is understudied, especially in the endurance context. Thus, the aim of this study is to determine whether relaxation techniques may improve a cycle-ergometer time-to-exhaustion task. Moreover, we explored the effects of two

relaxation techniques with different mechanisms: Yoga Nidra (YN), a guided relaxation technique that induces a hypnagogic state blending deep rest with conscious awareness (1), and Body Scan (BS), a progressive muscle relaxation (PMR) technique that enhances bodily awareness while reducing muscular tension (2). Their influence on both performance and sleep parameters were assessed.

METHODS: Thirty-six participants performed four cycling sessions until exhaustion on a cycle-ergometer. The first two sessions aimed to determine the heart rate deflection point to ensure a comparable load across participants, while the third and fourth sessions worked as baseline (T0) and post-intervention (T1) tests, respectively. Participants were randomly assigned to either a relaxation technique group (YN; BS) or a Control (C) group. In each case, they underwent five days of their respective intervention between T0 and T1. From the second session onward, sleep was monitored using actigraphy-based monitoring for a total of 10 - 12 nights, depending on weekend presence.

RESULTS: First, we analyzed performance outcomes in the TTE test through a within-between-subjects RM-ANOVA to compare the time to complete the task associated with groups. The analysis showed improvements for both YN and BS groups when compared to the C group with a small effect ($F = 1.07$, $\eta^2 = 0.04$): YN: $T0=15,2\pm1,5$ min; $T1=16,3\pm1,7$ min. BS: $T0=14,9\pm1,4$ min; $T1=16,5\pm1,5$ min. C: $T0=17\pm1,3$ min; $T1=15\pm1,3$ min.

A RM MANOVA was performed for sleep variables and significant differences for groups were noted ($p=0.04$). Particularly, differences in the number of awakenings were found per group ($F=3.48$, $p=0.03$, $\eta^2=0.02$) and time ($F=4.90$, $p=0.02$; $\eta^2=0.02$): YN: $T0=16\pm4$; $T1=14\pm4$. BS: $T0=17\pm6$; $T1=16\pm5$. C: $T0=16\pm5$; $T1=16\pm5$.

Moreover, a trend was found in the interaction group*time for sleep latency ($F=2.41$; $p=0.09$; $\eta^2=0.01$): YN: $T0=26\pm21$ min; $T1=19\pm18$ min. BS: $T0=15\pm15$ min; $T1=20\pm19$ min. C: $T0=18\pm19$ min; $T1=17\pm17$ min.

CONCLUSION: In this study, relaxation techniques seem to be a promising approach to improve sleep quality and endurance performance. Regarding the two adopted techniques, YN yielded the most positive sleep effects, decreasing both the time to fall asleep and the number of awakenings after sleep onset, two crucial indicators for sleep quality.

BEYOND CURVATURE 'CONSTANT': INTENSITY-DEPENDENT VARIATIONS IN WORK ABOVE CRITICAL POWER

DI GENNARO, S., PANASCI, M., RUGGERI, P., FAELLI, E.

UNIVERSITÀ DEGLI STUDI DI GENOVA

INTRODUCTION: The Critical Power (CP) model describes the link between power and exercise duration and rests on two key assumptions: (i) the existence of a CP, representing the asymptote of the power-duration curve, and (ii) a fixed amount of work that can be performed above CP, referred to as the curvature constant (W). Previous research shows that test duration affects CP and W', with shorter trials yielding lower W'; however, it is unclear if this is due to the higher CP estimates or a true reduction in W'. Additionally, W exhibits a consistently large standard error of estimation, and its physiological significance remains unclear (1). Therefore we examine the difference between W and the actual work above CP ($W>CP$) at different intensities using different CP models and explore associations between W', $W>CP$, and well-established anaerobic markers.

METHODS: Nineteen cyclists completed a ramp test to determine the power at peak oxygen uptake (MAP). Then, they performed five trials to exhaustion (Tlim) at 130%, 115%, 100%, 85%, and 80% of MAP, and a Wingate test. Accumulated oxygen deficit (AOD) for each Tlim was calculated. CP and W, were computed by the 2- and 3-parameter hyperbolic models (2HYP and 3HYP), the Work-Time model (W-T), and the inverse-time model (1/T). Actual $W>CP$ during all Tlim were calculated. Pearson correlations were conducted to evaluate associations among variables and repeated measures ANOVA followed by Bonferroni post-hoc procedures to detect significant differences among conditions. Significance was set at $P<0.05$. All data are expressed as mean $\pm$ SD.

RESULTS: W derived from 2HYP and 3HYP were significantly higher than $W>CP$ at 130, 115, and 100% MAP ($P<0.01$). For both models, the $W>CP$ was higher at 85 and 80% compared with 130 and 115% MAP ($P<0.05$). W derived from W-T and 1/T were significantly higher than the actual $W>CP$ at 80% MAP ($P<0.05$). Notably, the $W>CP$ predicted by W-T was lower at 130% and 115% MAP compared to 100% and 85% MAP ($P<0.05$). A positive association was found between peak and mean power of the Wingate test, and the $W>CP$ during Tlim at or above 100% MAP, regardless of the model used ($P<0.05$). No significant correlations were observed between W (irrespective of the model) and maximal AOD. However, the $W>CP$ during the 130% MAP trial was correlated with the corresponding AOD for all models ($P<0.05$). Additionally, for the two hyperbolic models, this relationship also appeared for the $W>CP$ at 115% MAP ($P<0.05$).

CONCLUSION: Our findings highlight that W' may not be constant as previously assumed. Indeed, $W>CP$ shows an intensity-dependent behaviour, with lower values for shorter efforts, increasing for longer efforts until reaching a plateau at intensities between CP and MAP. Furthermore, W shows weak correlations with AOD and Wingate test results, reinforcing that W alone cannot fully capture an athlete's anaerobic capacity.

THE INFLUENCE OF MENSTRUAL CYCLE AND ORAL CONTRACEPTIVES ON PSYCHOLOGICAL AND PHYSIOLOGICAL PARAMETERS AT REST AND DURING SUBMAXIMAL CYCLING

SCHAFFARCZYK, M., GRONWALD, T.

MEDICAL SCHOOL HAMBURG

INTRODUCTION: Menstrual cycle (MC) and oral contraceptives (OC) create distinct hormonal environments. While MC phases are characterized by dynamic fluctuations of endogenous estrogen and progesterone, OC use suppresses these hormones, replacing them synthetically. Despite evidence suggesting phase-dependent variations in performance during the MC (1) and potential impairments under OC use due to hormonal suppression (2), findings remain inconsistent. To further address uncertainties, we conducted standardized testing across MC and OC cycles focusing on within-group changes and potential between group differences.

METHODS: Twenty-two eumenorrheic women (age: 30 ± 5 y, VO_{2peak} : 43 ± 6 ml/min/kg) and six women using OC (age: 29 ± 5 y, VO_{2peak} : 46 ± 6 ml/min/kg) performed standardized tests in specified phases (MC: early follicular (EFP), ovulatory (OP), midluteal phase (MLP); OC: early inactive pill (EIPP), late inactive pill (LIPP), mid active pill phase (MAPP)) for one ($n=6$), two ($n=22$) or three test cycles ($n=1$). Testing included the Short Recovery and Stress Scale (SRSS), assessment of heart rate measures (RR, HR, RMSSD, SDNN, DFAa1) at rest (pre- and post-exercise), and during a 15-minute submaximal incremental cycling test (SCT) with intensities set at 90% of first ventilatory threshold (VT) 1, 110% VT1, and 100% VT2. SCT included blood lactate concentration (BLC) testing and rating of perceived exertion (RPE). Linear mixed-effects models and Cohens d were used to analyze data for MC, while descriptive analyses and Cohens d were applied for OC due to the small sample size.

RESULTS: Pre-exercise SDNN showed MC effects ($p=0.037$), particularly between MLP with EFP ($p=0.083$, $d=0.58$) and OP ($p=0.052$, $d=0.44$). SRSS subscales emotional balance (EB; $p=0.038$) and emotional imbalance (EI; $p=0.031$) were significantly affected, notably between EFP and OP in MC (EB: 4.23 vs. 5.08, $p=0.034$, $d=-0.55$; EI: 3.66 vs. 2.70, $p=0.039$, $d=0.57$). In OC, all subscales except from EB, showed a substantial change between EIPP and LIPP or EIPP and MAPP ($d>0.80$). During SCT, most parameters were unaffected by MC and OC, except RPE, which showed significant MC effects ($p<0.001$) with moderate changes between EFP and OP for the first (11.9 vs. 11.3, $p=0.024$, $d=0.59$) and second intensity stage (15.1 vs. 14.6, $p=0.073$, $d=0.50$), and substantial changes for OC between EIPP and LIPP for the first stage (11.0 vs. 10.4, $d=1.55$).

CONCLUSION: MC and OC phases had limited physiological but notable psychological effects. EFP (MC) and EIPP (OC) were associated with higher perceived stress and lower recovery. A closer examination of the SRSS subscales exhibited primarily emotional changes for MC, while OC showed substantial alterations in other facets like lack of activation or physical performance capacity. These findings emphasize the role of hormonal variability in psychological outcomes, even when physiological parameters remain largely unaffected.

SEX DIFFERENCES IN DURABILITY DURING CYCLING EXERCISE

PASTORIO, E., SPILLANE, P., SQUIRES, E., BENYAHIA, L., WILSON, H., COLOSIO, M., FELLES, C., MENDITTO, A., CLARKE, S., MINION, B., PEARMAIN, W., BROWNSTEIN, C., PORCELLI, S., ANSDELL, P.

NORTHUMBRIA UNIVERSITY

INTRODUCTION: In cycling, a rider's capacity to maintain high power outputs (PO) after accumulating a certain amount of work represents a key determinant of elite performance [1]. Indeed, the most successful competitive male (M) road cyclists have shown lesser reductions in the power output profile that occurs as exercise proceeds, also called "durability" [2]. However, while females (F) are well reported to be more fatigue-resistant than M during various tasks [3], no research has compared durability between sexes. Therefore, this study aimed to investigate durability (measured as changes in sub-maximal and maximal markers of performance) and the underpinning physiological mechanisms in both sexes following 90 minutes of heavy intensity cycling.

METHODS: 32 cyclists (16M, age 29 ± 6 years, VO_{2peak} 58 ± 6 ml.kg⁻¹.min⁻¹ and 16F, age 26 ± 3 years, VO_{2peak} 51 ± 3 ml.kg⁻¹.min⁻¹) visited the laboratory on two occasions. In visit 1, participants performed an incremental exercise test to exhaustion. In visit 2, they performed 90 minutes of heavy intensity cycling (HVY) at 110% of gas exchange threshold (GET), followed by the same incremental test performed in visit 1. During HVY, pulmonary ventilation (VE), oxygen uptake (VO_2), carbon dioxide production (VCO_2), heart rate (HR), and rating of perceived exertion (RPE) were recorded, and blood lactate (bLa) was collected. Before (PRE) and immediately after (POST) HVY, maximal voluntary isometric contraction force (MVIC), voluntary activation (VA) and potentiated twitches (100Hz, 10Hz, Qtw) of the knee extensors were assessed.

RESULTS: Peak PO (M 410 ± 56 vs F 269 ± 34 W), PO at GET (M 226 ± 42 vs F 135 ± 20 W), and at respiratory compensation point (RCP, M 331 ± 51 vs F 221 ± 35 W) were higher in M vs F (all $p<0.001$). During HVY, VE, HR, gross efficiency and RPE increased over time (all $p<0.001$) without sex differences. Time $\times$ sex interactions were detected for HR ($p=0.008$) demonstrating greater increases in M, and RER ($p<0.001$) with greater decreases in F. A sex effect was found for bLa ($p=0.029$) and VO_2 (%peak, $p=0.012$), which were greater in M compared to F. After HVY, PO at GET (M $-16 \pm 15\%$ vs F $-3 \pm 12\%$) and at RCP (M $-13 \pm 10\%$ vs F $-6 \pm 9\%$) decreased more in M than F ($p=0.013$ and $p=0.048$, respectively). Peak PO (M $-13 \pm 9\%$ and F $-8 \pm 7\%$, $p=0.073$) and VO_{2peak} (M $-8 \pm 9\%$ and F $-6 \pm 6\%$, $p=0.884$) decreased similarly in both sexes. MVIC ($-17 \pm 10\%$), po-

tentiated twitches at 100Hz ($-15\pm 13\%$), 10Hz ($-34\pm 15\%$), Qtw ($-27\pm 12\%$), and VA ($-6\pm 6\%$), decreased from PRE to POST (all $p<0.001$), without sex differences ($p\geq 0.096$).

CONCLUSION: Females exhibited lesser reductions in submaximal thresholds, whereas data recorded at peak exercise decreased similarly in both sexes, and no sex differences were observed in the changes in neuromuscular function. These results highlight the need to consider sex-specific training prescription and pacing strategies for long duration events.

THE ACUTE RESPONSES TO REPEAT-SPRINT TRAINING IN HYPOXIA IN ELITE TRACK ENDURANCE CYCLISTS

BARRATT, G., BUCKLEY, J., ROBERTSON, E., LEO, P., GIRARD, O., BELLENGER, C., STANLEY, J.

UNIVERSITY OF SOUTH AUSTRALIA

INTRODUCTION: Repeat-sprint training in hypoxia (RSH) is increasingly used by elite athletes to improve repeat-sprint ability under normoxic conditions [1]. RSH involves performing a series of "all-out" sprints (3-10s) with brief recovery periods (<60 s) [2] in a hypoxic environment (i.e., simulated altitude of ~ 3000 m) [3]. However, the physiological responses to varying sprint durations, particularly in elite cyclists, remain unclear. This study aimed to determine how different RSH sprint durations affect acute physiological responses in elite track endurance cyclists.

METHODS: Nineteen elite track endurance cyclists completed a two-week RSH training block, incorporating four repeat-sprint sessions into their regular training and racing. RSH sessions were prescribed at simulated altitude of ~ 3000 m (FiO₂: 14.5%) in a normobaric hypoxic chamber using three protocols: RSH-6 (4 x 5 sprints, 6s sprint:24s rest), RSH-10 (3 x 5 sprints, 10s sprint:20s rest), and RSH-6/10 (4 x 5 sprints, sets 1 and 3 – 6s sprint:24s rest; sets 2 and 4 – 10s sprint:20s rest). Athletes performed all sprints seated, starting with a cadence of 40rpm for 6s sprints and 70rpm for 10s sprints, aiming to exceed 120rpm during all sprints. A fixed effects linear mixed model (LMM) was used to assess differences between sprint durations (6s vs 10s sprints) and protocols (RSH-6, RSH-10 and RSH-6/10).

RESULTS: Mean and peak sprint power output ($p=0.006$), mean and peak sprint torque ($p=0.001$) and vastus lateralis re-oxygenation between sprints ($p=0.001$) were greater in 6s sprints compared to 10s sprints. The 10s sprints resulted in higher work per sprint and peak cadence ($p=0.001$), larger decrements in mean power across a set ($p=0.001$), higher blood lactate accumulation with each set ($p=0.001$), and greater vastus lateralis de-oxygenation during sprints ($p=0.001$). Between session analyses demonstrated that RSH-6 had significantly higher mean and peak power outputs and torque outputs compared to RSH-10 ($p<0.001$) and RSH-6/10 ($p<0.001$). RSH-10 elicited higher heart rate and blood lactate accumulation across the session, along with lower vastus lateralis de-oxygenation during sprints compared to RSH-6 ($p=0.001$) and RSH-6/10 ($p=0.001$).

CONCLUSION: In elite cyclist undertaking RSH, 6s sprints durations elicited a stronger neuromuscular response (i.e. greater torque) while sets of 10s sprints resulted in larger decrements in power and torque, and higher blood lactate accumulation and oxygen extraction. Using 6s sprints or 10s sprints during RSH in elite track cyclists therefore could be used to target both neuromuscular and metabolic adaptations respectively.

DEVELOPMENT AND APPLICATION OF ROTATIONAL SHOT PUT TECHNIQUE ANALYSIS SYSTEM

DEFENG, Z., WU, Y.

SHANGHAI RESEARCH INSTITUTE OF SPORTS SCIENCE

INTRODUCTION: The development of the rotational shot put technique analysis system aimed to enhance athletes performance through advanced artificial intelligence technologies. The system was designed to quickly capture and analyze biomechanical data of human motion, providing coaches and athletes with technical evaluations, thereby optimizing training effects.

METHODS: System Architecture and Key Technologies

The system primarily consists of two parts: the client and the server. Client includes a human-computer interaction module and a data acquisition and processing module, responsible for data input, display, and user interaction. Server includes a model invocation module and an offline training module, responsible for invoking deep learning models for pose estimation and data processing. Key technologies include a 3D human pose estimation algorithm, which utilizes an adaptive fusion method, combining epipolar expansion and triangulation techniques based on epipolar geometry constraints, improving adaptability to complex scenarios such as occlusion and enhancing pose estimation accuracy, a smoothing model, which improves the stability of pose sequences and reduces noise interference through smoothing processing,

and a heartbeat mechanism, ensuring smooth communication between the client and server, guaranteeing real-time and accurate data processing.

Specialized Action Technique Diagnosis

The system is specifically designed for the rotational shot put athletes, providing detailed technical evaluation. Users can input training or competition data to generate diagnostic reports containing speed, amplitude, angle, time, and et al. Reports offer detailed technical analysis and feedback, helping coaches and athletes identify technical shortcomings.

System Validation

To verify the accuracy and reliability of the system, we set up the rotational shot put technique analysis system alongside the qualisys motion capture system in an experimental setting. Six athletes performed three rotational shot put throws, with both systems capturing the entire motion and analyzing kinematic parameters. Bland-Altman plot and ICC analysis were used to assess the consistency and correlation of measuring results between the two systems, respectively.

RESULTS: Validation **RESULTS:** The Bland-Altman plot showed high consistency in measuring results between the two systems. ICC analysis indicated a high correlation between the two systems. These results demonstrate that the rotational shot put technique analysis system has high accuracy and reliability, providing precise technical analysis outcomes for athletes and coaches.

CONCLUSION: The rotational shot put technique analysis system is an accurate and reliable technical analysis tool, offering new methods and approaches for rotational shot put technique analysis. Through this system, coaches and athletes can conduct detailed technical evaluations and training optimizations, thereby improving athletic performance.

THEIA 3D MARKERLESS VS. MARKER-BASED MOTION CAPTURE: COMPARING SHOULDER KINEMATICS IN OVERHEAD MOVEMENTS

KÜNZEL, C., CROCI, E., GEHRING, D., MÜLLER, A.M., MÜNDERMANN, A.
UNIVERSITY OF FREIBURG

INTRODUCTION: The analysis of shoulder kinematics during overhead movements can reveal important information for performance optimization and injury prevention in sports such as handball and tennis. Marker-based motion capture systems provide highly accurate joint angle measurements and are commonly used in sports science and clinical research. However, their use in field environments is limited due to long preparation and post-processing times. While markerless motion capture, like Theia 3D, presents a promising alternative, its accuracy for overhead shoulder kinematics remains unclear. Therefore, we aimed to compare shoulder kinematics during overhead movement tasks between Theia 3D and a marker-based motion capture system.

METHODS: Twenty participants performed overhead movements including full arm scaption, abduction and flexion while synchronized markerless (Theia 3D, v2023.1) and marker-based (Qualisys) motion capture data were collected. Reflective markers were placed on landmarks of the upper extremities and trunk according to the International Society of Biomechanics (ISB) guidelines [1]. For both approaches data were processed with a low-pass Butterworth filter at 6 Hz cut-off and shoulder kinematics were reconstructed using the X-Z-Y sequence for scaption and abduction tasks and the Z-X-Y sequence for flexion tasks [2]. Coefficients of multiple correlation (CMCs) and root mean square errors (RMSEs) were calculated for the kinematic waveforms for each angle and movement task.

RESULTS: In general, markerless and marker-based trajectories showed similar patterns for all movements, indicated by good to excellent CMCs (>0.75) for all angles and movement tasks. However, larger differences between systems were observed near the turning point of the movement, when the arms reached the maximum overhead position. Mean RMSEs were smallest for the abduction angle, ranging from 5.9° to 9.1° , followed by the flexion angle ranging from 8.7° to 12.1° and the internal rotation from 16.5° to 24.1° .

CONCLUSION: While Theia3D v2023.1 showed general agreement in movement patterns compared to the marker-based system, notable differences in absolute joint angles were observed, particularly for the internal rotation angle. This suggests that Theia3D, in the tested version v2023.1, is not suitable for use in performance analysis and injury prevention in sports, where accurate measurements of overhead shoulder kinematics across three dimensions are essential. However, further refinement and training of the model on overhead movement tasks may enhance the accuracy of Theia3D for these tasks, making it a potent alternative for assessing shoulder kinematics in the future.

LIGHTS, CAMERA, ACTION: THE IMPACT OF LIGHTING AND CAMERA POSITIONING ON THREE-DIMENSIONAL GAIT KINEMATICS USING MARKERLESS MOTION CAPTURE

WALKER, J., THOMAS, A., NICHOLSON, G., TUCKER, C.B., LUNN, D.E.
LEEDS BECKETT UNIVERSITY

INTRODUCTION: Markerless motion capture (MMC) has emerged as a potential solution to motion capture in logistically challenging environments (e.g., outside a motion capture laboratory). As such, many studies compare MMC (e.g., Theia3D [1]) with conventional marker-based methods to understand agreement between systems. These studies often take

place in a laboratory environment, where factors like lighting and camera position can be optimised for 3D coverage. However, many environments where MMC might be employed have suboptimal lighting or limited space for ideal camera placement (e.g., hospital or gymnasium). This study aimed to understand the effects of lighting and camera positioning on MMC performance, by synchronously comparing with a marker-based system.

METHODS: Fifteen adults walked (3 km/h) and ran (12 km/h) on an instrumented treadmill (Gaitway3D; h/p/cosmos), whilst a 14-camera optoelectronic motion capture system (Oqus 7+, Qualisys) collected retroreflective marker trajectories [2]. Video data were collected synchronously with 12 high-speed cameras (100 Hz; Miquis, Qualisys). To compare the effect of lighting, data were collected under four randomised lighting conditions (1069, 692, 455, and 289 lux). Video cameras evenly surrounded the capture volume (SURR), but to compare the effect of camera position some cameras were removed post-collection to replicate a corridor (CORR) setup, and a setup with bias towards anterior views (FRONT) under one lighting condition (1069 lux). Videos were processed using Theia3D. Hip, knee, and ankle joint range of motion (ROM) was computed in all three planes with Visual3D and compared between lighting conditions and camera setups using marker data as a reference system.

RESULTS: Significant interactions were found for all joints when lighting was changed, with less lighting leading to lower hip frontal ROM, higher knee and ankle frontal ROM, and higher ROM in all transverse angles ($p < 0.05$). Despite systematic differences between marker data and MMC, there were generally no interactions with lighting in the sagittal plane. There were significant differences between camera setups, particularly in frontal and transverse planes ($p < 0.05$). SURR and FRONT underestimated ROM compared with marker data, where CORR was in some cases more similar ($p \geq 0.05$).

CONCLUSION: Lighting and camera positioning need to be considered when using MMC, especially if kinematics in the frontal or transverse planes are of interest (e.g., in injury "screening" assessments). Equally, the translation of system comparison studies into the field-based adoption of MMC needs to be approached with caution, as external factors like lighting and camera position affect the difference between systems. Finally, if a motion capture environment has compromised lighting or limited space for camera setup, the accuracy of MMC might be limited.

VALIDATION OF COMPUTER VISION BASED KINEMATIC ANALYSIS USING LATERAL VIEW VIDEOS IN ERGOMETER ROWING

KORNFEIND, P., KABAS, S., BACA, A.

CENTRE FOR SPORT SCIENCE AND UNIVERSITY SPORTS, UNIVERSITY OF VIENNA

INTRODUCTION: Kinematic analysis in rowing is critical for optimizing performance and technique and difficult to realize in everyday training due to the high effort involved. Computer vision (CV) offers automated solutions [1], yet validation remains essential [2]. This study compared the results of CV-derived joint angles at key rowing phases (catch/end position) with manual digitization of three different evaluators using an open-source analysis software in elite rowing.

METHODS: Eighteen healthy Austrian national rowers (age: 23.1 ± 3.5 years; experience: 6.2 ± 2.1 years) performed a 2000 m all-out test on a rowing ergometer. Lateral-view videos (4k@120 fps) were recorded with an action camera (GoPro 12 Black) at linear optic settings and 5 consecutive strokes after 500 m rowing distance were chosen for the later analysis. A commercially available analysis tool (RowerUp 2025) was used for the automated detection of joint centers and angle calculations while two experienced evaluators (both rowing experts) performed a manual analysis using Kinovea software (2024.1). The calculated joint angles (hip, knee, ankle) at catch and end positions have been compared using paired t-tests, intraclass correlation coefficient (ICC) was used to assess agreement between the methods.

RESULTS: High agreement was observed for the angles in the knee ($ICC = 0.87$) and ankle joint ($ICC = 0.92$). Shoulder and hip joint center detection showed slight discrepancies impacting the absolute hip angle accuracy ($4.21 \pm 5.89^\circ$, $p = 0.020$). However, the intraindividual variability was acceptable ($ICC > 0.80$) for all joint angles. Regarding the automatic detection of the catch/end position (timing), the CV system demonstrated robust temporal synchronization (mean difference: < 0.05 s). Critical background and contrast situations (e.g. dark background & black rowing suite) resulted in a slightly larger deviation in the detection of joint centers.

CONCLUSION: CV-based kinematic analysis provides valid intraindividual comparisons despite minor absolute inaccuracies in shoulder/hip joint localization. This supports its utility for training feedback and longitudinal monitoring in elite rowing, also thanks to a very well-designed operating concept and user interface (GUI). Next step would be the validation against marker-based 3D-kinematic data under laboratory conditions but also in practical training environment with different camera alignments (position & orientation) [3] and varying clothing situations (e.g. long vs. short rowing suites, different color combinations).

FRONTAL PLANE ANALYSIS OF GOLF SWINGS: DETECTING INDIVIDUAL AND PROFICIENCY DIFFERENCES USING COMPUTER VISION

YAMAMOTO, K., HASEGAWA, Y., SUZUKI, T., SUZUKI, H., TANABE, H., FUJII, K.
HOKUSEI GAKUEN UNIVERSITY

INTRODUCTION: Golf swings involve complex, multi-degree-of-freedom movements, and understanding individual and expertise-related variations is crucial for optimizing performance. Previous studies, such as Yamamoto et al. (2023), have shown that sagittal plane markerless motion analysis can successfully identify proficiency differences and individual swing characteristics, but its applicability to frontal plane motion remains unexplored. In golf, the analysis of movements in the frontal plane is crucial for understanding body sway, including head sway, which contain essential information for making fast and accurate contact between the club and the ball. Additionally, this study aims to conduct this investigation using a low-cost and simplified method.

METHODS: Twenty-eight golfers (beginner to expert) hit 20 shots using a 7-iron. High-speed video (240 Hz) was utilized to record frontal plane movements. Pose estimation via HRNet extracted joint positions, and key swing events were identified. Head and pelvis coordination patterns were analyzed via ear and hip joint midpoints.

RESULTS: Three distinct coordination patterns were identified: (a) The head and pelvis moved backward together (opposite to the shot direction). (b) The pelvis moved backward while the head remained stable. (c) The head moved forward (toward the shot direction) while the pelvis moved backward.

The distribution of these coordination patterns showed no significant correlation with expertise level, suggesting that these variations represent individually acquired movement patterns rather than universally expertise-dependent characteristics.

CONCLUSION: This study analyzed golf swing patterns in the frontal plane using a simple method (high-speed video data and pose estimation with computer vision). As a result, the coordination between the head and body could be broadly classified into three distinct movement patterns. Furthermore, these movements could be more broadly divided into a translational swing (a) and rotational swings (b, c), where the head movement differed.

This difference may correspond to allocentric, and egocentric movements as described by Swinnen et al. (1997), suggesting that in complex motor tasks, strategies for generating large forces or achieving precise movements are not limited to a single approach.

COMBINED EFFECTS OF HIGH-INTENSITY INTERVAL TRAINING AND SODIUM NITRITE SUPPLEMENTATION ON METABOLIC AND INFLAMMATORY BIOMARKERS IN TYPE 2 DIABETIC RATS

EFTEKHARIRANJBAR, S.1,7, FRIGERIO, F.2,7, BERTOLLO, M.1, POURRAHIM, A.3, CARDINALI, L.4, BALDARI, C.5, GUIDETTI, L.6, DONINI, L.7, MIGLIACCIO, S.7

1UNI OF G. D'ANNUNZIO CHIETI-PESCARA, 2SAN RAFFAELE ROMA OPEN UNI, 3UNI OF MOHAGHEGH ARDABIL, 4LINK CAMPUS UNI, 5 ECAMPUS UNI, 6UNI NICCOLÒ CUSANO, 7SAPIENZA UNI OF ROME

INTRODUCTION: Type 2 diabetes mellitus is a chronic, progressive metabolic disorder marked by insulin resistance, increased inflammation, and oxidative stress (1). While high-intensity interval training (HIIT) has shown substantial benefits in modulating angiogenesis and flogosis (2), sodium nitrite (NaNO₂) supplementation has emerged as a promising agent for enhancing insulin sensitivity and reducing oxidative stress (3). Thus, our study was conducted to elucidate the effects of sodium NaNO₂ and HIIT on metabolic and vascular dysfunction biomarkers of subclinical chronic inflammation.

METHODS: To this aim diabetic rats, obtained by applying the nicotinamide-streptozotocin method, were used as experimental animal model. An overall sample of 25 male rats was assigned to one of 5 groups: control animals, diabetic animals, diabetic+NaNO₂ supplementation, diabetic+HIIT, and diabetic+HIIT+NaNO₂ supplementation. Exercise intervention consisted of an 8-week HIIT protocol with increasing intensity and duration, adjusted every 2 weeks based on reassessed maximum running speed. NaNO₂ was administered in 3 doses via tail injection (12 nmol/kg each), with a one-week interval among doses. Specific biomarkers (i.e., TNF-alpha, MuRF1, PI3K, Klotho, and Resistin) were measured in rat cardiomyocytes by ELISA. One-way ANOVA and Kruskal-Wallis tests were used for between-group comparisons, followed by Dunnett's T3 and Dunn-Bonferroni post-hoc tests.

RESULTS: As compared to control animals, diabetic animals displayed higher MURF-1 and TNF-alpha levels (p=0.047 and p=0.002, respectively), while greater Resistin levels were apparent both in diabetic (p=0.007) and HIIT animals (p=0.008).

Finally, increased Klotho levels emerged in the NaNO₂+HIIT and NaNO₂ groups ($p=0.001$ and $p=0.044$, respectively) compared to diabetic animals whereas significantly higher PI3K levels were apparent both in control ($p<0.001$) and NaNO₂+HIIT ($p=0.017$) rats.

CONCLUSION: In conclusion our results show that while combined intervention (NaNO₂+HIIT) effectively increased both Klotho and PI3K levels, isolated NaNO₂ supplementation selectively ameliorated Klotho levels at the cardiomyocyte level of diabetic rats. When administered alone, HIIT was not effective in contrasting diabetes-induced alterations in inflammatory and metabolic biomarkers in an experimental diabetic animal model.

EFFECTS OF DIGITALLY MONITORED TIME-RESTRICTED EATING AND HIGH-INTENSITY INTERVAL TRAINING IN ADULTS WITH OVERWEIGHT OR OBESITY: A RANDOMIZED CONTROLLED TRIAL

HAGANES, K., BAKER, J., MOHOLDT, T.

NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY

INTRODUCTION: Time-restricted eating (TRE) and high-intensity interval training (HIIT) have emerged as two promising alternatives to the current diet and physical activity recommendations for improving cardiometabolic health. In our previous study, 7 weeks of TRE combined with supervised HIIT (TREHIIT) reduced fat mass, visceral fat, and HbA1c and improved cardiorespiratory fitness (CRF) in women with overweight/obesity (1). The effects of TREHIIT in free-living conditions with minimal follow-up remain unclear. We investigated the effects of a digitally monitored TREHIIT intervention completed outside the laboratory on fat mass and secondary cardiometabolic health outcomes in men and women with overweight/obesity.

METHODS: We randomized 52 adults (50% female, 37.5 ± 6.9 years, body mass index (BMI) 33.0 ± 4.1 kg/m²) 1:1 to a 7-week TREHIIT intervention or a control group (CON). The intervention included 3 weekly HIIT sessions performed as the participants' preferred aerobic activity at $\geq 90\%$ maximal heart rate, and a ≤ 10 -h/day TRE window with ad libitum energy intake. All HIIT sessions were performed in free-living conditions after one supervised introductory session. Participants in TREHIIT received one weekly follow-up via telephone. Participants in CON received no intervention nor weekly follow-up. The primary outcome was fat mass change. We measured secondary body composition outcomes, CRF, and cardiometabolic health markers in fasting blood samples. We analyzed between-group differences using linear mixed models and considered $p < .01$ statistically significant for secondary outcomes.

RESULTS: Forty-two participants completed the study. We found no statistically significant difference in fat mass (-1.0 kg, 95%CI -2.3 to 0.4 , $p=.146$). Participants in TREHIIT had reduced body mass (-2.1 kg, 95%CI -3.4 to -0.8 , $p=.002$) and tendencies of reduced muscle mass (-0.7 kg, 95%CI -1.3 to -0.2 , $p=.013$). CRF, measured as absolute and relative peak oxygen uptake, increased after TREHIIT (0.4 L/min, 95%CI 0.1 to 0.6 , $p=.008$ and 3.4 mL/min/kg, 95%CI: 0.9 to 5.9 , $p=.010$, respectively). There were no statistically significant between-group differences in remaining secondary outcomes.

CONCLUSION: TREHIIT in a real-world setting with digital follow-up did not reduce fat mass among adults with overweight/obesity. However, CRF significantly increased after TREHIIT, and the improvement was similar to that observed in our previous study of 7 weeks supervised TREHIIT. These findings suggest that a thrice weekly HIIT intervention is feasible without extensive supervision and can induce important improvements in cardiovascular health, but additional support may be required for effective fat mass reduction.

EFFECTS OF ONCE-WEEKLY AND THRICE-WEEKLY HIGH-INTENSITY INTERVAL TRAINING ON LEAN MASS IN ADULTS WITH CENTRAL OBESITY: A PRELIMINARY SECONDARY ANALYSIS OF A RANDOMIZED CONTROLLED TRIAL

LEUNG, C., BERNAL, J., YU, A., SIU, P.

THE UNIVERSITY OF HONG KONG

INTRODUCTION: Preservation of lean mass is critical to maintain good health, especially in individuals with obesity. In the obese population, the loss of lean mass can lead to sarcopenic obesity and impose significant detriment in functional independence, quality of life, and even the management of obesity and its comorbid conditions, such as diabetes. Although resistance training is well-established as an exercise strategy to mitigate the loss of lean mass, its implementation at the public health level is limited due to barriers such as access to equipment and knowledge on how to perform the movements correctly. High-intensity interval training (HIIT) is a popular exercise strategy in the general and obese popula-

tion with robust benefits on cardiorespiratory and adiposity health. However, its effects on lean mass are inconclusive, as evidence in the literature is mainly derived from studies employing cycling HIIT with small sample sizes (e.g., 10 participants per group). Thus, limiting its interpretation and application to the broader community. This study presents the secondary findings of a randomized controlled trial that examined the effects of once-weekly and thrice-weekly walking/jogging HIIT on lean mass in adults with central obesity.

METHODS: In this three-arm, assessor-blinded, randomized controlled trial, 315 adults (Age: 48 ± 13 ; BMI: 28.7 ± 3.8) with central obesity (waist circumference ≥ 80 cm for women and ≥ 90 cm for men) were randomized in a 1:1:1 ratio to once-weekly HIIT (H1: $n=105$), thrice-weekly HIIT (H3: $n=105$) and usual care (CON: $n=105$). Usual care participants attended a 150-minute health education class every 2 weeks for 16 weeks. HIIT participants received 75 minutes of supervised HIIT per week for 16 weeks. Training was conducted on a treadmill using the 4x4-min protocol, which consists of four 4-min intervals at 85-95% peak heart rate with a 3-min active recovery between each interval. Outcome assessments were conducted before and after the 16-week intervention. Appendicular lean mass (ALM), lower limb lean mass (LLM) and upper limb lean mass (ULM) was assessed using dual-energy x-ray absorptiometry. Generalized estimating equations was used to assess the treatment effects, with baseline values used as covariates.

RESULTS: After 16 weeks of intervention, ALM, LLM and ULM was significantly greater in the once-weekly (ALM: H1 vs CON: $+0.58$ kg; $P<0.0001$) and thrice-weekly HIIT group (ALM: H3 vs CON: $+0.66$ kg; $P<0.0001$) compared to the CON group. No significant difference was found between once-weekly and thrice-weekly HIIT for all outcomes (ALM: H3 vs H1: $+0.08$ kg; $P=0.49$).

CONCLUSION: Walking/jogging HIIT performed for 75 minutes a week (regardless of once-weekly or thrice-weekly) can induce modest improvements in lean mass relative to control in adults with central obesity. These findings enhance the role of HIIT as a public health exercise strategy to provide holistic health benefits ranging from cardiorespiratory health to lean mass.

EFFECTS OF DIFFERENT INTENSITIES OF HIGH-INTENSITY INTERVAL TRAINING ON CARDIAC FUNCTION IN OBESE WOMEN

HAN, Q.

HUMBOLDT UNIVERSITÄT ZU BERLIN

INTRODUCTION: Obesity is a major global public health issue, particularly among women, increasing the risk of cardiovascular diseases, diabetes, and metabolic disorders. According to the World Health Organization, approximately 39% of adults are overweight or obese, with a higher prevalence among women. High-intensity interval training (HIIT) has emerged as an effective exercise intervention for reducing fat mass and improving cardiovascular health. Compared to moderate-intensity continuous training (MICT), HIIT is more time-efficient while inducing significant physiological adaptations. However, the effects of different HIIT volumes remain unclear, especially in obese women. This study investigates the effects of high-volume (HV-HIIT) and low-volume (LV-HIIT) HIIT on body composition and cardiac function in obese women.

METHODS: A randomized controlled trial was conducted with 40 obese women (BMI ≥ 30) aged 18–40 years. Participants were randomly assigned to HV-HIIT, LV-HIIT, MICT, or a control group. All training sessions were conducted on a Wattbike. HV-HIIT sessions lasted more than 15 minutes with interval periods of 4–6 minutes, whereas LV-HIIT sessions were under 15 minutes with 30-second to 1-minute intervals. MICT sessions lasted 45 minutes at 60–75% of maximum heart rate, while the control group received no exercise intervention.

Body composition was assessed using bioelectrical impedance analysis (BIA). Cardiac function was measured via echocardiography, including ejection fraction (EF), mitral valve inflow velocities (E/A ratio), stroke volume, and cardiac output. One-way ANOVA was used to analyze group differences, with LSD post-hoc testing.

RESULTS: Baseline characteristics showed no significant differences between groups ($p > 0.05$). After intervention, HV-HIIT reduced body fat percentage from 35.22% to 33.82% and BMI from 24.84 kg/m^2 to 24.44 kg/m^2 . LV-HIIT showed a reduction in body fat percentage from 37.38% to 36.25% and BMI from 25.49 kg/m^2 to 24.94 kg/m^2 . MICT also induced positive changes ($p < 0.01$) but was less effective than HIIT. HV-HIIT increased EF from 70.16% to 74.86% and improved the E/A ratio from 2.01 to 2.55 ($p < 0.05$). LV-HIIT increased EF from 67.71% to 76.04%, but E/A ratio changes were not significant. Cardiac output and stroke volume improved across all intervention groups, with no significant inter-group differences.

CONCLUSION: Both HV-HIIT and LV-HIIT effectively improved body composition and cardiac function in obese women. The minimal differences between the two suggest that LV-HIIT could serve as a time-efficient training alternative for improving cardiovascular health and reducing obesity-related risks.

HIIT VS. MICT: OPTIMAL EXERCISE DOSE FOR MAXIMIZING CARDIORESPIRATORY FITNESS IN HEALTHY AND CV RISK POPULATIONS - A DOSE RESPONSE META-ANALYSIS

ZA DON, N.3, MATTIONI MATURANA, F.1, COCKS, M.3, NIEß, A.M.2, THUISSEN, D.H.J.1, DAWSON, E.A.

<1> LIVERPOOL JOHN MOORES UNIVERSITY; <2> RADBOUD INSTITUTE FOR HEALTH SCIENCE; <3> UNIVERSITY HOSPITAL OF TüBINGEN, GERMANY

INTRODUCTION: High-intensity interval training (HIIT) is a time-efficient and effective exercise modality, offering comparable or superior benefits to moderate-intensity continuous training (MICT) across various populations. However, variations in HIIT session durations limit insight into the optimal dose-response relationship. Indeed, some protocols last nearly as long as typical aerobic exercise training. This study aimed to determine the optimal HIIT and MICT doses for improving cardi-

orespiratory fitness in healthy individuals and those with elevated cardiovascular risk factors (CVRf) using a dose-response meta-analysis.

METHODS: A one-stage random effects dose-response meta-analysis was conducted to examine the nonlinear relationship between exercise dose (min/session) and changes in maximal oxygen uptake ($\Delta\text{VO}_{2\text{max}}$). Optimal exercise dose was identified as the effect doses corresponding to 50%, 80%, and 100% of the maximal observed effect.

RESULTS: The dose-response meta-analysis revealed that HIIT achieved 80% and 100% of its maximal effect ($\Delta\text{VO}_{2\text{max}}$ = 3.45 and 4.31 mL/kg/min) in 11.4 minutes and 23.2 minutes, respectively. In comparison, MICT required 52.4 and 63.0 minutes to achieve 80% and 100%, $\Delta\text{VO}_{2\text{max}}$ = 3.30 and 4.13 mL/kg/min. In healthy individuals, time-efficiency of HIIT was particularly pronounced, where it showed a strong non-linear response (second spline term = -5.439, $p < 0.001$), with optimal dose of 5.2 min (50%), 10.1 min (80%), and 20.0 min (100%). In contrast, MICT followed a linear response, with doses of 13.2 min, 26.2 min, and 63.0 min for equivalent effects. In individuals with elevated cardio-metabolic risk, HIIT showed a weaker non-linearity (second spline term = -0.764, $p = 0.025$), with optimal doses of 6.6 min (50%), 12.9 min (80%), and 28.2 min (100% of maximal effort), while MICT required similar doses as the overall analysis (39.6 min, 53.7 min, and 63.0 min for 50%, 80% and 100% of maximal effort).

CONCLUSION: This meta-analysis identifies a nonlinear relationship between HIIT session duration and $\text{VO}_{2\text{max}}$ improvements, with optimal adaptations occurring within 20 minutes per session. HIIT provides comparable or greater benefits than MICT in a fraction of the time – MICT required 2.7- to 6.2-fold longer duration than HIIT, with the greatest differences observed at lower percentages of maximal effect (i.e., lower $\Delta\text{VO}_{2\text{max}}$), supporting its use as a time-efficient training strategy to improve cardiorespiratory fitness across populations

CARDIORESPIRATORY FITNESS, FUNCTIONAL FITNESS AND BODY COMPOSITION AMONG BREAST CANCER SURVIVORS: A RANDOMISED, CONTROLLED NON-INFERIORITY TRIAL COMPARING REMOTE VERSUS PARTLY-SUPERVISED EXERCISE

STRUSZCZAK, L., WALHIN, J.P., BETTS, J., THOMPSON, D., BERESFORD, M., TURNER, J.E.

UNIVERSITY OF BATH/ UNIVERSITY OF EXETER

INTRODUCTION: There were ~2.3 million cases of female breast cancer diagnosed worldwide in 2022 (1). Exercise training has a positive effect on survival, disease recurrence and all-cause mortality. Barriers that hinder employing supervised exercise programmes in oncology settings, include staff training and capacity, resources and facilities, accessibility and costs. Remotely-supported exercise training is an alternative that can bring about beneficial health effects. This randomised, controlled non-inferiority trial investigated whether 8 weeks of remotely-supported exercise training changes cardiorespiratory fitness, functional fitness and body composition by a magnitude that is not meaningfully inferior to changes caused by partly-supervised exercise training among female breast cancer survivors.

METHODS: After randomisation, $n=30$ (57 ± 6 years, $\text{VO}_{2\text{max}}$ 28.9 ± 6.1 mL/kg-1-min-1, BMI 25.3 ± 3.3 kg-m-2) female breast cancer survivors completed 8 weeks of partly-supervised ($n=15$) or remotely-supported ($n=15$) exercise training. The partly-supervised group undertook two supervised and one unsupervised session per week progressing from 55-70% $\text{VO}_{2\text{max}}$ and 35-50 min. The remotely-supported group were prescribed the same total duration of exercise per week progressing from 105-150 min. Intensity was prescribed using heart rate targets corresponding to 55-70% $\text{VO}_{2\text{max}}$. $\text{VO}_{2\text{max}}$, functional fitness measurements, body composition (via dual-energy x-ray absorptiometry) and blood pressure was assessed pre- and post-intervention.

RESULTS: Adherence was higher in the partly-supervised group ($87 \pm 7\%$) compared to the remotely-supported group ($64 \pm 25\%$; $p=0.01$). The remotely-supported group exhibited changes in one functional fitness measurement (timed up and go, difference to partly-supervised; 95% CI -0.8 to 0.4 s) and one measure of body composition (percentage body fat, difference to partly-supervised; 95%CI -0.6 to 0.5 kg-m-2) that were non-inferior in magnitude to the partly-supervised group. It was inconclusive whether changes among the remotely-supported group for $\text{VO}_{2\text{max}}$ (difference to partly-supervised; 95% CI -3.3 to 1.1 mL/kg-1-min-1), blood pressure (difference to partly-supervised; 95% CI systolic; -3 to 12 mmHg, diastolic; -5 to 6 mmHg), 6 minute walk (difference to partly-supervised; 95% CI -54.0 to 0.4 m), or sit to stand (difference to partly-supervised; 95% CI -3 to 2 repetitions), were non-inferior in magnitude compared to the partly-supervised group.

CONCLUSION: 8 weeks of remotely-supported exercise may be an alternative to 8 weeks of partly-supervised exercise for influencing functional fitness (assessed by timed up and go) and percentage body fat. It remains inconclusive whether remotely-supported exercise is an alternative to 8 weeks of partly-supervised exercise for influencing cardiorespiratory fitness, functional fitness (assessed by 6-minute walk, sit to stand) and blood pressure.

ROWING AND ADAPTED PHYSICAL ACTIVITY FOR BREAST CANCER SURVIVORS: EFFECTS ON LYMPHEDEMA, MOBILITY, STRENGTH AND PSYCHOLOGICAL WELL-BEING

NUCCI, G., PELLICANÒ, M.1, BARLASSINA, S.1, SPIANTINI, M.1, AMORE, A.1, PIANCA, R.1, ROVERA, F.2, GRANDE, A.2, GALVANI, C.1,3

1UNIVERSITÀ CATTOLICA DEL SACRO CUORE, MILANO; 2BREAST UNIT, VARESE; 3IGEO - ITALIAN GROUP ON EXERCISE ONCOLOGY

INTRODUCTION: In women with breast cancer, the most common complications after surgery include the development of lymphedema and a reduction in mobility and strength in the operated limb, leading to a negative impact on psychological well-being¹. Studies suggest that rowing or an adapted physical activity (APA) program may be a viable strategy to mitigate the negative effects of breast cancer and its treatment^{2,3}. The purpose of the study was to examine the effects of rowing on arm lymphedema, mobility, strength and psychological well-being in breast cancer survivors participating in a 6-month APA program.

METHODS: The project Effect and efficacy of Rowing in breast Cancer survivors (ERICE) involved 27 women with breast cancer (age: 56.6 ± 6.5 yrs; BMI: 23.9 ± 3.0 kg/m²; stages I, II, or III; surgery at least 6 months to a maximum of 20 years ago), who trained 3 times a week for 6 months with sculling (a form of sliding-seat rowing moving the boat with two oars per rower), online APA sessions and walking. The analysis conducted at baseline (T0) and at the end of the training program (T1) included arm lymphedema (Arm Volume_AV), mobility (Back Scratch_BS) and strength (Hand Grip_HG) evaluation. Additionally, Functional Assessment of Cancer Therapy – Lymphedema (FACT-B+4) and Rosenberg Self-Esteem Scale (RSES, Italian version) were administered. A minimum adherence of 75% to the program was required.

RESULTS: During the 6-month intervention, 19 women completed the program and 13 of them achieved the required adherence (N: 6_NAD vs N: 13_AD). No variation in AV of both operated (OA) and non-operated (NOA) arms was observed (OA: T0, 1566.7 ± 274.6 vs T1, 1567.8 ± 279.3 ; NOA: T0, 1513.1 ± 254.3 vs T1, 1557.5 ± 265.4 cm³). Despite this, an improvement in both operated and non-operated arms BS (OA: T0, 2.0 ± 7.6 vs T1, 3.0 ± 7.8 ; NOA: T0, 3.3 ± 7.3 vs T1, 4.1 ± 7.2 cm) was noticed, with a greater improvement in HG performance in women who achieved the required adherence (OA: Δ AD, 1.2 ± 2.4 vs Δ NAD, -3 ± 1.4 kg, $p=0.0029$; NOA: Δ AD, 1 ± 1.7 vs Δ NAD, -2.6 ± 2.2 kg, $p=0.0044$). Psychological well-being (FACT-B+4: T0, 123.0 ± 15.1 vs T1, 122.3 ± 14.8 score) and self-esteem (RSES: T0, 20.0 ± 5.1 vs T1, 20.74 ± 5.87 score) remained stable.

CONCLUSION: An APA program combined with sculling revealed to have a positive impact on flexibility and strength. It is important to emphasize that improvements in physical parameters were observed only among participants achieving at least 75% of adherence.

HIGH-INTENSITY EXERCISE DURING CHEMOTHERAPY IMPROVES MUSCLE STRENGTH AND PRESERVES CARDIORESPIRATORY FITNESS 12 MONTHS AFTER COMPLETION OF TREATMENT IN BREAST CANCER PATIENTS.

WIESTAD, T., VIKMOEN, O., THORMODSEN, I., FLUGE, Ø., MELLA, O., BERNTSEN, S., NORDIN, K., RAASTAD, T.

HAUKELAND UNIVERSITY HOSPITAL

INTRODUCTION: Physical exercise during treatment may counteract some of the adverse effects following (neo-)adjuvant chemotherapy for breast cancer. However, the optimal exercise intensity and whether the benefits of exercise during chemotherapy continue into survivorship is not well-known^{1,2}. The aim of the current study was to examine the effects of high (HIT) vs. moderate (MIT) intensity exercise during chemotherapy on cardiorespiratory fitness, muscular endurance, body composition and muscle strength in patients with breast cancer 12 months following completion of chemotherapy.

METHODS: Women diagnosed with stage I-III breast cancer (n=80) was randomized to either a HIT or MIT training group. Both groups performed home-based endurance training and supervised strength training twice a week over the course of chemotherapy (approximately 12-24 weeks) at an intensity of 80-90% of heart rate reserve (HRR) and 1RM (HIT) or 40-50% of HRR and 1RM (MIT). Measures of VO₂max, muscle strength, body composition and muscular endurance were performed before (T0), immediately after (T1) and 12 months after the completion of chemotherapy and training (T2). In total, 55 participants (HIT, n=26, MIT, n=29) completed follow up measures.

RESULTS: VO₂max decreased in both groups during chemotherapy (T0-T1, HIT: -19%, $p<0.01$, MIT: -14%, $p<0.01$), but were not different from baseline values 12 months later (T0-T2) HIT: -4%, $p=0.07$ MIT: -3%, $p=0.80$). There was no significant difference between the groups.

HIT increased chest press strength at T1 (8%, $p=0.03$) and tended to have an increase at T2 (7%, $p=0.06$). There was no change in the MIT group (T1: 4%, $p=0.24$, T2: 5%, $p=0.27$) and no significant difference between the groups.

Leg press strength increased in HIT at T1 by 5% ($p<0.05$) and at T2 by 32% ($p<0.01$) and in MIT at T2 by 13% ($p=0.03$) but not at T1 (0%, $p=0.93$). There was a significant difference between the groups at T2 ($p=0.04$) but not at T1.

Leg extension strength increased in the HIT group at T2 (11%, $p=0.04$) but not at T1 (1%, $p=1.00$). There was no change in the MIT group (T1: -1%, $p=0.39$, T2: 6%, $p=0.43$) and no significant difference between the groups.

Muscular endurance did not change in either group.

Lean body mass increased in both groups at T1 (HIT: 2%, $p<0.01$, MIT: 3%, $p<0.01$) but not at T2 (HIT: 0%, $p=0.91$, MIT: 0%, $p=0.23$). There was no significant difference between the groups.

Fat mass increased in the HIT group at both T1 (4%, $p<0.05$) and T2 (10% ($p<0.01$)) with no change in the MIT group (T1: 2%, $p=0.92$, T2: 4% ($p=0.14$)).

CONCLUSION: Both high and moderate intensity exercise was effective in preserving cardiorespiratory fitness 12 months after completion of chemotherapy for breast cancer, but HIT improved muscle strength more than MIT.

EFFECTS OF LAND- AND WATER-BASED AEROBIC EXERCISE ON CANCER-RELATED FATIGUE IN BREAST CANCER SURVIVORS: PRELIMINARY FINDINGS FROM THE WATERMAMA RANDOMIZED CLINICAL TRIAL

ALBERTON, C., ANDRADE, L., XAVIER, B., PINHEIRO, V., CARVALHO, M., CUESTA-VARGAS, A., PINTO, S.
FEDERAL UNIVERSITY OF PELOTAS

INTRODUCTION: Cancer-related fatigue is one of the most substantial challenges faced by breast cancer survivors, underscoring the importance of developing effective strategies to mitigate its impact on this population. This study aimed to evaluate the effects of land- or water-based aerobic exercise programs, compared to a health education program, on cancer-related fatigue in breast cancer survivors.

METHODS: The WaterMama trial is a randomized, single-blinded, three-arm, parallel, superiority trial (NCT05520515) [1]. It enrolled women aged ≥ 18 years who had completed primary treatment for stage I-III breast cancer. Participants were randomly allocated (1:1:1) into one of three groups: 1) water-based aerobic exercise (WG), 2) land-based aerobic exercise (LG), and active control (CG). The WG and LG completed two weekly 45-minute sessions in the corresponding environments, plus a weekly health education session (45 minutes) for 12 weeks. The CG received only the weekly health education program (45 minutes) for 12 weeks. Cancer-related fatigue was assessed at baseline and post-intervention using the Piper Fatigue Scale. Post-intervention data are presented as mean [95% CI] and analyzed using Generalized Estimated Equations ($\alpha = 5\%$).

RESULTS: A total of 49 participants were randomized into WG ($n = 17$; 53.1 ± 12.4 years), LG ($n = 16$; 51.1 ± 10.6 years), and CG ($n = 16$; 59.5 ± 11.2 years) and included in an intention-to-treat analysis. Preliminary data showed a significant post-intervention reduction in total fatigue ($p=0.047$) and behavioral/severity scores ($p<0.001$) across all groups, with no differences among them and no significant group $\times$ time interaction. Mean post-intervention values for total fatigue and behavioral/severity scores corresponded to 3.3 [2.3-4.7] and 2.5 [1.5-4.0] points for WG, 3.1 [2.3-4.2] and 2.3 [1.4-3.8] points for LG, and 2.4 [1.5-4.0] and 2.1 [1.2-3.9] points for CG, respectively. The affective meaning, sensory, and cognitive/mood domains remained unchanged across all groups, with no significant group $\times$ time interaction.

CONCLUSION: Water- and land-based aerobic exercise programs did not demonstrate superiority over health education alone in reducing cancer-related fatigue among breast cancer survivors. This result may be attributed to the baseline fatigue levels being classified as mild, potentially limiting the magnitude of improvement. Nevertheless, significant improvements in total fatigue and behavioral/severity scores were observed post-intervention across all groups. These preliminary findings suggest that while all interventions contributed to reducing total fatigue, the additional benefits of aerobic exercise beyond health education alone may be limited in this population.

PROSTATE CANCER CELL SPHEROID FORMATION CAPACITY IS REDUCED BY RUNNING RACE-CONDITIONED HUMAN SERA.

BALDELLI, G., AVANCINI, A., BUDEL, L., GENTILINI, V., BORSATI, A., TONIOLO, L., CONTI, A., MILELLA, M., SCHENA, F., BRANDI, G., PILOTTO, S., TARPERI, C., DE SANTI, M.
UNIVERSITY OF URBINO CARLO BO

INTRODUCTION: Prostate cancer is one of the most commonly diagnosed cancers in men worldwide. The advances in diagnostic and therapeutic options associated with a usually moderate intrinsic biological aggressiveness have led to an increase in survival rate. To date, more than 90% of patients are alive at five years, but the high prevalence of the disease needs effective strategies to reduce the recurrence risk. In this sense, epidemiological evidence suggests that physical activity is associated with a lower cancer incidence and recurrence. Nevertheless, the underlying mechanisms of action are poorly understood. This study aimed to evaluate the effects of two different running races (5 Km and 10 Km) in the modulation of spheroids formation capacity of prostate cancer cells.

METHODS: 13 healthy subjects (mean age 47.7 ± 16.1 years; body mass index 24.6 ± 2.3 kg/cm²) performed two running races, 5km- and 10 km-long, interspersed by 2 weeks of wash-out time. The tumorigenic potential of prostate cancer cell line LNCaP was assessed through the 3D in vitro culture technique (soft agar assay), stimulating cells with sera collected

before (PRE), immediately after (POST), and 3 hours after (POST 3h) running races. The spheroid formation ability was evaluated after 3 weeks of incubation, using GelCount (Oxford Optronix), an automated high throughput imaging and analysis system that optimizes the measurement of the spheroid number.

RESULTS: Overall, 11 and 7 subjects performed the 5km and 10km races predominantly above the anaerobic threshold. In both running races, the spheroids formation analysis showed a significant average reduction in the tumorigenic capacity of LNCaP cells when stimulated with POST and POST 3h sera, compared to PRE sera. POST versus PRE sera analysis revealed that after the 5 km race, 10 out of 13 exercise-conditioned sera induced a reduction $> 5\%$ ($-24.51 \pm 13.21\%$) in the number of spheroids; a similar degree ($-22.44 \pm 11.85\%$) was observed after the 10 km race, in 9 out of 13 participants. This effect further improved when considering the POST 3h sera. In this case, all the sera from the 5 km and 12 out of 13 of those collected in the 10km race induced a reduction $> 5\%$ in spheroids number in comparison with PRE sera (-38.96 ± 17.89 and $39.92 \pm 17.12\%$, respectively). Interestingly, no significant differences have been found in the effects of sera comparing the two running distances.

CONCLUSION: These preliminary results suggest that acute training sessions reduce the spheroid formation of prostate cancer cells. This finding allows interesting speculations about the potential mechanisms underlying the impact of physical exercise in reducing the risk of prostate cancer recurrence to be further validated and explored. Moreover, the present work offers suggestions concerning the prescription, indicating that even a relatively short running distance may produce similar effects to a long one, with important implications for the real-world setting.

A VEGAN DIET PROVIDING THE RDA FOR PROTEIN SUPPORTS FREE-LIVING DAILY MYOFIBRILLAR PROTEIN SYNTHESIS RATES COMPARABLY TO AN ISONITROGENOUS OMNIVOROUS DIET IN HEALTHY OLDER ADULTS

MONTEYNE, A., VAN DER HEIJDEN, I., MURTON, A.J., ABDELRAHMAN, D.R., STEPHENS, F.B., WALL, B.T.

UNIVERSITY OF EXETER

INTRODUCTION: A mycoprotein-rich high-protein vegan diet supports daily myofibrillar protein synthesis (MyoPS) rates to a similar extent as an isonitrogenous omnivorous diet in older adults. However, it remains unclear if vegan diets compromise daily MyoPS and, thus, muscle adaptive responses to exercise at lower protein intakes, especially when consisting of a more diverse array of non-animal-derived foods. We assessed the impact of a vegan diet providing the RDA for protein on daily free-living MyoPS rates over one week, in rested and exercised muscle, compared to a high-quality isonitrogenous omnivorous diet in older adults.

METHODS: Twenty-two healthy older adults (male [m]/female [f]; 12/10; age: 67 ± 4 y; BMI: 25 ± 3 kg/m²) participated in a randomised, parallel-group trial. Following 3 days of consuming their habitual diets, participants consumed a 7-day vegan diet (VEGAN; n=11; m/f, 5/6), providing 0.8 g/kg bm/day of protein (predominantly from mycoprotein, pea, oat, rice, and spirulina-containing foods), or an isonitrogenous omnivorous diet (OMNI; n=11; m/f, 5/6) containing 69% animal-derived protein. On days 1, 3, and 5 of the dietary intervention period participants performed a bout of unilateral resistance exercise. Skeletal muscle and saliva samples were collected during the habitual and dietary intervention periods to assess daily MyoPS in rested and exercised tissue using deuterated water.

RESULTS: Dietary protein intake during the intervention period decreased by 26% compared to habitual intakes ($P < 0.001$). Despite this, daily MyoPS rates in rested muscle remained unchanged between the habitual and intervention periods (OMNI: 1.56 ± 0.32 to 1.37 ± 0.24 %/d; VEGAN: 1.53 ± 0.41 to 1.43 ± 0.24 %/d; $P = 0.81$). Resistance exercise increased MyoPS rates by 18% from habitual levels (OMNI: 1.74 ± 0.26 %/d; VEGAN: 1.88 ± 0.28 %/d; $P < 0.001$), resulting in 29% higher MyoPS rates in exercised muscle compared to rested muscle during the intervention ($P < 0.0001$). MyoPS rates were similar between OMNI and VEGAN groups at all time points, in both rested and exercised muscle (all $P > 0.05$).

CONCLUSION: A feasible vegan diet incorporating high-quality protein sources, while providing less protein than habitual intakes yet meeting the RDA, supports daily MyoPS rates to a similar extent as an isonitrogenous omnivorous diet. This demonstrates the utility of vegan diets to support skeletal muscle remodelling in older adults.

THE BIOAVAILABILITY OF INSECT COMPARED TO ANIMAL PROTEIN IN YOUNGER, MIDDLE-AGED AND OLDER ADULTS

RUTHERFORD, J., ELLIOT, R., THATCHER, R., KNOTT, G., VON GERICHTEN, J., FIELDING, B., MANDERS, R.

UNIVERSITY OF SURREY

INTRODUCTION: A global shift towards sustainable food sources is now emerging, largely due to the damaging environmental impact from producing animal foods. Insects are a novel source of sustainable protein due to their high protein content and lower drain on natural resources [1]. This is particularly relevant for older adults, as protein becomes increasingly more important in later life to maintain muscle as we age, which is crucial for reducing frailty, falls and early mortality [2]. We aimed to investigate the digestibility via gastric emptying (GE) of an insect-derived protein compared to whey protein to find out if insects could present a bioavailable source of protein to support human skeletal muscle. A secondary aim was to identify any impact of ageing on the digestibility of insect protein.

METHODS: In a randomised double-blind crossover design, 30 healthy adults were separated into three age groups: younger ($n=10$, 25.9 ± 5.5 yrs), middle ($n=10$, 46.7 ± 4.9 yrs), and older age ($n=10$, 76.5 ± 4.2 yrs). After overnight fasting, baseline breath and blood samples were collected. Participants then consumed a cricket or whey protein muffin (20g protein) containing a carbon-13 (^{13}C) octanoic acid tracer to measure GE via expired air as $^{13}\text{CO}_2$. Breath samples were collected at regular intervals for 4-hours postprandially. Blood samples were also collected at the same timepoints to measure plasma amino acid concentration. A week later, the process was repeated with the opposite muffin. Modelling was used to analyse and interpret GE data, determining the time to peak ^{13}C release from the stomach (t lag) and the time for 50% of ^{13}C to empty into the small intestine (t half). One-way and two-way ANOVAs and paired t -tests assessed differences in means between protein sources and age groups, with statistical significance set at $p < 0.05$.

RESULTS: Both protein sources resulted in a similar excretion of $^{13}\text{CO}_2$ in all age groups, with ~28% of the ^{13}C recovered at 240 minutes after ingestion for cricket and whey, with no differences between protein sources in t lag or t half ($p > 0.05$). There were also no differences between age groups in t lag or t half for either protein source ($p > 0.05$).

CONCLUSION: GE does not appear to differ between cricket and whey protein and is not impacted by ageing. This indicates that the digestibility of an insect protein is similar to that of a well-characterised animal protein in healthy humans.

THE EFFECT OF HMB SUPPLEMENTATION AND HIGH-INTENSITY FUNCTIONAL EXERCISE ON BODY COMPOSITION, TESTOSTERONE AND CORTISOL CONCENTRATION, AND ISOMETRIC KNEE EXTENSION IN TRAINED AND UNTRAINED MALES

DURKALEC-MICHALSKI, K., PODGÓRSKI, T., MURAWA, M., STEFFL, M., MARCHELEK-MYSLIWIEC, M., CZLAPKA-MATYASIK, M., NOWACZYK, P.M.

POZNAN UNIVERSITY OF PHYSICAL EDUCATION, DEPARTMENT OF SPORTS DIETETICS

INTRODUCTION: The study verified the hypothesis that 3-week supplementation with a free liquid form of beta-hydroxy-beta-methylbutyrate (HMB; 90 mgHMB/kgFat-free mass[FFM]) would result in the improvement in body composition, selected hormones, and indices of isometric knee extension, and the magnitude of these changes will be amplified after introducing high-intensity functional training (HIFT) units as an adjunctive stimulus.

METHODS: The randomized double-blind placebo-controlled parallel study was performed in 30 trained (TR; 28.6 ± 9.4 yrs) and 30 untrained (UTR; 33.9 ± 8.0 yrs) males. After the baseline (BAS) visit, participants were randomly allocated into the HMB (TR_HMB, $n=15$; UTR_HMB, $n=15$) or the placebo (TR_PLA, $n=15$; UTR_PLA, $n=15$) group. There were two 3-week treatment periods: 1) SUP – ingestion of either HMB or PLA and performing the usual training cycle (TR) or lack of training (UTR), and 2) SUP+FGB – ingestion of either HMB or PLA and implementing the additional exercise stimuli (TR and UTR) in the form of two Fight Gone Bad (FGB) workouts per week. The following procedures were performed: body composition (FFM and fat mass [FM]) content using the BodPod®; Cosmed, Italy), total body water content (TBW) using electrical bioimpedance (BIA-101 BIVA Pro ASE, Akern Srl. Italy), blood analysis (cortisol [COR], total and free testosterone [TT and FT]), and maximal voluntary isometric contraction knee extension (Biodex Medical System Inc., New York, USA; peak [PT] and average torque [AT]).

RESULTS: BM, FM, or FFM did not change across the study visits in the studied groups. In TR_PLA percentage of TBW was significantly higher at SUP+FGB ($63.9 \pm 4.3\%$) compared to BAS ($61.4 \pm 3.4\%$) and SUP ($63.1 \pm 2.9\%$) visits ($p = 0.022$); TBW in L was significantly higher at SUP (55.4 ± 9.0 L; $p = 0.041$) and SUP+FGB (56.0 ± 9.0 L; $p = 0.004$) compared to BAS (53.7 ± 8.8 L) visit. The concentration of COR and TT did not change in any of the treatment groups. In the TR_PLA group, the concentration of FT was significantly lower at SUP (13.4 ± 3.2 pg/mL) compared to BAS (17.5 ± 7.4 pg/mL; $p = 0.024$). TT/COR or FT/COR did not change in any of the groups. In UTR_PLA absolute and relative PT was significantly higher at SUP+FGB compared to BAS (296 ± 39 vs 281 ± 35 Nm, $p = 0.003$ and 323 ± 56 vs 292 ± 46 Nm/kg, $p = 0.008$); while AT absolute and relative AT were significantly higher at SUP and SUP+FGB compared to BAS (SUP: 279 ± 43 vs 267 ± 31 Nm, $p = 0.014$; SUP+FGB: 286 ± 37 vs 267 ± 31 Nm, $p < 0.001$ and SUP: 304 ± 55 vs 292 ± 46 Nm/kg, $p = 0.029$; SUP+FGB: 312 ± 54 vs 292 ± 46 Nm/kg, $p < 0.001$).

CONCLUSION: Regardless of training status, HMB supplementation did not affect body composition, COR, TT, FT concentration, TT/COR, FT/COR, or PT and AT. Surprisingly, PLA supplementation had a favorable effect on TBW content. Moreover, PLA supplementation in combination with HIFT stimuli increased PT and AT. The content of glycerin and the bitter taste of PLA preparation might evoke hydration and ergogenic effects in the studied groups.

INCREASED PHYSICAL ACTIVITY AND PROTEIN INTAKE ARE ASSOCIATED WITH GREATER STRENGTH, BALANCE AND LEAN MASS, BUT NOT MUSCLE PROTEIN SYNTHESIS, ACROSS THE MENOPAUSE TRANSITION.

SVENSEN, E., KOSCIEN, C., ABDELRAHMAN, D., MURTON, A., ALAMDARI, N., WALL, B., STEPHENS, F.

UNIVERSITY OF EXETER

INTRODUCTION: Reduced sex hormone production during menopause is thought to accelerate age-related decline in muscle mass, strength, and balance. Dietary protein ingestion (PI) and physical activity (PA) are essential to stimulate skeletal muscle protein synthesis (MPS), facilitating muscle reconditioning, retention and function. This study aimed to

explore the role of PI and PA on changes in muscle mass, strength, balance, quality, MPS, and expression of genes involved in protein turnover across the menopause transition.

METHODS: Seventy-one, moderately active pre- (PRE; n=27; 46.1 ±3.2yrs), peri- (PERI; n=16; 51.5 ±2.0yrs) and post-(POST; n=28; 56.2 ±2.5yrs) menopausal females were included. Menopause status was determined by serum follicle-stimulating hormone (PRE<17, PERI<30, POST>30IU.L-1) and menstrual cycle history. 7-day PA was quantified by accelerometer and 3-day diet diaries analysed for PI. Peak torque of hip abduction (HA) and flexion (HF) was measured by isokinetic dynamometer. Balance was measured with the Y-balance test in anterior, posterolateral (PL) and posteromedial (PM) directions. Thickness (MT) and quality (MQ) of the rectus femoris (RF) were determined with B-mode ultrasound. Percentage lean (LM) and fat (FM) mass was analysed by DXA. Muscle biopsies were collected to measure 3-day free living MPS rates using ²H₂O, and expression of 12 genes using RT-qPCR. One-way ANOVAs tested for differences in all variables between groups. Linear regression evaluated the relationship of PA and PI on outcome measures. ANCOVAs with PA and PI as covariates were performed on significant predictors.

RESULTS: HA and HF did not differ across menopause groups (P<0.05). Anterior (PRE 23.1±4.1, PERI 20.4±4.2, POST 20.9±4.1%; P=0.064) and PM (PRE 53.1±9.1, PERI 49.1±6.6, POST 47.9±9.2%; P=0.075) tended to be lower over menopause. PL was greater in PRE (43.3±7.9%) vs POST (37.6±7.5%) (P=0.024), but not PERI (41.2±7.4%). LM (PRE 64.2±6.3, PERI 59.8±7.3, POST 61.5±7.3%; P=0.269) and FM (PRE 31.7±6.6, PERI 36.3±7.2, POST 34.8±7.3%; P=0.244) did not differ across groups. MT was lower in POST (15.9±3.0mm) vs PRE (19.1±2.9mm, P<0.001) and PERI (18.8±3.2mm, P=0.006). MQ, MPS, and gene expression did not differ across menopause groups (P>0.05). PA positively correlated with HA (R² 0.098, P=0.009), PL (R² 0.058, P=0.043) and PM (R² 0.063, P=0.035), and 5 of the 12 genes (RPS6KB1 (R² 0.190, P=0.033), MTOR (R² 0.274, P=0.009), EIF4EBP1 (R² 0.208, P=0.025), FOXO3 (R² 0.249, P=0.013), FBXO32 (R² 0.244, P=0.014)). PI between 1.2–1.8g/kg/d positively correlated with LM (R² 0.246, P<0.001) and negatively with FM (R² 0.241, P<0.001). When covaried for PA and PI, only MT remained different across menopause (P=0.018).

CONCLUSION: Increased protein intake may ameliorate the reduction in muscle mass across the menopause transition. However, lower muscle strength and balance across the menopause is likely due to reduced physical activity, rather than hormonal changes.

WHEY PROTEIN SUPPLEMENTATION REDUCES INFLAMMATION AND IMPROVES HIGH PHYSICAL PERFORMANCES IN WELL-TRAINED ENDURANCE AND POWERFUL ATHLETES

BOUHLEL, E., BEN MHAMED, M., ZARROUK, F., ZAOUALI, M.

FACULTY OF MEDICINE

INTRODUCTION: Whey protein supplementation is mainly used in powerful athletes to enhance muscle mass and maximal power output. There are few studies on the effects of whey protein in endurance athletes. Thus, the aim was to evaluate the effects of 2 months of whey protein supplementation of 30 g/day on body composition, selected biochemical parameters and high-intensity physical performance in a group of well-trained endurance and power athletes.

METHODS: Each group (endurance or power) was randomly divided into 2 groups: a whey group (n = 20) and a control group (n = 9). In both groups, body composition, biochemical parameters, peak power (PP) and mean power (MP), as well as Wingate fatigue index (FI), and maximum aerobic speed (MAS) were assessed before and after the intervention. Both groups continued to follow their specific training programs during the two-month intervention.

RESULTS: For endurance subjects and after the intervention, body mass increased in the whey group (3.8%, p < 0.001), with a decrease in fat mass % (p < 0.004) and an increase in muscle mass of the lower limbs (p < 0.001). Resting plasma values of aspartate aminotransferase (AST) and alanine aminotransferase (ALT), creatine kinase (CK), C-reactive protein (CRP), total cholesterol, LDL-cholesterol (all at p < 0.05), and urea (p < 0.01) were reduced in the whey group after the intervention, with an increase in HDL-C. The control group showed no change. The whey group had increased PP, MP and fatigue index (p < 0.001, p < 0.001 and p < 0.05 respectively), as well as MAS (p < 0.05) after the 2-month intervention. The control group showed no significant changes in these measures.

For powerful subjects, the results are quite similar, with some differences, notably in terms of reduction in the % of fat which approaches statistical significance. We found no changes in ALT and AST, but a decrease in CK and CRP. In terms of performance, the intervention involved improvement in Wingate parameters (PP, MP and FI) but no changes were observed in MAS in the group of supplemented power athletes. On the other hand, we did not note any changes in the control group.

CONCLUSION: Whey protein supplementation combined with 2 months of endurance or resistance training results in reduction in body fat, but an increase in lower limb muscle mass. CK and CRP were reduced both similarly in endurance and powerful athletes. These changes were accompanied by improvements in PP and MP and FI. However, MAS was improved mainly in endurance athletes. These data suggest that protein supplementation is beneficial for endurance and powerful athletes with some differences related probably to the training process. Thus, the supplementation could be recommended to promote recovery and high-intensity physical performance.

OP-SH01 Athlete Psychology

DISTANCE RUNNERS STORIES OF SPORT INJURY AND DISORDERED EATING

DAVIS, F., WADEY, R., WINTER, S., DAY, M., EVERARD, C., MORRIS, R.

ST MARYS UNIVERSITY, TWICKENHAM

Objective

Sport injury and disordered eating are timely and impactful issues in distance running. Yet, despite growing recognition of the sociocultural complexity of these issues, the nexus between them has not yet been explored. Taking a sociocultural perspective, this study aims to critically explore the relationship between sport injury and disordered eating in distance runners across their athletic careers.

METHODS: Ten distance runners participated (M age: 25.7) who had endured a range of injuries throughout their career (e.g., acute, chronic, overuse, career-ending). Life story interviews (N=28) and visual methods (i.e., photographs) were used to assist the participants in telling their stories. Data were analysed using dialogical narrative analysis and represented through creative non-fiction. Methodological rigour was strengthened through member reflections, reflexivity, and critical friends.

RESULTS: Five creative non-fiction stories were constructed: Is it good for me?, I knew I'd gone too far, Maybe it wasn't too late for me?, Is this what normal feels like?, and I love food too much. These stories illustrated how embodiment of sociocultural practices influenced the thoughts, feelings, and behaviours of athletes throughout their careers, revealing the complex interplay between sport injury and disordered eating.

Discussion: The ways in which this study extends literature is threefold: (1) by bridging the fields of the psychology of sport injury and disordered eating in sport, we have offered a nuanced and novel understanding of the sociocultural factors underpinning distance runners' experiences, (2) the use of two methods of data collection enabled a more in-depth understanding of participant experiences rather than relying solely on verbal articulation, (3) the use of creative non-fiction provides an innovative approach to knowledge dissemination, enabling broader engagement and application in athlete education. To this end, the stories challenge the dominant performance narratives, highlighting their embodiment, resistance, and reimagining. Sharing these stories holds promise to promote interdisciplinary ways of working in research and practice.

BASIC PSYCHOLOGICAL NEED SATISFACTION DURING THE DAY AS A PROTECTIVE FACTOR REGARDING ATHLETES' SLEEP QUALITY AND SLEEP DEFICIT

FRYTZ, P., ELBE, A.M.

LEIPZIG UNIVERSITY

INTRODUCTION: Even though athletes need sufficient restorative sleep to cope with the demands of competitive sport, they often experience a sleep deficit due to late competitions, intense training sessions, and dual demands (Walsh et al., 2021). Behavioral strategies such as sleep hygiene, sleep extension and daytime naps are frequently employed to reduce this sleep deficit (Cunha et al., 2023). Besides these strategies, studies indicate that psychological determinants like the satisfaction of basic psychological needs (autonomy, competence, relatedness; Ryan & Deci, 2000) during the day may also improve sleep quality (Campbell et al., 2015). This study aims to investigate this relationship in a cohort of competitive athletes (N=66).

METHODS: At the beginning of the study, 66 competitive athletes (M=21.06 years, SD=5.05; 74.2% female) from individual and team sports answered one-time questionnaires on general sleep quality (PSQI) and satisfaction of needs in the sleep (BPNSS-S) and in the sports domain (PNSEG). Of those, 48 athletes (M=20.00 years, SD=4.44; 66.7% female) took then part in a two-week sleep tracking. The participants wore actigraphs (Motionwatch 8) for 14 nights to measure objective sleep parameters (e.g., sleep onset latency, sleep duration, sleep efficiency). Individual sleep deficit and subjective sleep quality were recorded via morning sleep logs. In daily evening logs, athletes reported their daily basic need satisfaction, pre-sleep arousal and training load.

RESULTS: The results showed that better general sleep quality (PSQI) was associated with the satisfaction of needs in sleep (autonomy: $r=-.46$, $p<.001$; competence: $r=-.49$, $p<.001$; relatedness: $r=-.30$, $p=.013$) and in sport (autonomy: $r=-.246$, $p=.046$; competence: $r=-.266$, $p=.031$). Multilevel analyses revealed that daily need satisfaction reduced cognitive pre-sleep arousal on the same evening ($p=.001 - p<.001$). A higher global need satisfaction led to higher subjective sleep quality and duration ($p=.037 - p<.001$) as well as lower individual sleep deficit and sleep onset latency ($p=.032 - p=.001$).

Discussion: The results indicate that general basic psychological need satisfaction can be interpreted as a protective factor regarding athletes' sleep quality and therefore support the assumptions of the "Basic Psychological Need Theory". This study helps to unravel the sleep dynamics of athletes and to highlight potential interventions for optimizing athletes' sleep such as the adaptation of training and sleep schedules according to athletes' satisfaction of psychological needs.

“NO ONE SEEMS TO KNOW WHAT WE SHOULD BE DOING”: DEVELOPING A FRAMEWORK TO GUIDE THE IMPLEMENTATION OF MENSTRUAL CYCLE TRACKING IN APPLIED SETTINGS

CARMICHAEL, M., ROBERTS, A., PERRY, K., CLARKE, A.C.

LA TROBE UNIVERSITY

INTRODUCTION: Calls for sex-specific athlete support have increased discussion and apparent uptake of menstrual cycle tracking (MCT), although there is limited guidance for its use in sport. This project explores athletes' and practitioners' perspectives and experiences of MCT and presents a user-informed framework to guide practitioners when implementing MCT.

METHODS: The framework is based on the outcomes of three conceptually related studies; 1) a survey of practitioners ($n = 141$) on current MCT and education practices in high performance sport, 2) semi-structured interviews with athletes ($n = 6$) and practitioners ($n = 8$) exploring factors influencing the implementation of MCT, and 3) an investigation into the efficacy of an education intervention for athletes ($n = 45$) as a strategy to support MCT.

RESULTS: The survey shows few practitioners require (9%), while some encourage (36%), athletes to track. Practitioners who educated athletes/staff on menstrual-related topics were more likely to encourage athletes to track ($p = .004$) and discuss menstrual health (MH) with support staff ($p < .001$).

Interviews with athletes and practitioners highlighted the barriers and challenges that prevent the uptake or limit the effectiveness of MCT. At a societal level, menstrual stigma and lack of MH knowledge create discomfort in MCT and related communication. At an organisational level, competing health and performance priorities and practical constraints (i.e., time, resources, expertise) prevent or disrupt MCT. Finally, at an individual level, athletes' attitudes towards MH and practitioners' ability to provide support to athletes may influence compliance with and effectiveness of MCT.

Following two education workshops athletes answered significantly more MH questions correctly, made less 'I am not sure' responses, and rated their knowledge higher ($p < .001$), with improvements retained 3 months post-intervention. Likelihood to communicate with teammates increased post-intervention ($p = .01$) and was maintained, while there was no change in their likelihood to communicate with support staff ($p > .05$).

CONCLUSION: It is likely that education promotes opportunities for communication and helps athletes and staff understand why MCT is conducted. Addressing factors such as organisational priorities and individual attitudes should also be a priority, as is menstrual stigma, knowledge, and attitudes of both athletes and coaching staff. As such, the proposed framework highlights how social, organisational, and individual factors contribute to the implementation and effectiveness of MCT, and how promoting education and communication may assist across each of these factors.

A NOVEL, FUTSAL-SPECIFIC DECISION-MAKING TASK ELICITS SIMILAR PSYCHOPHYSIOLOGICAL STRESS RESPONSES TO WELL-ESTABLISHED PSYCHOLOGICAL STRESS TASKS.

ANGUS, D., PAINE, N., PLATEAU, C., GOOSEY-TOLFREY, V., BARKER, J.

LOUGHBOROUGH UNIVERSITY

Introduction: Making decisions at crucial moments has been demonstrated to be a potential stressor in association football (soccer). However, the focus of research to examine the relationship between sporting decision-making and mental or physical stress is typically scant. To investigate the ubiquitous link between stress and decision making, we developed a novel task using video simulations in futsal, a 5-a-side derivative of football. Our novel study therefore aimed to assess the psychophysiological stress response to a novel futsal-specific decision-making task and compare this response to well-established psychophysiological stress tests from the literature.

Methods: 25 healthy males with a minimum 2 years playing experience in football/futsal completed a baseline rest period, followed by 4 separate stress tests interspersed with 15 minutes recovery. The tests were the Paced Auditory Serial Addition Test (PASAT), Stroop Colour Word Test (SCWT), Mirror Tracing Task (MTT) and a novel Futsal-Specific Decision-Making Task (FDMT) and were completed in a randomised order. Non-invasive beat-to-beat cardiovascular (CV) and self-report stress responses were assessed throughout the stress protocol. Generalised estimating equations (GEEs) were used to determine changes in CV markers in response to stress, with reactivity calculated as the difference between the prior resting period and the stress task.

Results: Across the entire stress protocol, there were main effects for time in systolic blood pressure (SBP), diastolic blood pressure (DBP), mean arterial pressure (MAP), heart rate (HR) and cardiac output (CO; p 's $< .001$). Post hoc analysis demonstrated increased SBP, DBP and MAP to the FDMT compared to baseline (p 's $< .001$). SBP, MAP, HR and CO decreased following the FDMT, during recovery (p 's $< .001$). To compare changes in CV reactivity across the different stress tasks, there were significant differences in the CV reactivity to stress in SBP, DBP, MAP, HR and CO (p 's $< .001$). Post-hoc tests indicated SBP, DBP, MAP, HR and CO reactivity were significantly lower in the FDMT compared to the PASAT (p 's $< .001$). DBP, MAP and HR reactivity were also lower in the FDMT compared to the MTT (p 's $< .023$). There were no differences in reactivity values between the FDMT and SCWT for SBP, DBP, MAP, HR and CO (p 's $> .182$). There were increases in self-reported perceived stress for the FDMT ($p < .001$), but higher perceived stress was observed in the PASAT ($p < .001$) and MTT ($p < .002$). Finally, there were no differences in self-reported stress between the SCWT and FDMT ($p = 1.000$).

Conclusion: Our novel FDMT elicited increases in traditional CV stress response markers, which was comparable to other psychophysiological stress tasks such as the SCWT but lower than the PASAT and MTT. This suggests the FDMT could be used as a decision-making task to examine potential changes in CV markers of stress.

EXPLORING ELITE SPORTS IN THE THEATER: A MIXED-METHOD ANALYSIS OF WORK AND PERFORMANCE ABILITY, AND WORKPLACE CHALLENGES IN PROFESSIONAL DANCE

HOFMANN, H., BIALLAS, B.

GERMAN SPORT UNIVERSITY COLOGNE

INTRODUCTION: The definition of professional dance encompasses its classification as a performing art; however, it is characterized by physical and mental abilities comparable to elite sports. The training load of professional dancers ranges from 19.1 to 27.5 hours per week, with occasional increases to 35.5 hours. Additionally, the professional environment is marked by a lack of autonomy due to the presence of power structures, which introduces various cultural, interpersonal and situational stressors. In summary this results in mental concerns including depression, anxiety, and chronic fatigue. However, less is known about the interplay of these factors. The objective of this study is to explore the nature of elite sport within the context of occupational theater structures, examining potentials for enhancing performance and health.

METHODS: An exploratory sequential mixed-method approach was utilized. The qualitative part involved interviews with dancers and leaders in German theaters ($n = 25$). The focus was on the working conditions and to identify potential areas for enhancing performance and health. Collected data was analyzed using qualitative content analysis according to Mayring. The following quantitative part incorporated sociodemographic data, and the work ability index (WAI). Items for enhancing performance and health synthesized from the qualitative results were asked to be ranked with respect to individual preferences/requirements. A total N of 75 theater dancers participated (28.76 ± 7.74 years; 62.7% female, 36% male, 1.3% as non-binary). Statistical analysis included Kruskal-Wallis rank sum test.

RESULTS: The qualitative analysis demonstrated that the prevailing working conditions exhibited a preservation of tradition. Additionally, no specific focus on relevant exercise physiology aspects including planning and controlling of the training load was identified. This accompanied with knowledge deficits in sport science topics among the dancers and leaders. The mean WAI score was 37.19 ($SD \pm 7.18$) from 49 points, with a majority of participants demonstrating moderate (36%) to good (33.3%) work ability. Demi-soloists demonstrated a significantly lower WAI score of 25.8 (Kruskal-Wallis chi-squared = 5.2141 , $df = 1$, p -value = 0.0224). The top-ranked option, chosen by 49.3% of respondents, was Dancer support and care comparable to elite sports. In second place, at 41.3%, was the Optimization of regeneration and transition phases, and in third place, at 34.7%, was Planning certainty.

CONCLUSION: In comparison to elite athletes, the working conditions for professional dancers are not sufficiently aligned with the demands of the job. The aim should be to integrate sports science knowledge within the performing arts by implementing training science and sport psychology. This could lead to a balance between artistic pursuits and sports science support, while implementing structural changes to enhance overall performance and health.

OP-PN16 Respiratory / Pulmonary Physiology

EFFECTS OF HIGH ALTITUDE (HA) AND HEAVY PHYSICAL EXERCISE ON LUNG MECHANICS OF ITALIAN ALPINE SOLDIERS

TAGLIAPIETRA, G., PASQUALE, P., VENERONI, C., DELLACÀ, R., AGAZZI, G., BIZZOTTO, D., DANGELO, G., CARIA, E., PRATALI, L., MRKIC SPOSTA, S., COGO, A.

UNIVERSITY OF LAUSANNE, 2RESTECH, 3MILAN POLITECNICO, 4PISA UNIVERSITY, 5PAVIA UNIVERSITY, 6NATIONAL ITALIAN RESEARCH COUNCIL, 7UNIVERSITY OF FERRARA, 8HIGH ALTITUDE CAMP PROJECT RESEARCH TEAM

INTRODUCTION: An increasing number of individuals reach HA for sports, leisure and work. HA hypoxia induces adaptive responses in unacclimatized lowlanders, including pulmonary vasoconstriction. The increase in pulmonary artery pressure and endothelial permeability during HA exposure may lead to lung extravascular fluid accumulation (interstitial edema, IE), affecting lung mechanics, mainly impairing the elastic properties of the respiratory system. Similarly, intense physical exercise (E) may lead to the development of IE. However, the effects of HA and E on pulmonary resistance (R) and reactance (X) have been poorly investigated. We aimed to study the impact of HA and E on lung mechanics in healthy men.

METHODS: Lung mechanics of 36 soldiers of the Italian Alpine Corps (age: 34 ± 9 yr; height: 179 ± 7 cm; weight: 77 ± 8 kg) were assessed by respiratory oscillometry during quiet breathing, at rest and after an intense, standardized E. R and X were measured at 5, 11 and 19 Hz using the Resmon pro full device (RESTECH, Italy) at sea level (SL), and at 3375 m (Torino Hut, Mont Blanc). HA assessments were performed as follows: Day 1, 1-h post-arrival by cable car and after E; Day 2 at rest in the morning and after E; Day 3 at rest in the morning. At the same time, acute mountain sickness (AMS) symptoms were evaluated with the Lake Louise score (LLS). Post hoc comparisons with Bonferroni correction were performed following significant results ($p < 0.05$) from Friedman tests. Subjects were stratified into 3 groups: A (young officers), B (special forces operators) and C (military alpine guides). Between-group differences were explored using Kruskal Wallis test.

RESULTS: R5, R11, R19 significantly decreased from SL to HA (i.e R5: 2.66 ± 0.84 vs. 2.28 ± 0.91 cmH₂O/(s/L), $p < .001$; other values not shown). X5 and X11 significantly changed from SL to HA on Day 1 (-0.796 ± 0.236 vs. -1.006 ± 0.417 , $p < .001$; 0.028 ± 0.318 vs. -0.127 ± 0.345 cmH₂O/(s/L), $p < .001$), Day 2 (-1.001 ± 0.532 , $p = 0.019$; -0.132 ± 0.345 cmH₂O/(s/L), $p <$

.001) and Day 3 (-0.985 ± 0.424 , $p = 0.002$; -0.172 ± 0.503 cmH₂O/(s/L), $p < 0.001$). Spearman correlations revealed a moderate but significant relationship between X5 on Day 1 and LLS on Day 2 ($p = -0.334$, $p = 0.046$).

E induced variations in X5 were more pronounced at HA even if not significant (SL: 0.006 ± 0.192 , Day 1: -0.020 ± 0.289 , Day 2: -0.044 ± 0.306 cmH₂O/(s/L); $p > 0.05$).

$\Delta X5$ between pre- and post-E revealed significant differences between groups B and C on Day 1 (-0.122 ± 0.149 vs. 0.131 ± 0.265 cmH₂O/(s/L); $p = 0.016$).

CONCLUSION: As expected, R decreased at HA due to reduced air density. HA and E lead to acute changes in lung mechanics, with primarily HA increasing respiratory system stiffness, probably due to lung IE development. To note that X5 changes preceded the development of AMS. Military alpine guides showed a more favourable E response at HA, suggesting better lung compliance, likely due to physiological adaptations acquired from prior HA exposure.

ALTERATION IN LUNG DIFFUSION CAPACITY DURING A MOUNTAIN ULTRAMARATHON

RABERIN, A., CALLOVINI, A., GIARDINI, G., MILLET, G.P.

UNIVERSITY OF LAUSANNE

INTRODUCTION: Participation in mountain ultramarathons (MUM) has increased rapidly in recent years. One of the most extreme MUM, the Tor des Géants, is characterized by 330 km with a cumulative elevation gain of +24,000m and altitude ranging between 322 and 3,300 m.

While it is known that such MUMs alter pulmonary volume and ventilatory flow, there is a paucity of data comprehensively assessing their effects on lung diffusing capacity (DL), and its kinetics during the race. Therefore, the aim of this study was to investigate changes in DL during and after a MUM.

METHODS: A total of 53 volunteers participated in the study, but only 25 completed the race (i.e., 47% dropouts, in line with the overall rate). Participants underwent lung diffusing capacity before (pre-), after 148.7 km (mid-), and immediately (< 1-h) after (post-) the race. Pulmonary function was evaluated at pre- and post-.

DL was assessed using the single-breath method with carbon monoxide (DLCO) and nitric oxide (DLNO), while pulmonary function was evaluated through the maximal flow-volume curve (HypAir, MGC Diagnostics, Saint Paul, MN), following standardized procedures. DLCO values were corrected for hemoglobin concentration (Hb201+, Hemocue, Ängelholm, Sweden).

RESULTS: Forced vital capacity (-5.9%), forced expiratory volume in the first second (-5.7%), and peak expiratory flow (-7.1%) were significantly lower at post- compared to pre-.

From pre- to mid-, alveolar volume (-6.8%, 7.6 ± 1.4 vs. 7.0 ± 1.2 L, $p < 0.001$), DLCO (-13.3%, 35.9 ± 6.1 vs. 33.4 ± 6.1 mL·min⁻¹·mmHg⁻¹, $p = 0.008$), DLNO (-11.4%, 175 ± 31 vs. 156 ± 39 mL·min⁻¹·mmHg⁻¹, $p = 0.001$), and membrane diffusing capacity for carbon monoxide (DmCO) (-11.5%, 152 ± 27 vs. 140 ± 27 mL·min⁻¹·mmHg⁻¹, $p < 0.001$) decreased, but they were not further impaired during the second part (mid- to post-) of the race.

KCO and KNO (i.e., DLCO and DLNO expressed as the rate of gas transfer per unit of alveolar volume, respectively), were not modified from pre- to mid- (KCO: 4.79 ± 0.46 vs. 4.76 ± 0.56 mL·min⁻¹·mmHg⁻¹·L⁻¹, NS; KNO: 23.5 ± 2.4 vs. 23.01 ± 2.13 mL·min⁻¹·mmHg⁻¹·L⁻¹, NS) but were lower at post- (KCO: 4.58 ± 0.57 mL·min⁻¹·mmHg⁻¹·L⁻¹, $p = 0.018$; KNO: 22.03 ± 2.45 mL·min⁻¹·mmHg⁻¹·L⁻¹, $p < 0.001$).

The volume of lung capillaries exposed to alveolar air decreased from pre- to mid-race (96 ± 19 vs. 87 ± 17 mL, $p = 0.002$) and further declined at post- (82 ± 17 mL, $p = 0.007$). However, the DLNO/DLCO ratio remained constant across all time points.

CONCLUSION: DL alterations were driven by reduced alveolar volume during the first half of the race, while a decrease in lung capillary volume exposed to alveolar air likely contributed to further changes in the second half. The decline in DmCO, with a stable DLNO/DLCO ratio, suggests impaired membrane permeability.

In conclusion, mountain ultramarathons result in a precociously observed substantial decline in lung diffusing capacity, with further pulmonary alterations occurring later during the race.

DIFFERENCES IN BREATHING RESERVE ACROSS A WIDE RANGE OF TRAINING STATUSES

RODRÍGUEZ REDONDO, B., BENÍTEZ-MUÑOZ, J.A., BENITO, P.J., CUPEIRO, R., ALCOCER-AYUGA, M., ROJO-TIRADO, M.A., RAMOS-CAMPO, D.J., PEINADO, A.B.

UNIVERSIDAD POLITÉCNICA DE MADRID

INTRODUCTION: It has been shown that individuals with a breathing reserve (BR) less than 20% had a higher maximal oxygen uptake (VO₂max) than those with a BR greater than 20% (1,2). Regrettably, the maximum voluntary ventilation (MVV) used to calculate BR was estimated from force expiratory volume in 1s (FEV₁), even though recent studies have demonstrated that there is a significant difference between measured and estimated MVV (3). Therefore, the purpose is to assess differences in BR, with directly measured MVV, across a wide range of training statuses.

METHODS: We examined 198 males (41 ± 10 yrs, 74.0 ± 8.1 kg, 175.2 ± 6.5 cm, $18.5 \pm 6.8\%$ fat) and 60 females (37 ± 14 yrs, 59.1 ± 8.4 kg, 164.7 ± 6.1 cm, $25.7 \pm 8.6\%$ fat) who performed a baseline MVV and a ramp incremental exercise test (consisting of a 3-min warm-up at 4-6 km/h followed by an incremental phase starting at 4-8 km/h, with speed increasing by 1 km/h per minute) to assess maximal ventilation (VEmax) and VO₂max. BR was calculated by the following equation: $BR = (1 -$

$V_{Emax}/MVV \times 100$. Participants were classified based on BR depletion (yes/no) and categorized into low, medium, or high training levels according to VO_{2max} tertiles.

RESULTS: A main effect of training status on BR was found ($F(2,249)=7.43$; $p<0.001$; $\eta^2p=0.056$). Pairwise comparisons showed higher BR in low (males: $24.59 \pm 17.09\%$; females: $21.36 \pm 13.93\%$) than in medium (males: $16.73 \pm 10.5\%$; females: $17.02 \pm 13.52\%$; $p=0.022$; $d=0.53$) or high training status (males: $14.56 \pm 12.93\%$; females: $12.09 \pm 10.65\%$; $p<0.001$; $d=0.82$). Moreover, females exhibited a lower BR than males ($F(1,249)=5.39$; $p=0.021$; $\eta^2p=0.021$; $d=0.46$). The number of individuals who depleted the BR did not differ between the different training statuses in either males ($\chi^2(2)=5.37$; $p=0.068$) or females ($\chi^2(2)=0.46$; $p=0.794$).

CONCLUSION: Lower BR was only observed in individuals with high or medium training status compared to those with low training status, and the number of individuals who depleted BR was not different between training statuses. These results allow us to better understand that reaching maximum possible ventilation during exercise (i.e., depleting the BR) is not a cause for ceasing exercise more prevalent in individuals with high training status, indicating that performance limitation by the respiratory system due to BR depletion is not more likely in individuals with the highest training status.

DOSE-DEPENDENT EFFECT OF INSPIRATORY MUSCLE WARM-UP ON RESPIRATORY MUSCLE FATIGUE, EXERCISE TOLERANCE AND PHYSIOLOGICAL RESPONSES TO INCREMENTAL EXERCISE

GOMES BERNARDES, A., GABARDO, J.M.2, MITAMURA, F.M.3, ALTIMARI, L.R.2, AGUIAR, A.F.3, DELL'ANNA, S.1,4, BALDARI, C.1, BUZZACHERA, C.F.4

1 E-CAMPUS UNIVERSITY, ITALY; 2 NORTH UNIVERSITY OF PARANÁ, BRAZIL; 3 STATE UNIVERSITY OF LONDRINA, BRAZIL; 4 UNIVERSITY OF PAVIA, ITALY.

INTRODUCTION: Traditionally, exercise performance has not been considered to be limited by ventilation or respiratory muscle function. However, prior reports suggest that respiratory muscle fatigue may influence exercise tolerance following prolonged submaximal exercise, as well as during short-term maximal exertion. Approaches such as inspiratory muscle warm-up (IMW) have emerged as plausible strategies for alleviating respiratory muscle fatigue and, arguably, enhancing exercise performance. While some studies have reported significant improvements, others have found no notable effects, suggesting that IMW may not significantly impact exercise tolerance. The underlying reasons for these discrepancies may stem, in part, from differences in the relative load of maximal inspiratory pressure (%MIP) prescribed during IMW. This hypothesis, however, remains unexplored. Therefore, we investigated the effects of different IMW loads on respiratory muscle fatigue, exercise tolerance, and physiological responses to incremental exercise in healthy adults.

METHODS: Ten recreationally active men (mean age 22 ± 2 yrs; VO_{2max} : 44 ± 4 mL·kg⁻¹·min⁻¹) attended the laboratory on four separate occasions. On Day 1, participants underwent a familiarisation with the procedures and measurement of MIP, a key indicator of inspiratory muscle strength. On Days 2-4, participants performed a ramp-incremental exercise test on a cycle ergometer to volitional exhaustion. Each test was preceded by an IMW, which involved two sets of 30 breaths using a Powerbreathe® device, with loads set at 15%, 40%, and 60% of MIP. Pulmonary gas exchange and ventilation data, along with near-infrared spectroscopy (NIRS)-derived muscle oxygenation parameters, were continuously monitored throughout the tests. Respiratory muscle fatigue was assessed by measuring MIP before IMW and 30 sec post-exercise tests. Perception of dyspnoea was assessed using a category, modified Borg scale.

RESULTS: Respiratory muscle fatigue was significantly attenuated (-8%; $P<0.05$) following IMW at 40%, but not at 15% or 60% of MIP. However, perceived dyspnoea at both before (0.7 ± 0.3 , 0.6 ± 0.2 , and 0.6 ± 0.2) and after (9.0 ± 0.3 , 9.2 ± 0.3 , and 9.2 ± 0.3) the exercise test did not differ across the IMW loads (15%, 40%, and 60%, respectively) ($P > 0.05$). Similarly, no significant differences were observed in pulmonary gas exchange and ventilation, or NIRS-derived muscle oxygenation parameters between the different IMW loads during the exercise tests ($P > 0.05$). Exercise tolerance, as indicated by time to exhaustion (777 ± 79 s, 774 ± 71 s, and 775 ± 70 s), also remained comparable across the IMW loads ($P > 0.05$).

CONCLUSION: Our findings suggest that IMW, regardless of the prescribed relative load, does not appreciably influence respiratory muscle fatigue, exercise tolerance, or physiological responses to incremental exercise in healthy adults. However, further research is needed to explore alternative IMW protocols and exercise modalities.

OXYGEN STORAGE, DIVING RESPONSE AND PERFORMANCE IN COMPETITIVE FEMALE ARTISTIC SWIMMERS

RODRÍGUEZ-ZAMORA, L., GAMBLE, S., MONTIEL-ROJAS, D.

ÖREBRO UNIVERSITET

INTRODUCTION: Recent changes in artistic swimming (AS) rules emphasize prolonged apnea periods. During apnea, spleen contraction increases circulating hemoglobin (Hb), enhancing oxygen buffering capacity. While spleen contraction and lung volumes are well-documented in freedivers [1], their role in AS remains unexplored. This study investigated pulmonary function as well as the spleen contraction and the diving response during an apnea series in female artistic swimmers in relation to their competition category and performance scores.

METHODS: Twelve competitive artistic swimmers were divided into two groups based on their competition level: youth (YO, n=6, 14.5±0.8 years) and junior/senior (JS, n=6, 18.5±3.0 years). Testing was conducted prior to competing in the Nationals. Body composition was assessed by bioimpedance. Static and force spirometry tests were used to determine lung volumes and flow rates [2]. Each athlete then performed three maximal static apneas with 2-minute rest in between. Spleen volume (SV, mL), measured via ultrasound, and hemoglobin concentration (Hb, g/L) were assessed before the 1st apnea and immediately after the 3rd apnea. Heart rate (HR, bpm) and oxygen saturation (SpO₂, %) were continuously monitored throughout the apneas, with mandatory termination if SpO₂ dropped below 70%.

RESULTS: Both groups presented no significant differences in body composition, including weight (59.9±10.7 kg, p=0.240), height (167±6 cm, p=0.378), and total fat percentage (24.8 ± 5.6 % body weight, p=0.936). Regarding spirometry values, JS exhibited significantly higher forced vital capacity (FVC, 5.14±0.85 vs. 3.93±0.41 L, p=0.026), forced expiratory volume in 1 second (FEV₁, 4.19±0.75 vs. 3.06 ± 0.26 L, p=0.010), peak expiratory flow (PEF, 7.80±1.14 vs. 5.25±1.01 L/s, p=0.004), and forced expiratory flow at 25–75% of FVC (FEF₂₅₋₇₅, 4.04±0.53 vs. 2.84±0.60 L/s, p= 0.009) compared to YO. However, no significant differences were observed between groups in vital capacity (VC, 3.95±0.76L, p=0.065) or FEV₁/FVC ratio (80.2±6.3 %, p=0.394). The maximal apnea duration did not significantly differ between groups (JS: 123±60 s vs. YO: 74±30 s, p=0.132). However, HR diving response was only significant in the JS group across all three apneas (Apnea 1: 74.3±9.7%, Apnea 2: 73.3±11.2%, Apnea 3: 76.4±11.1% of baseline HR, p<0.05). The absolute splenic contraction was significant for both groups (average 39.1±23.1 mL, p<0.001), whereas baseline Hb concentration remained unchanged after the test. A strong positive correlation between maximal apnea time and competition scores was only observed in the SJ group (rho=0.866, p=0.033).

CONCLUSION: In competitive AS, superior pulmonary function and an enhanced diving response may contribute to success. These findings indicate that apnea training are a valuable component in competitive female AS.

MAXIMAL VOLUNTARY ISOMETRIC FORCE VERSUS RATE OF FORCE DEVELOPMENT IN HAMSTRING ASSESSMENT AFTER ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTION WITH GRACILIS AND SEMITENDINOSUS GRAFT

VESPA, D., ANGELOZZI, M., VENOSA, M., FERMO, D., CIUFFINI, A., CACCHIO, A.

UNIVERSITY OF LAQUILA

INTRODUCTION: After anterior cruciate ligament (ACL) reconstruction with doubled gracilis and semitendinosus (DGST) many studies have pointed out how difficult is to restore neuromuscular parameters like maximal voluntary isometric force (MVIF) and rate of force development (RFD) of quadriceps and how it remains altered even 6-9 months post-surgery. Currently, studies regarding the behavior of the knee flexor muscles are still limited. The aim of this pilot study is to investigate the deficits and trends of these parameters also in hamstrings.

METHODS: 12 male amateur sport subjects who underwent ACL reconstruction with DGST technique and did not have other concomitant injuries (age: 28aa±3aa; weight: 71Kg±13Kg) have been selected. All participants completed a 6-month rehabilitation program with specific hamstring exercises. The protocol included isometric dynamography tests of the hamstring on prone leg curl (HAM_OKC) with a knee flexion angle of 60° (from the ground). All data were sampled at 1000 Hz. The parameters of MVIF and RFD at 30, 50 and 90% of MVIF (RFD30; RFD50; RFD90) have been assessed. The tests were performed at 3- and 6-months post-surgery (3PS – 6PS). For each variable, the values of the operated limb were compared to the uninvolved limb at 3PS and 6PS. The results were reported as mean and SD as well as side-to-side asymmetries. The data were compared using Students t-test for paired data (p<0.05).

RESULTS: The results show a statistically significant difference in all parameters investigated for the HAM_OKC tests performed at 3PS and at 6PS. The Side-to-side asymmetries are as follows: HAM_OKC test at 3PS (MVIF: -40%; RFD30: -33%; RFD50: -37% RFD90: -46%); HAM_OKC at 6PS (MVIF: -29%; RFD30: -17%; RFD50: -22% RFD90: -36%). At the clinical follow up all the test's results are good or excellent.

CONCLUSION: All parameters showed a progressive improvement between the tests performed at 3PS compared to those at 6PS. The most deficient parameters in HAM_OKC at 6PS are the MVIF and the RFD90, unlike the results highlighted on the quadriceps, as reported by previous studies, where the main deficit is about all the RFD parameters. The MFVI and the RFD90 are strongly connected to cross-sectional area of the muscle and it has been also shown that ST muscle atrophy was not accompanied by a compensatory hypertrophy of the other hamstring muscle. The different behavior of RFD30 and RFD50 in the hamstrings compared to what is expressed in the literature for the quadriceps could depend on the lower sensitivity of the hamstrings to the phenomena of arthrogenic and neuromuscular inhibition. The discrepancy with the results obtained in other studies, where the biggest deficit was in the early phase of RFD, could be attributed to the different test setting, the time after surgery, the way to calculate the RFD parameters and rehabilitation program. Fur-

ther studies are certainly needed to understand the residual deficit affecting the hamstrings and thus improve recovery paths.

BEYOND PHYSICAL RECOVERY: PSYCHOLOGICAL, SOCIAL, AND CONTEXTUAL FACTORS IN RETURNING TO SPORT AFTER HAMSTRING INJURIES.

DI LIBERTO, S., GUEx, K., BIZZINI, M., STROKES, D., BLAKE, C., MATTHEWS, J.
UNIVERSITY COLLEGE DUBLIN

INTRODUCTION: Return-to-sport (RTS) criteria are widely used in sports to assist specialists in decision-making. In addition to biomechanical recovery, psychological readiness plays a critical role in successful RTS and reducing re-injury risk. The importance of psychosocial factors in RTS decisions has been highlighted in the international Consensus statement for hamstring injury management. Researchers emphasize psychosocial aspects, with 98.3% of experts supporting the inclusion of emotional and psychological well-being in RTS screening (Paton et al., 2023). Despite this, research on psychosocial factors in RTS after hamstring injuries remains unclear. This scoping review examines psychological, social, and contextual factors influencing RTS after hamstring injuries.

METHODS: This review followed Scoping review guidelines from the JBI Manual for Evidence Synthesis. The research protocol was registered in Open Science Framework (OSF) (<https://doi.org/10.17605/OSF.IO/8RK7E>). Between March and December 2024, systematic searches were conducted in Medline, Embase, PsycINFO, CINAHL, SPORTDiscus, Scopus, and ProQuest. Eligible studies included English, French, German, Spanish, and Italian articles across study designs, provided they addressed psychosocial or contextual management in RTS after hamstring injuries. Grey literature (theses and dissertations) was also considered. Data extraction included participant demographics, methodologies, psychological and social measures, and psychological readiness definitions. The Mixed Methods Appraisal Tool (MMAT) assessed methodological quality, while the Oxford Centre of Evidence-Based Medicine (OCEBM) evaluated the included studies.

RESULTS: Out of 1882 retrieved records, 12 studies met the inclusion criteria, representing four study designs. A total of 799 athletes and 546 professionals were included, with only 124 females, highlighting gender imbalance. About 50% of studies focused on football (soccer), mostly within Europe (58%), with others in Asia, Oceania, and South America. Psychological readiness was central to the RTS process but lacked a clear definition. Self-reported measures such as recovery timelines, comfort during sprinting, and subjective feelings were common, but no standardized assessment tool was used. Contextual stressors, including motivation and team-related factors, influenced psychological readiness. Athlete pressure was also key, as they often set unrealistic expectations due to fear of losing their team position. Team dynamics and poor communication impacted RTS decisions, shaped by institutional resources and cultural differences. Social factors, though underexplored, played a role. External pressures from media, sponsors, and agents sometimes conflicted with recovery decisions. Five of the 12 studies attempted to define psychological readiness, including confidence, resilience, and emotional regulation, but a unified conceptual definition was lacking.

CONCLUSION: Athlete perceptions, external pressures, and resource availability shape recovery, yet frameworks remain inconsistent. The results highlight heterogeneity, methodological limitations, and the lack of standardized tools. A better understanding of these factors could optimize the RTS decision-making process and promote long-term athlete health-related quality of life.

THE EFFECT OF BLOOD FLOW RESTRICTION ON MUSCULAR ACTIVATION AND VASCULAR STRUCTURES DURING NORDIC HAMSTRING EXERCISES

YUKSEL, F.1, GUZEL, N.2, TOR, O.B.3, AKKAN, K.2
ORDU UNIVERSITY (1) GAZI UNIVERSITY (2) BALIKESIR UNIVERSITY (3)

INTRODUCTION: Blood flow restriction training (BFRT) has gained popularity for enhancing muscle strength and hypertrophy by restricting venous return while maintaining partial arterial inflow. While BFRT has been investigated in various training modalities, its effects when combined with Nordic hamstring exercise (NHE) remain unclear. This study aimed to explore the impact of BFRT during NHE on neuromuscular activation of the hamstring muscles and endothelial function.

METHODS: A randomized, single-blind study was conducted with fourteen physically active, healthy male participants (mean age: 27.5 ± 1.24 years). Each participant's lower limbs were randomly assigned to either the BFR group or the control group. In the BFR condition, blood flow was restricted at 60% of arterial occlusion pressure using an inflatable cuff. Participants performed three sets of five repetitions of NHE. Neuromuscular activation of the semitendinosus (ST) and biceps femoris (BF) muscles was recorded using surface electromyography (sEMG) during each repetition. Endothelial function was assessed using flow-mediated dilation (FMD) via Doppler ultrasound before and after exercise. Additionally, the ankle-brachial index (ABI) and popliteal artery diameter were measured to evaluate vascular responses.

RESULTS: No statistically significant differences in FMD values were observed between the BFR and non-BFR groups before and after exercise ($F(1,13) = 0.156$, $p = 0.7$, partial $\eta^2 = 0.012$). Popliteal artery diameter increased significantly in both groups post-exercise (BFR: $p = 0.004$; Non-BFR: $p = 0.000$), but there was no difference between groups ($p = 0.942$). Neuromuscular activation of both ST and BF muscles decreased across sets in both groups, with no significant differences between groups (ST: $F(2,26) = 1.172$, $p = 0.448$, partial $\eta^2 = 0.09$; BF: $F(2,26) = 1.442$, $p = 0.527$, partial $\eta^2 = 0.1$). The ABI values remained stable across conditions, with no significant differences noted.

CONCLUSION: The findings of this study suggest that the incorporation of BFRT during NHE does not provide additional benefits in terms of neuromuscular activation and endothelial function when compared to traditional NHE. Despite prior

evidence suggesting that BFRT may enhance muscle activation, our results indicate that its application in high-intensity eccentric exercises such as NHE does not yield significant improvements.

From a vascular perspective, short-term application of BFRT did not negatively impact endothelial function, as indicated by stable FMD and ABI values. These findings suggest that BFRT, when applied within controlled parameters, is a safe intervention for vascular health in trained individuals.

Future research should investigate the chronic adaptations of BFRT combined with eccentric training to determine whether prolonged exposure elicits beneficial neuromuscular and vascular adaptations.

MAXIMUM-SPEED SINGLE-LEG BRIDGE TEST: A NOVEL APPROACH FOR RAPID HAMSTRING MUSCLE ENDURANCE EVALUATION

SANO, Y., KAWABATA, M., SUMIYA, Y., WATANABE, Y., MURASE, M., SHIMONO, Y., KENMOKU, T., WATANABE, H., TAKAHIRA, N.

KITASATO UNIVERSITY GRADUATE SCHOOL

INTRODUCTION: Hamstring strain injuries frequently occur in sports involving sprinting, with high demands placed on the hamstrings during high-speed biarticular movements. The Single-Leg Bridge Test (SLBT) evaluates hamstring muscle endurance but lacks speed regulation and requires prolonged testing [1]. To address these limitations, the Maximum-Speed Single-Leg Bridge Test (MS-SLBT) was developed, combining high-speed elements with SLBTs benefits [2]. This study aimed to evaluate muscle activation and motion characteristics during 20 repetitions of the MS-SLBT to determine its suitability for assessing hamstring muscle endurance.

METHODS: A cross-sectional observational study was conducted with 26 recreational male athletes. During the MS-SLBT, participants placed their heel on a 40-cm platform and were instructed to "push down through the heel and raise the buttock as fast and high as possible". Surface electromyography was used to measure muscle activity, including median frequency (MDF) and amplitude, in the semitendinosus (ST), biceps femoris (BF), and gluteus maximus (GM) during 20 repetitions of the MS-SLBT. Motion characteristics, including buttock-raising height, buttock-raising speed, and heel-bearing force, were assessed. All variables were analyzed across 18 repetitions (2nd–19th) to evaluate changes over the test. MDF (Hz) and amplitude (%MVIC) were compared using a two-way repeated-measures ANOVA and a linear mixed model, while motion characteristics were analyzed with a one-way repeated-measures ANOVA, followed by Dunnett's test (baseline: 2nd repetition, $p < 0.05$).

RESULTS: MS-SLBT decreased the MDF of the ST and BF from 231 to 196 Hz and 227 to 193 Hz ($p < 0.01$), respectively, without significant changes in the GM (from 118 to 115 Hz, $p = 0.23$). The MDF slope for ST and BF decreased significantly more than that for GM ($p < 0.001$), while no significant difference was found between ST and BF ($p = 0.037$). MS-SLBT increased the amplitude of the ST and BF from 77 to 113 %MVIC and 102 to 133 %MVIC ($p < 0.01$), respectively, with the increase observed after the 6th repetition for the ST and the 9th repetition for the BF. Regarding motion characteristics, during later repetitions, the buttock-raising speed and heel-bearing force decreased by 8.9% and 9.0%, respectively ($p < 0.01$), without significant changes in the buttock-raising height (+1.1%, $p = 0.24$).

CONCLUSION: Twenty MS-SLBT repetitions, completed in 30 s, revealed MDF reduction and amplitude increases for the ST and BF, with reduced buttock-raising speed and heel-bearing force during later repetitions. The MS-SLBT is a practical, specific tool for evaluating hamstring muscle endurance.

HAMSTRING MUSCLE DAMAGE DURING MAXIMAL, HIGH-SPEED ECCENTRIC EXERCISE: THE ROLE OF METABOLIC STRESS

SCHWIETE, C., BROICH, H., WAHL, P., MESTER, J., BEHRINGER, M.

GOETHE UNIVERSITY

INTRODUCTION: Exercise-induced muscle damage (EIMD) has traditionally been attributed primarily to mechanical stress during eccentric exercise (1,2). However, recent evidence suggests a substantial metabolic component, particularly concerning oxygen demands and microcirculatory dysfunction (3,4). This study examined whether changes in muscle oxygen saturation (SmO₂) and ventilatory parameters (VO₂/VCO₂) play a role in EIMD in trained individuals performing high-speed eccentric exercise.

METHODS: Thirty trained male participants completed five sets of 15 maximal, seated eccentric hamstring curls at 210°/s. Near-infrared spectroscopy measured SmO₂ in the m. biceps femoris, while spirometry recorded oxygen uptake (VO₂) and carbon dioxide production (VCO₂). EIMD markers included peak torque, shear-wave elastography, creatine kinase, and perceived muscle soreness were assessed pre- and post-exercise, and on the following four days.

RESULTS: Peak torque declined by 25.6% at 48 hours post-exercise, coinciding with the peak in creatine kinase levels. Shear-wave elastography indicated increased hamstring stiffness immediately post-exercise ($p < 0.001$), normalizing within 24 hours. VO₂ and VCO₂ rose by approximately 50% within sets, whereas SmO₂ decreased by 13% and rebound-

ed 25% during rest intervals. Linear regression showed that VO₂ increases during the intervention significantly predicted peak torque after 48 hours ($p = 0.005$) and accounted for 25.5 % of the variance.

CONCLUSION: These findings reveal that mechanical stress alone does not fully explain EIMD. Incorporating metabolic considerations into training and recovery may alleviate EIMD and reduce injury risk, particularly in high-speed protocols. Future research should clarify mechanistic links between metabolic and mechanical stressors.

OP-MH37 Lifestyle

IMPACT OF NIGHT SHIFT WORK ON VASCULAR FUNCTION IN HEALTHY ADULT WORKERS

HIROYASU, M., HIRASAWA, A., MATSUSHIMA, S., SAITO, S., HORINO, M., FUKUIE, M., SUZUKI, R., TAKANO, D., SAKURAI, A., MATSUDA, T., SHIBATA, S.

KYORIN UNIVERSITY, TOKYO, JAPAN ; TOYO UNIVERSITY, SAITAMA, JAPAN

INTRODUCTION: Night shift work, including shift work, forces workers to adopt irregular lifestyles that can adversely affect human physiology. In particular, impaired vascular function increases the risk of atherosclerotic disease, an important occupational health issue. While previous studies have shown that vascular endothelial function decreases after night shift work, it remains unclear whether this is temporary. A chronic decrease may lead to serious health risks such as cardiovascular disease and stroke, highlighting the need for effective lifestyle interventions. The aim of this study was to compare vascular endothelial function (flow-mediated dilation (FMD)) and structural markers of arterial stiffness (brachial-ankle Pulse Wave Velocity (baPWV), Ankle Brachial Index (ABI)) between the Day Work Group (DWG) and the Night Shift Work Group (NSWG) and to examine associations with lifestyle factors.

METHODS: Forty healthy adult workers (20 each in DWG and NSWG), classified based on their current night shift work status. In a cross-sectional design, body composition, blood tests, vascular stiffness markers (baPWV, ABI) and FMD were assessed. Lifestyle factors, including dietary intake, physical activity, and sleep, were monitored for one week. Dietary intake was assessed using a smartphone app, and physical activity and sleep were assessed using an accelerometer. Group comparisons and correlations with lifestyle factors were analyzed. The Shapiro-Wilk test was used to test for normality; t-tests or Mann-Whitney U tests were used to compare groups, and Pearson or Spearman coefficients were used to analyze correlations.

RESULTS: There were no significant differences in age, BMI or work history. NSWG had significantly higher body fat mass (14.9 ± 5.0 kg vs. 11.8 ± 3.3 kg, $p=0.03$) and body fat percentage ($25.4 \pm 6.3\%$ vs. $21.0 \pm 5.5\%$, $p=0.02$). NSWG showed higher hs-CRP (0.05 ± 0.06 mg/dL vs. 0.01 ± 0.02 mg/dL, $p=0.03$) and leptin levels (8.5 ± 6.1 ng/mL vs. 5.3 ± 3.3 ng/mL, $p=0.02$). Systolic and mean blood pressure were significantly higher in NSWG ($p<0.05$), but no differences were observed in baPWV or ABI. FMD was significantly lower in NSWG than in DWG ($4.0 \pm 1.9\%$ vs. $7.0 \pm 2.9\%$, $p<0.01$). In NSWG, FMD correlated negatively with sedentary behavior (≤ 1.5 METs; $r=-0.47$, $p=0.04$) and positively with light activity ($1.6-2.9$ METs; $r=0.52$, $p=0.02$).

CONCLUSION: NSWG showed significantly lower FMD than DWG, with no differences in baPWV and ABI. This suggests that night shift work may chronically affect vascular endothelial function, whereas structural atherosclerotic changes require longer exposure. The association between FMD and physical activity suggests that lifestyle improvements may help reduce the risk of atherosclerosis in night shift workers. Future longitudinal and intervention studies are needed to evaluate the effects of increasing physical activity and reducing sedentary time on FMD.

AEROBIC PERFORMANCE AND BODY COMPOSITION: INSIGHTS FROM RECREATIONAL FOOTBALL

PÓVOAS, S.1,2, KRUSTRUP, P.2, CASTAGNA, C.3,4

1.UNIVERSITY OF MAIA/CIDESD, MAIA, PORTUGAL, 2.UNIVERSITY OF SOUTHERN DENMARK, ODENSE, DENMARK, 3.PEGASO UNIVERSITY, NAPLES, ITALY, 4.TECHNICAL DEPARTMENT, FIGC, COVERCIANO, ITALY

INTRODUCTION: The Yo-Yo Intermittent Endurance Level 2 Test (YYIE2) is widely used to estimate cardiorespiratory fitness in recreational footballers using the aerobic performance construct. However, the shuttle-running nature of the YYIE2 protocol may pose challenges for overweight and untrained individuals. The present study examines the relationship between

body composition parameters, assessed by dual-energy X-ray absorptiometry (DEXA), and aerobic performance and aerobic fitness measures (YYIE2 performance and $\text{VO}_{2\text{peak}}$, respectively) in recreational football players.

METHODS: Three hundred male recreational footballers (age: 39 ± 6 years, YYIE2: 427 ± 167 m, $\text{VO}_{2\text{peak}}$: 38.57 ± 6.28 mL.kg⁻¹.min⁻¹, body mass: 83.6 ± 13.1 kg, stature: 173.7 ± 6.2 cm) participated in this cross-sectional study. Body composition parameters, including body mass, lean mass, fat mass percentage, android and gynoid fat mass, were measured using DEXA scans. YYIE2 performance was recorded as total distance covered, and cardiorespiratory fitness was determined via $\text{VO}_{2\text{peak}}$. Pearson correlation analysis was conducted to assess relationships between body composition variables and aerobic performance and aerobic fitness measures.

RESULTS: YYIE2 performance was largely associated with $\text{VO}_{2\text{peak}}$ ($r=0.753$, $p<0.001$). Moderate negative correlations were found between YYIE2 and body mass ($r=-0.435$, $p<0.01$), while $\text{VO}_{2\text{peak}}$ demonstrated a large negative correlation with body mass ($r=-0.530$, $p<0.01$). Android fat mass was largely negatively correlated with both YYIE2 ($r=-0.531$, $p<0.001$) and $\text{VO}_{2\text{peak}}$ ($r=-0.612$, $p<0.001$). Gynoid fat mass also showed moderate negative correlations with both YYIE2 ($r=-0.350$, $p<0.01$) and $\text{VO}_{2\text{peak}}$ ($r=-0.425$, $p<0.01$). Fat mass percentage displayed large and very large negative correlations with YYIE2 ($r=-0.674$, $p<0.001$) and $\text{VO}_{2\text{peak}}$ ($r=-0.709$, $p<0.001$), respectively. Correlations with lean mass were weaker, highlighting the dominant role of fat accumulation in limiting aerobic performance and aerobic fitness.

CONCLUSION: This study highlights the significant impact of body composition on aerobic performance and aerobic fitness in recreational male footballers. Fat mass, particularly in the abdominal region, is a key limiting factor for both YYIE2 performance and $\text{VO}_{2\text{peak}}$. These findings suggest that targeted interventions aimed at reducing abdominal fat may lead to substantial improvements in aerobic fitness, aerobic performance and overall fitness in recreational football players.

THE ACUTE EFFECTS OF SLEEP FRAGMENTATION ON NEUROMUSCULAR PERFORMANCE

SLUNECKO, M., SOMBORATZ, S., CSAPO, R.

UNIVERSITY OF VIENNA

INTRODUCTION: Acute sleep loss can impair physical performance, with reduced sleep duration being consistently linked to decreased performance [1]. One common form of sleep loss, sleep fragmentation – characterized by repeated sleep interruptions – is a common problem among athletes [2], but its effects on neuromuscular performance have not been well researched and remain unclear. Thus, this study aims to examine the impact of induced sleep fragmentation on neuromuscular performance.

METHODS: Fifteen trained adults (8M/7F, 25.8 ± 2.4 years, 174.5 ± 6.3 cm, 77.3 ± 9.6 kg) participated in a randomized crossover study comparing two sleep conditions: fragmented (INT) and habitual sleep (CON), separated by a 5-night washout phase. Fragmentation was induced by having participants wake up every 2 hours for two consecutive nights, requiring them to turn on the lights and complete a brief task. Time in bed was standardized across conditions, based on a 7-night baseline average, and monitored using wearable technology. Following the sleep conditions, lower limb strength was assessed using an isokinetic dynamometer with a leg press adapter (ISOMED 2000). Maximal voluntary isometric contraction strength (MVIC) was tested at a 60° knee angle. Strength endurance was evaluated through a concentric-eccentric isokinetic test ($20-90^\circ$ knee ROM) at 90 mm/s with 15 all-out repetitions. Total work (W_{tot}) and a fatigue index (FI), reflecting the decline from the first three (MF3) to the last three repetitions, were separately calculated for the eccentric and concentric phases. Paired t-tests were used to compare all outcome measures between sleep conditions ($\alpha = 0.05$).

RESULTS: Time in bed (INT: 7.6 ± 0.6 h, CON: 7.8 ± 1.0 h, $p=0.47$) and time asleep (INT: 6.6 ± 0.5 h, CON: 6.8 ± 0.9 h, $p=0.38$) did not differ significantly between conditions. No significant difference was found for MVIC (INT: 4.04 ± 0.94 kN, CON: 4.22 ± 0.87 kN, $p=0.25$, $d=0.31$). For concentric efforts, W_{tot} was significantly lower after INT (5.15 ± 1.39 kN) than after CON (5.32 ± 1.33 kN) ($p=0.04$, $d=0.59$). Despite no change in concentric FI (INT: $54.1 \pm 12.2\%$, CON: $52.8 \pm 13.1\%$, $p=0.57$, $d=0.15$), the concentric MF3 was lower after INT (2.16 ± 0.51 kN) than after CON (2.29 ± 0.47 kN) ($p=0.04$, $d=0.57$) indicating a higher starting force level after CON nights.

During the eccentric efforts, no significant differences were observed for W_{tot} (INT: 6.68 ± 1.91 kJ, CON: 6.84 ± 1.68 kJ, $p=0.33$, $d=0.26$), FI (INT: $49.1 \pm 13.7\%$, CON: $46.1 \pm 11.1\%$, $p=0.38$, $d=0.23$) and MF3 (INT: 3.21 ± 0.76 kN, CON: 3.45 ± 0.82 kN, $p=0.09$, $d=0.48$).

CONCLUSION: Even with unchanged total sleep duration, the sleep fragmentation intervention caused a notable decline in concentric force production during an isokinetic leg press task. The fatigue index remained stable between conditions, but the participants produced greater concentric force at the beginning of the trial and greater total work. No changes were observed for the MVIC and eccentric outcome measures.

COGNITIVE PERFORMANCE PREDICTION USING PHYSIOLOGICAL, PHYSICAL, AND LIFESTYLE RELATED DATA: A PILOT STUDY

GINESTRETTI, L., BARDINI, S., LAZZARI, J., SANTAMBROGIO, M.D.

POLITECNICO DI MILANO

INTRODUCTION: Wearable devices have revolutionized physiological and activity monitoring, enabling a shift from reactive to proactive healthcare. Within this context, improving cognitive performance remains challenging due to its reliance on multiple factors, including physical activity, physiological markers, and lifestyle habits. While machine learning models have been used to predict cognitive states, few effectively account for individual variability aimed at cognition improvement. This study introduces a multimodal regression framework that integrates physiological, sports, and lifestyle data to enhance the predictive accuracy of cognitive performance while focusing on the interpretability of model predictions.

METHODS: Data were collected from 30 healthy participants (mean age 25.43 ± 7.36 years, 21 males, 9 females). Physiological and activity metrics were obtained using Garmin smartwatches, while dietary intake was logged to assess nutritional impact. Metabolic data were collected through indirect calorimetry. Two processing pipelines were developed: one extracting features from physiological signals and physical activity, and another using raw time-series data. The first approach, which focused on feature extraction, was implemented with Random Forest and XGBoost models, while the second approach, based on LSTM networks, aimed to capture temporal dependencies.

RESULTS: Model performance was evaluated using mean absolute error (MAE), with a naïve baseline of 0.286. Feature-based models significantly outperformed the baseline, with Random Forest achieving an MAE of 0.1587 and XGBoost improving to 0.147, while the LSTM-based approach was less effective. To interpret model predictions, SHAP analysis was applied, revealing that moderate-intensity physical activity from the previous day had the strongest influence on cognitive performance, followed by stress range, respiration rate, and heart rate-derived metrics. In some cases, physical activity alone contributed up to 80% of the predicted outcome. Lifestyle factors such as nutrition played a moderate role. In contrast, demographic factors and metabolic data had minimal predictive value.

CONCLUSION: This study demonstrated that feature-based models can effectively predict cognitive performance, with physical activity and stress being the most influential factors. The findings highlight the importance of individualized modeling to enhance prediction accuracy. Future research should focus on expanding datasets, exploring advanced deep learning architectures, and incorporating real-time feedback to improve cognitive performance itself. Integrating wearable data with AI-driven insights represents a promising step toward personalized cognitive performance monitoring and enhanced well-being.

Invited Symposium

IS-SH01 ECSS-FEPSAC Invited Symposia-Psychological First Aid: Welfare strategies at major sports events

IMPLEMENTING PSYCHOLOGICAL FIRST AID PROTOCOLS IN SPORTS: TOOLS AND INSIGHTS FROM THE FIELD

BARIC, R.

UNIVERSITY OF ZAGREB

Psychological First Aid (PFA) has emerged as an important tool for supporting athletes' mental health in high-stakes environments like major sporting events. Renata Barić, an esteemed Sport Psychologist and Professor at the University of Zagreb, shares insights into implementing PFA protocols tailored to the dynamic, stress-intensive environment of elite sports. Her approach emphasizes immediate, targeted responses to emotional and psychological crises, equipping sports psychologists, coaches, and support staff with essential skills for mitigating acute stress and trauma. Drawing from her extensive research and practice, The presentation will cover best practices for recognizing early signs of mental health risks and delivering intervention strategies that are both compassionate and culturally sensitive. This presentation will highlight how PFA is integrated into existing welfare frameworks, providing a preventive approach to athlete support and fostering resilience in sports communities.

WELFARE AND WELL-BEING IN ELITE SPORTS: MENTAL HEALTH INTERVENTIONS IN THE PARIS 2024 OLYMPICS

MANSI, V.

PRIVATE PRACTICE OR WESTCOAST INSTITUTE OF NEUROSCIENCES

As the Welfare Officer for India at the Paris 2024 Olympics, Dr. Mansi Vora provides a unique perspective on how Psychological First Aid (PFA) is applied to ensure the well-being of athletes, officials, and staff. In this session, Dr. Vora will delve into the practical application of PFA at one of the world's largest and most demanding sporting events. She will explore the challenges welfare officers face in recognizing and addressing mental health risks in real-time, especially under high-stress and high-visibility conditions. Through case studies and reflections from Paris 2024, Dr. Vora will illustrate how welfare networks operate collaboratively to provide swift interventions, reduce stress-related impacts, and promote resili-

ence among team members. Emphasizing the role of welfare officers, this talk underscores how PFA fosters a proactive, ethical approach to safeguarding mental health, particularly in the context of an international multi-sport event. Attendees will gain insight into developing a welfare infrastructure that protects mental health, enhances performance, and respects the dignity of each participant.

SAFEGUARDING THROUGH PSYCHOLOGICAL FIRST AID: BUILDING A CULTURE OF SAFETY IN SPORT

VISERAS, G.

INTERNATIONAL OLYMPIC COMMITTEE

Gloria Viseras, a former Olympian and Senior Project Manager IOC Safe Sport Unit/IOC Safeguarding Officer. brings an invaluable perspective on implementing Psychological First Aid (PFA) as a core component of safeguarding in sports. Having dedicated her career to advocating for child protection and safe sport practices, she will share her experience in integrating PFA protocols across large-scale international events. Her talk will address how PFA not only serves as an immediate response to trauma but also as a foundational element in creating a culture of safety, respect, and well-being within sport. In her presentation she will discuss the critical role of education, awareness, and policy development in equipping coaches, staff, and support teams with skills to identify and respond to crises, including recognizing signs of abuse or distress. Through real-life examples and collaborative safeguarding models, her insights offer a vision for embedding PFA as a preventative and responsive practice that transcends individual interventions, aiming to foster a universally safe and inclusive sporting environment. Gloria Viseras has coordinated the activity of the Welfare officers in Paris 2024 Olympic Games.

OP-PN19 Exercise and Energy Intake

METABOLIC EFFECTS OF MODERATE VERSUS HIGH-INTENSITY TRAINING ACCOMPANIED BY CALORIE-RESTRICTED DIET IN OVERWEIGHT ADULTS WITH TYPE 2 DIABETES

GHOLAMI, F., DELVARYAN ZADE, M., IRANPOUR, M., SAEIDPOUR, A., SHERAFAT, F., HAJIANI, N.

SHAHROOD UNIVERSITY OF TECHNOLOGY

INTRODUCTION: Diabetes management is increasingly focusing on lifestyle interventions and high-intensity interval training is getting more attention in clinical setting for being effective and time-efficient. However, the comparative effectiveness of different exercise protocols remains a crucial area for investigation. The present study aimed to compare the effects of energy-matched moderate-intensity continuous training (MICT) and high-intensity interval training (HIIT) accompanied by a calorie-restricted diet on metabolic measures in overweight and obese individuals with type 2 diabetes (T2D).

METHODS: This randomized clinical trial included 42 overweight or obese participants with T2D who were randomly assigned to three groups: MICT, HIIT, and a control group with no intervention. MICT was performed at an intensity of 55%-65% of heart rate reserve, while HIIT comprised of running at 85% heart rate reserve interspersed with one minute walking at the intensity corresponding to 40-45% heart rate reserve. Both experimental groups followed a calorie-restricted diet for 12 weeks, incorporating a 20% caloric deficit. Measurements of body composition and resting metabolic rate via indirect calorimetry were made before and 48 hours following the last session. In addition, blood samples were collected for the analysis of fasting glucose, 2-h postprandial glucose, HbA1c, insulin, lipid profile, ALT, AST, creatinine and urea. Data were analyzed using one-way ANOVA and Tukey's post hoc tests with significance set at $p < 0.05$.

RESULTS: Both MICT and HIIT significantly reduced fasting blood glucose, 2-hour postprandial glucose, hemoglobin A1c, insulin resistance, ALT, AST, creatinine levels, total cholesterol and triglycerides. Besides re significant reduction in weight (...% in MICT and ...% in HIIT) and body mass index (...% in MICT and ...% in HIIT) were observed. However, no significant differences were observed for insulin levels, resting metabolic rate, urea, low-density and high-density lipoprotein when comparing the experimental groups with the control group ($p > 0.05$). Furthermore, no significant differences were found between the experimental groups concerning the variables ($p > 0.05$).

CONCLUSION: The findings suggest that in sedentary, overweight individuals with T2D, the energy expenditure during exercise might play a more critical role than exercise intensity itself in weight loss and improving metabolic indices. Both MICT and HIIT can yield comparable results in metabolic outcomes, allowing for flexibility in exercise prescription while promoting adherence. This has practical implications for diabetes management, encouraging individuals to engage in whichever modality suits their preferences and schedules, as similar health benefits can be achieved in a shorter duration with HIIT. Future research should explore long-term sustainability and adherence to these exercise interventions, as well as the psychosocial factors influencing exercise choices among this population.

SYNERGISTIC EFFECTS OF TIME-RESTRICTED EATING AND RESISTANCE TRAINING ON HEPATIC FAT REDUCTION IN PATIENT WITH METABOLIC SYNDROME: RESULTS FROM THE TERA RANDOMIZED CONTROLLED TRIAL

STERNFELD, R.1, YAVETZ, R.1, LAHAV, Y.1, REIN, M.2, ZELBER-SAGI, S.2, GEPNER, Y.1

1. DEPARTMENT OF EPIDEMIOLOGY AND PREVENTION MEDICINE, SCHOOL OF PUBLIC HEALTH, FACULTY OF MEDICINE AND HEALTH SCIENCES, AND SYLVAN ADAMS SPORTS INSTITUTE, TEL-AVIV UNIVERSITY, TEL-AVIV, ISRAEL. 2. SCHOOL OF PUBLIC HEALTH, FACULTY OF SOCIAL WELFARE AND HEALTH SCIENCES, UNIVERSITY OF HAIFA, HAIFA, ISRAEL.

INTRODUCTION: Metabolic dysfunction-associated steatotic liver disease (MASLD) affects ~30% of the global population and is strongly associated with obesity and metabolic syndrome (MetS). Time-restricted eating (TRE) and resistance training (RT) independently improve metabolic health, but their combined effects on hepatic fat content (HFC) and glycemic control remain unclear. This study investigates the synergistic impact of TRE and RT on HFC and glycemic markers in patients with MetS, independent of weight loss.

METHODS: The TERA study, a 10-week randomized controlled trial (RCT), included 76 overweight/obese adults (40-60 years) with MetS, who were randomized into TRE alone (n=26), RT with a normal diet (ND+RT, n=25), and TRE combined with RT (TRE+RT, n=25). The TRE diet limited food intake between 12:00 PM and 8:00 PM, whereas the ND group adhered to a standard eating pattern without time restrictions. All groups adhered to iso-caloric diets with a protein intake of 1.5 g/kg/day. RT sessions were conducted with up to three participants and supervised three times per week. Each 60-minute session included a full-body workout consisting of nine exercises targeting major muscle groups. HFC, measured by magnetic resonance spectroscopy, and glycemic markers were assessed pre- and post-intervention. Data were analyzed using ANCOVA, with baseline values as covariates, and logistic regression was applied for dichotomous variables.

RESULTS: Of the initial 76 participants, 68 completed the study: 22 in the TRE alone, 22 in the ND+RT, and 23 in the TRE+RT groups. Following the 10-week intervention, although weight loss was minimal in all groups (0-1.6 kg), significant differences were observed between ND+RT and both TRE alone (1.8 kg, $p = 0.01$) and TRE+RT (1.57 kg, $p = 0.01$), with no difference between TRE alone and TRE+RT (0.25 kg, $p = 0.57$).

Compared to TRE alone ($-4.6\% \pm 6.4$, relative change $-24.3\% \pm 29.6$), HFC reductions were significantly greater for the TRE+RT group ($-7.1\% \pm 7.7$, relative change $-41.1\% \pm 31.6$, $p < 0.05$ for both), but not for the ND+RT ($-5.5\% \pm 6.8$, relative change $-32.6\% \pm 27.6$). A $>30\%$ reduction in HFC was achieved by 73.9% of participants in the TRE+RT group compared to 59.1% in the ND+RT group ($p = 0.23$) and 40.9% in the TRE group ($p = 0.028$). The TRE+RT achieved the largest reductions in insulin (-5.2 ± 10.2 $\mu\text{U/ml}$) and HbA1c ($-0.07 \pm 0.12\%$), followed by moderate reductions in the ND+RT group (insulin: -2.6 ± 12.7 $\mu\text{U/ml}$; HbA1c: $-0.07 \pm 0.27\%$), and minimal changes with TRE alone (insulin: -0.97 ± 9.5 $\mu\text{U/ml}$; HbA1c: $-0.03 \pm 0.24\%$). However, none of these differences reached statistical significance compared to TRE alone.

CONCLUSION: In overweight/obese adults with MetS, TRE+RT demonstrated significantly greater reductions in HFC compared to TRE alone, independent of substantial weight loss. These findings highlight the distinct advantages of combining TRE with RT for managing MASLD and emphasize the role of RT in HFC reduction, potentially mediated by improved insulin sensitivity.

PLASMA LIPIDS AMONGST OLYMPIC WOMENS 7S RUGBY PLAYERS: DO THEY DIFFER BY RISK OF LOW ENERGY STATUS?

BLACK, K., MATKIN-HUSSEY, P., BAKER, D.

UNIVERSITY OF OTAGO

INTRODUCTION: Problematic Low Energy Availability (LEA) can result in Relative Energy Deficiency in Sport (REDs) which has multiple adverse health effects. Research investigating its impact on cardiovascular health is limited and conflicting, but suggests problematic LEA is associated with unfavourable lipid profiles and endothelial dysfunction. To date no studies have investigated the cardiovascular effects amongst elite team sport players.

METHODS: Eighteen players of Māori or Pacifica descent who were part of the Olympic women's 7s squad participated in this study. The Low Energy in Females Questionnaire (LEAF-Q) was used to group players as at risk or not at risk of LEA. Blood samples were collected and measured for plasma lipids, and inflammatory markers. Arterial stiffness was measured by pulse wave velocity (PWV) (SphygmoCor Xcel PWV and PWA system, AtCor, Medical Pty Ltd). Energy intakes were obtained via three day diet records, which were analysed via Foodworks using the New Zealand database.

Independent sample t-tests were performed, significance set at $p \leq 0.05$. Results are presented as mean $\pm$ standard deviation, mean difference (95% confidence intervals).

RESULTS: Similar to other research ten (55%) players were classed as at risk of LEA. Those at risk of LEA had a significantly lower energy intake ($8053 \pm 1,999$ kJ vs $11,072 \pm 1,951$ kJ, $p = 0.05$). Low-density lipoprotein was moderately higher by 11.3% in those at risk (2.42 ± 0.75 mmol.L⁻¹ vs 2.14 ± 0.45 mmol.L⁻¹, 0.15 (95%CI: 0.73, -0.43) mmol.L⁻¹) $p = 0.19$. Whereas high-density lipoprotein concentrations were 10.7% lower, but not statistically different between groups (1.50 ± 1.31 vs 1.64 ± 0.44 mmol.L⁻¹, 0.29 (95% CI: 0.07, -0.65) mmol.L⁻¹ $p = 0.31$). There was no statistically significant differences for ApoA nor ApoB, $p > 0.05$. There was a small elevation pulse wave velocity (6.55 ± 1.54 ms⁻¹ for those at risk compared to not at risk 5.69 ± 1.11 ms⁻¹ (0.86 ms⁻¹ (2.40, -0.68) $p = 0.22$).

CONCLUSION: There is a small body of literature suggesting athletes at risk of LEA have different blood lipid profiles compared to those not at risk. It is plausible that decreases in estrogen seen with REDs are responsible for changes in plasma lipids. However, not all studies have shown differences in lipid profiles. The results from the current study were not significantly different, but may have some clinical relevance. The large standard deviations and small sample size likely contrib-

ute to the lack of statistical findings, but this study does reflect the small pool of elite female 7s players. This study shows female 7s players at risk of LEA which may impact their cardiovascular health. Therefore, all involved in Rugby 7s should be aware of REDs. Further, specialist medical teams should lead diagnosis and treatment, as signs of REDs can also signify other health conditions.

THE EFFECTS OF HIGH INTENSITY INTERVAL TRAINING IN HYPOXIA ON GLUCOSE REGULATION AND INSULIN SENSITIVITY IN SEDENTARY INDIVIDUALS WITH OVERWEIGHT OR OBESITY

SOO, J., GOODS, P., GIRARD, O., DELDICQUE, L., LAWLER, N., CHARLESWORTH, J., FAIRCHILD, T.

MURDOCH UNIVERSITY

INTRODUCTION: Obesity and reduced physical activity are closely associated with impaired insulin sensitivity and glucose regulation. High intensity interval training (HIIT) increases reliance on muscle glycogen, and consequently results in improved insulin sensitivity. Consequently, HIIT in hypoxia may enhance these effects. Accordingly, the aim of this research was to investigate the chronic effects of a 10-week HIIT intervention in hypoxia on insulin sensitivity and glucose regulation in sedentary individuals with overweight and obesity.

METHODS: 30 sedentary individuals with overweight or obesity (36 ± 7 yrs, BMI 33.9 ± 6.5 , body fat percentage: $40.2 \pm 7.0\%$) underwent 10 weeks (3 session/week) of exercise training which consisted of 2 weeks of standardised training in normoxia followed by 8 weeks of HIIT training with (HYP) or without hypoxia (NOR). Each session consists of four to six, 1-min cycling bouts performed at a rating of perceived exertion (RPE) of 16 interspersed with 4-min of recovery at RPE 10, and resistance exercise (comprising 4 different exercises, always performed in normoxic conditions). Body composition and glucose tolerance (via an oral glucose tolerance test; OGTT) was examined before and after the 10-week training program. The primary analyses included all data irrespective of dropouts and completeness of outcome measures (intention to treat). Linear mixed method models were used with condition, time, and interaction defined as the fixed effects and participants as random effects.

RESULTS: There was no significant effect on glucose area under the curve (AUC) during the OGTT in either condition (pre-post diff: HYP: -47 ± 131 mmol/L/120min; NOR: $+31 \pm 92$ mmol/L/120min, $p=.55$). Within-group differences in insulin AUC was reduced after training in HYP (-1346 ± 2209 mU/L/120min, $p=.03$, $g=0.26$) but not NOR (-270 ± 1165 mU/L/120min, $p=.28$, $g=0.11$) with no difference between groups ($p=.73$). Insulin AUC normalised for glucose AUC was not significantly different in either condition. There was no difference in insulin resistance (HOMA2-IR) following training in both groups (HYP: 1.34 vs 1.38; NOR: 1.12 vs 1.06, $p=.41$, $g=0.03$). Within group differences in fat mass (FM) and fat free mass (FFM) were reduced and increased, respectively in HYP (FM: -0.97 ± 1.89 kg, $p=.03$; FFM: $+1.89 \pm 2.6$ kg, $p=.04$) but not NOR (-0.51 ± 2.85 kg, $p=.29$; FFM: $+0.21 \pm 1.76$ kg, $p=.36$).

CONCLUSION: Perceptually regulated HIIT performed in hypoxia demonstrated a tendency for improvement in body composition compared to matched training in normoxia. Additionally, reductions in insulin AUC suggest an improvement in insulin sensitivity, although this did not reach statistical significance. Participants were however, normoglycemic at baseline, possibly limiting substantial changes in metabolic outcomes. Future studies are needed to investigate the efficacy of HIIT in hypoxia on glycemic control in individuals with impaired glycemic function.

Invited Symposium

GESTATIONAL PARENT & CORD BLOOD METABOLOME LINKS TO PHYSICAL ACTIVITY STATUS IN PREGNANCY

ADAMO, C.

UNIVERSITY OF OTTAWA

Background: Gestational physical activity (PA) reduces the risk of pregnancy and birth complications, such as gestational diabetes, gestational hypertension, and macrosomia. While the benefits of PA during pregnancy are well documented, the mechanisms behind these effects remain unclear. Studying the metabolome and how it responds to PA can be valuable in understanding these mechanisms. Investigating the metabolome response to PA may clarify these mechanisms, yet limited data exist on the metabolomic profile of gestational parents (gesP) and cord blood metabolome associations with PA. **Purpose:** We aimed to i) examine the association between PA and gesP serum metabolome in mid-pregnancy, ii) explore cord blood metabolome associations with PA for participants who maintained their PA status from mid (24-28 weeks) to late gestation (34-38 weeks). **Methods:** Twenty-nine participants were classified as "active" or "inactive" based on their objectively assessed (accelerometer) PA data. Untargeted metabolomics using Ultra-Performance Liquid Chromatography-Quadrupole Time-of-Flight Mass Spectrometry provided a global metabolic profile, with data processed in MS-DIAL and analyzed via MetaboAnalyst 6.0. **Results:** Based on the clustering of the samples in PCA and PLS-DA plots, no major serum metabolome differences were found between physically active and inactive pregnancies. Inactive participants were shown to have higher pipecolic acid, a lysine derivative. Receiver Operating Characteristic (ROC) analysis revealed that pipecolic acid and phosphatidylcholine (18:1e/8-HEPE) exhibited a fair ability to discriminate between the active and inactive groups ($AUC > 0.7$). The cord blood metabolome analysis revealed a moderate separation between the metabolome of babies born to active vs. inactive pregnancies. Babies born to active pregnancies showed significantly

lower levels of phenylalanine, valine, threonine, lysophosphatidylcholine (LPC) 16:0, LPC 18:2, LPC 18:1, O-acetylcarnitine, and 5-hydroxyindole-3-acetic acid. ROC analysis identified several metabolites with discriminatory power in cord blood. The marked difference between the gesP and cord blood metabolomes suggests a closer correlation between cord blood metabolome and the placental metabolome than gesP serum metabolome. Conclusion: Gestational PA can affect the gesP and fetal metabolome, with the magnitude of the effect being much higher in the fetus. The protective effects of gestational PA likely modulate pathways involving the identified metabolites, possibly by enhancing antioxidant capacity and reducing inflammation.

MATERNAL-PLACENTAL-FETAL CYTOKINES & METABOLITES RELATED TO PHYSICAL ACTIVITY

ACOSTA-MANZANO, P.

UNIVERSITY OF GRAZ

Pregnancy induces remarkable immunometabolic changes in physiology to support maternal, placental-fetal demands, thus ensuring a successful gestation. Challenges to homeostasis are common in pregnancy. For some women, particularly those exposed to an adverse lifestyle (e.g., suboptimal eating habits, sedentary time, sleep hygiene, or stress), these alterations might lead to adverse short- and long-term outcomes. Indeed, the harmful consequences related to a dysfunctional metabolic machinery in pregnancy have the potential to negatively affect not only one life, but two (the mother and child), and possibly the next generation. Consequently, research institutions are focused on identifying effective strategies to promote an optimal maternal and intrauterine environment, and to break the maternal-fetal intergenerational diabetes cycle. In this regard, physical activity (PA) and exercise are promising tools to optimize metabolic control during pregnancy, and thus avoid potential complications and future diseases, such as obesity. Unfortunately, available evidence remains scarce and inconclusive, leaving many questions unanswered. To address this knowledge gap, we have led and collaborated on several pregnancy clinical studies examining the impact of PA on maternal, placental and fetal phenotypes, as well as the biological mechanisms driving PA beneficial adaptations. We have demonstrated that maternal PA and concurrent exercise of moderate to vigorous intensity can optimize the inflammatory profile of pregnant women with a healthy weight and with overweight-obesity, and of their fetuses. Exercise was also found to slightly attenuate the maternal-fetal pro-inflammatory status (pro-inflammatory cytokines) associated with excessive weight gain. Additionally, our results showed that the influence of exercise on traditional maternal metabolites (e.g., lipids) was minimal, except in those exercisers who increased the levels of specific cytokines (IL-8), where exercise was related to lower maternal total cholesterol and low-density lipoprotein-cholesterol gains. Regarding placental adaptations, we have shown that sedentary time during pregnancy is related to higher placental IL-6 gene expression and lower cord blood IL-6 content, while moderate-to-vigorous PA has minimal influence. Moreover, we identified placental IL-6 gene expression as a potential mechanism linking sedentary behaviour to neonatal adiposity. Finally, our recent findings suggest that exercise modulates key placental cytokines and metabolites involved in placental-fetal adaptations in a sex-dependent manner. Thus, this lecture will provide deeper insights into how maternal sedentary time, PA and exercise influence maternal, placental and fetal cytokines and metabolites in pregnant women with a healthy weight status and/or with overweight/obesity. The target audience of this lecture are exercise scientists, physiologists, and clinicians working with pregnant women and children.

INFANT CYTOKINES & METABOLITES RELATED TO MATERNAL EXERCISE TYPES & CLINICAL IMPACT

MAY, L.

EAST CAROLINA UNIVERSITY

World-wide there are increasing rates of non-communicable diseases, such as obesity, and cardiovascular disease, especially in women of child-bearing age. Thus, it is critical to develop strategies to prevent the intergenerational cycle of obesity. Data supports that maternal physical activity (PA), and exercise positively influence pregnancy outcomes and offspring health. However, little is known about maternal exercise type on infant health phenotype via metabolite and inflammatory signatures. To elucidate the biological mechanisms behind positive adaptations to maternal exercise and identify potential targets for clinicians and future interventions, we assessed infant metabolite & inflammatory markers; women did aerobic (AE), strength (SE), combination (aerobic + strength, AESE), or attention-control (CON) for 24+ weeks of pregnancy. We hypothesized that any maternal exercise type will be associated with improved infant metabolite and inflammatory profile. Blood samples from the infant were processed with Untargeted metabolomics using Liquid Chromatography-Quadrupole Time-of-Flight Mass Spectrometry (LC/MS/MS) for a global metabolic profile, as well as multiplex kits for pro- and anti-inflammatory cytokine expression. Based on clustering, there are 4 distinct metabolite signatures from infants exposed to maternal exercise types. There are specific pathways that are up- and down-regulated in the exercise-exposed infants relative to infants from controls; however, there are also exercise-type specific metabolite changes as well. Additionally, key cytokine expression (i.e., IL-6, IL-8) are different based on exercise-type exposure in utero. We will discuss the impact of maternal exercise mode on infant cytokine and metabolomic phenotype relative to infants of those in the non-exercise group. Maternal exercise is also associated with metabolic pathways associated with controlling appropriate inflammation in infants of exercisers compared to infants of controls. Our data suggests that any maternal exercise type can improve infant cytokine and metabolomic phenotype. These changes in offspring cytokine/inflammation and metabolomic signature suggest improved overall phenotype and thus could decrease the propensity to develop obesity and associated cardiometabolic conditions later in life. The target audience of this lecture are

researchers in the field of physical activity in pregnancy, clinicians working with pregnant women and children, as well as exercise professionals.

OP-PN01 Physiology of Fatigue I

MUSCULAR RESPONSES TO ACUTE AND CHRONIC FINGER FLEXORS BLOOD-FLOW RESTRICTION TRAINING IN EXPERIENCED SPORT CLIMBERS.

PERRIN, T., RANDY, H.1, SANTAL, P.1, DOUTRELEAU, S.1, GUINOT, M.1, COUDURIER, M.1, HUGUES, X.2, QUAINÉ, F.2, CAHOUE, V.2, KERHERVE, H.A.3, MARILLIER, M.1, BRUGNIAUX, J.V.1

UNIVERSITÉ GRENOBLE ALPES <1,2>; UNIVERSITÉ RENNES 2 <3>;

INTRODUCTION: In sport climbing, high-load resistance training (HLRT) is traditionally used for performance enhancement, with an important part of it dedicated to improving finger specific isometric flexor digitorum (FD) muscle strength and endurance. However, specific FD training at high intensity can be traumatic, often leading to injuries in climbers. Low-load blood-flow resistance training (LLBFR) has been shown to be a promising substitute to HLRT for promoting strength and endurance while reducing mechanical stress on tissues (e.g. lower training loads). However, the physiological responses associated with LLBFR to climbing-specific exercises are poorly understood. Therefore, the aims of the study were to i) examine acute and chronic muscular responses to LLBFR during climbing specific FD training, and ii) compare these responses to HLRT.

METHODS: An acute and a chronic phase were completed. The acute phase involved 15 advanced to elite climbers who conducted two bouts of three sets of FD intermittent exercise on a hangboard under two experimental conditions in a randomized order: 1) HLRT (~70% maximal voluntary contraction, MVC); 2) LLBFR (~40% MVC with a cuff pressure of 60% of the individual limb occlusion pressure). Finger flexors muscle oxygenation was measured throughout exercise by near-infrared spectroscopy; muscle fatigue was quantified as MVC decrement 1, 5 and 15 min post exercise. Perceived discomfort, effort, and finger pain were assessed at the end of each set. Moreover, 36 advanced to elite climbers participated in the chronic study phase and were randomized to 3 groups: LLBFR, HLRT and a control group (CON). Participants of the LLBFR and HLRT groups conducted the specific training session presented in the acute study phase twice a week over 5 weeks, while the CON group maintained their usual climbing routine. FD MVC, endurance and oxygenation and brachial artery blood flow during contraction were measured before and after the training protocol.

RESULTS: The acute study phase demonstrated higher muscle fatigue in LLBFR than in HLRT 1 min post exercise ($25 \pm 8\%$ vs $19 \pm 7\%$ of MVC loss, $p=0.016$), which recovered faster, leading to similar fatigue between the two modalities 15 min post exercise. LLBFR led to greater muscle deoxyhemoglobin values ($+20 \pm 25\%$, $d=0.9$), greater upper-limb discomfort during inter-sets recoveries, and less finger pain during exercise. The chronic phase showed that LLBFR and HLRT induced similar improvements in FD MVC ($+9 \pm 8\%$, $d=1.0$ and $+13 \pm 11\%$, $d=1.2$, respectively), and endurance ($+22 \pm 15\%$, $d=1.7$ and $+24 \pm 21\%$, $d=1.2$, respectively).

CONCLUSION: Climbing specific LLBFR FD training led to comparable chronic muscular adaptations to HLRT, while reducing exercise intensity and FD pain. These chronic adaptations may be due to the repetitive acute higher metabolic stress during LLBFR sessions, illustrated by the higher muscle fatigue and greater deoxygenation, despite lower mechanical stress.

HIGH-VELOCITY ISOTONIC KNEE-EXTENSION FATIGUING EXERCISE AFFECTS MOTOR UNIT BEHAVIOUR

GATTI, M., CARBONARO, M., BOTTER, A., PORCELLI, S.

UNIVERSITÀ DEGLI STUDI DI PAVIA

INTRODUCTION: Performance fatigability alters neuromuscular function in a task-dependent manner [1,2]. In isometric conditions, the motor-unit (MU) discharge behavior appeared to be adjusted differently when performing intermittent or sustained contractions [3]. After knee-extension isokinetic exercise at slow speed, MU discharge rate increased to overcome peripheral impairments [4]. During daily life, dynamic tasks at various speed are usually performed and it remains unclear how high-velocity contractions affect MU discharge characteristics. This study aimed to investigate the MU behavior immediately after a maximum-velocity isotonic fatiguing exercise.

METHODS: Healthy young participants ($n=16$, 4 females) underwent a fatiguing task consisting in 80 maximal-velocity isotonic contractions (1 every 3 s) at 40% of the maximal voluntary isometric contraction (MVIC) torque [5]. Power output was quantified at the initial and final phases of the exercise. MVIC with voluntary activation (VA) and potentiated resting twitch (St) were assessed, through femoral nerve stimulation, before (PRE) and immediately after (POST) the exercise. Vastus lateralis high-density electromyography signals were recorded during isometric contractions at 25% of MVIC (10s ramp + 10s plateau) both in PRE and POST. MU spike trains were decomposed and edited. Recruitment threshold (RT) of each MU was normalized by the MVIC PRE to categorize MUs into early-recruited (0-12.5% MVIC) and late-recruited (LR; 12.5-25.0% MVIC) populations. Mean discharge rate (DR) was analyzed during recruitment (first 5 spikes) [6] and plateau phase (10s) of each MU. The coefficient of variation (CoV) of force was calculated during the plateau at target force.

RESULTS: Power output started from 247 ± 81 W and it decreased by $36 \pm 18\%$. MVIC torque declined from 168.1 ± 39.4 Nm to 110.9 ± 31.5 Nm ($p < 0.001$). VA and St torque decreased in POST (all $p < 0.04$). Global EMG amplitude increased after the fatiguing task ($p = 0.02$). During ramps, RT did not change (24.9 ± 6.1 Nm; $p > 0.05$). Mean DR increased during recruitment phase (7.9 ± 1.7 to 8.6 ± 2.6 pps in POST; $p = 0.007$) but not during plateau. Notably, only the LR MUs exhibited increased DR both at recruitment (7.8 ± 1.5 to 8.9 ± 2.9 pps; $p = 0.002$) and plateau phases (10.0 ± 1.6 to 10.8 ± 2.5 pps; $p = 0.02$). CoV of force increased from $2.6 \pm 0.9\%$ (PRE) to $3.8 \pm 2.4\%$ (POST; $p = 0.03$).

CONCLUSION: High-velocity fatiguing task induced loss of muscle force and power due to impairments in both voluntary activation and muscle contractile properties. Following the maximal-velocity fatiguing task, mean motor unit recruitment discharge rate increased while only late-recruited MUs showed a higher discharge rate in the plateau phase. Thus, in fatiguing state, impaired central motor drive and excitation-contraction coupling affect motor unit behavior to maintain absolute force output

USE OF SUBJECTIVELY REPORTED PARAMETERS OF PHYSICAL AND MENTAL FATIGUE, SLEEP AND STRESS FOR ASSESSMENT OF ULTRA-ENDURANCE CYCLING INDUCED COGNITIVE IMPAIRMENT (VELOREALITY)

LISMANE, D., ZOLOVS, M., REIHMANE, D.

RIGA STRADIŅŠ UNIVERSITY

INTRODUCTION: Objectively determined physical and mental fatigue has detrimental effects on cognition. However, subjective perception of fatigue can vary significantly from person to person. The aim of this study was to determine an extent to which subjectively reported parameters (SRPs) of physical and mental fatigue can be used to assess cognitive performance.

METHODS: 39 male and 4 female amateur cyclists (38.8 ± 8.7 y/o, BMI: 25.2 ± 2.8 kg/m²) who completed an ultra-endurance cycling race in under 24-hours completed cognitive function test battery (Stroop test (ST), Finger tapping test (FTT)) pre-race, post-race and ~20h in the recovery period. Additionally, following SRPs were evaluated: sleep hours, sleep quality, mental fatigue, physical fatigue, physical strength, stress levels during the previous day, effort to answer the questions in a scale from 1 to 10. Changes between the timepoints were assessed by one-way repeated measures ANOVA or Friedman test. The association between cognitive function test variables that changed significantly and SRPs was analysed using mixed model regressions.

RESULTS: Significant change in all SRPs except for stress levels during the previous day was observed from pre- to post-race ($p < 0.001$). While in recovery sleep quality, mental fatigue and effort to answer the questions had returned to pre-race levels, there was a significant increase in sleep hours, physical fatigue and reduced physical strength reported. The increase in muscle pain in post-race (from 2 (1;2) to 5 (4;8) was sustained in recovery (5 (3;7), $p < 0.001$).

The post-race ST average time for correct reaction of all 3 stages increased: by 22, 35 and 68 ms ($p < 0.001$), correspondingly. Stage 1 and 3 values returned to baseline in recovery, yet stage 2 showed an improvement compared to baseline (from 651 (88) to 630 (89) ms, $p < 0.001$). Performance in ST stage 2 was associated with a better sleep quality, reducing the average time for correct reactions by 10.10 ms ($p < 0.001$) for a point increase. In stage 3, average time for correct reactions was increased by stress levels during the previous day by 12.80 ms ($p = 0.015$) and decreased physical strength by 12.70 ms ($p = 0.006$) per point.

FTT showed impaired performance of the non-dominant hand in post-race; average number of taps decreased from 54.7 (6.4) to 52.0 (6.9), $p < 0.001$, average interval between taps increased from 189.0 (22.5) to 202.0 (27.1) ms, $p < 0.001$ and returned to baseline in recovery. Higher effort to answer questions was associated with a diminished performance in the FTT for non-dominant hand ($p = 0.028$).

CONCLUSION: A single SRP cannot estimate the changes in cognition, but perceived effort to answer the questions is associated with fine motor performance measured by FTT, and sleep quality, stress levels and physical strength are associated with executive functions measured by ST.

A DETAILED INVESTIGATION OF THE NEGATIVE EFFECT OF MENTAL FATIGUE ON PHYSICAL PERFORMANCE: A RANDOMIZED Crossover TRIAL WITH 117 PARTICIPANTS

HABAY, J., SCHAMPHELEER, E., ARENALES ARAUZ, Y.L., DE PAUW, K., PATTYN, N., VAN CUTSEM, J., ROELANDS, B.

VRIJE UNIVERSITEIT BRUSSEL, ROYAL MILITARY ACADEMY, RESEARCH FOUNDATION FLANDERS

INTRODUCTION: Mental fatigue (MF) is defined as a psychobiological state that arises after a period of prolonged demanding cognitive activity. Research has shown that MF negatively influences physical performance, which has been linked an increase in the rate of perceived exertion (RPE). However, there are still numerous variables, such as pacing and other subjective values, that have been underexplored in the negative impact of MF on physical performance. The aim of the present study is to examine these specific variables and their interaction to get a clearer image on how MF affects physical performance.

METHODS: 117 participants (60σ , 32.2 ± 8.6 y, 22.6 ± 2.6 kg/m², 47.6 ± 9.4 ml/min/kg) were included in this randomized crossover trial, consisting of a familiarization, intervention and control visit. MF was induced using a 45 min Stroop task, while the control condition consisted of a documentary of the same duration. The level of MF was checked using a visual

analogue scale (MVAS) and by analysing performance on a pre/post GoNoGo task. Physical performance was assessed using a 15 min cycling time trial (TT). Primary outcomes include distance covered, power output and cadence. Secondary outcomes collected during the TT were physical fatigue (PVAS), RPE, MVAS, lactate, blood glucose, motivation (MotiVAS) and mental demand (NASA-TLX). Paired sample t-tests and linear models (or non-parametric equivalents) were used for analysis.

RESULTS: Mental fatigue was successfully induced, as seen in the interaction effect between condition and time in the subjective level of MF ($F=122.78$; $p<0.001$; $\eta^2=0.15$) and GoNoGo task performance ($F=24.74$; $p<0.001$; $\eta^2=0.08$). A trend towards significance was found regarding the influence of MF on TT distance ($t=-1.92$; $p=0.058$; $d=0.20$), with a significant negative influence on cadence ($t=-2.06$; $p=0.042$; $d=0.22$). This significant influence is also seen when comparing cadence values throughout the TT ($F=26.65$; $p<0.001$; $\eta^2=0.02$). There was no influence of MF on the mean ($V=1749$; $p=0.300$; $r=0.08$) and maximal ($V=2245$; $p=0.162$; $r=0.10$) power output. Linear models also showed significant increases in RPE ($F=7.19$; $p=0.007$; $\eta^2=0.005$), PVAS ($F=18.30$; $p<0.001$; $\eta^2=0.01$) and MVAS ($F=288.56$; $p<0.001$; $\eta^2=0.19$) values collected during the TT in the MF condition. A trend towards a significant decrease in motivation in the MF condition before the start of the TT was also found ($t=1.87$; $p=0.064$; $d=0.19$). There was no effect of MF on mental demand, blood glucose and lactate ($p>0.05$).

CONCLUSION: The present study shows a significant effect of MF on a number of variables that were collected during the TT, with specific influences on pacing and the different collected subjective variables, and with a large degree of interindividual variability between the over 100 included participants. Not only can these results be used to further update current mechanistic models of MF, it also informs us on the different possible pathways of future research, such as a focus on this extensive variability.

CURRENT PRACTICE AND RECOMMENDATIONS FOR THE QUANTIFICATION AND INDUCTION OF MENTAL FATIGUE IN MOVEMENT SCIENCE

SCHAMPHELEER, E., HABAY, J., PROOST, M., ARENALES ARAUZ, Y.L., RUSSELL, S., ROOSE, M., BIAN, C., MEEUSEN, R., DE PAUW, K., ROELANDS, B.

VUB

INTRODUCTION: Mental fatigue (MF) is a complex psychobiological state, resulting from prolonged cognitive activity, known to significantly impair physical and cognitive performance. Despite extensive research, inconsistencies in methodologies for inducing and quantifying MF hinder comparability across studies and lead to inconsistent findings. A standardized approach is essential to enhance methodological rigor, ensure reproducibility and advance our understanding of MF. However, a comprehensive synthesis of procedures employed for inducing and measuring MF, and clear guidelines, remain lacking.

METHODS: A review of the literature was conducted to present an overview of the methods currently used to induce and quantify MF in movement science. This review critically evaluates their strengths and limitations and introduces a structured framework to utilize or design cognitive tasks to induce MF. Additionally, an in-depth analysis of MF quantification methods was performed, considering subjective, behavioural, and physiological measures, with the benefits and drawbacks of each. Finally, to improve research consistency, reporting guidelines were developed.

RESULTS: Based on 106 reviewed studies, two frameworks (MF induction and quantification) and a checklist-based reporting guideline were developed.

The Three Task Properties Framework provides a structured approach to design MF-inducing tasks, emphasizing three core elements: task duration, difficulty and nature. Context is central to the framework, as it influences all aspects of both induction and control tasks. Depending on the study's objectives, trade-offs between task properties may be necessary, such as adjusting task duration in favor of difficulty or complexity.

Three primary MF quantification domains were identified. Physiological measures are considered the most 'objective' measure of MF, however they are typically costly and technically demanding. Behavioural assessments are considered the most 'valid' but make it difficult to isolate specific MF effects. Finally, subjective measures are considered the most 'sensitive', however, they are susceptible to response bias. Ideally, researchers should use an outcome of at least two domains to quantify MF as holistically as possible.

To enhance research consistency and transparency, the SPeCIFY (Settings, Protocol establishments, Confounders, Individuals, Framework, and Yield) reporting guidelines were developed. The SPeCIFY guidelines address essential aspects such as environmental settings, protocol specifics, participant characteristics, and control of confounding factors.

CONCLUSION: By presenting frameworks for MF induction and quantification, this review provides a structured approach to improving the methodological quality of MF research and generalizability of study results. Moreover, by designing the SPeCIFY reporting guidelines, the present review offers a tool to enhance study transparency and replicability, addressing the key challenge of methodological variability.

Invited Symposium

IS-PN01 Human skeletal muscle plasticity studied with single-nuclei RNA sequencing and novel spatial proteomic approaches

SINGLE NUCLEI TRANSCRIPTOMICS TO UNRAVEL THE MECHANISMS OF SKELETAL MUSCLE HOMEOSTASIS IN DISUSE

BOTTINELLI, R.

UNIVERSITY OF PAVIA

Inactivity can be considered a pandemic, causing 5 million deaths per year, decreasing exercise tolerance and dramatically increasing disease risks. The major phenomena occur at the level of muscle (loss of mass and strength), nervous system (impairment in central and peripheral motor control) and metabolism (impaired oxidative metabolism and insulin resistance). So far, most studies aiming to clarify the mechanisms underlying muscle deterioration following disuse focused on structure and function of muscle fibers and on intracellular pathways controlling muscle mass, metabolism, and redox balance. However, a clear and comprehensive explanation of why loss of muscle mass and force occurs is still lacking, especially in humans. Global transcriptomics recently provided important clues on the mechanisms underlying muscle adaptations. However, such approach has some important limitations. It has been recently understood that up to 40% of all skeletal muscle nuclei are not from myofibers and that although satellite cells are the stem cells regenerating skeletal muscle fibers, other resident mononuclear cell populations (including Fibro-Adipogenic Progenitors (FAPs), endothelial cells and immune cells) play important roles not only in regeneration, but also in normal muscle homeostasis in conditions such as disuse and ageing. Global transcriptomic analysis fails to assess individual cells gene expression. Hence, the complex interactions among muscle fibers and mononuclear cells in muscle homeostasis are missed. One of the ways to address most of the above limitations is to extract all nuclei from muscle samples and perform single nuclei RNA-Seq (snRNA-Seq). The key advantages of such approach are: (i) define clusters of nuclei representing different mononuclear resident cell types and nuclei of muscle fibers (NMJ; myotendinous junction (MTJ); nuclei along the length of muscle fibers or myonuclei) by means of specific marker genes (ii) study gene expression of each cluster of nuclei, addressing the heterogeneity of gene expression among different cells and of different nuclei of muscle fibers. This approach should enable to address the interplay among the heterogeneous cell populations orchestrating muscle homeostasis. Prof Bottinelli will guide the audience through the journey to study human skeletal muscle deterioration following disuse with the above-mentioned approaches, the findings and limitations that each of them entail together with preliminary findings obtained applying snRNA-Seq on human muscle samples from young subjects before bed rest, after 10 and 21 days of BR and after 3 weeks recovery.

A TRANSCRIPTOMIC AND SPATIAL PROTEOMIC ATLAS OF HUMAN AGING AND SARCOPENIA

MONTI, E.

STANFORD UNIVERSITY

Ageing is associated with a progressive decrease in muscle mass and strength. Sarcopenia is the clinical manifestation of the extreme age-related muscle atrophy and weakness, and affects approximately 50 million people worldwide. Severe consequences of sarcopenia include increased frailty and reduction in ability to perform basic life functions, leading to higher risk of falls, increased healthcare costs, institutionalization, and mortality risk. Diagnosing and treating sarcopenia is challenging because of the complex pathophysiology of sarcopenia, which is a multifactorial syndrome. Current research lacks comprehensive studies investigating the mechanisms involved in sarcopenia development and progression in humans, which hinder the ability to identify biomarkers for its diagnosis and effective drugs to slow down its progression. Dr. Monti will present data showing transcriptomic (snRNA-seq, single cell RNA-seq, ATAC-seq) and proteomic changes observed in aging and late aging as well as data personally generated from 67 muscle biopsies from 15 young (18-35 years old) and 52 aged (>70 years old) stratified for sarcopenia according to the most updated guidelines. These samples were processed using snRNA-seq and, for the first time, CODEX spatial proteomics technologies, with the aim to generate the first matched transcriptomic and spatial proteomic atlas of human aging and sarcopenia, encompassing changes in muscle cell type composition and spatial interaction and changes in gene and protein expression. Evidence that will be presented show increased muscle denervation and transcriptomic changes in the neuromuscular junction nuclei, altered mitochondria biogenesis, complexes and metabolism confirmed by western blot analyses are aging signature exacerbated by sarcopenia. Further, sarcopenia leads to increase in immune and pro-fibrotic cells (fibro-adipogenic progenitors, FAPs), alterations in their transcriptome and cell-cell spatial interaction. The lab Dr. Monti currently works in has demonstrated with prostaglandin E2 (PGE2) to be a beneficial molecule for muscle regeneration. Decrease in PGE2 and increase in its degrading enzyme 15-PGDH were shown in old mice, and 15-PGDH inhibition rejuvenated muscle strength, force and mitochondria in old mice. Dr. Monti will show evidence for 15-PGDH to be upregulated specifically in sarcopenic patients muscles, and novel insights derived from snRNA-seq and CODEX that show how the increase in this enzyme may be implicated in sarcopenia development.

RESISTANCE TRAINING AND MUSCLE DISUSE. ENHANCING MUSCLE PLASTICITY ANALYSIS WITH DEEP VISUAL PROTEOMICS

MURGIA, M.

UNIVERSITA DEGLI STUDI DI PADOVA

Skeletal muscle plasticity is a highly complex phenomenon, as this tissue is composed of multinucleated cellular units, slow and fast muscle fibers, with different molecular and physiological properties. In her talk, prof. Murgia will describe single fiber proteomic workflows and their limitations. She will present a novel mass spectrometry-based proteomic approach, Deep Visual Proteomics (DVP), allowing to tackle the analysis of single human muscle fibers from a spatial angle. DVP allows to analyze subcellular compartments of muscle fibers in a fiber type-resolved manner. DVP uses high-resolution imaging to guide automated laser-capture microdissection (LMD) of tissue sections, which is then followed by MS-based proteomic profiling. At the core of the workflow is artificial intelligence (AI)-guided image analysis, that allows single-cell/single shape classification and subsequent LMD-based isolation. We applied DVP to frozen sections of human skeletal muscle, with various fiber type-resolving staining as well as fluorescent lectins to mark fiber borders and guide AI-based segmentation. Compared to previous single fiber proteomic workflows, based on fibers freshly dissected under a stereomicroscope, there are at least three major practical advantages of the new DVP-based workflow on frozen tissue: i) minimal handling time from biopsy collection to freezing, making it potentially compatible with the analysis of highly reversible post-translational modifications; ii) no loss of highly soluble cytosolic proteins in the isolation solution and iii) easier multicentric sample collection due to the compatibility of the workflow with frozen tissue. The added conceptual value of DVP is that it allows to carry out proteomics of muscle subcellular compartments in a fiber type-resolved manner. Prof. Murgia will provide some data concerning the application of this workflow to study skeletal muscle plasticity in response to different activity conditions and loading states.

SEX-DIFFERENCES BETWEEN FEMALE AND MALE TRAIL RUNNERS WITH EQUAL PERFORMANCE CAPACITY.

CALLOVINI, A., CALLOVINI, A., MATTIVI, M., FORNASIERO, A., CUNIBERTI, G., ZOPPIROLI, C., BETTEGA, S., PALUMBO, M., FORRER, T., PELLEGRINI, B., BORTOLAN, L., MILLET, G.P., SCHENA, F.

CERISM - UNIVERSITY OF VERONA

INTRODUCTION: The sex gap in endurance performance ranges from 8–12% across most sports and is greater in uphill events due to lower maximal oxygen uptake, lean-to-fat mass ratio, muscle mass, and fewer fast-twitch fibers in women. Yet, sex-differences between females (F) and males (M) with similar absolute performance (e.g., same-race finishing time) remain unexplored, particularly in mountain sports. This study aimed to investigate these differences in recreational trail runners.

METHODS: 53 runners (11 F, 42 M) completed a 26 km, 1920-m D+ trail race. Within 3-weeks before the race (Pre-), they performed i) anthropometrical measures; ii) a graded treadmill (slope 10%) running test to exhaustion to assess aerobic capacity, vertical velocities (Vv in vertical m per h, mv.h⁻¹) and running energy cost (REv) at maximal (Max) and second ventilatory threshold (VT2); iii) knee extensors' maximal voluntary contraction (MVC) and rate of force development (RFD). The weekly training volume (WTV) of the 3 months preceding the race was retrieved from a popular training platform. MVC and RFD were reassessed within 20 min after the race (Post-). From the total sample, F were matched to 11 M with similar performance, and sex-differences analyzed with unpaired Student's t-tests.

RESULTS: Race time of F and M was identical (246±28 min, p=0.994). No difference in WTV was found (335±135 vs 318±131 min, p=0.802). F presented lower body mass index (21.1±1.2 vs 23.3±1.5 kg.m⁻², p=0.001), lean body mass (LBM) (47.5±4.0 vs 64.4±4.0 kg, p=0.004), and higher fat mass (16.2±2.2 vs 11.3±4.2%, p=0.004). VO₂ (ml.kg⁻¹.min⁻¹) was similar at Max and VT2 (53.5±4.3 vs 56.9±4.8, p=.139 and 48.6±3.6 vs 51.8±5.4 ml.kg⁻¹.min⁻¹, p=0.122), also when expressed relative to LBM (VO₂/kgLBM; Max: 63.7±4.7 vs 64.1±5.3, p=.922; VT2: 57.9±3.9 vs 58.4±5.2 ml.kgLBM⁻¹.min⁻¹, p=.870). Lower Vv and higher REv relative to LBM (REvLBM) were found in F at both Max (1030±98 vs 1127±83 mv.h⁻¹, p=0.020 and 3.74±0.40 vs 3.42±0.27 ml.kgLBM⁻¹.mv⁻¹, p=0.040) and VT2 (896±92 vs 983±81 mv.h⁻¹, p=0.020 and 3.91±0.34 vs 3.57±0.27 ml.kgLBM⁻¹.mv⁻¹, p=0.018). When normalized to LBM, MVC (11.3±1.9 vs 11.4±1.5 N.kgLBM⁻¹, p=0.960) and RFD (34.0±8.2 vs 33.8±6.2 N.kgLBM⁻¹, p=0.942) were comparable between sexes. However, the relative pre-to-post decline was lower in F for MVC (-4.1±15.8 vs -17.3±10%, p=0.032) and tended to be lower for RFD (-5.3±32.6 vs -26.3±17.2%, p=0.093).

CONCLUSION: Despite comparable performance, training volume, and VO₂/kgLBM, females had reduced vertical velocities at Max and VT2, likely due to higher REvLBM. These results suggest that the observed uphill sex-differences (9% in Vv in the present study) are not only due to lean-to-fat mass ratio. Moreover, females lower post-race decline in neuromuscular function confirms reduced muscle fatigability. These findings suggest that women rely on different strategies to achieve similar performance, emphasizing the need for sex-specific training/pacing approaches.

CONTRIBUTIONS OF CHANGES IN MUSCLE FUNCTION, KINEMATICS, AND RUNNING VOLUME TO IMPROVEMENTS IN RUNNING ECONOMY AFTER PLYOMETRIC TRAINING IN MIDDLE-AGED RUNNERS

EIHARA, Y., TAKAO, K., MAEO, S., KANEHISA, H., ISAKA, T.

RITSUMEIKAN UNIVERSITY

INTRODUCTION: Middle-aged runners make up over half of all recreational runners [1] and are highly motivated to improve their endurance running performance [2]. Running economy plays a key role in endurance performance and can be enhanced by incorporating plyometric training into daily running routines [3]. Although improvements in running economy after plyometric training are suggested to be attributable to changes in muscle functions [4], kinematics [5], and running training modality/volume [6], it remains unclear which factors contribute the most in middle-aged runners. This study aimed to identify the key factors influencing the effects of plyometric training combined with daily running on running economy of middle-aged runners.

METHODS: Thirty-five male endurance runners (30-50 years) performed plyometric training twice per week for 10 weeks. The program included countermovement jumps (CMJ), jump rope, and hopping. Participants were asked to maintain their regular running volume during the intervention. Measurements were taken before and after the intervention for muscle strength (knee extension/flexion, ankle dorsiflexion/plantarflexion torques), jump performance (CMJ, drop, and rebound jump), running-related variables (running economy and kinematics) at 80% velocity of VO₂max. In addition, long-distance running (≥ 3000 m per session) and interval training (multiple runs of <3000 m per session) volumes before and during the intervention were obtained from participants' training logs. A repeated-measures correlation analysis assessed relationships between changes in running economy and other variables, with p-values corrected using the Holm-Sidak method. Stepwise regression analysis was performed with the changes in running economy as a response variable and those of the variables that showed significant correlations with running economy changes ($P < 0.05$) as independent variables.

RESULTS: Plyometric training combined with daily running significantly improved running economy (3.8%, $P = 0.004$). The change in running economy was significantly correlated with those in drop and rebound jump height and index (height/ground contact time), and interval training volume ($r = -0.582$ to -0.453 , $P \leq 0.007$). Furthermore, the changes in drop jump height and interval training volume were identified as significant explanatory variables for the improvement in running economy ($R^2 = 0.338$, $P = 0.006$).

CONCLUSION: Incorporating plyometric training into daily running effectively enhances the running economy in middle-aged runners. The magnitude of improvement in running economy is influenced by increases in drop jump height and interval training volume. These findings suggest that plyometric training programs should be designed to enhance drop jump height while incorporating more interval training to improve running economy efficiently.

THE EFFECTIVENESS OF COLD AND HOT WATER IMMERSION IN MITIGATING POST-RUNNING FATIGUE DEPENDS ON THE EXERCISE INTENSITY AND THE PARAMETERS BEING ASSESSED

DUTRA, Y., TAVARES, P., CHENG, A., ZAGATTO, A.

UNESP

INTRODUCTION: Cold and hot water immersion (CWI/HWI) are commonly used to mitigate post-exercise fatigability [1]. However, fatigue mechanisms are task-dependent, with the type of exercise influencing its causes and characteristics [2]. Given the specific mechanisms by which CWI and HWI may affect recovery [1], their efficacy in mitigating post-exercise fatigability may be task-dependent [3]. Therefore, this study aimed to investigate the effectiveness of CWI and HWI, compared to a placebo condition and passive rest, in mitigating fatigability following different running efforts.

METHODS: On separate occasions, recreationally trained runners underwent different recovery interventions after performing either a 40-min continuous run at a velocity corresponding to the respiratory compensation point (vRCP) (CONT, $n = 12$, maximal oxygen uptake: 48.5 ± 3.4 mL/kg/min) or an intermittent run at a velocity 50% above vRCP (HIIT; $n = 10$, maximal oxygen uptake: 49.5 ± 4.5 mL/kg/min). The recovery interventions included cold water immersion (11°C, 15-min), hot water immersion (41°C, 45-min), immersion in colored water (placebo; 26°C, 10-min), or passive rest sitting on a chair (10-min). Before and up to 24 hours after exercise, cardiac parasympathetic activity, maximal voluntary contractions (MVCs) and evoked responses of the knee extensors were assessed using the twitch interpolation technique. Additionally, cardiorespiratory responses were monitored during a brief effort (3-min run at 80% of vRCP). A two-way repeated-measures ANOVA was used to evaluate the effects of the interventions in both CONT and HIIT conditions, and partial eta squared was calculated to estimate effect sizes (ES). Statistical significance was set at $p < 0.05$.

RESULTS: The ratio of the root mean square of electromyography activity of the vastus lateralis during MVCs to the amplitude of the evoked M-wave (RMS/M-wave) was higher 2 and 4 h after CONT when HWI was used, compared to placebo and passive rest (interaction effect, $p = 0.01$, $ES = 0.18$). In contrast, following HIIT, RMS/M-wave was higher 4 h post-exercise when CWI was used, compared to placebo and passive rest (interaction effect, $p = 0.01$, $ES = 0.25$). Furthermore, cardiac parasympathetic activity was higher 2 h after CONT and HIIT when CWI was used compared to placebo and passive rest (interaction effect, $p < 0.01$, $ES > 0.27$), and oxygen uptake during brief efforts was lower over 24 h after CONT and HIIT when HWI was used compared to placebo and passive rest (condition effect, $p < 0.01$, $ES > 0.16$).

CONCLUSION: In conclusion, CWI seems to mitigate central fatigue after CONT, while HWI appears to mitigate central fatigue after HIIT. In both CONT and HIIT, CWI increases cardiac parasympathetic activity 2 h post-exercise, whereas HWI reduces oxygen uptake during brief submaximal efforts over the following 24 hours.

UPHILL VS. DOWNHILL: PHYSIOLOGICAL DETERMINANTS OF PERFORMANCE IN A SHORT TRAIL RACE

MATTIVI, M., CALLOVINI, A., FORNASIERO, A., CUNIBERTI, G., ZOPPIROLI, C., BETTEGA, S., PALUMBO, M., FORRER, T., PEL-LEGRINI, B., BORTOLAN, L., SCHENA, F.

UNIVERSITÀ DI VERONA

INTRODUCTION: Performance in trail running races is multifactorial and the classical endurance model (1) is less strongly associated with trail running performance compared to road running (2). Several studies have analyzed the determinants of these races as a whole, but little research is present on whether and how performance factors vary between different uphill and downhill race sections. This study aims to identify which physiological factors determine performance of a trail race (TOT) and to assess whether these factors differ when considering only the uphill (UH) and downhill (DH) sections.

METHODS: 54 trail runners (42 M, 12 F) completed a 26 km, 1920m D+ trail race (Malcesine Baldo Trail). Each subject underwent laboratory testing within three weeks before the competition (-pre). Tests included: body composition (%fat); maximal voluntary contraction (MVC/kg) and local endurance (LE) of knee extensor; countermovement jump (CMJ) and reactive force index (RSI); uphill incremental running test to exhaustion (fixed 10% slope) during which were measured oxygen consumption and speed at maximal ($\text{VO}_{2\text{max}}$ and v_{max}), ventilatory thresholds and energetic cost (CE). On race day, MVC, LE, CMJ, and RSI were reassessed within 20 minutes after finishing the competition (-post). Total race times (TimeTOT) and intermediate times for uphill (TimeUH) and downhill (TimeDH) segments were obtained from the official race timing system. Correlations and linear enter and stepwise regressions were performed.

RESULTS: For all our analysis (TOT, UH and DH), the best model found is formed by v_{max} , CE, LE-pre (adjR²: 0.76, 0.77, 0.67, for all $p < 0.01$); however CE and LE-pre variables do not significantly improve the predictive ability in any of the three conditions (all $p > 0.05$). UH and DH differ in terms of correlated strength factors: for UH, MVC/kg-pre ($r = -0.27$) and CMJ-pre ($r = -0.34$) ($p < 0.05$); for DH, RSI-pre ($r = -0.38$) and LE-pre ($r = -0.3$) ($p < 0.05$). The predictive power of the classical model ($\text{VO}_{2\text{max}}/\text{kg}$, % $\text{VO}_{2\text{VT}2}$, CE; adjR²: TOT 0.58, UH 0.63, DH 0.47, all $p < 0.01$) is lower than the above-mentioned model for all three conditions. $\text{VO}_{2\text{max}}/\text{kg}$ alone predicts UH better than DH (adjR²: UH 0.58, DH 0.47, both $p < 0.01$).

CONCLUSION: The classical performance model show a low predictive power of performance in this short trail race, although, the $\text{VO}_{2\text{max}}/\text{kg}$ alone is a good predictor of UH section, in line with previous studies (3) (i.e. single-factor determination higher than DH). Previous studies have found an interaction between lower-limb strength factors and performance in races of similar distances (4-5). Our data suggested that for UH, maximal strength and the ability to elevate the centre of gravity are more crucial, while for DH, muscle-tendon reactivity appears to play a more significant role.

THE EFFECT OF 90 AND 120 MIN OF RUNNING ON THE DETERMINANTS OF ENDURANCE RUNNING PERFORMANCE IN WELL-TRAINED MALE MARATHON RUNNERS

ZANINI, M., FOLLAND, J., BLAGROVE, R.

<1> LOUGHBOROUGH UNIVERSITY [MZ, JF, RB] <2> THE OPEN UNIVERSITY [MZ]

INTRODUCTION: Marathon performance is largely determined by maximal oxygen uptake ($\text{VO}_{2\text{max}}$), fractional utilization at lactate threshold (FULT), and running economy (RE) [1], with speed at lactate threshold (sLT) closely associated with marathon speed. Whilst these determinants are thought to deteriorate during prolonged exercise [2,3], except for RE [4], their temporal changes with fatigue remain largely unknown. This study aimed to measure the changes in $\text{VO}_{2\text{max}}$, FULT, RE, and sLT after running for 90 and 120 min in the heavy-intensity domain.

METHODS: Fourteen well-trained marathon runners ($\text{VO}_{2\text{peak}}$ 63.1 ± 5.8 ml·kg⁻¹·min⁻¹; marathon time $2:46:58 \pm 0:10:37$ h:min:s) completed three separate visits to determine sLT, FULT, and $\text{VO}_{2\text{peak}}$ under the following conditions (sessions): unfatigued, and after two prolonged runs, one of 90 and one of 120 min at a fixed speed (10% Δ between LT lactate threshold 2). During the runs, respiratory gases were collected at 15 min intervals to quantify RE and fractional utilization at trial's speed (FURun). One-way repeated measures ANOVA was used to quantify differences between conditions, with significance defined as $P < 0.05$ and effect size calculated as η^2 .

RESULTS: Participants ran at 14.1 ± 0.9 km·h⁻¹, covering 28.2 ± 1.8 km in the 120 min trial (26.0–33.0 km). Non-linear changes were found with decreases in $\text{VO}_{2\text{peak}}$ (-3.1%, $p = 0.04$ (post-90); -7.1%, $p < 0.001$ (post-120)) and subsequent increases in FULT (+2.8%, $p = 0.03$ (post-90); +4.9% $p = 0.01$ (post-120)), while RE (ml·kg⁻¹·km⁻¹) deteriorated more linearly with time (by 4.2% (post-90) and 5.8% (post-120), both $p < 0.001$). Similarly, sLT decreased non-linearly, from 14.0 ± 0.9 to 13.5 ± 1.0 (post-90, $p = 0.01$) and 13.0 ± 1.1 km·h⁻¹ (post-120, $p < 0.001$). Furthermore, FURun increased substantially, from 79.3% at 15 min, to 85.6% at 90 min and 90.6% at 120 min ($p < 0.001$).

CONCLUSION: In conclusion, all three performance determinants and sLT changed following 90 min, and particularly 120 min of prolonged running. These dynamic changes have strong implications for running performance and, considering the particularly exacerbated changes between 90 and 120 min, would particularly affect longer duration events such as the marathon.

ENHANCING MOTOR IMAGERY EFFECTIVENESS WITH TENDON VIBRATION

MALEJAC, V., ROZAND, V., GUILLOT, A., LAPOLE, T.

JEAN MONNET UNIVERSITY

INTRODUCTION: Motor imagery (MI) is the mental representation of movement without concurrent execution. The fact that MI can lead to similar brain cortical areas activation than actual movement makes it a valuable training for patients with motor impairments. The effectiveness of MI training is influenced by the quality of mental representation (i.e. MI vividness), that is further correlated to corticospinal excitability measurements [1]. MI can be enhanced by simultaneous movement [2], but when movement is impossible, tendon vibration (TV) may be an alternative to provide movement-like proprioceptive feedbacks. This study investigated whether combining MI with TV is likely to enhance MI vividness.

METHODS: Ten healthy participants (8 males and 2 females, 24.9 ± 6.3 years) completed one test session. Transcranial magnetic stimulation (TMS) was used to elicit motor-evoked potentials in the right hand's flexor carpi radialis muscle at increasing stimulating intensity during four conditions: at rest (REST), during the mental representation of a maximal right wrist flexion (MI), during the application of tendon vibration on the right wrist (TV) and during the combination of MI and TV (MI+TV). At each of the 6 tested TMS intensities, MI, and TV and MI+TV trials were applied for 10 repetitions lasting 6s with 6s of rest in-between. The area under the input-output curve was computed to quantify corticospinal excitability during each condition.

RESULTS: The MI and VT conditions exhibited increases in corticospinal excitability with magnitude of $139.83\% \pm 124.30\%$ ($p < 0.05$) and $142.42\% \pm 75.20\%$ ($p < 0.01$) when compared to REST, respectively, and with no difference between MI and TV conditions ($p = 0.99$). Moreover, the MI+TV condition showed a $295.23\% \pm 153.30\%$ increase in corticospinal excitability when compared to REST ($p < 0.01$), with values reached being greater than those observed for MI ($p < 0.01$) and TV ($p < 0.01$).

CONCLUSION: The key finding of this study is that combining TV and MI allowed to increase corticospinal excitability compared to MI alone, suggesting that the application of TV improved MI vividness. Overall, these results suggest that TV could therefore strengthen MI effects in individuals unable to perform voluntary movements, likely through TV-related proprioceptive feedbacks, offering a promising non-invasive approach for motor rehabilitation.

A NOVEL EXPERIMENTAL PARADIGM TO MANIPULATE THE MOTOR AND COGNITIVE DEMAND OF PSYCHOMOTOR TASKS

BERGEVIN, M., PAGEAUX, B., RAINVILLE, P., ROY, M., MANGIN, T.

UNIVERSITE DE MONTREAL

INTRODUCTION: In everyday life, motor and cognitive demands are intricately related. Effort is the intentional mobilization of resources towards a task, and its perception is the awareness of this mobilization. Current experimental paradigms investigating effort and its perception isolate motor and cognitive demands (1). As integrative views of effort considering the mobilization of motor and cognitive resources are emerging (2), experimental paradigms manipulating both types of demands are needed to better understand how each domain impact effort and its perception. This study aimed to develop an experimental paradigm to manipulate both motor and cognitive demands during psychomotor tasks. We hypothesized that effort perception would increase with both types of demands.

METHODS: Two experiments were done ($n=20$ each), during which participants completed bimanual psychomotor tasks with computer mice (exp 1) or handgrip dynamometers (exp 2). The task consisted of identifying arrow directions displayed on a computer screen. In both experiments, there were three levels of cognitive demand; easy: identify arrow directions displayed in the center of the monitor (congruent responses), moderate: identify the opposite arrow direction (50% incongruent responses), difficult: identify opposite arrow direction (50% incongruent responses) displayed on the left and right sides of the screen (~50% of arrows pointing away from their spatial location). In exp 2, participants performed the same task and responded by squeezing either hands on handgrip dynamometers at one of two levels of motor demands: 5%

and 30% of maximal voluntary force. Performance was measured with accuracy (correct vs incorrect responses) and response time (time taken for response validation). Effort perception was measured with visual analogue scales after each 30-s block.

RESULTS: In exp 1, participants reported greater perceived effort with higher cognitive demand (main effect of cognitive demand, $p < .001$). In exp 2, participants reported greater perceived effort with higher motor and cognitive demands (main effects of motor and cognitive demands, $p < .001$). In both experiments, accuracy decreased (main effects of motor and cognitive demands, $p < .001$) while response time increased (main effects of motor and cognitive demands, $p < .048$) with both types of demands.

CONCLUSION: Increasing both motor and cognitive demands lead to greater perceived effort. This experimental paradigm can be used in future studies to explore effort and its perception by manipulating the motor and cognitive demands of the task. From a fundamental perspective, this will be useful to explore the neural correlates of effort and its perception. From a clinical perspective, this paradigm can be adapted into rehabilitation programs of clinical populations with cognitive and motor deficits, such as stroke patients.

ENHANCING TRIP-RESISTING SKILLS VIA PERTURBATION-BASED GAIT TRAINING USING A RESISTIVE KNEE BRACE IN HEALTHY YOUNG ADULTS

ALBUQUERQUE PLACIDO, M., WERTH, J., EPRO, G., XIAO, P., KARAMANIDIS, K.
LONDON SOUTH BANK UNIVERSITY

INTRODUCTION: Perturbation-based gait training effectively improves fall resisting skills, which are retainable over years (1) and can be partly transferred to real world scenarios (2). An essential component to recover balance following trip-like perturbations is the ability to increase the base of support (BoS) via modulation of leg-extensor muscular output. We aimed to develop a mechatronic system which unpredictably perturbs knee-extensor muscular output during gait and prove its effectiveness to enhance trip-resisting skills via repeated perturbations in healthy young adults.

METHODS: 20 young adults performed a functional gait training session on a treadmill using an electromagnetic resistive knee brace perturbing neuromuscular control during the swing phase of the gait cycle. Gait perturbations were conducted via a combination of unpredictable and sustained perturbations within a period of 20 min walking. Transfer to recovery actions in trip-like perturbation was assessed using pulling forces at subjects' ankle either in early swing (elevating strategy: ELE; $n=10$) or mid swing phase (lowering strategy: LOW; $n=10$). Twenty matched controls experienced the transfer task either with elevating or lowering strategies. 3D motion capture was used to analyse joint kinematics and centre of mass (CoM) trajectories, allowing for the calculations of margin of stability (MoS) and BoS. Leg-extensor muscular activity was determined during walking using EMG and normalised to MVC.

RESULTS: Knee muscular perturbations during walking led to a reduction in MoS and BoS (more instable body configuration) in relation to normal walking and caused a change in neuromuscular control by increasing EMG activity in the monoarticular knee extensors during swing phase and in the plantar flexors during push-off ($p < .05$). In the transfer tripping-task, the LOW group showed a higher MoS and BoS at touchdown of the perturbed leg in relation to the control group ($p < .05$) and required less recovery steps to reach positive MoS values following perturbation. Statistical parametric mapping identified differences in lower limb joint kinematics following a trip-like perturbation, with greater knee extension angles for LOW compared to control ($p < .05$). There were no differences between ELE and controls in the analysed parameters during tripping.

CONCLUSION: Unpredictable and sustained perturbations at the knee during walking lead to adaptive changes in balance recovery responses which were transferred to trip-like perturbations, hence highlighting the relevance of knee extensor neuromuscular function for fall resilience. However, due to differences in neuromuscular control between elevating and lowering strategies, the effectiveness of knee extensor perturbation-based exercises in transferring locomotor adaptive changes to various trip scenarios seems to be limited.

SPECTRAL POWER AND EVENT-RELATED POTENTIALS ASSOCIATED WITH COGNITIVE-MOTOR DUAL-TASK BALANCING IN EARLY PARKINSON'S DISEASE

PESKAR, M., MANGANOTTI, P., GRAMANN, K., MARUSIC, U.
SCIENCE AND RESEARCH CENTRE KOPER

INTRODUCTION: Individuals with Parkinson's Disease (PD) often compensate for impaired automatic balance control by recruiting additional attentional resources for motor tasks. However, as the disease progresses, cognitive function also deteriorates, further compromising postural stability. The interaction between cognitive and motor systems in the early stages of PD remains insufficiently understood. This study aimed to elucidate behavioral and neurophysiological changes in early-stage PD, providing a more precise characterization of disease-related deviations from healthy cognitive and motor functioning.

METHODS: Eighteen individuals with PD (mean age: 62.9 ± 6.6 years) and 18 age-matched healthy controls (mean age: 62.9 ± 6.4 years) performed three tasks: (i) a balance single-task in a semi-tandem stance (ST-sts), (ii) a visual oddball single-task featuring conflicting Stroop color-word stimuli (ST-Stroop), and (iii) a dual-task (DT) combining both. Postural stability was assessed via center-of-pressure displacement using a force plate, while neurophysiological responses were recorded using 128-channel electroencephalography (EEG).

RESULTS: Participants with PD exhibited reduced ($p = .009$) and slower ($p = .008$) postural sway compared to controls. Additionally, less sway was observed during DT than ST ($p < .001$). EEG analyses revealed distinct spectral activity patterns across both groups: central midline low-frequency (delta, theta) power increased with cognitive load ($p < .012$), centroparietal beta desynchronization intensified with motor engagement ($p < .050$), and parietal alpha desynchronization was more pronounced in DT ($p = .025$), underscoring the functional roles of specific frequency bands in cognitive-motor integration. Additionally, PD participants compared to healthy controls exhibited prolonged event-related P300 responses ($p = .034$), a component associated with conflict resolution, suggesting compensatory neural strategies or impaired neural efficiency.

CONCLUSION: In PD, reduced sway may result from postural rigidity and tonic muscle activation, whereas in DT, it may reflect resource competition between cognitive and motor demands. The findings demonstrate that in medicated participants with early-stage PD, the cortical power spectra are indistinguishable from that of healthy controls. At the same time, data indicate that the cognitive-related evoked potentials might offer more sensitivity to disease-specific cortical changes and that selective attention capacities may be more vulnerable than sensory acuity in early PD.

YIPS-SPECIFIC FACILITATION OF CORTICOSPINAL EXCITABILITY DURING MOTOR IMAGERY OF BASEBALL PITCHING

YAMASAKI, D., KANEKO, N., OKEGAWA, T., NAKAZAWA, K.

THE UNIVERSITY OF TOKYO

INTRODUCTION: Yips is defined as a psycho-neuromuscular impairment that disrupts the execution of fine motor skills in sports performance [1]. Yips is associated with abnormal muscle activity and kinematics; however, its underlying neural mechanisms remain unclear. Major challenges in investigating these mechanisms are (1) the difficulty in eliciting yips symptoms in a controlled laboratory setting, which complicates comparisons between yips and non-yips conditions, and (2) the technical difficulties of measuring neural activity during dynamic movements, where motion artifacts can contaminate signals. Motor imagery (MI) offers a possible solution, as it elicits neural activity patterns similar to those during actual motor execution [2]. This study aimed to elucidate the neural mechanisms underlying yips by using MI and focusing on corticospinal excitability, which is a key component of motor command output.

METHODS: Fourteen male baseball players with yips symptoms participated in this study. During the experiment, participants were seated comfortably on a chair. Electromyographic activity was recorded from the flexor carpi radialis (FCR) and abductor pollicis brevis (APB) muscles of the dominant hand used for pitching. Transcranial magnetic stimulation (TMS) was applied over the primary motor cortex of the contralateral side of the dominant hand. Motor evoked potentials (MEPs) induced by TMS were used to assess corticospinal excitability. MEPs were measured 15 times with eyes closed under the following conditions: a) rest condition: relaxed state and no thoughts; b) yips-MI condition: kinesthetic MI of pitching with yips; c) no yips-MI condition: kinesthetic MI of pitching without yips. MEP amplitudes in the MI conditions were normalized to those in the rest condition. Wilcoxon signed-rank tests were used to compare MEP amplitudes across conditions, with statistical significance set at $p < 0.05$.

RESULTS: Both MI conditions significantly increased the MEP amplitudes in the FCR and APB muscles compared to the rest condition (yips-MI, FCR: $p < 0.01$, 210 ± 77 % (% of rest, rest=100%), APB: $p < 0.01$, 189 ± 66 %; no yips-MI, FCR: $p < 0.05$, 172 ± 93 %, APB: $p < 0.05$, 139 ± 49 %). Furthermore, MEP amplitudes were significantly higher in the yips-MI condition than in the no yips-MI condition (FCR: $p < 0.01$, APB: $p < 0.05$).

CONCLUSION: This study is the first to employ a within-subject comparison to examine the neural mechanisms of the yips using MI. Although MI is known to facilitate corticospinal excitability in the muscles recruited in the imagined movement [3], our results revealed yips-specific facilitation of corticospinal excitability. These suggest that the symptoms of yips are associated with heightened motor-related neural activity. These findings provide important fundamental knowledge and a methodology for developing future strategies to overcome yips.

OP-BM21 Neuromuscular Fatigue

BIOMECHANICAL, FATIGUE, AND MUSCLE DAMAGE RESPONSES TO ECCENTRIC QUASI-ISOMETRIC CONTRACTIONS: FINDINGS FROM MULTIPLE STUDIES

KOZINC, Ž.

UNIVERSITY OF PRIMORSKA, FACULTY OF HEALTH SCIENCES, IZOLA

INTRODUCTION: Eccentric quasi-isometric (EQI) contractions are gaining attention due to their theorized benefits for muscle endurance, tendon stiffness, and hypertrophy (Oranchuk et al., 2019). However, these claims remain largely speculative. This series of exploratory studies aims to examine the biomechanics, fatigue patterns of EQI contractions, and compare their acute effects with traditional exercise modes

METHODS: Three studies examined EQI contractions across different muscle groups and loading conditions. Study 1 investigated EQI knee extensions and flexions in 16 active participants, analysing torque, fatigue, and range of motion (RoM). Study 2 compared plantarflexion EQIs at 75% and 90% of maximal voluntary isometric contraction (MVIC) in 20 participants, assessing contraction time, torque impulse, and fatigue. Study 3 contrasted EQI and isokinetic heavy-slow resistance exercise in 32 participants, evaluating neuromuscular performance, pain, and RoM across multiple time points.

RESULTS: Study 1 showed distinct fatigue responses between extensors and flexors, with extensors exhibiting greater peak torque loss (16.6% vs. 13.3%) and shifts in the optimal angle (+7.4%) following EQI contractions. Knee flexors demonstrated higher intra-repetition velocity and more stable RoM across repetitions. Study 2 found no significant effect of EQI on MVIC torque, but EQIs at 75% MVIC resulted in 34% longer contraction duration, 23% greater torque impulse, and 19% increased RoM compared to 90% MVIC. Study 3 demonstrated that EQI induced lower fatigue, pain, and perceived effort than isokinetic heavy-slow resistance exercise while accumulating greater total torque impulse. Additionally, EQI participants experienced a smaller reduction in MVIC force torque post-exercise ($\eta^2 = 0.16$), and pain levels remained significantly lower across all time points ($\eta^2 = 0.32$).

CONCLUSION: EQI contractions exhibit distinct biomechanical and fatigue characteristics depending on muscle group and loading conditions. Knee extensors may be more susceptible to EQI-induced fatigue than flexors, and moderate loading (75% MVIC) may optimize torque impulse and RoM in plantarflexion EQIs. Compared to isokinetic heavy-slow resistance exercise, EQI appears to induce less fatigue and post-exercise pain, suggesting potential advantages in rehabilitation settings. However, given the exploratory nature of these studies, further research is required to substantiate these findings and establish practical applications.

THE LEVEL OF UNILATERAL MOTOR PERFORMANCE-INDUCED FATIGUE DOES NOT INFLUENCE THE IMMEDIATE MOTOR PERFORMANCE FATIGUE OF THE CONTRALATERAL LIMB AFTER ECCENTRIC EXERCISE OF THE KNEE EXTENSORS

COLSON, S., DA SILVA, F., SERRANO, Q.A., GIODA, J.

UNIVERSITÉ CÔTE D'AZUR

INTRODUCTION: Although crossover fatigue, defined as a decline in maximal voluntary isometric contraction in the non-exercised contralateral homologous muscle, is still debated in the literature, recent studies have shown that eccentric contractions impair contralateral motor performance. However, to date, no study has evaluated the influence of the fatigue level induced in the exercised muscle group on contralateral motor performance fatigue. Therefore, this study aimed to investigate the impact of two exercises involving submaximal unilateral knee extension eccentric contractions, which induce different levels of fatigue, on crossover fatigue. We hypothesized that motor performance-induced fatigue in the exercised muscle group would influence the magnitude of crossover fatigue.

METHODS: Fifteen participants, comprising 8 males (aged 22.3 ± 3.6 years) and 7 females (aged 20.1 ± 1.7 years), randomly underwent unilateral submaximal eccentric exercises of the knee extensors performed at 80% of maximal voluntary eccentric contraction (MVEC) until a reduction of 20% (FAT20%) or 40% (FAT40%) in maximal voluntary isometric contraction (MVIC) of the exercised limb (EL) was achieved. Motor performance fatigue (i.e., central and peripheral factors assessed via percutaneous nerve stimulation) were collected before (PRE), immediately after (POST), 2 minutes (POST2), 5 minutes (POST5) and 10 minutes after (POST10) the fatiguing exercises on both the EL and the non-exercised limb (NEL). Perceived motor fatigue and perceived muscle soreness were assessed at PRE, and POST and POST10, respectively.

RESULTS: Contralateral motor performance fatigue was evident after both fatiguing exercises ($p < 0.05$). Although the level of fatigue induced in the EL at POST was greater after FAT40% ($-44.9 \pm 8.9\%$ of MVIC produced at PRE) compared to FAT20% ($-24.3 \pm 5.9\%$), this fatigue level did not significantly influence the significant decline in MVIC in the NEL ($-8.3 \pm 10.2\%$, vs $-8.8 \pm 10.5\%$ after FAT20% and FAT40%, respectively). While significantly impaired in the EL ($p < 0.001$), no significant alterations in neuromuscular parameters (i.e., central or peripheral factors) were observed in the NEL. However, a global increase of perceived motor fatigue at POST ($p < 0.001$) and perceived muscle soreness at POST10 in both limbs was observed ($p < 0.001$). Fatigue in the EL was maintained up to 10 minutes in a lower extent after FAT20% compared to FAT40% (PRE-POST2: -17.6% vs -30.9% ; PRE-POST5: -15.0% vs -32.7% ; PRE-POST10: -15.7% vs -27.2% , respectively). In the NEL, the loss of MVIC at POST10 was no longer significantly different from PRE following FAT20%, whereas it remained significantly altered until POST10 following FAT40%.

CONCLUSION: The current study highlights that the level of fatigue in the EL did not influence crossover fatigue in the NEL. Although motor performance fatigue in the EL involved peripheral and central alterations, increased global perceived motor fatigue may likely account for the crossover fatigue in the NEL.

HOW DOES EXERCISE-INDUCED FATIGUE ALTER NEUROMUSCULAR CONTROL DURING THREE-POINT JUMP SHOTS IN HIGHLY TRAINED BASKETBALL PLAYERS?

LI, Y.1, ZHANG, M.1, SUN, Q.1, GAO, X.2, WANG, Z.1, GONG, B.1, WANG, Z.1, CHEN, Y.1, CHEN, J.1, HUO, B.1

1:CAPITAL UNIVERSITY OF PHYSICAL EDUCATION AND SPORTS 2:BEIJING INSTITUTE OF TECHNOLOGY

INTRODUCTION: Exercise-induced fatigue significantly impairs three-point jump shot accuracy by affecting neuromuscular control, including muscle activation patterns and postural balance (1). However, the underlying mechanisms of these impairments remain unclear. Muscle synergies are low-dimensional control modules organized within the central nervous system that coordinate muscle activation to produce efficient movement patterns (2). Synergy analysis offers a valuable approach to understanding how multiple muscles work together to optimize shooting performance (3). This study aimed to compare the muscle synergies of highly trained basketball players during three-point jump shots before and after exercise-induced fatigue to better understand neuromuscular coordination under fatigued conditions.

METHODS: Fifteen highly trained male basketball players participated in this study. Fatigue was induced through a high-intensity protocol combining shuttle sprints and vertical jumps to simulate game-related conditions (4). During pre- and post-fatigue testing, participants performed three-point jump shots continuously on force plates until three successful and three unsuccessful attempts were recorded, following a standardized warm-up and immediately after fatigue induction. Surface electromyography (EMG) was recorded from 16 muscles across the trunk, upper, and lower extremities during the shooting task. Muscle synergies were identified using non-negative matrix factorization (NNMF) to compare neuromuscular coordination before and after fatigue (5).

RESULTS: We observed five muscle synergies in successful shots before fatigue, which were reduced to four after fatigue. Unsuccessful shots consistently displayed four synergies both pre- and post-fatigue. Fatigue caused a merging of muscle synergies during the preparation phase, shifting from distinct upper and lower limb activation pre-fatigue to continuous co-activation post-fatigue, closely associated with changes in the center of pressure. During the ball elevation phase, the modular organization of muscle synergies remained unaffected with fatigue. However, significant alterations were observed in the motor modules and primitives of synergy 4 (responsible for push-off), particularly in the tibialis anterior (left: $d = -1.06$; right: $d = -1.47$) and gastrocnemius lateral (left: $d = 1.61$; right: $d = 1.66$) muscles, resulting in distinct muscle activation patterns and temporal shifts. The time-to-peak of synergy 4 vectors occurred significantly earlier before fatigue than after ($d = -0.71$).

CONCLUSION: The changes in the central nervous systems modular control strategies highlight neuromuscular adjustments that are essential for maintaining shooting performance and accuracy under fatigue. Therefore, coaches and athletes should incorporate targeted neuromuscular training programs aimed at optimizing muscle synergy patterns and improving postural control, ensuring athletes can sustain performance even under fatigued conditions.

THE EFFECTS OF VISUAL FEEDBACK, EXTERNAL FOCUS OF ATTENTION, AND VERBAL ENCOURAGEMENT ON RESISTANCE TRAINING PERFORMANCE, MOVEMENT MECHANICS, PHYSIOLOGICAL AND PSYCHOLOGICAL MARKERS OF FATIGUE

JUKIC, I., HIRSCH, S., KING, A., HELMS, E., MCGUIGAN, M.

ABERTAY UNIVERSITY; AUCKLAND UNIVERSITY OF TECHNOLOGY; UNIVERSITY OF TORONTO; TONAL SYSTEMS, INC.

INTRODUCTION: Performing resistance training with maximal intent enhances neuromuscular adaptations, often encouraged through external focus cues, visual feedback (VF), or verbal encouragement (VE). While these strategies aim to increase movement velocity (MV) and movement velocity maintenance (MVM), their effects on acute physiological, psychological, and biomechanical responses remain unclear. This study examined the impact of VF, external focus of attention (EFA), and VE on MV, MVM, neuromuscular, metabolic, and perceptual fatigue proxies, and mechanical energy expenditure (MEE) during resistance training.

METHODS: Nineteen resistance-trained individuals (6 females; 13 males) completed one-repetition maximum (1RM) and 12RM tests in the free-weight back squat, followed by familiarisation with rating of perceived exertion (RPE), rating of fatigue (ROF), and exercise enjoyment scales. Participants then performed four experimental sessions consisting of two sets of 10 repetitions at 12RM. The first session served as a control condition (CON) without external cues, while VF, EFA, and VE were applied in randomised order in subsequent sessions. Blood lactate (BL) was collected pre- and post-exercise, and countermovement jumps (CMJs) were performed before and after squatting to assess neuromuscular function. Biomechanical data were captured using 50 retro-reflective markers on anatomical landmarks, allowing for joint-specific and total MEE evaluation.

RESULTS: Linear mixed-effects model analyses (diagnostics cleared) revealed that VF elicited the greatest MV, followed by EFA and VE (all $p < 0.001$). MVM was higher in VF and EFA than in CON ($p < 0.05$), indicating better velocity retention in these conditions. Interestingly, BL and CMJ height did not differ between conditions, suggesting acute metabolic and neuromuscular responses were unaffected. RPE and ROF were lowest in VF ($p < 0.001$), with no significant differences among the remaining conditions ($p > 0.05$). Exercise enjoyment was highest in VF, exceeding EFA ($p = 0.016$) and CON ($p = 0.001$), indicating that VF promoted a more positive training experience. Total MEE was greater in VF compared to CON ($p < 0.001$), with all joints exhibiting increased expenditure. The spine showed the greatest proportional increase in MEE,

particularly in the second set, suggesting altered movement mechanics and a greater spinal contribution when training with VF.

CONCLUSION: VF proved most effective for optimising MV and MVM and reducing perceptual fatigue, making it a valuable tool for coaches, sport scientists, and rehabilitation professionals. However, its association with increased spinal MEE suggests potential biomechanical trade-offs, highlighting the need for careful monitoring and coaching to mitigate inefficient or altered movement mechanics. EFA also provided notable benefits, making it a viable alternative when VF is unavailable. These findings offer practical insights for refining resistance training strategies to enhance both performance and safety.

EFFECT OF NEUROMUSCULAR FATIGUE ON MUSCLE FIBRE CONDUCTION VELOCITY IN YOUNG MALES AND FEMALES

WANG, D., WU, R.2, DE VITO, G.3, JIANG, J.1, SHAO, C.1, LUO, W.1, CHEN, X.1, LOWERY, M.M.2

1 SHANGHAI UNIVERSITY OF SPORT, CHINA; 2 UNIVERSITY COLLEGE DUBLIN, IRELAND; 3 UNIVERSITÀ DI PADOVA, ITALY

INTRODUCTION: Muscle fatigue is characterized by an exercise-induced reduction in force generation capacity, involving both neural and muscular mechanisms. Muscle fibre conduction velocity (MFCV) has been widely used to examine changes in muscle fibre excitability during fatigue and can also reflect progressive recruitment of motor units (MUs), due to its linear relationship with the fibre diameter (1,2). However, studies investigating potential differences in the effect of fatigue on MFCV between males and females remain limited. This study aimed to examine the sex differences in neuromuscular responses during and after sustained submaximal isometric contraction.

METHODS: Thirty-one healthy young adults (16 females: 21.7 ± 2.1 yr) performed sustained submaximal isometric fatiguing contraction of the knee extensors (KE) at 30% maximal voluntary isometric contraction (MVIC) until task failure. MVICs of the KE were recorded before, immediately after and throughout 10 min of recovery. During recovery, an MVIC was performed at 0, 2, 5 & 10min (post 0, 2, 5, 10) after the end of the fatiguing contraction. High-density surface EMG signals from the vastus lateralis muscle were recorded simultaneously throughout. EMG root mean square (RMS) amplitude and median frequency (MDF) were assessed during MVICs and, with MFCV, during the fatiguing contraction. Values corresponding to 10% intervals of the endurance time were selected and normalized to their initial values for statistical analysis.

RESULTS: Males were stronger ($p < 0.001$) with greater BMIs ($p < 0.05$) than females. There was no significant difference in endurance time (113.3 vs 114.9s) and post-fatigue MVIC% reduction (22.8 vs 30.7%) between sexes. During the fatiguing contraction, a similar increase in RMS% was observed in both sexes (all $p < 0.01$), however, females exhibited a greater decrease in MDF% ($p < 0.001$) and MFCV% ($p < 0.05$) compared to males. Moreover, during recovery, females showed a greater increase in MDF% (16.8 vs 9.2%) and MVIC% (14.2 vs 2.6%) from post 0 to post 2 ($p < 0.05$).

CONCLUSION: In this study, no differences were observed in endurance time or post-fatigue MVIC% decline between sexes. However, females showed a greater linear decline in MDF% and MFCV% during the fatiguing task. Additionally, females exhibited superior recovery of MVIC% and MDF% after fatigue. These findings suggest that 1) males may adopt a different MU recruitment strategy to maintain the sustained force production, possibly by recruiting more high-threshold, higher MFCV MUs during the fatiguing contraction. This may be due to their larger diameter and proportional area of the type II fibres. 2) females may benefit from greater muscle perfusion and higher capillarization of the muscle bed, facilitating more efficient removal of metabolic by-products, thus faster recovery.

COMBINED TRAINING AS A SAFE AND EFFECTIVE STRATEGY TO ENHANCE MUSCLE STRENGTH WITHOUT COMPROMISING SHOULDER-ARM VOLUME AND DISABILITY IN SURVIVORS OF BREAST CANCER: THE EFICAN RCT

ESTEBAN SIMÓN, A., DÍEZ-FERNÁNDEZ, D.M., ARTÉS-RODRÍGUEZ, E., RODRÍGUEZ-PÉREZ, M.A., SORIANO-MALDONADO, A.
UNIVERSITY OF ALMERÍA

INTRODUCTION: With increasing survival rates, a growing number of women live with the long-term effects of breast cancer and its treatments, including reduced muscle mass and strength, impaired upper-limb function, diminished cardiorespiratory fitness, lower quality of life, and risk of lymphedema. Evidence suggests that exercise, particularly combining resistance and aerobic training, can help mitigate these effects. The primary aim of the EFICAN trial was to evaluate the effects of a 12-week combined training program on muscle strength in breast cancer survivors. Secondary outcomes included shoulder-arm volume and disability, body composition, cardiorespiratory fitness, quality of life, cancer-related fatigue, and depression.

METHODS: A randomized trial was conducted with 60 women who had completed surgery, chemotherapy, and/or radiotherapy within the past ten years. Participants were randomized to exercise (EG; two weekly resistance training sessions + 10,000 daily steps) or control (CG; 10,000 daily steps). Baseline and post-intervention assessments included muscle

strength, shoulder-arm volume and disability, body composition, cardiorespiratory fitness, quality of life, cancer-related fatigue, and depression.

RESULTS: The EG (32 participants) showed significant improvements in overall muscle strength (0.718; 95%CI: 0.361–1.074, $P<0.001$, $d\text{-Cohen}=1.04$), upper-limb strength (0.727; 95%CI: 0.294–1.160, $P=0.001$, $d=0.87$), and lower-limb strength (0.709; 95%CI: 0.324–1.094, $P=0.001$, $d=0.96$) compared to the CG (28 participants). Secondary analyses indicated that surgical and treatment characteristics did not influence the intervention's effects on lymphedema or upper-limb problems. However, increased upper-limb strength was associated with reduced shoulder-arm problems (-0.429 ; $P=0.020$). Regarding body composition, chemotherapy was linked to increased fat mass ($B=2.313$, $P=0.034$), fat percentage ($B=3.282$, $P=0.003$), and visceral fat ($B=1.434$, $P=0.011$) in the CG. No significant differences were observed in other variables.

CONCLUSION: A 12-week combined training intervention improved muscle strength without compromising shoulder-arm volume and disability, regardless of the surgical and treatment history. Although no significant changes were seen in other variables, risk factors for lymphedema did not impact training outcomes, reinforcing the recommendation to exercise the affected limb. Additionally, chemotherapy was associated with worsened body composition in the CG, suggesting that exercise may help counteract these adverse effects, which are critical for long-term prognosis. The findings indicate that increased upper-limb strength may help alleviate shoulder-arm problems, further supporting the integration of combined training into post-cancer rehabilitation programs. This study underscores the importance of exercise in reducing the negative effects of cancer treatment, reinforcing its role as a key component in breast cancer survivorship care.

THE EFFECTS OF TWO MULTIMODAL EXERCISE PROGRAMS (FACE-TO-FACE VS ONLINE) ON PHYSICAL AND FUNCTIONAL OUTCOMES IN BREAST CANCER SURVIVORS: A RANDOMIZED CONTROL TRIAL.

CASTELLANOS-MONTEALEGRE, M.1,2, CASLA-BARRIO, S.1,3, PAREJA-GALEANO, H.4, CANTERO, L.1, HARO, J.1, AYUSO-CHICO, M.1

1. EXERCISE AND CANCER CENTERS. 2. UNIVERSIDAD CASTILLA-LA MANCHA. 3. UNIVERSIDAD PONTIFICIA COMILLAS. 4. UNIVERSIDAD AUTÓNOMA DE MADRID

INTRODUCTION: Physical exercise programs has been demonstrated to reduce many of the side effects of cancer and its treatments, primarily by addressing alterations in body composition, CRF, and fatigue, all of which are associated with quality of life and survival [1, 2]. Despite these benefits, it is estimated that only 36% of breast cancer survivors adhere to the exercise recommendations for cancer survivors set by the World Health Organization (WHO) [3]. In this Randomized Control Trial (RCT), we examined the impact of a face-to-face oncological exercise program compared with an online oncological exercise program on body composition, CRF, fatigue, and quality of life in patients with breast cancer in stage IA to IIIB.

METHODS: Women diagnosed with primary breast cancer (stages IA to IIIB); aged 18 years or older were included in this study. Patients assigned to the intervention group underwent a multimodal exercise program intervention for 16 weeks. This intervention was conducted both in-person at the training center and online to enhance participant adherence.

Both oncological exercise programs included resistance, endurance, balance, and proprioception exercises, with intensity ranging from 55% to 95% of heart rate reserve (HRR). Each session lasted 75 minutes and was structured as follows: 10 minutes of warm-up involving joint mobilities, balance exercises, and aerobic exercise. This was followed by two 20-minute bouts of combined endurance and resistance exercises at an average intensity of 70-75% HRR with 30 to 60 second bouts of high-intensity activity of 85% to 100% HRR. Resistance exercises were developed with free weights of 8 exercises of 3x10 or 3x15.

RESULTS: 40 patients in the intervention group and 34 in the control group completed the study. In the intervention group, 14 (35.9%) patients participated in the online program, while 25 (64.1%) attended the in-person sessions. The attendance rates for the intervention group were 89.5% in both instances. Specifically, for the online group, 84.02% of the sessions were conducted online, while 15.98% of the attendance occurred in person. Conversely, for the in-person intervention, 76.64% of the sessions were face-to-face, and 23.35% of the attendance was through online classes. No differences in attendance between interventions were observed ($p=0.997$). In addition, no significant differences between interventions were observed in physical (cardiorespiratory fitness, functional capacity, and body composition) or emotional (fatigue and quality of life) variables.

CONCLUSION: The multimodal physical exercise interventions (online and face-to-face) in this study prove to be effective not only in improving fitness and body composition, but also in promoting different exercise strategies, and improving the accessibility of exercise programs for patients far from sports centers. This accessibility is crucial in ensuring high levels of adherence to these programs and adapting the intervention to the personal situation of patients.

THE IMPORTANCE OF PROFESSIONALLY SUPERVISED AND STRUCTURED EXERCISE PROGRAMS IN CANCER PATIENTS: A 16-WEEK PROSPECTIVE STUDY USING THE EQ-5D QUESTIONNAIRE

CASLA-BARRIO, S.1,2, CASTELLANOS-MONTEALEGRE, M.1,3, CASLA-BARRIO, S.1,3, PAREJA-GALEANO, H.4, CANTERO, L.1, HARO, J.1, AYUSO-CHICO, M.1

1. EXERCISE AND CANCER CENTERS. 2. UNIVERSIDAD PONTIFICIA COMILLAS. 3. UNIVERSIDAD CASTILLA-LA MANCHA. 4. UNIVERSIDAD AUTÓNOMA DE MADRID

INTRODUCTION: The benefits of exercise in cancer patients are well established; however, its effectiveness largely depends on proper structuring, supervision, and professional guidance. Poorly designed or inadequately supervised pro-

grams may fail to provide optimal outcomes or even pose risks. This study evaluates the impact of a structured and professionally guided 16-week exercise program on health-related quality of life (HRQoL) in cancer patients, using the EQ-5D questionnaire to quantify improvements and their economic implications.

METHODS: A total of 195 cancer patients (95% female, mean age 54.30, (SD=15.07) years) participated in this professionally supervised exercise intervention. The sample included patients in different treatment stages: 30% undergoing active treatment, 30% on hormone therapy, 22% metastatic, and 17% without active treatment. The intervention consisted of 16 weeks of high-intensity cardiovascular and strength training, conducted twice per week in a controlled setting with trained professionals ensuring safety, adherence, and individualized adaptation.

The EQ-5D questionnaire, a validated tool assessing five health dimensions (mobility, self-care, usual activities, pain/discomfort, and anxiety/depression), was administered at baseline and post-intervention. The EQ-5D index score was calculated using Spanish reference values, and quality-adjusted life years (QALYs) were estimated based on HRQoL changes.

RESULTS: Following the professionally structured intervention, there was a significant improvement in HRQoL, with the EQ-5D index increasing by 0.061 (SD=0.03) points from baseline ($p = 0.02$). This corresponds to an annualized gain of 0.061 QALYs per patient, a clinically meaningful enhancement in quality of life.

Economic analysis, based on Spain's willingness-to-pay (WTP) threshold (€20,000–€30,000 per QALY gained), suggests that this structured program generates an estimated economic benefit of €1,220 to €1,830 per patient. Given the cohort size ($n = 195$), the total potential economic impact ranges between €237,900 and €356,850.

CONCLUSION: This study underscores the critical role of structured and professionally supervised exercise programs in maximizing benefits for cancer patients. The significant improvements in HRQoL and economic impact reinforce the need for these interventions to be delivered by trained professionals who can ensure individualized adaptation, safety, and adherence. In contrast, unsupervised or poorly structured programs may fail to provide similar outcomes or even pose risks to vulnerable patients.

To fully integrate exercise into oncology care, it is essential to standardize structured programs, ensuring they are led by qualified professionals who can adapt interventions to patients' clinical status, treatment phase, and physical capacity. Future research should focus on optimizing program scalability while maintaining high safety, efficacy, and cost-effectiveness standards.

EFFECTS OF EXERCISE QUANTITY AND INTENSITY ON CANCER CACHEXIA: PHYSICAL AND PSYCHOLOGICAL EFFECTS

PEYRACHON, R., RICHARD, C., LIÈVRE, A., CHAORY, K., RÉBILLARD, A.

UNIVERSITY OF RENNES, M2S-EA7470, F-35000 RENNES, FRANCE

INTRODUCTION: Cancer cachexia leads to a loss of muscle mass associated with a decrease in quality of life, treatment response, and patient survival. Once cachexia is established, there is no cure, and it is recommended to limit its progression by combining medical, nutritional, and exercise interventions. Indeed, cachexia induces metabolic and muscular alterations that are counterproductive to exercise-induced adaptations. The benefits are beginning to be identified in cancer patients suffering from cachexia, but further studies are needed (Cheung, 2023). Furthermore, a recent study highlights that the effects of exercise on muscle mass may depend on compliance to the program, suggesting a possible dose-response relationship (Parent, 2025). The aim of this study is to evaluate the effects of the intervention based on the quantity and intensity of exercise practiced by cachectic cancer patients (CCP).

METHODS: 15 CCP participated in a supervised exercise program combining endurance and resistance training. Over a 3-month period, CCP could engage in exercise sessions twice a week, each lasting one hour. The number and intensity (HRR) of exercise sessions were recorded. Physical condition assessments included body composition, strength, and endurance. Psychological condition assessments included quality of life (QoL) and cancer-related fatigue (CRF). Results were analyzed in terms of compliance and compared with the evolution of cancer patients without cachexia (CPWC).

RESULTS: CCP completed $74 \pm 17\%$ of the prescribed sessions at a mean intensity of $68.6 \pm 8.8\%$ HRR. The program led to significant benefits in cancer cachexia symptoms, increasing BMI, muscle mass, endurance, and lower limb strength, while counteracting loss of appetite ($p < .05$). Despite these improvements, QoL and CRF were not impacted, whereas improvements were observed in CPWC. Regarding the dose-response relationship, despite a trend, no significant correlations were found between changes in muscle mass or endurance and the amount of exercise performed ($r = -0.35$, $p = .21$; $r = 0.17$, $p = .55$) or the session intensity ($r = -0.14$, $p = .63$; $r = -0.24$, $p = .41$).

CONCLUSION: CCP engage in the program and experience physical and nutritional benefits. Exercise improves weight, muscle mass, appetite, endurance, and strength. These findings highlight the importance of incorporating exercise into cachexia management. According to our results, a frequency of 1.5 to 2 sessions per week for three months seemed sufficient to yield positive outcomes. Within our small sample, no clear dose-response or intensity-response relationship emerged, although a trend suggested a reduction in muscle mass benefits with increased compliance. Strangely, exercise did not lead to psychological benefits in terms of quality of life and perceived fatigue. This could be explained by disease progression and its visibility, which may remain a barrier to social engagement. Research will continue to refine the effects of exercise according to patient characteristics.

EFFECTS OF A 3-MONTH EXERCISE INTERVENTION IN PATIENTS WITH ADVANCED PANCREATIC CANCER UNDERGOING CHEMOTHERAPY: A SINGLE-ARM FEASIBILITY STUDY

BORSATI, A., ADAMOLI, G., TONIOLO, L., CIURNELLI, C., BELLUOMINI, L., TRESTINI, I., TREGNAGO, D., INSOLDA, J., SCHENA, F., MILELLA, M., PILOTTO, S., AVANCINI, A.

UNIVERSITY OF VERONA

INTRODUCTION: Patients with pancreatic cancer face severe physical and psychological burdens due to the aggressiveness of the disease and the side effects of treatment, which contribute to a decline in quality of life and survival. Exercise has shown benefits in mitigating symptoms and improving physical fitness. However, the feasibility of structured exercise programs during treatment for pancreatic cancer remains challenging. This study evaluates the feasibility and preliminary effects of a 3-month exercise intervention in this population.

METHODS: Patients with pancreatic cancer treated at the Oncology Unit of the University of Verona Hospital Trust were invited to participate in a 3-month structured exercise intervention, with the freedom to choose between a home-based or gym-based program. Both modalities included individually tailored twice-weekly sessions of aerobic and resistance training and each session comprised a warm-up, aerobic training, five resistance exercises using elastic bands, and a cool-down with stretching. The primary outcome was feasibility, assessed through recruitment rate, attendance, adherence, dropout rate, tolerability, and safety. Secondary endpoints, assessed at baseline and post-intervention were: i) cardiorespiratory fitness evaluated with the six-minute walking test ii) muscle strength assessed with the handgrip strength test iii) flexibility measured with the back scratch and chair sit and reach tests, iv) body mass index and waist-hip ratio, and v) quality of life evaluated with the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire. Descriptive statistics and paired t-tests were used to analyze the results.

RESULTS: Of the 30 patients enrolled, 18 completed the intervention, with a recruitment rate of 83% and a dropout rate of 40% (n=12), primarily due to disease progression. All participants were undergoing chemotherapy, and 87% had metastatic cancer. Twelve patients chose the home-based program, while six opted for the gym-based format. Median attendance was 80%, adherence to prescribed exercise volume was 79%, and tolerability was 100%. Two non-severe adverse events were recorded. Post-intervention, significant improvements were observed in upper limb flexibility ($p=0.045$), moderate-intensity physical activity ($p=0.004$), and total weekly physical activity ($p=0.020$). Although no significant changes were detected in cardiorespiratory fitness, muscle strength or anthropometric measures, participants reported significant improvements in emotional ($p=0.042$) and social functioning ($p=0.009$), along with a reduction in appetite loss ($p=0.008$).

CONCLUSION: A highly tailored exercise program is feasible and well-tolerated in patients with pancreatic cancer undergoing chemotherapy. Moreover, the intervention was effective in enhancing quality of life, highlighting the potential role of exercise in supportive care for this population.

EFFECTS OF EXERCISE TRAINING INTENSITY ON RUNNING CAPACITY AND SKELETAL MUSCLE METABOLIC GENE EXPRESSION IN A MOUSE MODEL OF LOWER EXTREMITY PERIPHERAL ARTERY DISEASE

KOJIC, S., DROZDOVSKA, S., WANG, L., MAZZOLAI, L., ROSENBLATT-VELIN, N., MILLET, G.P., PELLEGRIN, M.

UNIVERSITY OF LAUSANNE

INTRODUCTION: Lower extremity peripheral artery disease (PAD), caused by the buildup of atherosclerotic plaque that narrows the lower extremity arteries, is a global health concern. PAD patients often experience ischemic muscular pain during exercise, which leads to a significant decline in functional capacity. Exercise training is a first-line treatment for PAD; however, the comparison of the effectiveness of different exercise training intensities on skeletal muscle adaptations is lacking.

This study compared the effects of moderate-intensity continuous training (MICT) and high-intensity interval training (HIIT) on endurance capacity and mRNA expression of metabolic genes in skeletal muscles of mice with PAD.

METHODS: Male C57BL/6 mice underwent surgical ligation of the right common iliac artery and were then divided into three groups: sedentary (SED), MICT (40 minutes of running at 70% of maximal aerobic speed), and HIIT (8x 2.5 minutes running at 90% of maximal aerobic speed, interspersed with 2.5 minutes running at 50% of maximal aerobic speed). Mice were subjected to treadmill running 3 times/week for 8 weeks. Maximal running distance was determined by an incremental exhaustion test.

Quantitative PCR (qPCR) was performed to determine skeletal muscle mRNA expression of markers involved in the metabolism of glucose (GLUT-4, HK2, PFK), lactate (LDHA), lipid (CD36, HSL), as well as markers related to mitochondrial biogenesis and oxidative metabolism (PGC-1 α , TFAM, mtND6, CS, CYTB). Analyses were performed in both non-ischemic and ischemic gastrocnemius (primarily fast-twitch fibers), and soleus (primarily slow-twitch fibers) muscles.

RESULTS: At the end of the study, maximum running distance was significantly greater in both MICT and HIIT mice compared to SED (439 $\pm$ 33.2 m in MICT vs 470.0 $\pm$ 32.0 m in HIIT vs 311.6 $\pm$ 21.2 m in SED, $p < 0.05$), with no significant difference between MICT and HIIT.

In the ischemic gastrocnemius muscle, HIIT upregulated the mRNA expression of PFK, CD36, HSL, and CS ($p < 0.05$ vs SED), while in the non-ischemic gastrocnemius, only CS expression was increased ($p < 0.05$ vs SED). MICT did not significantly alter the mRNA levels of metabolic genes in either the ischemic or non-ischemic gastrocnemius muscle.

In the ischemic soleus muscle, HIIT increased mtND6 and CYTB mRNA expression ($p < 0.05$ vs SED). In the non-ischemic soleus, HIIT upregulated PGC-1 α and CYTB while downregulating CD36 and HK2 ($p < 0.05$ vs SED). MICT upregulated the mRNA expression of GLUT-4, LDHA, TFAM in the ischemic soleus muscle ($p < 0.05$ vs SED), but had no impact on gene expression in the non-ischemic soleus.

CONCLUSION: MICT and HIIT are equally effective in improving endurance capacity in PAD mice. However, HIIT induces greater skeletal muscle transcriptional adaptations compared to MICT in our mouse model of PAD.

SUBCELLULAR PROTEOMIC NETWORKS UNDERLYING ACUTE AND CHRONIC EXERCISE RESPONSES IN HUMAN SKELETAL MUSCLE

REISMAN, E., TAYLOR, D., YU, D., CARUANA, N., HUANG, C., BISHOP, D., HAWLEY, J., HOFFMAN, N.

AUSTRALIAN CATHOLIC UNIVERSITY

INTRODUCTION: Mitochondria serve as critical signalling hubs, integrating and relaying intracellular information to facilitate skeletal muscle adaptations to exercise. Despite known roles of mitochondrial (MITO) protein signalling and translocation between other organelles (i.e., the nucleus and cytosol), major knowledge gaps remain in our understanding of the complex muscle subcellular protein networks underlying acute responses to exercise and exercise training.

METHODS: A total of 197 vastus lateralis muscle biopsies were collected from 20 untrained men and 20 untrained women (26.5 $\pm$ 5.9 y, BMI 24.9 $\pm$ 3.4 kg/m², VO₂max 31.1 $\pm$ 5.6 mL/min/kg) pre, mid, post, and 3 h-post an acute bout of high-intensity interval exercise (HIIE) and following 8 wk HIIE training (4 sessions/wk). The acute HIIE session consisted of four 4-min workouts based on individual maximum power output and lactate threshold, with 2-min rest. Subcellular fractionation workflows were developed to isolate MITO, nuclear (NUC) and cytosolic (CYTO) fractions from snap-frozen human muscle biopsies using differential centrifugation. Global mass spectrometry-based proteomic analysis was then performed to map acute and chronic exercise-induced changes in protein abundance and potential protein translocation between subcellular compartments.

RESULTS: Proteomic and bioinformatic analysis of 591 total muscle subcellular fractions mapped acute and chronic exercise-induced dynamics of MITO, NUC, and CYTO protein abundance. We quantified 1440 total proteins in the MITO fraction, representing over 40% of all annotated MITO proteins. Differential expression analysis revealed significant changes (adjusted $p < 0.05$ versus pre) within the MITO fraction mid (102 proteins), post (604), and 3 h-post (376) acute exercise, and following 8 weeks of training (611). HIIE acutely downregulated MITO ribosomal proteins and proteins involved in MITO fission/fusion dynamics, whereas proteins related to reactive oxygen species were upregulated. Robust upregulation of MITO proteins was observed following training, consistent with other molecular markers of MITO biogenesis (e.g., citrate synthase activity, transmission electron microscopy). In the NUC fraction, 491 total proteins were significantly regulated (216 up and 275 downregulated, respectively) across all time points, including robust regulation of auxiliary proteins linked to ribonucleotide processes. There were no sex differences in subcellular proteomes observed in response to acute and chronic exercise.

CONCLUSION: These subcellular proteomic datasets represent one of the most extensive human muscle proteome analyses to date and a valuable resource of the intricate subcellular networks underlying acute exercise responses and training-induced adaptations. Collectively, these datasets highlight the overall lack of subcellular proteomic sex differences and key pathways that warrant further investigation including MITO protein translation and fission/fusion machinery.

AGING DETERIORATES SKELETAL MUSCLE MITOCHONDRIA INDEPENDENTLY FROM PHYSICAL ACTIVITY: NEW INSIGHTS FROM A TRANSLATIONAL APPROACH

FELLES, C., PILOTTO, A., ANSALDO, M., NERI, M., GIUSTI, L., PELLEGRINO, M.A., BOTTINELLI, R., RE, R., LAURETANI, F., ALCAZAR, J., BOTTER, A., FRANCHI, M., PORCELLI, S.

UNIVERSITY OF PAVIA

INTRODUCTION: Aging inevitably results in a decline in whole-body cardiorespiratory fitness (1). Impairments in muscle oxidative metabolism serves as key contributing factor to age-related cardiorespiratory fitness reduction, potentially driven by alterations in mitochondrial content, distribution and function (2). However, some studies suggest aging does not lead to mitochondrial impairments when high level of physical activity are maintained and there is ongoing debate in the scientific literature (3,4). This study aimed to clarify the relationship between aging, mitochondria and training by investigating muscle oxidative capacity through both in-vivo and ex-vivo technique to characterize mitochondrial function, content, and distribution in human skeletal muscle of active and sedentary older individuals.

METHODS: Forty young sedentary adults (YG, n=40; 24 $\pm$ 4 yrs) and fifty older individuals (O, n=50; 68 $\pm$ 10 yrs) were recruited. Free-living physical activity was monitored by accelerometry and used to stratify O into active (OA) and sedentary (OS) groups. All participants completed a cycling incremental test to assess maximal pulmonary oxygen uptake (VO₂peak). In-vivo vastus lateralis muscle oxidative function was estimated as oxygen uptake recovery rate constant (k) during intermit-

tent arterial occlusions after brief exercise by near-infrared spectroscopy (5). Muscle biopsies from vastus lateralis were collected in a subsample of subjects (n=40). High-resolution respirometry was used to assess mitochondrial respiration. Immunohistochemistry analysis and Citrate Synthase activity assay were performed to determine fibre cross-sectional area (fCSA), mitochondrial content and distribution.

RESULTS: YG showed higher VO₂peak (35.2±7.4 ml/kg/min) compared to O (24.1±5.6 ml/kg/min, p<0.001). k was higher in YG compared to O (p<0.001), without differences between OA and OS (p=0.83). After adjusting for physical activity, age negatively correlated with VO₂peak and k (both p<0.01). Mitochondrial respiration was not affected by age or physical activity. In both YG and O, type I and type II fibers differed for TOM20 (p<0.03). Markers of mitochondrial content were lower in O, compared to YG (p<0.05). OA and OS did not show any difference in the mitochondrial markers investigated (p = 0.29).

CONCLUSION: Cardiorespiratory fitness and skeletal muscle oxidative capacity were negatively affected by age but the age-related decline in muscle oxidative metabolism was not preserved or restored by physical activity. Mitochondrial function did not change with age or according to physical activity level in older individuals, suggesting changes mitochondrial content and distribution during aging may disrupt mitochondrial network integrity and connectivity, potentially having a greater impact on in-vivo muscle oxidative capacity.

SALIVARY PROTEOME CHANGES FOLLOWING AN INTEGRATED NEUROMUSCULAR TRAINING (INT) INTERVENTION IN SCHOOL CHILDREN

HOMS AVILA, J., VASILEVA, F., FERRUSOLA-PASTANA, A., JÒDAR-PORTAS, A., PRATS-PUIG, A.

ESCOLA UNIVERSITARIA DE LA SALUT I L'ESPORT EUSES-UNIVERSITAT DE GIRONA

INTRODUCTION: Integrated Neuromuscular Training (INT) is defined as an exercise program that integrates strength and general conditioning tasks (e.g., basic motor skills) alongside specific exercises (e.g., agility, dynamic stabilization, coordination, plyometrics). The early application physical exercise intervention such as INT has beneficial effects on reducing the risk of cardiovascular disease and has great anti-inflammatory potential. Saliva presents a non-invasive alternative for detecting inflammatory, metabolic and cardiovascular risk factors in pediatric population. This study aims to explore the impact of an INT intervention on the salivary proteome.

METHODS: Thirty-nine schoolchildren were included in the study [7.53±0.33 years; 56% girls]. Control group (n=16) who followed a standard physical activity protocol for 3 months, and intervention group (n=23), who followed an INT protocol. Salivary proteome analysis was performed by nano HPLC-Orbitrap mass spectrometry (MS/MS). The fragments obtained were compared with UniProt database, allowing the identification proteins from two fragments. Volcano Plot were used to identify relevant and significant changes in protein expression levels (m/z) between groups, control and intervention.

RESULTS: A total 2231 proteins were identified by mass spectrometry. By comparing both groups control versus intervention before and after intervention, a total of 52 proteins presented adjusted p value below 0.05 (p-value (Fold-Change) >0.05), of which 39 proteins having a fold-change above 1.5 (log₂=1.5). From those, 22 proteins were significantly upregulated, and 17 proteins were downregulated. Among them, proteins involved in energy metabolism and cardiovascular risk, such as PFKM, AK1 and OXTC1 showed lower expression levels in the intervention group, along with proteins involved in the inflammatory response, such as NR1P1 and PLA2G4E, which also exhibited lower expression levels in the intervention group.

CONCLUSION: The INT intervention applied in primary schoolchildren is associated with a better cardiovascular and inflammatory profile, highlighting the positive impact of this intervention in schoolchildren. Our findings also demonstrate the utility of saliva to assess the risk for cardio metabolic disease in pediatric populations.

SALIVARY PROTEOMICS INSIGHTS INTO EXERCISE-INDUCED MOLECULAR ADAPTATIONS IN SCHOOL CHILDREN

FERRUSOLA PASTRANA, A., VASILEVA, F., HOMS, J., FONT-LLADÓ, R., LÓPEZ-ROS, V., PRATS-PUIG, A.

EUSES - UNIVERSITAT DE GIRONA

INTRODUCTION: Physical activity induces molecular adaptations detectable at proteomic level across multiple tissues, with skeletal muscle being one of the primary sites for these changes. However, the exploration of proteomic changes in saliva, particularly in school children, remains largely unexplored. This study aims to (1) investigate whether a neuromuscular training intervention elicits changes in the salivary proteome of school children, (2) identify which proteins are altered by the intervention and potentially derived from skeletal muscle and (3) examine if changes in these proteins correlate with physical activity, motor competence, strength, and health parameters.

METHODS: Saliva samples were collected from school children (age 7.7 ± 0.3) who participated in a three-month integrated neuromuscular training programme (INT; n = 23) and from a control group following standard physical education

classes (CON; n = 16). Physical activity levels (minutes per day spent in moderate-to-vigorous physical activity [MVPA]) and daily seated time were measured with a triaxial accelerometer (Actigraph). Motor competence (CAMSA), strength (hand-grip dynamometer) and health markers (blood pressure, body mass index [BMI], fat mass, and muscle mass) were also collected. Proteins were identified and quantified using Orbitrap mass spectrometry, and pathway and process enrichment analysis were performed using Metascape. Statistical analyses were performed using R Statistical Software (v4.4.1; R Core Team 2024).

RESULTS: A total of 2231 salivary proteins were identified. In the INT group, 86 proteins showed a log2 fold change >1 or <-1 (2-fold change expression), compared to 64 in the CON. The INT group had a higher number of proteins involved in enriched biological pathways and higher pathway similarity compared to the CON. The most enriched pathways included endosomal/vacuolar transport, epithelial cell differentiation and energy metabolism. Moreover, the summary of enrichment analysis with Pattern Gene Database (PaGenBase) revealed 6 enriched skeletal muscle-derived proteins (AK1, PFKM, MAPK12, SEMA7A, SPEG, MYH13) in the INT group, whereas none were detected in the CON group. Lower levels of AK1, PFKM, MAPK12, and SEMA71 were detected after the INT, while SPEG levels increased. Correlation analyses revealed negative associations between AK1 levels and BMI ($r_s = -0.41$, $p = .01$), and SEMA7A and grip strength ($r_s = -0.36$, $p = .03$). Additionally, SPEG levels were negatively correlated with daily seated time ($r_s = -0.39$, $p = .02$) but positively correlated with MVPA ($r_s = 0.36$, $p = .03$).

CONCLUSION: These findings suggest that the integrated neuromuscular training induces structured molecular adaptations detectable in saliva at the proteomic level, reinforcing the idea that exercise promotes coordinated molecular changes. Furthermore, the detection of skeletal muscle-related proteins in saliva highlights its potential as a non-invasive biomarker tool for monitoring exercise-related biological responses.

SUBLINGUAL CAFFEINE SPRAY DOES NOT ACCELERATE ABSORPTION, COGNITIVE BENEFITS, OR HEMODYNAMIC EFFECTS COMPARED TO CAFFEINATED BEVERAGES

BURR, J.1, MCCARTHY, D.1,2, STAPLETON, R.2, HANDY, R.3, AMANUAL, S.2, TSOROS, S.1, MILLAR, P.2

1 HUMAN PERFORMANCE & HEALTH RESEARCH LABORATORY, 3DEPARTMENT OF HUMAN HEALTH AND NUTRITIONAL SCIENCES, UNIVERSITY OF GUELPH, GUELPH, ON, CANADA; 2 HUMAN CARDIOVASCULAR PHYSIOLOGY LABORATORY, DEPARTMENT OF HUMAN HEALTH AND NUTRITIONAL SCIENCES, UNIVERSITY OF GUELPH, GUELPH, ON, CANADA; 3 DEPARTMENT OF HUMAN HEALTH AND NUTRITIONAL SCIENCES, UNIVERSITY OF GUELPH, GUELPH, ON, CANADA

INTRODUCTION: Buccal caffeine absorption bypasses digestion, can elicit peak serum caffeine concentration within ~30 min of administration, potentially accelerating cognitive benefits compared to ingestion. Caffeine mouth sprays are commercial products that involve sublingual delivery, but their ability to increase blood caffeine remains largely unknown.

METHODS: This study investigated whether caffeine mouth spray can accelerate the time to peak serum caffeine concentration compared to coffee or an energy drink. Fourteen regular caffeine users (6 males, 8 females; 24 ± 3 years, 69.9 ± 9.3 kg) abstained from caffeine for 16 h, ate a standardized breakfast, then consumed 60 mg of caffeine via either mouth spray, coffee, or energy drink in a randomized, crossover, open-label design (osf.io/m9t3v). Serum caffeine concentration was determined at baseline as well as 5, 10, 20, 30, 45, 60, 75, and 90-min post-caffeine ingestion via commercial enzyme linked immunosorbent assay. Blood pressure was measured via automated oscillometric cuff (BpTRU). At ~30 and ~90 min post-ingestion, cognitive function was assessed via Stroop test and digit symbol substitution task (Inquisit version 6, millisecond, Seattle, USA).

RESULTS: Serum caffeine level increased from baseline in all conditions ($p < 0.0001$) but did not differ between the mouth spray, coffee, and energy drink at any time point (all $p > 0.06$). Caffeine area under the curve was not different after mouth spray, coffee, or energy drink (61 [54-73], 82 [51-119], 68 [43-78] min*mg/L respectively, $p = 0.22$) nor was peak concentration (1.6 [1.2-1.8], 1.9 [1.4-2.4], 1.2 [0.8-3.0] mg/L respectively, $p = 0.19$). Within the mouth spray condition, serum caffeine was higher than baseline from 10 to 90 min ($p < 0.03$) but not at 5 min ($p = 0.50$), and peak concentration occurred 90-min after use. Average response latency per Stroop test (Time $p < 0.0001$) was different at all timepoints (baseline = 667 ± 81 ms, 30 min = 710 ± 89 ms, 90 min = 770 ± 154 ms, $p < 0.02$ for all), but was unaffected by condition ($p = 0.83$) or time*condition ($p = 0.27$). The number of correct responses relative to total responses and total correct responses on the digit symbol substitution task were unaffected by time, condition, or their interaction ($p > 0.22$ for all). Systolic blood pressure (time $p = 0.002$) was higher at 60 and 90 min vs. baseline (baseline: 102 ± 7 , 30-min: 106 ± 7 ; 90-min: 105 ± 8 mmHg, $p < 0.03$ for both), but unaffected by condition ($p = 0.20$) or time*condition ($p = 0.60$). Diastolic blood pressure was 69 ± 7 mmHg at baseline, 69 ± 6 mmHg at 30 min, and 71 ± 7 mmHg at 90 min (time $p = 0.08$, condition $p = 0.32$, time*condition $p = 0.92$).

CONCLUSION: In conclusion, sublingual caffeine administration via mouth spray did not accelerate the time to peak serum caffeine nor induce cognitive benefits compared to caffeinated beverages.

CAFFEINE SUPPLEMENTATION RESCUES REDUCED TRAINING QUALITY DUE TO LCHF DIET BUT CAFFEINE + CARBOHYDRATE IS BEST

BURKE, L., MERRELL, L., HEIKURA, I.A., CIVIL, R., SHARMA, A.P., LECKEY, J.J., MCKAY, A.K.A.

AUSTRALIAN CATHOLIC UNIVERSITY

INTRODUCTION: We have previously shown that training quality was reduced in elite athletes who undertook a low-CHO high-fat diet ketogenic LCHF diet. We wanted to confirm the reduced training metrics associated with such an intervention using an improved methodology, and to investigate whether this could be attenuated with caffeine supplementation. We also wanted to investigate effects of caffeine supplementation on cognitive function after exercise.

METHODS: Tier 3-5 (national to international) level race-walkers ($n=21$) completed 3 weeks of periodized training while adhering to diets of chronic LCHF or high carbohydrate availability (HCHO). During baseline, where all athletes followed HCHO, and then 3 intervention weeks, we monitored training quality and cognitive performance during a weekly tempo session (14 km with a 450 m elevation gain). On weeks 2 and 3, in a randomized crossover allocation, participants received 3 mg/kg caffeine or placebo (gum), 20 min before the session. Race-walking speed, heart rate, RPE, blood metabolites and Stroop word-color test metrics were collected.

RESULTS: Although LCHF athletes walked at a higher percentage of VO_{2max} speed at baseline compared to HCHO ($+3.4\%$, $p = 0.04$), relative speeds during Weeks 2 and 3 were lower (-5.2% ; $p = 0.01$ and -4.4% ; $p = 0.05$, respectively). Hill course completion for LCHF was slower by ~ 7 min (Week 1) to ~ 3 min (Week 3), compared to a 3.5 min improvement (Week 3) from baseline in the HCHO group. Compared to baseline, the 14 km hill session was faster ($p = 0.01$) with caffeine than placebo, without detectable differences in the magnitude of the effect between groups (HCHO: $+2.9\%$, LCHF: $+2.0\%$; $p=0.66$). Post-exercise Stroop metrics were also improved.

CONCLUSION: Caffeine supplementation partially rescued the performance impairment associated with an LCHF diet, but training quality remained lower than the combination of caffeine and high CHO availability.

EFFECT OF CAFFEINE ON FAT OXIDATION RATE DURING A ONE-HOUR OF MOUNTAIN CYCLING AT FATMAX.

RODRÍGUEZ CASTAÑO, A., RODRÍGUEZ-CASTAÑO, A.1, TRUJILLO-COLMENA, D.1, FERNÁNDEZ-SÁNCHEZ, J.1, DEL COSO, J.1, VILLALBA-CARLES, I., COLLADO-MATEO, D.1, SOLANO, V.1, RANIERI, L.1, GARCÍA-ORTIZ, C.1, CASADO, A.1

REY JUAN CARLOS UNIVERSITY

INTRODUCTION: The intake of between 3 and 6 mg/kg of caffeine increases the rate of fat oxidation during moderate-intensity exercise (1). Previous research has been conducted under highly standardized laboratory conditions which are different to real applicable contexts (2). Therefore, the objective of the present study was to determine the effect of caffeine intake on fat oxidation during a 1-h mountain bike session at Fatmax (i.e., the intensity at which maximal fat oxidation occurs). The hypothesis is that caffeine will lead to an increase in fat oxidation rate, as previously observed in laboratory settings (2). **METHODS:** A double-blind, randomized, counterbalanced and crossover experimental design was performed by 11 participants (male, healthy, recreational athletes with cycling experience, $VO_{2max} = 49.1 \pm 9.0$ ml/kg/min). Participants conducted a pre-experimental incremental test on a cycle ergometer to determine VO_{2max} and Fatmax. Cyclists ingested either 3 mg/kg caffeine or a placebo 60 min before completing a 1-h mountain bike test on a trail circuit at Fatmax in which O_2 uptake and CO_2 production was analysed through a portable gas analyzer. The circuit was designed by the research team with the aim of simulating a real mountain bike circuit. The intensity was fixed in both conditions using Global Position System (GPS) data, potentiometer pedals and split times. Statistical Package for Social Sciences software (SPSS, v.25, IBM, United States) was used to conduct the statistical analyses, and t-tests for related samples and two-way repeated measures ANOVA were performed. For the post-hoc analysis, the DMS adjustment factor was used. **RESULTS:** No significant effects of caffeine on the amount of fat oxidized (31.43 ± 14.39 g vs. 28.40 ± 10.81 g; $p = 0.23$), and carbohydrates oxidized (86.05 ± 32.33 g vs. 88.86 ± 42.64 g) were found ($p = 0.26$). Differences between conditions were neither observed in heart rate (131.73 ± 16.8 bpm vs. 132.64 ± 22.60 bpm; $p = 0.74$) nor perceived exertion during the test (9.8 ± 1.83 a.u. vs. 10.32 ± 1.96 a.u.; $p = 0.12$). **CONCLUSION:** In conclusion, caffeine intake had no effect on fat oxidation during a 1-h mountain bike test at Fatmax. The differences observed between these results and those obtained using laboratory cycle ergometers may be related to a reduced metabolic effect of caffeine provoked by the inclusion of an important technical component in the mountain bike test or altered by the different individual responses of participants. Future research with participants of a more homogeneous sport level and including both men and women would be of interest.

GREATER EXERCISE-INDUCED MUSCLE DAMAGE AFTER ECCENTRIC MUSCLE CONTRACTIONS WITH PRE-EXERCISE CAFFEINE SUPPLEMENTATION

MATSUMURA, T., ENDO, K.1, NONOYAMA, S.1, FUKUZAWA, K.1, DORA, K.2,3, KOJIMA, C.3, IEMITSU, M.1, ISAKA, T.1, HASHIMOTO, T.1

RITSUMEIKAN UNIVERSITY

INTRODUCTION: There has been recently growing interest among exercisers and researchers in the use of caffeine prior to resistance exercise as a “pre-workout supplement” and its effects on resistance exercise performance (1,2). This approach is based on the fact that caffeine acutely improves athletic performance, including muscular strength/power output (3). However, the higher eccentric exercise intensity involves the greater exercise-induced muscle damage (EIMD), which is accompanied by a reduction in muscle function and an increase in muscle soreness (4). Therefore, pre-exercise caffeine supplementation would increase EIMD by increasing the eccentric load during resistance exercise through improvements in eccentric contractile performance. We aimed to examine the impact of pre-exercise caffeine supplementation on EIMD after eccentric contractions.

METHODS: Fifteen healthy young males ingested 6 mg/kg of caffeine or placebo in a randomized, double-blind, counter-balanced, crossover design. Participants performed 100 maximal voluntary eccentric knee extensions using a dynamometer 1 h after the ingestion. Eccentric torque throughout the exercise was recorded and torque-time integral (TTI) was calculated as the exercise performance. Maximal voluntary isometric torque (MVIT) and muscle soreness were assessed before and 1, 24, 48 h after the exercise as indirect EIMD markers. Total TTI throughout the exercise task was compared between conditions with paired t test. The TTI in each set of exercise and the indirect EIMD markers were analyzed by two-way repeated ANOVA and paired t test or Wilcoxon signed-rank test (with Benjamini-Hochberg adjustment if necessary) as post hoc comparisons with effect size calculations.

RESULTS: Total TTI was significantly higher with caffeine compared to placebo ($P=0.001$, $g=0.34$). Time course analysis of TTI in each set showed a significant main effect of condition ($P=0.001$) and time ($P=0.018$), but no interaction ($P=0.548$), suggesting that caffeine maintained the improved eccentric contractile performance throughout the exercise. MVITs were significantly lower with caffeine than with placebo 24 h (Placebo: $90.4 \pm 16.5\%$, Caffeine: $78.2 \pm 23.5\%$, $P=0.031$, $g=-0.54$) and 48 h after the exercise (Placebo: $99.5 \pm 14.8\%$, Caffeine: $82.4 \pm 24.1\%$, $P=0.016$, $g=-0.79$). Muscle soreness was higher with caffeine than with placebo 24 h ($P=0.005$, $r=0.72$) and 48 h after the exercise ($P=0.005$, $r=0.73$).

CONCLUSION: Pre-exercise caffeine supplementation increases the EIMD after maximal voluntary eccentric knee extensions, i.e., greater reduction in voluntary torque and increased muscle soreness. Caffeine certainly acts as a “pre-workout supplement” to improve muscular performance during the bout of resistance exercise, but it should be applied to the resistance training with careful consideration for subsequent post-exercise conditioning.

EFFECTS OF CAFFEINE SUPPLEMENTATION AT DIFFERENT DOSES ON VERTICAL JUMP, WINGATE PERFORMANCE, AND 60M SPRINT IN MALE 100M SPRINTERS

MEI, T., LI, J.N., ZHANG, X.F.

BEIJING SPORT UNIVERSITY

INTRODUCTION: Caffeine (CAF) has been widely shown to enhance performance in various sports. However, most existing studies focus on team sports or prolonged repeated sprints, with limited attention given to high-intensity anaerobic exercises, such as sprints. This study aims to investigate the effects of different doses of caffeine supplementation on the performance of 100-meter sprinters, providing practical supplementation strategies for improving sprinter performance.

METHODS: Twenty-one male 100-meter sprinters (age: 20 ± 1.45 years, height: 181 ± 4.87 cm, weight: 74 ± 6.57 kg, 100-meter time: 11 ± 0.24 s) were recruited. A randomized crossover design was used, with three caffeine supplementation trials: placebo group (PLA, 0 mg/kg), CAF3 group (3 mg/kg), and CAF6 group (6 mg/kg), with a one-week washout period between each trial. Participants performed a warm-up 30 minutes after ingesting capsules and then completed a 60-meter sprint test 60 minutes post-ingestion. Performance indicators, including sprint time, reaction time, stride frequency, stride length, and rate of force development (RFD), were recorded. After a 10-minute rest, participants performed a counter-movement jump (CMJ) to measure jump height, followed by a 10-second Wingate test to assess peak power (PP) and mean power (MP). Repeated measures ANOVA was used to analyze all dependent variables, with a significance level set at $P < 0.05$.

RESULTS: The CAF3 and CAF6 groups showed significantly higher vertical jump heights compared to the placebo group (53.9 ± 1.1 , 55.5 ± 1.1 , and 51.4 ± 1.1 cm, respectively, $P < 0.001$). PP and MP were also significantly higher in the caffeine groups compared to the placebo group (PP: 867.4 ± 29.1 , 871.0 ± 24.5 , and 797.7 ± 30.9 W, $P < 0.001$; MP: 400.5 ± 31.7 , 396.7 ± 28.0 , and 282.5 ± 23.6 W, $P < 0.001$). The caffeine groups demonstrated significantly better 60-meter sprint times (7.094 ± 0.037 , 7.042 ± 0.035 , and 7.217 ± 0.044 s, respectively, $P < 0.001$). Reaction time was significantly reduced in the caffeine groups (0.162 ± 0.003 , 0.161 ± 0.003 , and 0.180 ± 0.003 s, $P < 0.001$). No significant differences were observed in stride length or stride frequency across groups (stride length: 1.44 ± 0.02 , 1.44 ± 0.02 , and 1.43 ± 0.02 m, $P = 0.593$; stride

frequency: 4.20 ± 0.05 , 4.32 ± 0.50 , and 4.28 ± 0.04 Hz, $P = 0.449$). The maximum and average RFD values were significantly higher in the caffeine groups compared to the placebo group (maximum RFD: 45.3 ± 0.9 , 50.0 ± 1.2 , and 40.3 ± 1.1 N/kg/s, $P < 0.001$; average RFD: 18.3 ± 0.9 , 20.5 ± 1.0 , and 15.1 ± 0.7 N/kg/s, $P < 0.001$).

CONCLUSION: Pre-exercise caffeine intake significantly improves CMJ, anaerobic capacity, and start performance in sprinters, but has no effect on stride length or stride frequency. There were no differences between 3 mg/kg and 6 mg/kg caffeine in enhancing anaerobic capacity and reaction time. However, 6 mg/kg caffeine is more effective than 3 mg/kg in improving CMJ, start speed, and RFD.

INDIVIDUAL DIFFERENCE IN MOTOR UNIT FIRING RATE MODULATION IS ASSOCIATE WITH BLOOD PRESSURE RESPONSE DURING EARLY PHASE OF EXERCISE IN YOUNG MALE BUT NOT IN FEMALE

TAKEDA, R., NISHIKAWA, T.1, KARAKI, M.1, IGAWA, K.1, OGOH, S.2, WATANABE, K.1

1. CHUKYO UNIVERSITY - TOYOTA CAMPUS, 2. TOYO UNIVERSITY

INTRODUCTION: Blood pressure (BP) response during exercise (Ex) exhibits significant variability, even among young normotensive individuals. One of the key mechanisms regulating BP during Ex is the exercise pressor reflex, which includes the mechanoreflex and metaboreflex. These reflexes are activated by mechanical and chemical stimuli induced by skeletal muscle contraction, which is regulated by motor unit (MU) behavior, particularly MU firing rate (MUFR) modulation. Notably, MUFR decreases in the early phase of Ex and subsequently increases in the later phase, although this pattern varies among individuals. Furthermore, the early phase of the BP response during Ex is primarily associated with the mechanoreflex, while the later phase is influenced by both the mechano- and metabo-reflex. Therefore, individual differences in MUFR modulation may be linked to variations in mechanoreflex-induced BP response during the early phase of Ex, and in mechanoreflex- and/or metaboreflex-induced BP response during the later phase in young normotensive individuals.

METHODS: Fifteen young males and seventeen females performed a 1-minute isometric knee extension Ex at 30% of their maximal voluntary contraction (MVC), followed by post-exercise muscle ischemia (PEMI). Beat-by-beat systolic BP (SBP) was continuously measured, and the slope of the linear regression between baseline and 30 seconds (early phase) and between 30 and 60 seconds (later phase) was analyzed for each individual. The change in mean arterial pressure (Δ MAP) from baseline to PEMI was calculated to assess individual differences in metaboreflex activity. High-density surface electromyography signals recorded during Ex were used to assess MUFR modulation. MUFR was analyzed via the slope of the linear regression between the start of Ex and 30 seconds (early phase) and between 30 and 60 seconds (later phase).

RESULTS: Although previous studies have reported that absolute knee extension torque can affect the BP response during Ex, no significant relationships were observed between MVC and BP response or MUFR modulation during Ex in either males and females ($P = 0.195 - 0.974$). In males, variability in SBP response was significantly associated with MUFR in the early phase of Ex ($P = 0.005$, $r = 0.682$), but not in the later phase ($P = 0.242$). Variability in Δ MAP was not associated with MUFR in both Ex phase ($P = 0.791$ and $P = 0.290$, respectively). However, Δ MAP was significantly associated with SBP response in the later phase ($P = 0.003$, $r = 0.712$). In females, no significant relationships were found between MUFR and BP response.

CONCLUSION: In males, individuals with a smaller decrease in MUFR exhibited a greater increase in the mechanoreflex-induced BP response during the early phase of Ex. In contrast, during the later phase, a greater increase in BP response was associated with higher metaboreflex activity rather than MUFR modulation. No significant relationships were observed in females.

IN-HOME LOW INTENSITY INTERVAL EXERCISE LOWERS SUPINE BLOOD PRESSURE IN PATIENTS WITH RESISTANT HYPERTENSION AND RESTRICTED MOBILITY FOR CLAUDICATION: A SEX-ORIENTED COHORT STUDY

CARUSO, L., PETTENUZZO, E., PIVA, G., CREPALDI, A., GAMBERINI, L., TRAINA, L., MANFREDINI, F., LAMBERTI, N.

UNIVERSITY OF FERRARA

INTRODUCTION: This observational cohort study aimed to assess overall and sex-dependent variations in office blood pressure measurements (OBPM) in a cohort of patients affected by intermittent claudication (IC) and resistant hypertension (RH) enrolled in an in-home low intensity interval walking program.

METHODS: From a cohort of 1205 patients with IC consecutively enrolled between 2011 and 2023, those with RH were included. All patients performed the in-home Test in-Train out pain-free walking program [1] composed of eight bouts of 1:1 interval walk:rest ratio at a prescribed speed, weekly increased from approximately 60 to 100% of habitual gait speed. The exercise program was updated during three intermediate visits and lasted for approximately 6 months. The OBPM were collected at baseline (T0), at circa-monthly visits (T1, T2, T3) and at the end of the program (T4) by the same medical doctor with the patient laying in supine position for at least 5 minutes. Variations in drug therapy were also collected.

RESULTS: A total of 220 patients were affected by RH (aged 73 ± 9 years; 170 males). All patients completed the exercise program (session completed $84 \pm 11\%$) without adverse events. Fourteen patients underwent changes in drug therapy during the follow up and were excluded. The remaining 206 patients presented a progressive decline of systolic blood pressure (SBP) ($t = -7.11$; $p < 0.001$) from T0 to T4 with a mean decrease of -10 ± 8 mmHg (from 159 ± 17 to -149 ± 17 mmHg) and of diastolic pressure of -1 ± 5 mmHg.

The repeated-measure analysis of variance excluded a significant sex per time interaction for both SBP ($p = 0.28$) and DBP ($p = 0.44$). In particular, women exhibited a significant decrease ($p < 0.001$) in SPB from 162 ± 17 to 152 ± 16 mmHg; $p < 0.001$) comparable to men (from 156 ± 16 to 146 ± 17 mmHg; $p < 0.001$).

CONCLUSION: In a population at high cardiovascular risk with claudication and RH, a low volume of structured low-intensity home-based exercise improved blood pressure control in both women and men, representing a favourable adjuvant to pharmacological therapy.

THE EFFECT OF A NOVEL 8-WEEK MULTI-EXERCISE, HOME-BASED ISOMETRIC RESISTANCE TRAINING PROGRAMME ON RESTING AND AMBULATORY BLOOD PRESSURE IN PRE- AND HYPERTENSIVE ADULTS

WRIGHT, B., ANTROBUS, M., JONES, P., BAROSS, A.
OXFORD BROOKES UNIVERSITY

INTRODUCTION: Isometric resistance training (IRT) is an alternative, time-efficient approach to hypertension management [1]. Yet established methods have restricted exercise variability and present participation barriers, including access to and cost of specialised non-portable equipment [2]. A novel cost-effective isometric training band (ITB) has safely demonstrated significant blood pressure (BP) reductions [3]. However, efficacy in pre- and hypertensive adults in unsupervised environments is yet to be established. Therefore, the present study compared the effects of an 8-week, home-based multi-exercise ITB intervention to volume matched isometric handgrip (IHG) on resting, and ambulatory blood pressure in pre- and hypertensive adults.

METHODS: Using a parallel randomised control trial, thirty-eight pre-hypertensive ($n = 17$, sBP 135 ± 1 mmHg) and stage 1 hypertensive ($n = 21$, 147 ± 6 mmHg) adults were recruited into a control (CON, $n = 13$), IHG ($n = 13$) or ITB ($n = 12$) group. Resting systolic (sBP), diastolic (dBP), mean arterial pressure (mBP), heart rate (HR) and ambulatory BP (24-hour, daytime, night-time) were measured at baseline and following 4, and 8 weeks of unsupervised home-based IRT (4 x 2-min bouts, 3x week). Data were analysed using factorial ANOVAs (time [pre-, mid- and post-testing] x group [CON, ITB, and IHG]) to examine any significant within and between group differences, with post-hoc effect sizes calculated using Cohen's d .

RESULTS: After 4 weeks resting sBP significantly reduced in the IHG (10.2 ± 4.1 mmHg, $d = -1.63$) but not in the ITB group (1.8 ± 4.1 mmHg, $d = -0.56$). Following 8 weeks resting sBP significantly decreased for both training groups (ITB: 9.0 ± 3.2 mmHg, $d = -1.36$; IHG: 12.0 ± 3.1 mmHg, $d = -1.48$) compared to CON, although not significant between training groups (2.3 ± 3.2 mmHg, $d = 0.32$). Comparably, significant reductions in 24-hour (ITB: 7.6 ± 1.5 mmHg, $d = 1.42$; IHG: 6.9 ± 1.5 mmHg, $d = 1.33$), daytime (ITB: 7.3 ± 1.6 mmHg, $d = 1.33$; IHG: 6.3 ± 1.5 mmHg, $d = 1.21$), and night-time sBP (ITB: 8.5 ± 1.7 mmHg, $d = 1.39$; IHG: 8.8 ± 2.1 mmHg, $d = 1.38$) occurred for both training groups after 8 weeks. Whereas reductions in 24-hour (6.2 ± 1.4 mmHg, $d = 1.2$) and daytime mBP (6.7 ± 2.5 mmHg, $d = 1.16$) occurred in the ITB group only. No significant decreases in resting or ambulatory dBP or HR occurred for either group.

CONCLUSION: The BP reductions in both training groups provide further evidence for the efficacy of IRT, however, results suggest the onset of effects may vary depending on modality. Importantly, the equivalent sBP reductions between training groups at 8 weeks highlight the potential of the ITB as a versatile, cost-effective, and accessible approach to IRT for BP management in pre- and hypertensive populations.

EXAMINATION OF THE DOSE-DEPENDENT EFFECTS OF ISOMETRIC RESISTANCE TRAINING ON DECREASES IN BLOOD PRESSURE IN PRE- AND HYPERTENSIVE ADULTS

BAROSS, T., BAXTER, B., CLARKE, A., SIMPSON, R., WRIGHT, B.
UNIVERSITY OF NORTHAMPTON

INTRODUCTION: Hypertension, a major risk factor for cardiovascular disease is near pandemic levels [1] with approximately 1.6 billion adults diagnosed worldwide [2]. Isometric resistance training (IRT) commonly performed thrice weekly (4 x 2-min contractions) is an established efficacious nonpharmacological intervention for the prevention and treatment of hypertension. A significant barrier to therapeutic exercise is time to undertake the intervention and despite the observed benefits, adherence and compliance remains low [3]. Whilst three times per week is the most commonly applied protocol there is no evidence to confirm that it is the most efficacious. Therefore, the study aim was to determine if a reduction in the weekly dose of IRT, would produce similar hypotensive responses to those reported with the more commonly used protocol.

METHODS: Thirty pre- and hypertensive individuals (Female, $n = 16$, age = 53 ± 9 yr; systolic blood pressure [SBP] range 133 – 161 mmHg; Male, $n = 14$, age = 52 ± 8 yr; SBP range 132 – 150 mmHg) were randomly assigned to perform IRT, once (IRT×1, $n = 10$), twice (IRT×2, $n = 10$), or thrice weekly (IRT×3, $n = 10$). Each training session consisted of 4 × 2-min contractions (upper, lower and whole body) at a perceived exertion (CR-10) of 4-5, with 2-min rest periods [4]. Resting and ambulatory blood pressure (BP; 24-hr, daytime, night-time) were measured prior to, at the mid-point and after a 10-week training period. A factorial ANOVA (time; pre-, mid- and post-training × group; IRT×1IRT×2, and IRT×3) was used to determine significant within- and between group differences, with post-hoc analyses undertaken using a Bonferroni correction.

RESULTS: Significant reductions in resting SBP were evident over time for both IRT×2 (mid-post, 5 ± 5 mmHg; $p = 0.007$, $d = 1.01$; pre-post, 9 ± 16 mmHg, $p = 0.017$, $d = 0.55$) and IRT×3 (mid-post, 5 ± 3 mmHg; $p = 0.008$, $d = 1.80$; pre-post, 9 ± 5 mmHg, $p = 0.016$, $d = 1.82$). Similarly, 24-hr SBP also significantly decreased in IRT×2 (mid-post, 8 ± 6 mmHg; $p = 0.003$, $d = 0.82$; pre-post, 7 ± 3 mmHg, $p = 0.023$, $d = 1.66$) and IRT×3 (mid-post, 6 ± 2 mmHg; $p = 0.020$, $d = 2.78$; pre-post, 8 ± 4 mmHg, $p = 0.010$, $d = 1.73$). There were no significant between-group differences at any time points ($p > 0.05$).

CONCLUSION: Both the twice and thrice weekly training protocols were identified as efficacious therapeutic exercise interventions to lower both resting and ambulatory SBP, which did not differ between groups at all three time points. The larger effects evidenced in IRT×3 resting and 24-h SBP indicate that thrice weekly training is the optimal for reducing BP, however twice weekly training can still reduce BP whilst overcoming time-related barriers.

ACUTE EFFECTS OF HIGH-INTENSITY INTERVAL EXERCISE IN HYPOXIA VS. NORMOXIA ON POST-EXERCISE OXYGEN CONSUMPTION AND LIPID OXIDATION IN INDIVIDUALS WITH OVERWEIGHT OR OBESITY: PRELIMINARY INSIGHTS.

COUVERT, A., RANCE, M., SORG, M., GUILLEMIN, F.G., CHOMARAT, C., LE NY, E., DONNADIEU, V., LASSEIGNE, L., DECASTER, A., BOISSEAU, N.

UNIVERSITÉ CLERMONT AUVERGNE

INTRODUCTION: High-intensity interval training (HIIT) effectively reduces fat mass (FM), including abdominal and visceral FM (1). Recent studies demonstrate that performing HIIT in hypoxia, compared to normoxia, enhances total and abdominal FM loss in individuals with overweight or obesity (2,3). However, the mechanisms underlying these body composition changes remain to be elucidated. This study therefore aimed to compare the acute effects of high-intensity interval exercise (HIIIE) performed in hypoxia versus normoxia on oxygen consumption (VO_2) and lipid oxidation during the first two hours of recovery in normoxia.

METHODS: Seven fasted participants (67 ± 3 years; body mass index: $31 \pm 5 \text{ kg}\cdot\text{m}^{-2}$) completed two HIIIE sessions (normoxia vs. hypoxia) on a cycle ergometer (WattBike). The first session was conducted under normoxia and consisted of 60 repetitions of (8s at 80-85% HRMax + 12s deceleration), with power output recorded. In the second session, performed under hypoxia, participants completed the same HIIIE while maintaining the same power output as in normoxia, ensuring that both sessions were matched for external load. Each session began with a 20-minute pre-exercise metabolic assessment, followed by a 10-minute standardized warm-up under normoxic conditions. HIIIE was then performed either in normoxia (normobaric room, 21% O_2) or hypoxia (normobaric room, 15% O_2). The 2-hour post-exercise recovery took place under normoxic conditions. Heart rate (HR) and rate of perceived exertion (RPE) were recorded throughout exercise. VO_2 and VCO_2 were measured, allowing for the calculation of the respiratory exchange ratio (RER) and energy expenditure (EE) before, during, and for two hours post-exercise in normoxia. Substrate oxidation ($\text{g}\cdot\text{min}^{-1}$) was calculated during the recovery period.

RESULTS: Both normoxic and hypoxic sessions induced similar mean HR ($p = 0.24$), VO_2 ($p = 0.31$), EE ($p = 0.24$), RER ($p = 0.49$), and RPE ($p = 0.67$) responses during exercise. Mean VO_2 ($\text{L}\cdot\text{min}^{-1}$) was higher during the 2-hour recovery period than before exercise in both conditions ($p = 0.02$), with no session effect ($p = 0.50$). While 2-hour recovery EE did not differ between normoxic and hypoxic conditions ($p = 0.50$), lipid oxidation tended to be higher after HIIIE performed in hypoxia ($p = 0.06$).

CONCLUSION: These preliminary findings suggest that performing HIIIE under hypoxic conditions may promote greater lipid oxidation during recovery compared to normoxia, despite similar energy expenditure. However, these results should be interpreted with caution and require confirmation with the full sample ($n=15$).

THE EFFECTS OF INTERMITTENT HYPOXIC TRAINING STRATEGIES ON MAXIMAL OXYGEN UPTAKE: A META-ANALYSIS WITH META-REGRESSION

KOHLBRENNER, D., GHAITH, A., KHOURI, CH., FOURNIER, J., CHACAROUN, S., ROBACH, P., MENDELSON, M., FLORE, P., MARILLIER, M., BRUGNIAUX, J., PÉPIN, J.L., TAMISIER, R., VERGES, S.

GRENOBLE ALPES UNIVERSITY

INTRODUCTION: Intermittent hypoxic training aims to enhance exercise performance and health, commonly expressed as maximal oxygen uptake (VO₂max). Currently applied methods are live-high train-low (LHTL), live-low train-high (LLTH), and passive hypoxic conditioning (PHC). Despite a substantial amount of studies published on the topic, no consensus exists on which method is effective in augmenting VO₂max. In addition, factors (i.e., hypoxic dose, exposure times) driving development of VO₂max most effectively are unknown. This work aimed to determine the effect of LHTL, LLTH, and PHC on VO₂max in healthy participants, and identifying factors associated with the amplitude of change in VO₂max.

METHODS: We conducted a systematic review with random-effects meta-analysis and meta-regression. Studies were identified through PubMed, EMBASE, and Web of Science. We included controlled and uncontrolled studies, calculating weighted within-group mean changes and between-group standardised mean differences. Athlete and non-athlete populations were analysed separately.

RESULTS: Of the 13248 identified studies, 147 were included for analysis, resulting in a sample size of 2668 participants. Of these participants, 1449 were considered athletes and 1219 were considered non-athletes. Meta-analyses indicated that LHTL (athletes: MD = 0.72; 95%CI = -0.23, 1.68; non-athletes: 1.06; -0.31, 2.43) and PHC (athletes: -0.54; -1.69, 0.61; non-athletes: 0.60; -0.75, 1.94) did not increase VO₂max significantly more than control. LLTH did increase VO₂max significantly more than control, both in athletes (1.17; 0.29, 2.05) and non-athletes (1.38; 0.61, 2.15). Multivariate meta-regression of all studies identified sample size to be significantly associated to the change in VO₂max (B = -0.15; 95%CI = -0.25, -0.05). The risk of bias in the included studies was substantial. We did not find evidence for publication bias.

CONCLUSION: LLTH showed a significant effect on VO₂max in both athletic and non-athletic populations, while LHTL and PHC did not. Although a considerable number of studies on intermittent hypoxic training strategies exists, high-quality placebo-controlled trials are still warranted for definite conclusions. Further, future studies should target investigating which characteristics (i.e., length and magnitude of exposure) of the hypoxic exposure are most beneficial.

UNRAVELLING THE IMPACT OF EXERCISE TIMING ON GLYCAEMIC CONTROL: A RANDOMISED CONTROLLED TRIAL

BRUGGISSER, F., INFANGER, D., HANSEN, H., KNAIER, R.

UNIVERSITY BASEL

INTRODUCTION: Impaired glycaemic control is a major risk factor for cardiovascular disease, the leading cause of death worldwide. Increasing physical activity is a key strategy to improve glycaemic control. The circadian system influences glucose metabolism, causing 24-hour fluctuations in plasma glucose with a peak later in the day. Metabolic responses may vary depending on the time of day during which exercise is performed. Evidence of diurnal variations in physical performance, combined with the timing of behaviours such as sleep and diet, suggests that the timing of exercise may influence adaptations and health outcomes. This study aimed to investigate the impact of exercise timing on glycaemic control and optimise metabolic health strategies.

METHODS: Sixty non-diabetic adults (36% female, mean [standard deviation] age 68 [6] years, BMI 24.1 [2.7] kg/m²) participated in this double-blind, randomised controlled trial. Participants were assigned to exercise at 8:00, 12:00, 16:00 or 20:00 (E-08, E-12, E-16, E-20) for 12 weeks, performing two strength and one endurance session weekly. A two-hour oral glucose tolerance test was performed before and after the intervention following an overnight fast. Serum glucose was measured at fasting and 10, 20, 30, 60, 90 and 120 min after ingestion of 75g dextrose. Glucose response was quantified as area under the curve (AUC) using the trapezoidal method. Treatment effects over time were analysed using analysis of covariance with estimated marginal means, adjusted for sex, age, lean mass and fat mass. Effect sizes were standardised using baseline standard deviations.

RESULTS: Fifty-two participants were analysed (E-08: n=14, E-12: n=15, E-16: n=7, E-20: n=16), with most dropouts due to missing more than two serum glucose values. Exercise adherence was excellent with 93% of all sessions completed. AUC decreased more in the E-16 group than in the others, with effect sizes being E-08: -0.21 (-0.68 to 1.10), E-12: -0.29 (-0.56 to 1.15) and E-20: -0.30 (-1.15 to 0.54), all considered small. Negative effect sizes, indicating a reduction in AUC, are considered beneficial for metabolic health. However, there was considerable uncertainty about these effects. Comparisons between the remaining groups showed negligible effect sizes (< 0.10).

CONCLUSION: The timing of exercise appears to influence metabolic adaptations, with different patterns observed between exercise groups. The results suggest that exercising at a time of day when glucose metabolism is less efficient (e.g. E-16) may lead to greater adaptations. However, the wide confidence intervals indicate considerable uncertainty in these results. Further research is needed to improve our understanding of the underlying metabolic mechanisms and to provide a scientific basis for integrating exercise timing into health and metabolic management strategies.

OP-MH36 Respiratory Disease

DECREASED MUSCLE OXYGEN SUPPLY AND EARLY FATIGUE DURING EXERCISE IN PATIENTS WITH SEVERE COPD AND HEALTHY INDIVIDUALS

GUTIERREZ, S., MIRANDA, C., VALDES, O., JALÓN, M., MENDOZA, L., PEÑAILILLO, L.
UNIVERSITY ANDRÉS BELLO

INTRODUCTION: Chronic obstructive pulmonary disease (COPD) is a leading cause of death worldwide, with muscle dysfunction in the lower limbs being a significant extrapulmonary manifestation (1). Muscle dysfunction is characterized by loss of muscle mass and function, resulting in limited exercise capacity and reduced quality of life. Systemic inflammation and oxidative stress are common manifestations of COPD and could impair muscle energy metabolism and oxygen utilization (2). These factors compromise oxygen delivery to muscles during exercise, affecting exercise performance in patients. In COPD patients, these factors likely contribute to early fatigue and reduced maximal aerobic capacity. Near-infrared spectroscopy (NIRS) provides a non-invasive method to assess muscle oxygenation in real time, offering insight into oxygen supply and utilization during exercise (3). This study aimed to compare muscle oxygen supply and uptake during a submaximal time to exhaustion (TTE) cycling test in COPD patients and healthy individuals.

METHODS: A cross-sectional observational study compared 12 healthy individuals (64 ± 6.7 years and FEV1 $104.67\% \pm 7.63$) and 12 patients with severe COPD (65 ± 5.3 years and FEV1 $40.67\% \pm 15.67$). Maximal aerobic capacity ($\text{VO}_{2\text{peak}}$) and power output (POMax) were measured using an incremental cycling test. The time-to-exhaustion (TTE) test was assessed with a constant-load test at 70% of the POMax . During TTE, muscle oxygenation was measured using NIRS in the vastus medialis, which assesses the concentration of total hemoglobin plus the concentration of myoglobin (tHbMb) in the muscle in real time and the percentage of muscle oxygen saturation (SmO_2). Furthermore, deoxyhemoglobin (HHb) was calculated as the tHbMb multiplied by the SmO_2 fraction. The area under the curve (AUC) of the variables SmO_2 , tHbMb, and HHb over time of TTE was calculated to represent the cumulative response. Additionally, heart rate, peripheral oxygen saturation (SpO_2), and perceived exertion (Borg's scale) were recorded during TTE. Data analysis was performed in RStudio using Student's t-test and analysis of variance (ANOVA).

RESULTS: COPD patients show a 29.1% lesser $\text{VO}_{2\text{peak}}$ ($p=0.02$) compared to healthy individuals. COPD patients performed 43.6% lesser time in the TTE than healthy individuals. The AUC during exercise time in TTE of HHb was 44.9% ($p=0.04$) lower in COPD patients, likely due to the significantly shorter TTE duration ($p<0.01$). The SmO_2 was similar (56.4% vs 51.2%, respectively) between groups ($p=0.28$). However, SmO_2 at 10% of the total time was 15% lower ($p = 0.02$) in healthy individuals than COPD, indicating reduced muscle oxygen uptake. The tHbMb increased similarly in both groups ($p=0.94$), reflecting comparable vascular responses.

CONCLUSION: This suggests that COPD patients have a reduced capacity to sustain submaximal effort, potentially due to lesser maximal oxidative capacity and impaired muscle oxygen delivery and utilization during exercise, which may lead to early fatigue.

EFFECT OF ADDING NEUROMUSCULAR ELECTRICAL STIMULATION TRAINING TO PULMONARY REHABILITATION IN PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE: RANDOMIZED CLINICAL TRIAL

TRABELSI, Y., TABKA, O., MEKKI, M., PAILLARD, T., ZAOUALI, M.
SOUSSE FACULTY OF MEDICINE

INTRODUCTION: Numerous studies have demonstrated postural balance impairments in patients with chronic obstructive pulmonary disease (COPD). To address this, pulmonary rehabilitation (PR) has been recommended, either alone or combined with traditional muscle-strengthening exercises. However, no study has explored the use of electrostimulation (ES) to improve postural balance in COPD patients. This study aims to assess the effectiveness of neuromuscular electrical stimulation (NMES) combined with pulmonary rehabilitation in enhancing walking tolerance and balance in COPD patients.

METHODS: Forty-five COPD patients were randomly assigned to either an intervention group ($n = 25$) or a control group ($n = 20$). The intervention group received neuromuscular electrical stimulation in addition to pulmonary rehabilitation, while the control group received only pulmonary rehabilitation, both three times per week over six months. Assessments were performed at baseline and after six months using a stabilometric platform, the Timed Up and Go test, the Berg Balance Scale, the 6-minute walking test, and maximal voluntary contraction measurements.

RESULTS: The intervention group showed significant improvements in exercise tolerance, with a greater distance walked on the 6-minute walking test (619.5 ± 39.6 m) compared to the control group (576.3 ± 31.5 m). The intervention group also demonstrated significant improvements in the Timed Up and Go test, the Berg Balance Scale, and maximal voluntary contraction ($P = 0.02$, $P = 0.01$, $P = 0.0002$, respectively). Additionally, there were significant improvements in the center of pressure (COP) in both mediolateral and anteroposterior directions, as well as in the COP area, with both eyes open and closed, in the intervention group compared to the control group ($P < 0.001$).

CONCLUSION: The use of neuromuscular electrical stimulation of lower-limb muscles added to pulmonary rehabilitation is more effective in improving walking tolerance and generating a better control of postural balance for patients with COPD than pulmonary rehabilitation alone. These findings may assist clinicians in designing more effective rehabilitation programs for patients with COPD.

GLOBAL HOTSPOTS AND TRENDS OF EXERCISE PRESCRIPTIONS FOR CHRONIC OBSTRUCTIVE PULMONARY DISEASE FROM 2000 TO 2024

FU, T., LIU, H.

HENAN UNIVERSITY

INTRODUCTION: Chronic obstructive pulmonary disease (COPD), a progressive respiratory disorder marked by irreversible airflow limitation and dyspnea, significantly reduces life quality and imposes global health burdens. Its clinical progression spans early symptoms (chronic cough, sputum production), intermediate-stage dyspnea, and advanced systemic manifestations (cyanosis, cardiopulmonary dysfunction), with mortality rates ranking third worldwide. While exercise interventions improve lung function, cardiovascular health, and psychological well-being in COPD patients, debates persist regarding optimal exercise modalities, intensity thresholds, and long-term efficacy. Excessive exertion may exacerbate dyspnea, cardiopulmonary strain, and muscle fatigue, underscoring the need for evidence-based exercise prescriptions. This study employs bibliometric analysis (2000–2024) to map global research trends in COPD exercise interventions, examining publication patterns, collaborative networks, and thematic evolution. By identifying knowledge gaps and fostering interdisciplinary collaboration, we aim to optimize exercise strategies for COPD management.

METHODS: We searched the Web of Science Core Collection database for literature related to COPD exercise prescriptions. The manual screening criteria applied were as follows: date range, January 01, 2000, to June 01, 2024; language, English; article type, article and review article. Finally, 738 articles were included in this study. CiteSpace, VOSviewer, and Bibliometrix R-package software were used to analyze the literature.

RESULTS: Research output in the field of exercise prescriptions for COPD can be divided into four phases: the exploratory period (2000–2008), surge period (2009–2016), exponential growth phase (2017–2020), and fluctuation period (2021–2024). The US leads the world in terms of the total number of publications, while BMJ OPEN from the UK has the highest number of publications. The longest-standing research topic is dyspnea, and airflow limitation has been identified as the core issue in this field. Anxiety, oxidative stress, inflammation, and dynamic pulmonary hyperinflation are practical challenges facing this domain. Respiratory pattern training, including diaphragmatic breathing, Pilates breathing, unidirectional breathing, pursed-lip breathing, and paced breathing, constitutes the primary exercise prescription for patients with COPD.

CONCLUSION: The number of publications on COPD has grown rapidly. Key research areas include quality of life, dyspnea, lung rehabilitation, and lung capacity. Future research directions include exercise prescription, resistance training, muscle function, anxiety, evaluating intervention effects, and optimizing respiratory patterns. Future studies should prioritize macro-level integrated exercise prescriptions highlighting multiple types of exercise and micro-level specifications of resistance training intensity, density, frequency, and period.

THE ROLE OF HIGH-INTENSITY INTERVAL TRAINING IN REDUCING LUNG INFLAMMATION AND APOPTOSIS FOLLOWING RENAL ISCHEMIA-REPERFUSION INJURY

TANG, C., LAI, C., LEE, I., CHEN, J., YU, C.

UNIVERSITY OF TAIPEI

INTRODUCTION: Renal ischemia-reperfusion (I/R) injury is a common complication in kidney, cardiac, and vascular surgeries (1). Acute kidney injury (AKI) has been linked to damage in distant organs, including the heart, lungs, liver, and brain, contributing to its high mortality rate (2). Previous studies show that a four-week high-intensity interval training (HIIT) program can reduce renal I/R injury and protect the heart. With HIIT gaining popularity for its time efficiency, fat loss, and health benefits (3), this study examines whether HIIT can also alleviate lung injury from renal I/R, potentially informing future exercise prescriptions for health promotion.

METHODS: Thirty male Sprague-Dawley rats were assigned to three groups: Sham, Renal I/R, and HIIT. The Sham group underwent abdominal opening without further intervention, while the other two groups underwent 60-minute renal artery occlusion followed by 24-hour reperfusion. Lung injury was assessed using the wet-to-dry weight ratio and concentrations of tumor necrosis factor- α (TNF- α), interleukin-1 β (IL-1 β), and interleukin-6 (IL-6) in bronchoalveolar lavage fluid (BALF). Serum TNF- α concentrations were measured using enzyme-linked immunosorbent assay (ELISA). Lung tissues were analyzed via hematoxylin and eosin (HE) staining to assess histological damage and terminal deoxynucleotidyl transferase dUTP nick-end labeling (TUNEL) staining to evaluate apoptosis.

RESULTS: The Renal I/R group exhibited increased lung histological damage, a higher wet-to-dry weight ratio, and enhanced apoptosis. TNF- α , IL-1 β , and IL-6 concentrations were elevated in both serum and BALF, along with increased TNF- α expression in lung tissue. In contrast, serum and BALF IL-10 concentrations were reduced. HIIT intervention alleviated lung histological damage, reduced the wet-to-dry weight ratio, and inhibited apoptosis. Additionally, it mitigated the elevation of TNF- α , IL-1 β , and IL-6 concentrations while attenuating the reduction of IL-10. Western blot analysis showed an upregulation of B-cell lymphoma 2 (Bcl-2) and a downregulation of Bcl-2-associated X protein (Bax) in lung tissue, suggesting enhanced anti-apoptotic signaling.

CONCLUSION: A four-week HIIT intervention significantly reduced renal I/R-induced lung injury, likely by modulating inflammatory cytokine production and inhibiting apoptosis. Given its efficiency and accessibility, HIIT may be a cost-effective strategy for disease prevention. Its potential lung-protective effects suggest benefits for pulmonary resilience and reduced risk of inflammation- or oxidative stress-induced lung injury. Further studies are needed to explore its broader implications for respiratory health, particularly in conditions linked to lung inflammation or ischemic injury.

OUR BRAIN IN TIME: WHAT ARE THE TIME DEPENDENCIES OF THE EFFECTS OF PHYSICAL ACTIVITY ON COGNITIVE PERFORMANCE?

RONCA, F.

KINGSTON UNIVERSITY

It has long been established that physical activity has a positive impact on brain health. As the field of Exercise & Neuroscience develops, it is important to determine how the elements of time may impact such effects in order to support effective interventions and tailored recommendations in this context. Over the past years, our lab has investigated the effects of age, development, time of day and exercise duration on diverse aspects of mental health and cognitive function. We have identified strong effects of chronotype and time of day on executive function and mood, where the beneficial effects of physical activity on the brain may be time-dependent. Equally, we have queried how long do such effects truly last through naturalistic studies with school children, university students and adult shift workers. This talk will embark on a discovery journey, starting from the effects of age on the development of executive function, slowly unpacking how biological clocks, time of day, exercise duration and intensity may all contribute to our optimal brain performance.

(PASSIVE) EXERCISE NEUROSCIENCE: REALISING UNTAPPED POTENTIAL TO SUPPORT COGNITION

TARI, B.

UNIVERSITY OF OXFORD

Regular active exercise (i.e., volitional aerobic/resistance exercise) has numerous health benefits, including, but not limited to, improved functional abilities (e.g., mobility), reduced risk of developing disease, and improved brain health and cognitive performance. However, some individuals (e.g., those with spinal cord injuries, cardiorespiratory disease, and/or movement impairments) may not be able to tolerate regular exercise sessions. This is salient because it is these individuals who suffer from the highest rates of cognitive impairment and may derive the greatest benefit from exercise interventions. Accordingly, an alternative to a traditional "active" exercise intervention is passive exercise. Passive exercise entails movement of the limbs via an external mechanical force and thus does not require volitional muscle control. The majority of research surrounding passive exercise describes its benefits in the context of physical rehabilitation; however, promising initial results hint at its utility to also support brain health and cognition. In particular, passive exercise has been shown to support cognitive function immediately following exercise cessation, and this benefit persists for nearly 30 mins. As well, previous work has demonstrated that passive exercise buffers the negative effects of mental fatigue, and simultaneously supports cognitive function. Accordingly, potential exists for this modality to support cognitive and overall health in additional contexts. This discussion will aim to expand on this potential.

ACUTE EXERCISE AND COGNITIVE PERFORMANCE: NEUROMODULATORY ROLE OF DOPAMINE

ANDO, S.

UNIVERSITY OF ELECTRO-COMMUNICATIONS

It is well established that physical activity, or regular habitual exercise, has beneficial effects on a broad array of cognitive functions. A large body of evidence also indicates that acute physical exercise at low to moderate intensity improves cognitive performance, demonstrated by a reduction in reaction time (RT). Decades of research has explored the physiological mechanisms underlying RT improvement induced by acute exercise including, but not limited to, neurochemicals, neurotrophins, cerebral blood flow, and cerebral metabolism. However, the mechanistic understanding of how this occurs is elusive and has not been rigorously investigated in humans. Using positron emission tomography (PET) with [¹¹C]raclopride, we have shown that acute exercise releases endogenous dopamine (DA) in the brain, and that endogenous DA release was correlated with improvements in RT of the Go/No-Go task. A critical step toward understanding how and why acute exercise improves RT is to identify what triggers RT improvement. Follow-up electrical muscle stimulation (EMS) studies demonstrated that EMS with moderate arm cranking improved RT, but RT was not improved following EMS alone or EMS combined with no load arm cranking. The novel mechanistic findings from these experiments suggest that endogenous DA is an important neuromodulator for RT improvement. Additional electrical muscle stimulation studies demonstrated that peripherally driven muscle contractions were insufficient to improve RT. Our novel findings extend our mechanistic understanding of neuromodulation in the human brain following acute physical exercise. The present findings are also likely to contribute to exercise prescription for neurological diseases as the DA systems are important to the

aetiology of neurobehavioural disorders including Parkinson's disease, attention deficit hyperactivity disorder, and schizophrenia.

OP-AP09 Training and Testing I - Running

TRAINING ADAPTATIONS BY REPEATING 2000 M OR 10X200 M DISTANCES AT RUNNING

USAJ, A.

UNIVERSITY OF LJUBLJANA, FACULTY OF SPORT

INTRODUCTION: Alterations in exercise performance follow the fluctuations in training characteristics in a complex and dynamic way. The aim of this study was to make a step towards a better determination of whether the different fluctuations in training velocities of short continuous or high-intensity interval running training are reflected in the adaptations achieved during repeated maximal and submaximal tests.

METHODS: Two groups of 9 and 10 recreational runners took part in a period of 20 training sessions in 5 weeks, consisting of: 2000 m runs (CR) or 10x200 m high-intensity interval training with 2-minute walking recoveries (HIIT). The training period was divided into phases based on the fluctuations in running velocities according to individual daily performance. Each training phase was characterised by its initial running velocity, the slope coefficient of the linear fit of the time course of the running velocities and the average sum of squared residuals calculated as the differences between the values from the linear fit and the actual running velocities. Adaptations were determined using the velocities of the maximal 2000 m trials (v_{2000}) before and after the training period and by submaximal 2x1000 m tests on the treadmill in each training phase, at the same velocity as the first 2000 m trial. During these tests, the gas exchange and the acid-base characteristics of the blood were measured. Repeated comparisons between the measured data for each phase and training method were analysed using repeated measures ANOVA or paired t-test. Both were set to $p < 0.05$.

RESULTS: The velocities of both training methods showed two phases, which were separated in CR and HIIT after about 10 training sessions. CR running velocity increased by 8% during the training period ($F=16.672$; $p > 0.001$, power=0.998). Differently, HIIT running velocity increased by 6% only in the first phase ($F=11.023$; $p > 0.01$; power=0.972) and remained stable until the end. CR increased maximal performance estimated by v_{2000} by 3% ($p=0.04$, power=0.52), while HIIT increased v_{2000} by 4% ($p=0.003$, power=0.909). During the submaximal 2x1000 m test, CR training lowered [LA] by approximately 21% ($F=7.717$; $p=0.005$; power=0.836), increased blood pH by 4% ($F=3.781$, $p=0.045$, power=0.462) and lowered Vo_2 by approximately 6% ($F=7.532$; $p=0.005$; power=0.85). HIIT had no effect on [LA] or pH, but decreased submaximal Vo_2 by 5% ($F=3.612$; $p=0.039$; power=0.474), but only in the first phase.

CONCLUSION: Both training methods influenced performance and other adaptations in different phases, which requires a more time sensitive testing design in the future. The decreased [LA] and increased blood pH during the submaximal test as an effect of the CR method could indicate effects on lactate metabolism, while the decrease in Vo_2 with both methods could indicate possible effects on running economy, but not with both methods simultaneously.

THE REPEATABILITY AND EFFICACY OF COMBINING FIXED-RATE AND SELF-PACED EXERCISE TO INDUCE THERMO-PHYSIOLOGICAL AND PERCEPTUAL STRAIN IN TRAINED RUNNERS

HOFFMANN, S., DI DOMENICO, I., WARMINGTON, S., COLLINS, P.

DEAKIN UNIVERSITY, AUSTRALIA

INTRODUCTION: Studies assessing sports clothing and its ability to maximise thermoregulation, comfort, and performance have used a variety of exercise protocols and environmental conditions. This has led to much conjecture surrounding the ability for sports clothing to keep wearers cool and comfortable during exercise in the heat. This study aimed to develop a testing protocol combining fixed-rate and self-paced exercise for the practical assessment of sports clothing, evaluate its repeatability, and confirm the level of thermo-physiological and perceptual strain induced.

METHODS: Eleven recreationally trained male runners (mean $\pm$ SD, age: 26.8 ± 5.6 years; VO_{2max} 59.2 ± 5.1 mL/kg/min; training volume 70.0 ± 26.6 km/wk) each completed two experimental trials in a climate chamber (temperature: 30.3 ± 0.2 °C; relative humidity: 67.6 ± 1.6 %). Each trial included a 30-minute fixed-rate run (FRR) on a motorised treadmill at 65% VO_{2max} followed by a 5 km time trial (TT) on a non-motorised treadmill. Oxygen consumption, heart rate (HR), core temperature (T_{core}), skin temperature, sweat loss, physiological strain index (PSI), rate of perceived exertion (RPE), and thermal sensation (TS) were monitored during the FRR. Duration and distance were recorded following the TT. A repeated-measures ANOVA was used to determine significant differences throughout the FRR. Relative reliability of TT distance and duration was determined using intra-class correlation coefficients (ICC) and 95% confidence intervals. Absolute reliability was determined using within-participant coefficient of variation (CV). Sufficient strain was achieved when participants reached 4 of the following 5 criteria during the FRR: ≥ 1.2 °C increase in T_{core} compared to rest; $HR \geq 77\%$ of HR_{max} ; $PSI \geq 7/10$; $RPE \geq 15/20$; TS of -3 indicating a 'hot' sensation.

RESULTS: No significant differences were observed between experimental trials for any thermal, physiological, or perceptual variables during the FRR ($p > 0.05$). High relative reliability was confirmed for TT duration (ICC=0.98, 95% CI: 0.94, 0.99,

$p < 0.001$). Moderate relative reliability was confirmed for TT distance (ICC=0.95, 95% CI: 0.83, 0.99, $p < 0.001$). Sufficient absolute reliability was achieved for TT duration ($CV = 1.1 \pm 1.1\%$) but not for TT distance ($CV = 2.1 \pm 1.6\%$). Of the 22 experimental trials completed, 17 induced sufficient thermo-physiological and perceptual strain.

CONCLUSION: This study confirmed the reliability and sensitivity of a novel protocol to evaluate thermal, physiological, perceptual, and performance-based outcomes during exercise in hot and humid conditions. The results verified the suitability of the protocol to induce sufficient strain in recreationally trained runners. This research provides a platform for coaches, athletes, and researchers to apply and adjust evidence-based guidelines when evaluating the interaction between clothing, athletic performance, and the heat.

THE INFLUENCE OF DRAFTING DURING AN INCREMENTAL SPEED TRACK TEST ON PERFORMANCE PHYSIOLOGICAL DETERMINANTS IN DISTANCE RUNNERS

CASADO, A., MORENO, G., TRUJILLO-COLMENA, D., RODRÍGUEZ-CASTAÑO, A., FERNÁNDEZ, J., LUQUE-CASADO, A., RANIERI, L., COLLADO-MATEO, D., MÉNTRIDA, D., DEL COSO, J.

REY JUAN CARLOS UNIVERSITY

INTRODUCTION: Speed during incremental track tests identifying physiological performance determinants in distance runners is typically set by matching sound signals and visual marks in the track (1). However, it requires from the subject being tested constant pace adjustments and overcoming the air resistance derived from speed and variable wind. Recent approaches include the use of a cyclist setting the pace in front of the runner to provide more reliable test outcomes without the interferences associated to the cost of the decision-making process involved in self-pacing and the absence of the drafting effect (i.e., reduction in air resistance derived from positioning just behind another athlete or cyclist) (2).

Therefore, the purpose of this study was to compare physiological performance determinants as well as the power exerted by runners, derived from an incremental track test in the presence and absence of drafting.

METHODS: A randomised, counter-balanced, crossover experimental design was performed. An incremental track test was performed twice by 20 male amateur and highly-trained distance runners (37 ± 11 years; 68.8 ± 6.9 kg; $VO_{2max} = 49.1 \pm 9.0$ ml/kg/min) in the presence and absence of drafting. This test followed the University of Montreal protocol, characterized by an incremental speed to exhaustion increasing 0.5 km/h every minute. Runners wore a backpack with a portable gas analyser (Metamax 3B, Cortex, Germany) to determine speeds associated to both ventilatory thresholds (VTs), VO_{2max} and maximal aerobic speed (MAS), a heart rate (HR) sensor (H10, Polar, Finland) to measure HRs associated to both VTs, and a potentiometer (Strydwind new, Boulder, USA) on the right shoe to measure running power associated to both VTs. For the drafting condition, runners were positioned directly behind a cyclist who set the pace, while in the non-drafting condition, runners performed the test while adjusting the speed to sound signals and visual marks in the track. A related-sample Students t-test was used to compare physiological performance determinants derived from each condition.

RESULTS: MAS was significantly higher in the drafting vs non-drafting test ($p = 0.020$; $d = 0.036$), while no other statistically significant differences were found in the rest of performance determinants ($p > 0.050$).

CONCLUSION: Track incremental running tests may also be drafted by a cyclist whereby their outcomes could not be affected by external and internal factors such as pacing ability and drafting absence. However, the MAS obtained may be faster than that measured without drafting.

IS THE MINIMUM LACTATE STEADY STATE AN OVERESTIMATION OF THE MAXIMUM LACTATE STEADY STATE IN RUNNERS?

SHAHIDI, S., ATAÇ, A., YALÇIN, M., KARABULUT, S.

ISTANBUL GEDİK UNIVERSITY

INTRODUCTION: Lactate thresholds are crucial for middle-distance training as they reflect the balance between lactate production and clearance. The minimum lactate steady state (MLSS), introduced in the late 20th century, is considered the highest intensity maintaining this balance (Heck et al., 1985). However, MLSS may overestimate the maximum lactate steady state (MLSSmax) in middle-distance athletes (Beneke, 2003). This study examines whether velocities below MLSS, determined via the lowest blood lactate concentration (V_{lm}), provide more reliable training benchmarks. We hypothesized MLSS overestimates MLSSmax and sub-V_{lm} velocities offer better lactate stability.

METHODS: Eight elite middle-distance runners (4 male, 4 female; age: 22 ± 4.2 years; weight: 66 ± 32.5 kg; height: 175 ± 3.5 cm; body fat: $10.8 \pm 2.1\%$) participated. Anthropometric data were collected using a stadiometer (Seca, Germany) and a bioelectrical impedance analyzer (TANITA, Japan). Testing included a 3000m time trial to calculate V₃₀₀₀, a 500m sprint and 800m incremental test, six 800m bouts at 86–97% V₃₀₀₀ to determine V_{lm}, and 30-minute runs at V_{lm} and sub-V_{lm} with blood lactate sampling at 10, 20, and 30 minutes.

RESULTS: At V_{lm}, athletes were unable to maintain stable blood lactate levels within a one mmol/L range over 30 minutes. Lactate concentrations increased significantly at 10 (4.3 ± 0.3 mmol/L), 20 (4.8 ± 0.4 mmol/L), and 30 minutes (5.2 ± 0.5 mmol/L; $p < 0.05$). This finding suggests that V_{lm} overestimates MLSS_{max}. Conversely, velocities below V_{lm} demonstrated better lactate stability, with concentrations remaining within one mmol/L of baseline. The mean lactate concentration at MLSS_{max} was 4.2 ± 0.4 mmol/L, compared to 4.5 ± 0.3 mmol/L at V_{lm}.

CONCLUSION: The results indicate that MLSS, as determined by V_{lm}, overestimates MLSS_{max} in elite middle-distance runners. Velocities below V_{lm} offer a more accurate and practical threshold for training prescription. Coaches and sports scientists are encouraged to adopt individualized lactate testing protocols to optimize performance and minimize over-training risks.

Invited Symposium

IS-MH03 Recent efforts by the International Ski and Snowboard Federation (FIS) to reduce the risk of injury in competitive snow sports for the Winter Olympic Games in Milano Cortina, Italy

INJURY PREVENTION IN ALPINE SKIING: HOW CAN WE ENHANCE ATHLETE'S SAFETY THROUGH DEVELOPMENTS IN SMART BINDINGS, AIRBAGS, AND CUT-RESISTANT UNDERGARMENTS FOR WORLD CUP ATHLETES

ELLENBERGER, L.

ETH ZÜRICH

Introduction In alpine skiing, equipment is crucial for both performance and safety. Given the high number of severe injuries in the World Cup, the International Ski and Snowboard Federation (FIS) faces the challenge of performance enhancement while minimizing risk. To address athlete's health, FIS established the Athlete Health Unit (AHU), collaborating with scientists, industry leaders, and other stakeholders to reduce injury rates. The AHU's approach includes a focus on both performance and personal protective equipment. This presentation delves into three equipment projects at various stages of progress, examining their challenges and solutions. 1. Cut-Resistant Undergarment: Implementation Challenges of a Proven Technology Cut-resistant undergarments offer reliable protection against ski edges in falls or collisions. A five-star FIS rating system ensures high-quality protection, but widespread implementation in competitive skiing remains a challenge. After a period of limited progress, with few products on the market, the technology is now set to become mandatory by the 2025/26 season. A significant number of products have since been submitted for certification, a development driven by dialogue and mediation efforts led by the AHU, as community-driven initiatives alone proved insufficient for broader adoption. 2. Airbag with Back Protector: From Concept to Mandatory Gear This season marks a milestone with the introduction of mandatory back protectors integrated with airbags in World Cup Downhill events. Currently, these systems are equipped with sensors that activate upon impact. Future advancements involving AI-driven algorithms could enable earlier detection of imminent falls, allowing deployment prior to impact and providing a protective buffer for the athlete's torso and spine. This section of the presentation will outline the journey from concept to implementation, showcasing the technological and safety advancements that made it possible. 3. Smart Binding: A Visionary Step Towards Injury Prevention The concept of a "smart binding" represents a promising future direction in injury prevention. Unlike traditional bindings, which have remained largely unchanged since the 1980s, smart bindings aim to incorporate adaptive release mechanisms. These mechanisms respond to specific fall dynamics and have the potential to set new safety standards in the sport. This section will introduce the project's initial research, potential design concepts, and the collaborative effort with manufacturers and stakeholders needed to bring this innovation to life. **Conclusion** This presentation offers an in-depth look at the interplay between equipment design and injury prevention, set within FIS's broader safety strategy. Through continuous innovation and collaboration with the skiing community, FIS aims to ensure that equipment not only enhances performance but also serves as a critical tool in reducing injury risk in competitive alpine skiing.

MITIGATION OF INJURY RISK IN SNOW SPORTS THROUGH ENHANCEMENT OF THE ATHLETES' PHYSICAL, MENTAL, AND SOCIAL RESILIENCE

SPÖRRI, J.

BALGRIST UNIVERSITY HOSPITAL, UNIVERSITY OF ZÜRICH

In various snow sports disciplines governed by the International Ski and Snowboard Federation (FIS), injuries are relatively frequent compared with other Olympic winter sports. Athlete-related risk factors are a promising key area to address with tailored injury prevention measures. However, despite decades of research, snow sports-related evidence is scarce and is related mainly to injury epidemiology and aetiology. In contrast, only a few studies have focused on developing, implementing and evaluating injury prevention measures. Guided by a tailored mixed-method framework and mandated by the FIS Athlete Health Unit (FIS AHU), an international collaboration of leading scientists and snow sports experts has approached the issue of athlete-related injury prevention through reviewing the current scientific literature, a systematic exploration of current prevention real-world practices and the motivations behind those practices, and four key consensus initiatives on injury registration, warm-up and cool-down, training and testing, and return to sport in competitive snow sports. The first part of the presentation will summarize and scope the current research on injury prevention in competitive snow sports in dependency on contextual factors such as sport discipline, sex and competition level. In the second part of

the presentation, a systematic compilation of practical expert knowledge based on qualitative stakeholder interviews is provided. The underlying qualitative studies revealed a wide spectrum of general mindsets, best practices and contextual factors that may inform effective injury prevention. Finally, to translate the current research practical knowledge to the specific settings of snow sports, in the third part of the presentation, the methodology and results of four in-depth consensus processes on the FIS recommendations about injury registration, warm-up, training/testing and return to sport in snow sports will be presented, and the lessons learned from the example of snow sports and the transferability of the underlying methodological framework to other sports and settings will be discussed.

MITIGATION OF INJURY RISK THROUGH COURSE DESIGN IN FIS ALPINE SKIING, SKI AND SNOWBOARD CROSS, BIG AIR AND SLOPESTYLE

GILGIEN, M.

NORWEGIAN SCHOOL FOR SPORT SCIENCES

Approximately 45% of all athletes participating in World Cup skiing are injured every winter (Florenes et al. 2009, 2012), and alpine skiing, cross and big air slopestyle are among the sports with the highest injury rates at the Olympic Games (Soligard et al. 2015). This leads to socio-economic costs and loss of value for FIS and stakeholders in the sports industry, as well as media value. Therefore, FIS is implementing several initiatives to reduce the risk of injury and unintentional events that compromise the integrity of athletes. Course design has been identified as a major contributor to injury risk in alpine skiing, cross and big air slopestyle (Levy et al. 2015; Randjelovic et al. 2014; Spörri et al. 2012, 2016). Previous research has shown that course design (course setting in alpine skiing, jump and rail section design in big air and slopestyle, snow built course features in ski and snowboard cross) is one of the main factors influencing gross biomechanical variables such as speed, forces, physical load and ground reaction force etc. (Gilgien et al. 2014, 2015, 2016, 2018, 2020, 2021; Kröll et al. 2016; Spörri et al. 2012, 2016; Supej et al. 2017), which in turn are related to injury risk. In alpine skiing, course setting has been shown to be an efficient regulator of skier biomechanics and is therefore probably the central regulator of aspects related to injury risk (Spörri et al. 2012, 2016). Recent research has shown that factors related to injury risk in alpine skiing, such as speed, forces, turning radius, can be manipulated by course setting adjustments (Gilgien et al. 2020, 2021; Spörri et al. 2012). In ski and snowboard cross, studies have shown that course design has different effects on injury risk for women and men, ski and snowboard. (Rieder 2022, Brusveen 2023) While the genders always compete on the same course, skiing and snowboarding do so occasionally, placing very high demands on the course builders who have to balance the course design to make it safe and challenging for each of the user groups. Similar relationships were found for big air and slopestyle, where women and men, ski and snowboard always compete on the same courses and jumps, placing high demands on the skills of course designers to meet these different needs for safety and attractive competitions for athletes and spectators (Linløkken et al. 2024, in press). Since course design has been identified as an important factor influencing both injury risk and sporting challenge, and as the FIS regulates course design, the FIS AHU and the IOC have initiated and implemented a number of scientific projects in Alpine Skiing, Cross and Big Air, and Slopestyle to help course builders reduce injury risk through the improvement of course design using technology and scientific methods. In this presentation, the researcher who has conducted most of these projects over the last decade will provide insights into published and unpublished work on course design.

RESISTANCE EXERCISE ELEVATES DAILY MYOFIBRILLAR PROTEIN SYNTHESIS RATES SIMILARLY IN MIDDLE-TO-OLDER AGED MALES AND FEMALES.

KORZEPA, M., MARSHALL, R.N., QUINLAN, J.I., ROGERS, L.M., BELFIELD, A.E., GLOVER, E.I., VAN LOON, L.J.C., WALLIS, G.A., BREEN, L.

UNIVERSITY OF BIRMINGHAM

INTRODUCTION: The decline in skeletal muscle mass, strength and function (sarcopenia) is observed from the 4th decade of life and accelerates beyond 60 years of age. Sarcopenia is underscored by an impaired muscle protein synthesis (MPS) response to anabolic stimuli, including protein feeding and resistance exercise training (RET). Sex-based differences in acute MPS have been reported and may explain divergence in sarcopenia trajectories and muscle adaptation to RET between older males and females. A paucity of studies shows no differences in acute MPS have been reported in middle-aged males and females. Measurement of longer-term free-living daily MPS rates in middle-to-older aged males and females, consuming a typical diet with or without RET, would provide valuable insight on sex-based differences in muscle mass regulation.

METHODS: Healthy middle-to-older aged males ($n=13$, 60 ± 7 y) and females ($n=12$, 63 ± 5 y) completed a 10-day experimental investigation in which they consumed a controlled diet containing 1g/kg day⁻¹ protein and completed high-volume unilateral knee extension RET every other day. Body fat was measured via dual x-ray absorptiometry (DXA). Deuterium oxide preload of 400ml and 50ml daily top ups was consumed, and muscle biopsy samples were obtained on days 0 and 10 to determine free-living daily myofibrillar protein synthesis (iMyoPS) rates in trained and untrained legs. Statistical

differences for sex only were identified using independent samples T-test or 2-way repeated measures ANOVA for sex and training differences. Statistical significance was set at $P < 0.05$ with data shown as mean $\pm$ standard deviation.

RESULTS: Total deuterium body water enrichment was significantly higher in middle-to-older age males than females (0.63 ± 0.14 APE vs 0.78 ± 0.14 APE, $P = 0.012$). DXA-derived body fat was significantly different between sexes ($24.7 \pm 5.3\%$ males vs $37.2 \pm 5.8\%$ females, $P < 0.001$). Training load in RET did not statistically differ between sexes ($P = 0.058$), but weight lifted was significantly different (males 42.9 ± 16.9 kg vs females 31.5 ± 8.4 kg, $P < 0.001$). Daily iMyoPS rates in the untrained leg did not significantly differ between sexes (1.26 ± 0.22 %day⁻¹ for males vs 1.37 ± 0.26 %day⁻¹ for females, $P = 0.246$). Notably, in the trained leg, there was also no significant difference in daily iMyoPS rates between sexes (1.45 ± 0.16 %day⁻¹ in males vs 1.48 ± 0.27 %day⁻¹ in females, $P = 0.823$). Daily iMyoPS rates in the trained leg were significantly higher than the untrained leg (8% higher in females, $P < 0.001$ and 16% higher in males, $P < 0.001$) with no significant difference between sexes ($P = 0.099$).

CONCLUSION: Free-living daily iMyoPS rates did not differ between middle-to-older aged males and females consuming a typical protein-containing diet. RET elevated daily iMyoPS rates compared to the untrained leg in the middle-to-older aged males and females, with no differences observed between sexes.

PRE-EXERCISE CAFFEINE INTAKE IMPROVES NEUROMUSCULAR ADAPTATION TO RESISTANCE TRAINING

MONTALVO ALONSO, J., DEL-VAL MANZANO, M., FERRAGUT, C., VALADÉS, D., PÉREZ-LÓPEZ, A.
UNIVERSIDAD DE ALCALÁ

INTRODUCTION: Numerous studies have demonstrated the ergogenic effect of acute caffeine intake in different sports actions. In resistance exercise, caffeine enhances velocity and power production at different loads and exercise types (e.g., bench press or back squat). However, it remains unclear whether the acute ergogenic effects of this supplement can accumulate over consecutive exercise sessions, specifically if prolonged caffeine intake before resistance exercise enhances neuromuscular adaptations. Therefore, this study aimed to evaluate the effect of pre-exercise caffeine intake during 8-weeks of velocity-based resistance training.

METHODS: Forty-eight resistance-trained participants (male/female: 24/24; age: 24 ± 4 years; training experience: 3.8 ± 3.3 years; 1RM/kg bench press: 1.1 ± 0.3 ; 1RM/kg back squat: 1.6 ± 0.6 ; caffeine intake: 50.5 ± 50.9 mg/day) participated in a double-blind, randomized, placebo-controlled trial. Participants completed an 8-week, twice-weekly velocity-based resistance training for bench press and back squat exercises at progressive loads (70-85%1RM). Four sets were performed per exercise until a 20% velocity loss occurred. Sixty minutes pre-exercise, they ingested 3 mg/kg of caffeine or placebo. Pre- and post-training tests included 1RM, muscular strength and power tests at 25%, 50%, 75%, 90% 1RM, and muscular endurance at 65% 1RM performing one set until task failure. Movement velocity was monitored in all cases. Moreover, acute caffeine effects were assessed before and after the intervention.

RESULTS: Resistance training significantly increased 1RM in both bench press and back squat (13-19%, $P < 0.001$), with caffeine supplementation resulting in greater improvements than placebo in bench press for both sexes (5.5%, $P = 0.043$) and in back squat specifically for females compared to males (8% vs 2%, $P = 0.021$). In bench press at 25% and 50%1RM, caffeine increased mean velocity (7% vs 14%, $P = 0.050$; 0.5% vs 9%, $P = 0.010$) and mean power (17% vs 38%, $P = 0.047$; 12% vs 20%, $P = 0.041$) compared to placebo. In back squat at 25%, 50% and 75%1RM, caffeine increased mean velocity (3% vs 20%, $P = 0.001$; 1% vs 13%, $P = 0.001$; 1% vs 16%, $P = 0.001$) and mean power (4% vs 21%, $P = 0.006$; 3% vs 15%, $P = 0.004$; 6% vs 11%, $P = 0.049$) compared to placebo. No sex differences were detected. Muscular endurance increased mean and peak power post-training in all groups ($P = 0.001$). Also, similar acute caffeine effect was found pre- and post-training. **CONCLUSION:** Caffeine intake (3 mg/kg of body mass) before resistance exercise enhances 1RM and promotes a higher mean and peak velocity at 25-50% in bench press and 25-75% in back squat exercise after 8-weeks of training in both male and female participants. Therefore, prolonged pre-exercise caffeine intake accelerates neuromuscular performance adaptations to resistance exercise to a similar extent in male and female participants.

THE EFFECTS OF 10 WEEKS OF TIME-RESTRICTED EATING, RESISTANCE TRAINING, AND THEIR COMBINATION ON LOW-GRADE INFLAMMATION IN PEOPLE WITH METABOLIC SYNDROME; A RANDOMIZED CONTROLLED TRIAL

YAVETZ, R., STERNFELD, R., LAHAV, Y., REIN, M., ZELBER-SAGI, S., GEPNER, Y.
TEL AVIV UNIVERSITY

INTRODUCTION: Low-grade inflammation, characterized by elevated adipokines, is a hallmark of obesity and defining feature of metabolic syndrome (MetS).

Time-restricted eating (TRE, 8 hours eating/16 hours fasting) and resistance training (RT) are both effective strategies for reducing low-grade inflammation markers and improving metabolic health. Yet, their combined effects on low-grade inflammation among people with MetS remain unclear.

METHODS: In a randomized controlled trial, 76 adults with MetS (age: 50.4 ± 5.3 years, BMI: 31.4 ± 3.9 kg/m²) were assigned to one of three groups for 10 weeks: normal diet with RT (ND+RT), TRE alone, or TRE combined with RT (TRE+RT). The ND+RT group followed a standard, unrestricted eating pattern, while the TRE groups limited food intake to 12:00–8:00 PM. All groups adhered to iso-caloric diets with 1.5 g/kg/day of protein intake. conducted three times per week, with up to three participants per session, each lasting 60 minutes and comprising nine full-body exercises targeting major muscle groups. Body composition was assessed using dual-energy X-ray absorptiometry (DXA) and serum levels of leptin, TNF- α , and IL-6 were measured pre- and post-intervention. Statistical analyses included paired t-tests for within-group changes,

ANCOVA for between-group comparisons, and Pearson correlations to examine associations between inflammatory markers and body composition.

RESULTS: Of the 76 participants enrolled, 68 completed the study, with a 95% compliance rate; TRE alone (n=23), ND+RT (n=23), and TRE+RT (n=22). Only TRE+RT group exhibited significant reductions in IL-6 (-0.36 ± 0.53 pg/ml, $p=0.01$) and TNF- α (-0.74 ± 1.3 pg/ml, $p=0.01$) compared to baseline, with ANCOVA confirming greater reductions in TRE+RT compared to TRE alone (IL-6: $p=0.01$; TNF- α : $p=0.03$).

Fat mass decreased significantly in all groups (TRE+RT: -2.4 ± 1.1 kg, ND+RT: -2.1 ± 1.8 kg, TRE Alone: -1.4 ± 1.4 kg; $p < 0.001$ for all). However, significant leptin reductions were observed only in ND+RT (-1.40 ± 2.0 ng/ml, $p = 0.003$) and TRE+RT (-2.80 ± 2.0 ng/ml, $p = 0.008$), with ANCOVA indicating significantly greater reductions in TRE+RT compared to TRE alone ($p = 0.03$). Notably, a strong positive correlation between fat mass reduction and leptin decline was observed only in ND+RT ($r=0.61$, $p=0.002$), whereas in TRE+RT, leptin reductions occurred independently of fat mass changes ($r=-0.12$, $p=0.39$), suggesting a potential distinct regulatory mechanism for leptin in this intervention.

CONCLUSION: Combining TRE and RT result in more pronounced reductions in leptin, IL-6, and TNF- α levels. These findings suggest that TRE combined with RT may modestly reduce low-grade inflammation and improve metabolic health in individuals with MetS.

POSTPRANDIAL AMINOACIDEMIA AND RESISTANCE EXERCISE-INDUCED SKELETAL MUSCLE ADAPTIVE REMODELLING WITH RECOMBINANT BOVINE B-LACTOGLOBULIN IN YOUNG ADULTS.

INTRODUCTION: Increasing concerns surrounding the long-term environmental impact of animal- and plant-derived protein production have instigated the search for sustainable alternative protein sources with properties to support skeletal muscle adaptive remodelling. In a series of complementary studies, the postprandial plasma amino acid response to a novel supplemental protein derived from recombinant bovine β -lactoglobulin (rBLG) was determined, alongside the muscle adaptive response to resistance exercise (RE), with dairy-derived whey protein (WHEY) as the comparator.

METHODS: Firstly, 8 healthy adults (M:F = 3:5; age: 24 ± 4 ; BMI: 23.5 ± 2.1 kg·m²) participated in a participant-blind randomised crossover study in which they ingested 0.3 g·kg⁻¹·mass⁻¹ of rBLG or WHEY with arterialised blood samples collected in the fasted state and over 240 min postprandially for measurement of plasma amino acid concentrations via UPLC-MS. In a separate double-blind randomised parallel group design, 24 healthy recreationally active men and women completed thrice-weekly progressive lower-body RE for 8 weeks, with twice daily supplementation of 0.3 g·kg⁻¹·mass⁻¹ rBLG (n: 12; age: 23 ± 6 ; BMI: 25.6 ± 3.4 kg·m²) or WHEY (n: 12; age: 25 ± 6 ; BMI 25.1 ± 3.1 kg·m²). RE sessions involved 3-4 sets of 8-12 repetitions of five exercises at 60-80% one repetition maximum (1RM). Training-induced changes in muscle strength and DEXA-derived leg lean body mass (LBM) were assessed.

RESULTS: Plasma essential amino acid (EAA) concentration increased following protein ingestion ($P < 0.001$), with no difference between rBLG and WHEY ($P=0.554$). Plasma leucine concentrations increased to a greater extent following ingestion of rBLG at 45 min (mean diff (95%CI): 77 (31 to 124) μ mol·L⁻¹; $P < 0.001$), 60 min (106 (59 to 152) μ mol·L⁻¹; $P < 0.001$), 90 min (92 (45 to 138) μ mol·L⁻¹; $P < 0.001$), and 120 min (47 (1 to 94) μ mol·L⁻¹; $P=0.041$), compared with WHEY. Mean plasma leucine incremental area under curve (iAUC) was greater following rBLG compared to WHEY (mean diff (95%CI) 10727 (7738 to 13716) μ mol·240 min·L⁻¹; $P < 0.001$). Leg LBM and leg press 1RM increased following training ($P < 0.05$), with no differences between rBLG and WHEY ($P > 0.05$). Total training volume and dietary intake over RE training did not differ between rBLG and WHEY ($P > 0.05$ for all). Data on the acute post-RE muscle anabolic response to rBLG and WHEY was not available at the time of writing but will be presented.

CONCLUSION: These novel data demonstrate that precision-engineered recombinant bovine β -lactoglobulin has the capacity to support skeletal muscle anabolism and adaptive remodelling in a manner that is comparable to dairy-derived whey protein.

EFFECT OF A COMMERCIAL ECDYSTERONE AND DIOSGENIN PRODUCT ON BODY COMPOSITION, PERFORMANCE AND ENDOCRINE SYSTEM IN RESISTANCE TRAINED ATHLETES - A 12-WEEK RANDOMIZED CONTROLLED DOUBLE-BLIND STUDY.

DISSEMOND, J., HELD, S.2, HAVERS, T.1, GEISLER, S.2, KOSTOV, T.3, DIEL, P.3, TUERSCHMANN, S.4, PARR, M.K.4, ISENMAN, E.1

1 IST UNIVERSITY OF APPLIED SCIENCES; 2 IST UNIVERSITY OF APPLIED SCIENCES; 3 GERMAN SPORTS UNIVERSITY COLOGNE; 4 FREIE UNIVERSITAET BERLIN

INTRODUCTION: Phytosteroids like ecdysterone (20-hydroxyecdysone, 20E) and diosgenin (DSG) are gaining attention due to promising results from in-vitro, animal, and human studies. Furthermore, combining different phytosteroids has become a common practice in supplementation. However, there is currently a lack of scientific data regarding the combined effects of 20E and DSG on performance, body composition, muscle thickness, liver and kidney function and endocrine system.

METHODS: To address this gap, a 12-week randomized controlled double-blind study was conducted with 24 healthy, resistance-trained men (31.1 ± 8.1 years; 182.0 ± 8.2 cm; 89.4 ± 13.9 kg). Participants were randomized into either the ecdysterone and diosgenin (EcDi) group or the placebo (Plac) group and performed free weight based resistance training

three times per week. The EcDi group consumed a commercial product containing ecdysterone and diosgenin three times daily. Assessments were conducted at four time points and included measurements of 1 repetition maximum (1-RM) for squat (SQ) and bench press (BP), body weight (BW), fat free mass (FFM), muscle mass (MM), fat mass (FM), and muscle thickness of the pectoralis major (PM) as well as along the proximal, middle, and distal regions of the anterior (i.e., M. rectus femoris and M. vastus intermedius; anterior quad) and lateral quadriceps femoris (i.e. M. vastus lateralis and M. vastus intermedius; Lateral quad). Liver and kidney function, as well as endocrine parameters, were measured pre- and post-intervention. Data were analyzed using a linear mixed model (LMM). Additionally, the 20E concentration of the product and its biological activity were evaluated using C2C12 cells after the intervention.

RESULTS: All 24 participants completed the study. Significant improvements in 1-RM SQ and BP were observed across both groups, indicating a time effect but no specific group effect. Similarly, for FFM, MM, FM, and muscle thickness (Mid quad at 30%, Lateral quad at 50%, and PM), significant time effect without group effects were identified. Supplement analysis revealed a content of 0.025% of the labeled 20E concentration, and no biological activity or hypertrophic effects were detected in the C2C12 cell line.

CONCLUSION: The substantial discrepancy between the reported and actual 20E concentration resulted in the absence of biological activity in C2C12 cells and may have contributed to the lack of group-specific effects. To improve research outcomes with phytosteroids, we recommend the following: (1) Verification of the actual concentration of active substance(s) in supplements, and (2) confirmation of their biological activity using in vitro models. Implementing these measures will help minimize inconsistencies and enhance the reliability of future studies.

Invited Symposium

IS-PN02 Power, Breath, and Beat: Exploring Female Muscular, Pulmonary, and Cardiovascular Physiology

THE REGULATORY ROLE OF FEMALE SEX HORMONES ON SKELETAL MUSCLE AND ADAPTATIONS TO EXERCISE TRAINING IN FEMALES

HANSEN, M.

AARHUS UNIVERSITY

Skeletal muscle mass is crucial for muscle function, metabolic health, and quality of life. In females, sex hormones play a significant role in the regulation of muscle mass. This presentation, based on human data, will demonstrate how estrogen plays a critical role in regulating muscle mass. The decline in estrogen levels during menopause is associated with reductions in muscle mass and function. Conversely, emerging human data demonstrate that estrogen enhances muscle hypertrophy during resistance training by increasing muscle protein synthesis, inhibiting muscle protein breakdown, and positively affecting satellite cell activation. Additionally, estrogen seems to have a positive influence on muscle strength. Taken together, the present data highlight that the female sex hormone profile may influence responsiveness to training. This presentation is aimed at sports scientists, exercise physiologists, healthcare professionals, and researchers interested in expanding their understanding of female-specific muscle physiology, particularly the role of estrogen in modulating skeletal muscle adaptations to exercise training.

SEX DIFFERENCES IN THE RESPIRATORY PHYSIOLOGY OF EXERCISE

SHEEL, B.

UNIVERSITY OF BRITISH COLUMBIA

With dynamic exercise there are increases in oxygen extraction and carbon dioxide production by the contracting musculature, and with heavy exercise, there are accompanying reductions in pH. An increase in ventilation is important when considering the ability to perform exercise as it serves to maintain blood gas homeostasis and regulate acid-base balance. Despite the biological need to match ventilation to metabolic demand, much of what we know is based upon studies that have primarily focused on young healthy men, whereas the response in young and older women has received limited attention. This proposed presentation will address this scientific gap by addressing two inter-related topics. First, in young athletic males a large alveolar-to-arterial oxygen difference develops and arterial oxygen tension, and oxyhemoglobin saturation fall with heavy exercise. Different from males, females demonstrate pulmonary gas exchange decrements during submaximal exercise intensities and at lower aerobic fitness levels, but this is controversial. In addition, the female master athlete has rarely been considered in this context, and recent findings in this rarely studied group will be presented. Second, in order to generate ventilation, the diaphragm and other respiratory muscles must contract cyclically. There are reports that in young females: (i) the diaphragm is resistant to fatigue and (ii) that cardiovascular response to high levels of respiratory muscular work is attenuated. Recent work that explores the interaction(s) between high levels of respiratory muscle work, the energetics of breathing, and diaphragm fatigue in young and post-menopausal females will be presented. The target audience is anyone interested in expanding their knowledge of female-specific respiratory physiology during exercise.

THE INFLUENCE OF SEX HORMONES ON CARDIOVASCULAR HEALTH AND ADAPTATIONS TO EXERCISE TRAINING IN FEMALES

HELLSTEN, Y.

UNIVERSITY OF COPENHAGEN

Whereas ageing is one of the strongest predictors of hypertension and cardiovascular events, physical activity is superior to any other alternative for maintaining cardiovascular integrity and health with age. Thus, although age per se is a factor, physical inactivity over many years is at least as detrimental to the cardiovascular system as is ageing. However, despite the fact that endurance training can have beneficial effects on cardiovascular health in both older males and females, evidence suggest that adaptive processes are slower in postmenopausal females compared to age matched males. The reason for this slower adaptation in older females is not fully clear but is thought to be related to the loss of estrogen at menopause. Estrogen has overall a marked impact on cardiovascular health, influencing aspects such as regulation of vascular tone, blood pressure, microvascular growth and antioxidant capacity. Consequently, when females loose estrogen at menopause, there is not only a reduced ability to adapt to training but there is also an accelerated decline in cardiovascular health. On the positive side, there is evidence indicating that; if females train at or shortly after, rather than many years after menopause, they adapt very well to training. And importantly, many of the positive effects of exercise are similar to those of estrogen. Although more research is needed in this area, these findings point at that sedentary females should be recommended to begin exercising at the menopausal transition to counteract the impact of estrogen loss. The talk addresses the influence of estrogen and estrogen loss on the cardiovascular system and the impact of exercise training in females. The target audience is anyone interested in cardiovascular physiology and in physical activity as a means of promoting healthy ageing, especially in females.

A SINGLE, UPPER SPINE-PLACED IMU REVEALS INSIGHTS INTO DIFFERENCES IN MOVEMENT STRATEGIES BETWEEN PLANNED AND REACTIVE MULTIDIRECTIONAL MOVEMENTS IN ELITE MALE HANDBALL PLAYERS

BÜCHEL, D., HEUVELMANS, P., GOKELER, A., BENJAMINSE, A., BAUMEISTER, J.

PADERBORN UNIVERSITY

INTRODUCTION: Handball is a high-intensity team sport that requires both physical and cognitive skills. Players must react to constantly changing game situations, executing rapid stop-and-acceleration actions. Reactive agility, the ability to move quickly in response to external cues, is crucial for performance. Developing accessible agility tests and informative outcome measures is essential for understanding athletes' behavior on the court. In this study, we investigated differences between elite handball players' planned and reactive agility tasks, focusing on acceleration derived from a single upper-spine-positioned inertial measurement unit (IMU). For a complementary insight into the coordination underlying altered acceleration, we additionally assessed lower extremity joint kinematics.

METHODS: Thirty-three elite male handball players from the highest divisions in Germany and Denmark participated. Each player performed five trials of an agility task under planned and reactive conditions. The task required athletes to swipe LED sensors arranged in a trapezoidal setup as quickly as possible. Response times (RTs) were recorded using proximity sensors (Fitlights, Canada). Upper-body acceleration was measured using an upper-spine-mounted IMU (Myomotion/Ultium, Noraxon, USA), focusing on early and later acceleration components. Statistical analyses of RTs and acceleration were conducted using Wilcoxon signed-rank tests. Eight additional IMUs were placed on the feet, shanks, thighs, pelvis, and lower spine to further examine movement patterns and track lower limb kinematics. Statistical non-parametric mapping was used to identify timing and amplitude differences in knee, hip, and foot dorsiflexion between planned and reactive tasks. A significance level of $p < .05$ was applied to all comparisons.

RESULTS: Results indicated significantly slower RTs in reactive tasks compared to planned ones (~200 ms, $p < .01$). Early movement phases exhibited increased upper-body acceleration in the reactive condition (~9%, $p < .01$), whereas peak acceleration in later phases remained unchanged. Analyses of joint kinematics revealed delayed movement initiation, more upright starting posture and a greater range of hip and knee flexion in reactive movements ($p < .025$).

CONCLUSION: Our observations suggest that handball players adjust their acceleration strategies in response to cognitive demands. Increased upper-body acceleration in the early movement phase of reactive conditions may reflect compensatory mechanisms due to movement uncertainty. The observed changes in joint kinematics, including a more upright posture and greater range of motion, complement this observation. Together, it could be speculated reactive runs require specific adjustments to body posture, leading to increased upper body acceleration in the early phase of movements. Tracking acceleration metrics via upper-spine IMUs during handball-specific movements provides an accessible and valuable approach for studying movement strategies in athletes.

USING COGNITIVE FUNCTIONS AND MACHINE LEARNING TO PREDICT SOCCER PLAYERS PERFORMANCE IN SMALL-SIDED GAMES

MONTEIRO, R., CHINAGLIA, A., TAHARA, A., MONTEIRO, P., TORRES, R., SANTIAGO, P.
UNIVERSITY OF SAO PAULO

INTRODUCTION: Soccer is a dynamic team sport characterized by high cognitive demand, where quick and efficient decision-making is necessary. Cognitive functions are directly related to how we interact with the environment and make decisions. The present study aimed to identify the key cognitive functions that best predict the performance of youth high-level soccer players on different demands of small-sided games using machine learning algorithms to differentiate the best- and worst-performing players.

METHODS: Forty-four male athletes (16.51 ± 0.57 years old) from the U-17 category of two soccer teams participated in the study. For on-field performance evaluation, a 28-round multiple small-sided games protocol was implemented, consisting of 4-minute 3 vs. 3 matches without a goalkeeper. Teams were mixed in every round. On-field performance metrics were: individual goals (IG) as a goal scoring measure, conceded goals (CG) for defensive performance, goals by teammates (GT) as a creativity measure; and net goals (NG) for overall performance. Cognitive flexibility, impulsivity, sustained attention, visuospatial working memory, and tracking capacity were assessed using the Psychology Experiment Building Language, and the Psychophysics software in Python. K-means clustering was applied to segment on field performance metrics into two groups: inferior and superior performance players. For identifying key cognitive functions that best predict different game demands, the five cognitive functions were combined in all possible ways, resulting in 31 datasets used to predict on-field performance levels with seven supervised machine learning algorithms. Grid search and cross validation were implemented for training and testing the algorithms. The 3 best models for each game demand were compared using one-way ANOVA and Tukey's post-hoc.

RESULTS: The standout machine learning models were K-nearest neighbors and neural networks (Multilayer Perceptron). The best models achieved balanced accuracies (BACC) between 69% and 72%, and overall accuracies ranging from 69% to 79%. For predicting IG, cognitive flexibility, and tracking capacity stood out (BACC: 69.6 ± 4.1 %). Sustained attention and visual working memory presented better results in predicting CG (BACC: 72.3 ± 1.1 %). Regarding GT, sustained attention, impulsivity and cognitive flexibility provided best predictions (BACC: 70.5 ± 5.9 %). Lastly, the combination of cognitive flexibility, impulsivity and visual working memory, precisely the executive functions, presented superior results in predicting NG (BACC: 69.3 ± 3.3 %).

CONCLUSION: Cognitive functions demonstrated the sensitivity to differentiate athletes performance in small-sided games and highlighted the cognitive functions combinations that better predicted different game demands. These findings demonstrate the potential of cognitive functions evaluation and machine learning application for sports performance analysis, athletes' selection, and research designs.

THE RELIABILITY AND VALIDITY OF A NEW DIGITIZED TOOL FOR PREDICTING THE MATURITY STATUS OF YOUTH SOCCER PLAYERS

MAZZEI, S., GUARNIERI, A.1, GAVIOLI, C.2, PRESTA, V.1, LAURENTI, F.1, GOBBI, G.1, MANDORINO, M.2, KAVANAGH, R.2, COUSTOU, S.2, LACOME, M.2, CONDELLO, G.1

1 DEPARTMENT OF MEDICINE AND SURGERY, UNIVERSITY OF PARMA; 2 PERFORMANCE AND ANALYTICS DEPARTMENT, PARMA CALCIO 1913

INTRODUCTION: Biological maturation reflects progress toward the adult state, involving structural and functional changes [1]. Growth spurt during adolescence is associated with an increased risk of injuries in youth soccer players. Hence, the monitoring of maturity status and the management of training load of youth players are necessary to avoid overload and injuries. The application of predictive equations to estimate maturity offset (MO) requires manual measurements, which are time-consuming and error-prone if applied at a large scale. Thus, the study aimed at assessing the reliability and validity of a computer vision model to automatically evaluate players standing and sitting height from individual photos, for the determination of the maturity status of elite youth soccer players.

METHODS: One hundred forty-six soccer players (age: 9–15 years) from an Italian elite soccer team were measured for standing and sitting height and weight, following ISAK protocols [2], and photographed twice in a standing position. Photos were processed to compute standing and sitting height using a computer vision algorithm (Ultralytics YOLO v9). Mirwald equation [3] was applied to calculate MO using manual heights measures and YOLO-derived heights. The internal consistency reliability of YOLO algorithms for the estimation of heights was assessed using Intraclass Correlation Coefficient (ICC), while absolute reliability was evaluated with coefficient of variation (CV) and standard error of measurement (SEM). Pearson product moment correlation was used to assess the strength of the association between MO calculated with manual heights measures (i.e., the criterion measure) and MO calculated with YOLO-derived heights, as a measure of concurrent validity. Bland-Altman plot was used to visually assess agreement between MO measures together with linear regression analysis for potential bias.

RESULTS: YOLO algorithms demonstrated excellent reliability for both standing (ICC=0.961; CV=1.98; SEM=0.531) and sitting (ICC=0.943; CV=3.49; SEM=0.518) height. Pearson correlation coefficient between MO calculated with manual heights measures and MO calculated with YOLO-derived heights showed a strong association ($r=0.981$; $p<0.001$). Bland-Altman plot inspection confirmed good data distribution within upper (0.723) and lower (-0.724) limits of agreement. Regression analysis revealed a significant B unstandardized coefficient ($B=0.34$; $p=0.038$).

CONCLUSION: The YOLO algorithms provided highly reliable and valid values for standing and sitting height, demonstrating a strong consistency and agreement with manual measurement of height. This approach offers a practical, time-efficient, and less invasive method for estimating maturity offset. Finally, a timely evaluation of the maturity status can also optimize the management of training load of soccer players.

IS THERE AN ALTERNATIVE TO QUANTIFY INTERNAL TRAINING LOAD? A COMPARISON BETWEEN AN ORIGINAL AND A MODIFIED SRPE SCALE IN PROFESSIONAL VOLLEYBALL PLAYERS

MASEL, S.

UNIVERSITY OF PHYSICAL CULTURE IN KRAKÓW, POLAND

INTRODUCTION: Subjective measures are commonly used to monitor athletes [1] and session rating of perceived exertion (sRPE) is introduced to quantify internal training load in professional sports [2]. It was proved to be effective to monitor training load and adjust it during the training process [3]. Originally, sRPE scale was developed by Foster as a modification of Borg's scale and is typically used for internal training load measurements [4]. In this study, in addition to Foster's sRPE scale (S1) a novel, modified version (S2) was proposed to broaden the typically used scale with more detailed information. Therefore, the aim of this study was to compare two scales (original S1 and modified S2) and establish its reliabilities.

METHODS: Twelve professional male volleyball players (age: 21.8 ± 2 years; volleyball training experience: 11 ± 2.9 years, body height: 193.2 ± 9 cm, body mass: 84 ± 10.1 kg) and two coaches (working cooperatively for 5 years) participated in this study. The study took place during the preparatory period for the team and the athletes took part in 48 sessions (17 group and 10 individual technical/tactical trainings; 16 gym sessions; 5 friendly games) over six weeks. Before each training session the coaches discussed the volume, intensity and tactical/technical complexity of a training session and proposed an intended sRPE in two scales for a given session. Afterwards, 30-45 minutes after each session the players evaluated their sRPE. The results of coaches' and players' perspectives on rating sessions in two scales were therefore statistically compared. Multiple T-tests were introduced to assess the significance of the measurements (p was set at <0.05) and Intraclass Correlation Coefficient to assess the reliability of the measurements. Also, training load (quantified as sRPE x time of training sessions) within two scales was quantified.

RESULTS: Within all sessions, in S1 there was found a significant difference between coaches and players ratings ($p < 0.01$) and moderate reliability (ICC = 0.625). In S2 there were no significant differences ($p=0.448$) and good reliability (ICC = 0.764). Training load measurements indicated that while using S1 the players' internal training load was 4.6% lower than internal training load prescribed by the coaches. Respectively, while using S2 the players' internal training load was only 0.5% lower than coaches' internal training load.

CONCLUSION: This study provides a novel understanding for internal training load measurements in professional sports. Results of this study suggest that a modified version of Foster's sRPE scale (S2) can be an effective alternative to S1 to monitor and adjust internal training load in professional sports. However, the results of this study should be applied with caution as S2 was scientifically established for the first time and more studies of this type are needed to verify its efficacy.

TRAVEL AND SLEEP: INDIVIDUAL VARIABILITY IN ELITE AUSTRALIAN FOOTBALLERS

KEMP, S., SPENCE, A., KELLER, B., DUCKER, K., GUCCIARDI, D.

CURTIN UNIVERSITY

INTRODUCTION: Sleep is fundamental for athlete health and performance. Insufficient or poor-quality sleep impairs physiological and cognitive function, ultimately affecting athletic performance. Elite athletes face unique challenges that can compromise sleep, including intense training, night-time competitions, and frequent travel. Travel, particularly across time zones, can create circadian misalignment, reduce sleep opportunity and degrade sleep quality due to unfamiliar sleep environments and inconsistent routines. While prior research has examined the acute effects of travel on sleep, few studies have observed athletes over extended periods to elucidate the long-term effects on sleep behaviours following travel.

METHODS: This pre-registered longitudinal study investigated the effects of travel on sleep in elite male Australian Football League (AFL) athletes ($n=22$; age = 23 ± 4 years; experience = 46 ± 17 games), from the same professional club, across the full 2024 AFL Premiership Season period (24 weeks). Sleep duration (minutes) was measured using a commercial wearable (WHOOP 4.0). Intra-individual and between-person travel effects were assessed by comparing sleep duration between home and away fixtures. Sleep-travel relationships were analysed using Dynamic Structural Equation Model (DSEM) in Mplus.

RESULTS: Across 3228 observations, sleep duration averaged 442 ± 77 minutes (7.34 ± 1.3 hours). Season fixtures included 12 home and 11 away matches. The Bayesian DSEM converged successfully (PSR ≈ 1.00). At the within-person level, travel had a small, non-significant positive effect on sleep duration ($\beta = 0.060$, 95% CI: -0.001, 0.115, $p = 0.026$). At the

between-person level, frequent travel was associated with a minor reduction in overall sleep duration ($\beta = -98.848$, 95% CI: -1076.887, 987.966, $p = 0.431$), although not statistically significant.

CONCLUSION: Using a longitudinal sleep analysis, we observed that regular travel did not significantly impact sleep, however substantial between-person variance suggests individual differences in sleep responses. Accounting for both within- and between-person variability within the same cohort enabled detection of individual differences in sleep adaptation. These findings highlight the need for individualised athlete sleep strategies rather than generalised team-wide recommendations. Future research should examine factors driving between-person variability, including chronotype, training load, travel scheduling, and external lifestyle influences, to develop tailored interventions for optimising athlete recovery and performance.

REGIONAL FASCICLE STRAIN AT BASELINE IS STRONGLY ASSOCIATED WITH INCREASES IN RESTING FASCICLE LENGTH BUT NOT MUSCLE THICKNESS AFTER ECCENTRIC EXERCISE TRAINING

NUNES, J., NOSAKA, K., BLAZEVIČ, A.J.

EDITH COWAN UNIVERSITY

INTRODUCTION: Eccentric exercise training has been suggested to increase resting muscle fascicle length (FL) through sarcomerogenesis, especially in distal regions, reducing injury risk and promoting distal hypertrophy [1-3]. Animal data indicates that a greater fascicle elongation (fascicle strain; ϵ PRE) during exercise promotes greater FL increases after training [4], although this has yet to be tested in humans. Simultaneously, detailed assessments of muscle function, including shifts in the muscle length of peak force production and shortening velocity [1,2], could help to identify the structural factors underlying any FL increases [1]. The present study investigated the hypothesis that increases in FL and muscle thickness (MT) would positively correlate with ϵ PRE and changes in muscle function.

METHODS: Distal and proximal tibialis anterior isokinetic eccentric ϵ PRE, as well as resting architecture (via ultrasonography), and muscle function (via dynamometry), were assessed in 12 trained men (26 ± 4 y) before and after 18 unilateral isokinetic eccentric dorsiflexion training sessions (6 wk, 3/wk, 2-4 x 6-10 rep-max, $10^\circ/\text{s}$). Distal-proximal net architectural responses were computed as the distal minus the proximal relative changes. Dorsiflexion function was assessed through maximum voluntary isometric (5 angles) and dynamic (concentric, eccentric; 3 velocities) tests.

RESULTS: Similar responses were found between distal and proximal regions for ϵ PRE (59% vs. 60%; $P=0.90$), FL (7% vs. 6%; $P=0.47$), and MT (11% vs. 7%; $P=0.58$), although the values substantially varied between regions within individuals. A strong correlation was observed between distal-proximal net ϵ PRE and distal-proximal net changes in FL ($r=0.79$, $P<0.01$) but not MT ($r=0.17$, $P=0.59$). However, no association was observed between region-averaged ϵ PRE and region-averaged FL ($r=0.04$, $P=0.91$) or MT ($r=0.03$, $P=0.92$). Training significantly ($P<0.05$) improved isometric peak torque at shorter and longer muscle lengths (12%) and broadened the torque-angle relation (14%). Rate of torque development was increased at longer (0-75ms: 52%; 0-250ms: 23%), but not shorter or moderate lengths ($P>0.05$). Concentric peak torque (20%) and work (12%), and eccentric peak torque (14%) were increased in all tests. Isometric peak torque angle and estimated maximum shortening velocity were not changed significantly ($P>0.05$).

CONCLUSION: Eccentric training increased FL and MT, which may influence both performance and injury risk [2], but changes were not specific to the distal region. Increases in FL were larger in regions with greater ϵ PRE, whether proximal or distal, although individuals with greater ϵ PRE did not exhibit greater increases in FL or MT. Serial sarcomere addition was likely not the primary driver of the FL increases, as some key functional adaptations were absent.

CONTRACTION INTENSITY-SPECIFIC FLUCTUATIONS IN MOTOR UNIT BEHAVIOUR ACROSS THE MENSTRUAL CYCLE

SPILLANE, P., JENZ, S., OHANLON, M., WIGBERS, A., BEAUCHAMP, J.A., BENEDETTO, A., NÉDÉLEC, É., HICKS, K.M., GOODALL, S., HECKMAN, C.J., PIASECKI, M., PIASECKI, J., PEARCEY, G.E/P., ANSDALL, P.

NORTHUMBRIA UNIVERSITY

INTRODUCTION: Motor unit (MU) behaviour is the foundation of force output and is influenced by persistent inward currents (PICs), which amplify and prolong synaptic inputs and allow gain control of motor output. Despite known sex differences in MU discharge rate (DR) (1) and the magnitude of PICs (2), little is known about whether gain control differs between the sexes or across the female menstrual cycle (MC). Recent work suggests fluctuations in oestrogen (E) and progesterone (P) might contribute to modulations in DR at low force output (3), but as contraction intensity rises, estimates of

PIC magnitude also increase (4). Examining MU behaviour during increasing intensity contractions might provide insight into the interactions between hormones and PICs. We hypothesised that DR and PICs would increase with contraction intensity, and intensity-specific increases will be enhanced when E concentration is elevated during the pre-ovulatory (OV) and mid-luteal (ML) phases; whereas elevated P concentration would blunt this increased gain in the ML phase.

METHODS: Thirteen females (27 ± 6 years) participated across three institutes, as part of a wider study. Participants reported a regular MC, confirmed by cycle tracking and urine ovulation testing, retrospectively verified with serum hormone concentrations. After one tracked cycle, participants visited the lab in three phases of the subsequent MC(s): early follicular (EF), OV, and ML. During each visit, participants performed triangular dorsiflexion contractions at 30, 50 and 70% maximum, and high-density electromyographic signals were sampled and decomposed into individual MU spike trains. Smoothed DRs were analysed for peak DR, and DR hysteresis (ΔF) using the paired MU analysis technique.

RESULTS: DR increased with contraction intensity, but was up to 10% higher during the ML phase compared to OV regardless of intensity ($+0.74$ - 1.99 pulses per second [pps]; $p \leq 0.043$). Estimates of PIC magnitude were modulated by MC phase and intensity. At 30%, ΔF was up to 12% greater at ML (5.89 ± 0.29 pps) compared to EF (5.19 ± 0.28 pps) and OV (5.33 ± 0.28 pps; $p \leq 0.003$) but not at 50 and 70% ($p \geq 0.139$). There was a significant interaction between phase and intensity ($p = 0.002$) whereby ΔF did not increase with intensity during the ML phase as it did in the other phases.

CONCLUSION: While DR was greater across all contraction intensities in the ML phase compared to OV, estimates of PICs across the MC were sensitive to contraction intensity, which presented as a saturation of PICs during the ML phase. This suggests that MC phase, and the associated fluctuations in E and P, do affect MU excitability, but these MC-related effects are diminished during higher intensity outputs. These data provide new mechanistic insight into motor output at a range of intensities across the MC.

HIT THREE TARGETS WITH ONE ARROW: ECCENTRIC TRAINING HAS GREATER POTENTIAL THAN STATIC STRETCHING FOR DECREASING PASSIVE STIFFNESS, NOT JUST INCREASING STRENGTH AND FASCICLE LENGTHS, IN THE HAMSTRINGS

KAWAMA, R., OKUDA, Y., TAKAHASHI, K., NAKAMURA, M., WAKAHARA, T.

DOSHISHA UNIVERSITY; NISHIKYUSHU UNIVERSITY

INTRODUCTION: Hamstring strain injuries are common in high-speed running-based sports, with up to 80% of cases affecting the biceps femoris long head (BFlh) [1]. Recently, high passive muscle stiffness has been identified as a risk factor for strain injuries [2], alongside low muscle strength and short fascicle lengths. Passive muscle stiffness has traditionally been recognized to chronically decrease with repeated passive lengthening (e.g., static stretching); however, its actual efficacy remains controversial [3]. Instead, during active lengthening (eccentric contraction), the combination of externally applied tensile and internally generated contractile forces theoretically imposes greater mechanical stress on muscle fibers and connective tissues [4], potentially leading to further decreases in passive muscle stiffness than static stretching. Here, we examined chronic adaptations of passive stiffness in the biarticular hamstring muscles after long-term eccentric-only knee flexion training (ECC) versus knee-extended static stretching (SS).

METHODS: Eleven healthy young males participated in a 10-week intervention (three sessions per week) involving ECC for one leg and SS for the other. The ECC consisted of three sets of 10 repetitions performed at 50% of maximal eccentric torque, within 50 to 100% of the maximal range of motion, at an angular velocity of $5^\circ/\text{s}$. The SS involved three sets of stretching held for the same duration as ECC, at 100% of the maximal range of motion. Before and after the intervention, the shear moduli and architectures of the BFlh, semitendinosus, and semimembranosus (SM) were assessed using shear wave elastography and diffusion tensor MRI, respectively. Maximal isometric knee flexion torque was measured with a dynamometer. These variables were analyzed using the generalized mixed-effects models.

RESULTS: The maximal isometric torque increased after ECC (57% [mean value], $p < 0.01$), but not after SS. The volumes of the three muscles substantially increased after ECC (22 to 42%, all $p < 0.01$), whereas BFlh volume did not increase after SS. The fascicle lengths of BFlh (34%) increased after ECC ($p < 0.01$), but not after SS. Notably, both shear moduli of BFlh (-11%) and SM (-25%) decreased after ECC (all $p < 0.05$), whereas only SM shear modulus (-18%) decreased after SS ($p < 0.01$).

CONCLUSION: This study provides the first evidence that ECC has greater potential than SS for decreasing passive stiffness of a specific muscle, as well as increasing muscle strength and fascicle lengths within a matched intervention period. Our findings represent an important first step toward reconsidering the conventional approach to a chronic decrease in passive muscle stiffness and may offer practitioners a more comprehensive and time-efficient strategy aimed at preventing BFlh strain injury.

EXPERIMENTALLY-INDUCED THERMAL PAIN AND NATURALLY OCCURRING MUSCLE PAIN HAVE DIFFERENT EFFECTS ON FORCE PRODUCTION DURING A FIXED PERCEIVED EFFORT HANDGRIP TASK.

O'MALLEY, C., MANGIN, T., BERGEVIN, M., MONTI, I., FULLERTON, C., MAUGER, A., RAINVILLE, P., PAGEAUX, B.

UNIVERSITY OF EXETER

INTRODUCTION: At fixed workloads, experimentally-induced or naturally occurring muscle pain increase perceived effort (PE) compared to innocuous conditions. However, potential differences or interactive effects between pain types on PE and motor behaviour are relatively unknown. We examined the changes in force production during a fixed PE task with concurrent experimental thermal pain and naturally occurring muscle pain. We hypothesised that both sources of pain would lead to a reduction in force during fixed PE tasks.

METHODS: Forty healthy active adults (50% female, 25 ± 4 years old) visited the laboratory twice to perform an intermittent (3s ON:OFF) isometric handgrip task performed at a light (13/100) or hard (50/100) PE intensity – visit order randomised. Each visit followed the same procedure, with an experimental and control condition interspersed by 2min rest – order randomised. Each condition involved two blocks (block 1 and block 2) of 5 contractions each, repeated 5 times. A painful thermal stimulation was applied specifically in block 1 of the experimental condition, while a non-painful warm stimulation (control) was applied in all other blocks. Participants rated thermal and muscle pain during a 30s rest period after each block on the category-ratio 100 scale. Force (peak and mean force, integral) and electromyographic (EMG) signals were continuously recorded. Data were analysed with repeated measures ANOVAs, with a-priori focus on i) the condition $\times$ block interaction to isolate the effect of thermal pain in block 1 of the experimental condition, ii) the intensity $\times$ condition $\times$ block interaction to determine the effect of PE intensity on thermal pain-related effects. Linear regression analysis was used to assess how muscle pain affected force production, while controlling for PE intensity, sex and their interaction.

RESULTS: The intensity effect on force and EMG (all $p < .001$) confirmed that participants understood the PE task. The condition $\times$ block effect revealed a higher force production (all $p < .002$, $\eta^2 > .212$) in the presence of thermal pain. There was no intensity $\times$ condition $\times$ block effect on force production (all $p > .570$, $\eta^2 < .003$). The linear regression analysis revealed that when muscle pain increased by one unit, there was a decrease of 0.37N peak force, 0.25N mean force, and 0.80N.s force integral (all $p < .001$).

CONCLUSION: Contrary to our hypothesis, when participants regulate their force production according to a fixed PE intensity, thermal pain leads to an increased force production. Alternatively, increased muscle pain is linked to a decrease in force production. The intensity of PE did not impact thermal pain-related effects on force production. When thermal pain is induced, exerting more force may be a distraction strategy that facilitates exercise-induced hypoalgesia. However, when experiencing muscle pain, increasing force is likely counterproductive as this would promulgate further muscle pain.

THE DISCHARGE CHARACTERISTICS OF MOTOR UNITS IN PERONEUS LONGUS AND BREVIS DIFFER DURING FOOT ABDUCTION AND ANKLE PLANTAR FLEXION.

LYKIDIS, A., AMIRIDIS, I.G., SAHINIS, C., ENOKA, R.M.

ARISTOTLE UNIVERSITY OF THESSALONIKI

INTRODUCTION: Peroneus Longus (PL) and Peroneus Brevis (PB) are activated during abduction of the subtalar joint and plantar flexion of ankle joint. Previous studies have found that PL exhibits greater EMG amplitude during abduction than plantar flexion from low-to-moderate target forces[1]. Moreover, the conduction velocity of muscle fiber action potentials differs between two functions[2]. These results suggest that the discharge characteristics of Motor Units (MUs) discharge likely differs between the two functions. The purpose of our study was to compare the discharge characteristics of MUs from peroneal muscles during abduction of the subtalar joint and plantar flexion of ankle joint.

METHODS: Nine active males consented to participate in the study. Ultrasound recordings were used to ensure the appropriate placement of the grid electrodes over the PL and PB muscles. The experimental procedure comprised of isometric contractions of abduction and plantar flexion of the foot at five target forces (5, 10, 20, 40 and 60% of MVC) during which HD-EMG recordings were obtained from PL and PB.

Force fluctuations during the steady contractions were quantified as the Coefficient of Variation for force (CoV force) separately for abduction and plantar flexion. Moreover, the MU discharge characteristics comprised Recruitment Threshold (RT), Mean Discharge Rate (MDR), Coefficient of Variation of InterSpike Interval (CoV ISI) and Standard Deviation of filtered Cumulative Spike Train (SD fCST).

Linear mixed models were used to compare muscles and functions at five target forces. In all models, muscles, functions, and target forces were specified as fixed factors, and participants were assigned as random factor.

RESULTS: Significant effects were found for all five outcome variables: (1) CoV force during abduction was significantly greater than that during plantar flexion ($p < 0.05$); (2) RT of MUs in PL was significantly greater during abduction than plantar flexion across all target forces ($p < 0.05$), whereas RT of MUS in PB was greater during plantar flexion than abduction ($p < 0.05$); (3) MDR increased linearly with target force ($p < 0.05$); (4) CoV ISI was significantly greater during abduction than during plantar flexion for both muscles; and (5) the variability in neural drive (SD fCST) was significantly less during abduction than plantar flexion ($p < 0.01$) and for PB compared with PL ($p < 0.05$).

CONCLUSION: These results indicate that the discharge characteristics of MUs in the peroneal muscles differ during foot abduction and ankle plantar flexion. These findings suggest that the neural drive to the muscles differs during the two actions.

AN IMMERSIVE AND HOLISTIC ONE-WEEK BLUE EXPERIENCE TO IMPROVE THE OVERALL WELL-BEING OF PERSONS WITH PARKINSON'S DISEASE: THE SAIL4PARKINSON PROJECT

NATALE, D., MELONI, M., MODUGNO, N., DELLA MORTE, S., CARTA, F., PERRA, E., DI GIROLAMO, C., CAMPLONE, P., BANDIERA, P., MANCA, A., DI BLASIO, A., CUGUSI, L.

UNIVERSITY OF SASSARI; UNIVERSITY OF VERONA

INTRODUCTION: The Sail4Parkinson (S4P) is a one-week adapted physical activity intervention program for persons with Parkinson's disease (PD), with the mission of combining physical training of water sports with the physical, emotional, and psychological stimulus that comes from contact with the sea and the lands around. The aim of this study was to investigate the acute effects of different innovative aquatic and mind-body activities on clinical, psychosocial, and motor symptoms in persons with PD after the S4P project week.

METHODS: Thirteen subjects (6M:7F, median Hoehn-Yahr: 2; range: 2-3) volunteered to participate in the one-week S4P project. From the second to the sixth day, several aquatic activities (i.e., sailing, surfing, paddling) were performed during the day after a daily session of mindfulness at sunrise, yoga, or tai chi at sunset. On the other hand, during the first (PRE) and the last (POST) day, main general and PD outcomes (i.e., anthropometrics, body composition, balance, muscular strength, upper-limb flexibility, heart rate variability, and quality of life) were assessed.

RESULTS: Repeated-measures ANOVA and adjusted post-hoc comparisons revealed significant changes in Fat-Free Mass (PRE-POST change: +1.80%; $p=0.049$) and Skeletal Muscle Mass (PRE-POST change: +2.69%; $p=0.044$). A significant reduction was observed in the time to complete the Five Times Sit-to-Stand Test (PRE-POST change: -14.75%; $p=0.002$) and the time to complete the Timed Up and Go Test (PRE-POST change: -15.93%; $p=0.005$). Balance evaluations showed a significant reduction in mediolateral oscillation length (PRE-POST change: -39.18%; $p=0.020$) and mediolateral oscillation velocity (PRE-POST change: -39.18%; $p=0.020$), both performed with open eyes. Non-parametric test run on clinical scores revealed a significant reduction in the Apathy Evaluation Scale (PRE-POST change: -20.61%; $p=0.028$).

CONCLUSION: Despite the short-term intervention, the S4P project demonstrated several beneficial effects on both motor and non-motor PD symptoms, reducing fall risk and apathy. Preliminary data suggest that these innovative activities may be valuable for this population, particularly in enhancing psychosocial well-being through teamwork and blue environmental stimuli. Therefore, promoting these activities to be repeated twice per year, for instance, and promoting similar training at home, could become an effective strategy for improving the management of PD and the overall quality of life of these persons.

EFFECT OF A 12-WEEK LIFESTYLE INTERVENTION PROGRAM ON FREE-LIVING GLYCEMIC PROFILE AND CARDIOMETABOLIC HEALTH IN BREAST CANCER SURVIVORS WITH METABOLIC SYNDROME

INTRODUCTION: Cancer treatments and a sedentary lifestyle increase the risk of type 2 diabetes (T2D) in breast cancer survivors (BCS). Lifestyle Interventions (LI), which provide physical activity (PA) and dietary guidance, may be an effective adjunctive treatment for BCS, but the impact of exercise training on glucose homeostasis remains inconclusive [1]. This study aimed to compare glucose variability indices between two groups of BCS participating in the MovIS clinical trial [2].

METHODS: BCS patients with metabolic syndrome ($n=27$, 52.3 ± 8.6 yrs [mean $\pm$ SD]) were randomized into a control group (CG, $n=12$) and an intervention group (IG, $n=15$). All patients received recommendations on PA and Mediterranean diet before beginning a 12-week trial, during which they kept a daily log for PA. IG patients also underwent a 3-times-a-week aerobic training program with progressive increases in exercise intensity (40-70% of heart rate reserve) and duration (20-60 min). Before (T0) and after (T1) the trial, participants' body composition (BIA), cardiorespiratory fitness (GXT estimated VO_2max), and cardiometabolic profile (routine laboratory parameters) were assessed along with glycemic variability (flash

glucose monitor - FGM), which was assessed over 14 days (12 ± 1.8 days) after T0 and before T1. Glycemic variability was calculated with the EasyGV software (v.9.0.R2). Statistical significance ($\alpha=0.05$) was determined using a Repeated Measures GLM (SPSS software v.17).

RESULTS: At T1, both groups significantly improved fat mass (CG -1.0%; IG -3.8%), triglycerides (CG -4.2% IG: -15.9%), insulin levels (CG -14.1%; IG -15.6%), and HOMA-IR (CG -13.7%; IG -16.3%). Cardiorespiratory fitness (IG +3.1%; IG +16.4%) and between-day glycemic variability index (CG +12.5%; IG -3.6%) significantly changed in both groups and resulted significantly better in the IG compared to the CG. Time spent within the normal glucose range (CG -11.0%; IG -1.8%) and with a glycemia above 180 mg/dL (CG: +1.1%; IG +0.7%) worsened at T1. Although time x group interactions were, respectively, nonsignificant and barely significant, CG changes were broader.

CONCLUSION: The LI program improved body composition and cardiometabolic health in BCS patients at high risk for T2D, with an overall, although nonsignificant, lower effectiveness in CG than in IG patients. Since aerobic training effectively increased cardiorespiratory fitness solely in the IG and given that selected parameters of the glycemic profile improved significantly more in the IG than in the CG group, improvements seem to be attributable to the supervised exercise as an adjunctive effect over guidance alone. However, other glycemic parameters did not improve in IG patients. Thus, further research is needed to support the role of aerobic training in improving glycemic profile in BCS at high risk of diabetes.

VIRTUAL REALITY-BASED EXERGAME FOR HOSPITALIZED CHILDREN WITH CANCER: AN EXPLORATORY STUDY ON COMPLIANCE, ACCEPTANCE AND EXERCISE INTENSITY.

DEFORGES, J., VU, A., GANDEMER, V., BONNEAU-LAGACHERIE, J., DROUADENNE, F., GASTINGER, S., BIDEAU, B., SOLADIÉ, C., RÉBILLARD, A.

UNIVERSITY OF RENNES 2

INTRODUCTION: Pediatric cancers represent 2270 new cases each year in France [1]. The disease and its treatments cause significant symptoms (e.g., fatigue, reduced quality of life). Exercise is recognized as a non-pharmacological intervention in pediatric oncology to mitigate the numerous side effects [1]. However, exercise is often restricted by the constraints of cancer treatments and hospitalization (e.g., isolation in sterile room, amputation, fatigue) [1]. Virtual Reality-based exergames (VRE) have shown promise in promoting physical activity [2] but their application in pediatric oncology remains underexplored. This study aims to assess the feasibility of a VRE for pediatric cancer patients undergoing treatment in a hospital setting. Specifically, it evaluates compliance and acceptance while assessing exercise intensity to ensure alignment with WHO recommendations (> 3 MET).

METHODS: Thirteen pediatric cancer patients (diagnosed with leukemia or sarcoma) participated in VRE sessions proposed four times during afternoons per week over a two-month period in the pediatric oncology unit of Sud Hospital, Rennes. The VRE used in this study was developed by the lab team and designed to resemble Beat Saber with additional adaptability options. A total of 131 sessions were analyzed to assess compliance rates (number of sessions offered relative to those proposed), Technology Acceptance Model [3] was used to assess acceptance and exercise intensity was assessed with Lee et al. model [4].

RESULTS: The VRE showed a solid compliance rate of 68%, with individual variability influenced by factors such as age, prior VR experience, and intended use. Acceptance was high, with a strong user experience rating ($5.36/6 \pm 0.51$), and no serious side effects were reported. The average exercise intensity per child reached 4.44 ± 1.91 MET, exceeding the moderate-intensity threshold.

CONCLUSION: The key findings indicate that this VRE practice is feasible and well-accepted in a pediatric oncology setting, providing effective moderate-to-vigorous exercise levels in accordance with WHO recommendations while ensuring patient engagement, despite individual differences. Expanding the variety of VR content could better cater to the needs of diverse age groups, particularly adolescents. Furthermore, integrating autonomous adaptation based on physiological and kinematic data could improve the programs effectiveness and engagement by targeting specific intensity levels.

FUNCTIONAL EVALUATION AND EXERCISE TRAINING FOR PEOPLE LIVING WITH CEREBELLAR ATAXIA: THE ATAEXER TRIAL

FAGGIAN, S., AGOSTINI, E., ROMITO, S., BONATO, G., CODIGNOLA, A., NEUNHAEUSERER, D., MARCOLIN, G., CARECCHIO, M., ERMOLAO, A.

UNIVERSITY OF PADOVA

INTRODUCTION: Cerebellar ataxia of various nature causes poor movement coordination; progressive deterioration of gait and balance control are the most disabling symptoms affecting independence in daily activities. No satisfying disease-specific treatment exists in neurodegenerative ataxias, and rehabilitation programmes are necessary. The ATAEXER Trial aims to provide a hybrid training intervention model, featuring a supervised outpatient training intervention, integrated with a home-based multicomponent exercise programme for people living with cerebellar ataxia. This study is the first to evaluate such a training model focused also on coordination and rhythm auditory stimulation in this population on clinical, functional and patient-related outcomes.

METHODS: Patients with mild neurodegenerative cerebellar ataxia still able to walk independently and healthy age-matched controls were included in this self-controlled clinical trial. Patients were assigned to an eight-week phase of usual care as control period (t0–t1) followed by an eight-week intervention phase (t1–t2) with an exercise training programme featuring four training sessions per week provided either in a supervised or non-supervised setting. The primary outcome was the change in the walking efficiency as cost of transport at the preferred walking speed, secondary outcomes were ataxia severity measured by clinical scales (SARA and Mini-BESTest) and patient-reported, as well as muscular endurance and strength, balance control and walking ability.

RESULTS: 7 individuals with mild cerebellar ataxia (spinocerebellar ataxia type 1=3, fragile X-associated tremor/ataxia syndrome=1, idiopathic cerebellar ataxia=3) and 9 healthy subjects completed the study. Adherence to the ATAEXER Trial was 100% and session attendance was 90%. Discriminability between ataxic and healthy subjects was a characteristic of almost all measured parameters, and the whole panel of outcome categories improved with the exercise programme. The cost of transport improved significantly only after the intervention phase (0.202 at t0, 0.206 at t1 and 0.183 mL·(kg·m)⁻¹ at t2). Walking ability during a goal-oriented stress-walk at fast speed and corresponding spatio-temporal parameters, as well as muscular endurance appeared most strongly associated to measures of clinical and self-reported ataxia severity ($Rho = 0.77$ to 0.86), while static balance control and muscular strength appeared less correlated.

CONCLUSION: The ATAEXER trial proved effective in improving ataxia severity; our findings suggest that a specific, hybrid exercise training programme may be considered as a standard clinical intervention in patients with cerebellar ataxia regardless the specific underlying neurodegenerative disease. In addition, a set of evaluations has been recommended with focus on (i) discriminability between healthy and cerebellar ataxic individuals, (ii) association with ataxia severity and (iii) responsiveness to an exercise training programme.

EFFECTS OF NORDIC WALKING TRAINING ON ENERGY COST IN PEOPLE WITH MULTIPLE SCLEROSIS

LIBERALI, G., MARTINIS, L., CORREALE, L., DELL ANNA, S., TAVAZZI, E., BERGAMASCHI, R., MONTOMOLI, C., BUZZACHERA, C.F., PEYRÉ-TARTARUGA, L.A.

UNIVERSITY OF PAVIA

INTRODUCTION: Multiple sclerosis (MS) is a chronic neurological disease that leads to various functional impairments, including gait disturbances. These disturbances can alter walking mechanics, potentially increasing energy expenditure during locomotion in people with MS. In healthy individuals, gait economy follows a U-shaped curve, influenced by the pendular mechanism of walking, which may be impaired in people with movement disorders. Considering the influence of gait economy on cardiorespiratory capacity and the scarce information on the U-shaped curve modifications in people with MS, this study aimed to examine the effects of an 8-week Nordic walking training program on the cost of transport in the MS population. Additionally, training induced changes in gait-related parameters, including optimal (OWS) and self-selected walking speed (SSWS), and the locomotor rehabilitation index (LRI), were also investigated.

METHODS: Nine individuals (6 women; mean age: 39.8 ± 7.67 yr) with definite relapsing-remitting MS (EDSS mean 1.66 ± 0.55) met the inclusion criteria and were enrolled in this study. All participants were tested before and after an 8-week Nordic walking training period. The 10-meter walking test was performed to assess self-selected walking speed. To evaluate the cost of transport, oxygen consumption was measured while individuals walked at three different speeds on a motorized treadmill (1 km/h, 3 km/h, and 5 km/h). After determining the cost of transport, OWS and LRI were calculated accordingly. We applied a linear mixed model using $\alpha=0.05$ (JASP software).

RESULTS: Regarding the overall training effects of energy cost at three-time speeds, no statistically significant effect of time ($p=0.30$) and interaction between time and speed ($p=0.139$) were found. However, there was observed a statistically significant effect of speed ($p<0.001$). Post hoc testing revealed a significant difference in energy cost at each speed ($p<0.001$). No significant pre- and post-training differences were found for the SSWS, OWS, and LRI.

CONCLUSION: The metabolic cost data showed a U-shaped trend similar to that reported in the literature for healthy individuals, which may be attributed to the low level of disability in the study sample. The maintenance of the cost of transport and LRI after the 8 weeks of Nordic walking may be due to the small sample size or the need for a longer training duration. However, further research on the energy cost of walking in individuals with MS is warranted, as it holds significant clinical implications, particularly for incorporating these parameters into the prescription of individualized exercise programs. This preliminary study provides noteworthy insights into the energetics and functionality of individuals with MS, highlighting the need for larger investigations to confirm these trends.

EFFECT OF HIGH-INTENSITY INTERVAL EXERCISE-CONDITIONED HUMAN SERUM ON BREAST CANCER CELLS

VALERO BRETON, M., LEDESMA-RONCERO, P., RODRÍGUEZ-MIRÓN, M., LÓPEZ-MORENO, M., GUTIERREZ-HELLÍN, J., IGLESIAS-BADIOLA, M., MENDOZA-LAIZ, N., SANTOS-TEJEDOS, C., ZBINDEN-FONCEA, H.

UNIVERSIDAD FRANCISCO DE VITORIA

INTRODUCTION: Physical exercise, particularly high-intensity interval exercise (HIIE), has demonstrated anti-tumor effects, partly through the release of myokines—proteins secreted during muscle contraction that facilitate inter-organ communication and regulate essential biological processes. Previous studies have shown that HIIE-conditioned human serum (HIIE-HS) can reduce the viability and proliferation of breast cancer cells. However, the precise molecular mechanisms underlying these effects remain unclear, highlighting the need to investigate the impact of HIIE-conditioned serum exposure. Therefore, this study examines the mechanisms by which MCF-7 and MDA-MB-231 breast cancer cell lines respond to human serum collected before and after HIIE, focusing on cell viability, apoptosis, transcriptome analysis, and key signaling pathways involved in tumor progression.

METHODS: MCF-7 and MDA-MB-231 breast cancer cells were incubated with human serum for 48 hours. Subsequently, cell viability was assessed using the MTT assay, while Western blot analyses targeted components of the Akt/mTOR pathway, apoptosis markers, and inflammation-related proteins. Apoptosis was further evaluated by flow cytometry using Annexin V and propidium iodide staining to distinguish early and late apoptotic cells. RNA sequencing was performed to assess transcriptional alterations induced by HIIE-HS, focusing on proliferation, cell cycle regulation, apoptosis, cell adhesion, and other key biological processes.

RESULTS: The main findings indicate a decrease in 4EBP1 phosphorylation, with trends observed in Akt and P70S6K1. Additionally, increases in pro-caspase 9 and pro-caspase 3 were detected. However, cleaved caspase-3 was not observed, suggesting potential apoptosis resistance, which was confirmed by flow cytometry. Modifications were also observed in inflammation-related proteins such as MyD88 and NF- κ B. RNA-seq analysis revealed an upregulation of apoptosis-related genes (e.g., TIPUH1) and negative regulators of cell proliferation (e.g., AZGP1), among others.

CONCLUSION: These findings highlight the molecular mechanisms through which HIIE-HS impacts breast cancer cells, enhancing the understanding of how physical exercise affects tumor progression. This evidence reinforces the need for further research into the therapeutic potential of physical exercise as an adjuvant strategy in breast cancer treatment.

BLOOD LIPIDS AND OXIDATIVE STRESS MARKER IN RESPONSE TO A FATMAX TEST IN HYPERBILIRUBINEMIA SUBJECTS WITH GILBERT'S SYNDROME

STELZER, T., KRIPP, A.M., DRAXLER, A., BRAGAGNA, L., MAQBOUL, L., FARAJ-ALLAH, D., HONEDER, L., HANDL, N., CHWOJKA, M., KÖNIG, D., WAGNER, K.H.

UNIVERSITY OF VIENNA

INTRODUCTION: In several studies, moderately elevated unconjugated bilirubin levels (UCB), as observed in Gilbert's syndrome (GS), have been associated with a lower risk for cardio-vascular diseases. People with GS have been frequently described to have lower blood lipids. Furthermore, bilirubin is known to be a potent antioxidant in the human metabolism. Some studies also indicated that elite athletes show higher UCB levels than non-athletes. Considering all these observations it seemed interesting to look closer at the effect of acute exercise on blood lipid levels and some oxidative stress parameters in response to a graded cycle ergometer test in GS subjects and healthy controls.

METHODS: In a human case control study, where controls were age and gender matched, 40 GS subjects ($UCB > 17.1 \mu\text{mol/l}$) and 40 controls (C) between 18 and 65 years of age were included. All participants were healthy, moderately physically active and nonsmokers. After having fasted for 12 h overnight, all subjects completed a graded exercise test on a cycle ergometer, which was terminated at $RER = 1.00$. Before and after the test venous blood samples were taken. Total (TC) and HDL cholesterol, as well as triglycerides were measured and LDL cholesterol was calculated with the Friedewald equation by a certified laboratory. UCB was measured via high performance liquid chromatography (HPLC). For oxidative stress parameters, photometric methods were used for the measurements of the ratio of reduced to oxidized glutathione (GSH:GSSG) and FRAP (ferric reducing antioxidant power). DNA-damage was assessed using the comet assay.

RESULTS: At baseline, GS subjects (86.68 ± 20.234) had significantly ($p = 0.041$) lower levels of LDL than C (96.23 ± 20.871). The rise in TC during exercise was significantly higher in C subjects ($p = 0.027$). UCB levels rose significantly higher in GS subjects ($p < 0.001$). Regarding oxidative stress parameters, the increase in the GSH:GSSG ratio was higher in C by trend ($p = 0.081$). No difference between groups was observed in the other oxidative stress parameters, however all FRAP, GSH and GSSG increased in all groups, whereas DNA-damage decreased. When dividing into two age groups (cut-off 35 years) GS subjects in the older group had significantly lower LDL levels and a lower TC:HDL ratio as well as a lower LDL:HDL ratio (all $p < 0.05$), whereas in younger subjects there was no significant difference at baseline. However, in younger subjects GSH levels were significantly higher in C subjects ($p = 0.037$).

CONCLUSION: This study again shows that the effect of bilirubin and its metabolism on blood lipid levels becomes more important with age. Furthermore, it seems that the graded exercise test had no impact on blood lipid levels, blood glucose or oxidative stress parameters. UCB levels seem to have no impact on the influence of exercise on the analyzed parameters. However, it is interesting that bilirubin metabolism of GS subjects seems to be more triggered by exercise compared to the normo-bilirubinemic controls.

THE ABSENCE OF CARNOSINE IMPACTS OXIDATIVE STRESS STATUS: A STUDY WITH CARNIS1 -/- RATS

FORMALIONI, A., SHIMIZU, M.H.M., MARIANO, K.A.A., PEREIRA, R.M., MUNHOZ, C.D., SEGURO, A.C., ARTIOLI, G.G.
UNIVERSITY OF SÃO PAULO

INTRODUCTION: Carnosine (β -alanyl-L-histidine) is a dipeptide with important biological functions abundantly expressed in excitable tissues such as the nervous system and the skeletal muscle. Carnosine has anti-inflammatory, antioxidant, anti-glycation and reactive carbonyl-quenching properties. However, the functions played by endogenous carnosine remain poorly understood in the literature. We investigated the impact of carnosine absence on oxidative stress induced by an acute physical exercise session (PE), and by an experimental chronic kidney disease model (5/6 Nx), in CARNIS1 knockout rats (KO) and wild-type controls (WT).

METHODS: 64 male 4 months-old wistar rats were used in two sub-studies: the PE study (WT Exercise: n=8, KO Exercise: n=8, WT Control: n=8, KO Control: n=8) and the 5/6 Nx study (WT Sham: n=8, KO Sham: n=8, WT 5/6 Nx: n=8, KO 5/6 Nx: n=8). The exercise protocol consisted of an acute 90-minute swimming session with a 3% body weight load attached to the tail. Kidney disease was induced by 5/6 nephrectomy, i.e., a full nephrectomy of the right kidney followed by the ligation of two branches of the left renal artery. The sham surgery served as a control. In the PE study, oxidative stress markers including superoxide dismutase (SOD) and catalase (CAT) activity, thiobarbituric acid reactive substances (TBARS), and protein carbonyl content were analyzed in the soleus muscle. In the 5/6 Nx study, these parameters were measured in kidney tissue, and GFR was assessed via inulin clearance (Cin). An one-way ANOVA was performed to compare groups and Mann-Whitney was used to assess GFR differences between WT and KO. All data are expressed as mean $\pm$ SD.

RESULTS: In the PE study, acute PE did not alter CAT, SOD, or TBARS concentrations but it increases protein carbonyl content, with no differences being observed between genotypes in the soleus muscle. The absence of carnosine led to a significant increase in TBARS levels after exercise in the KO control group compared to the WT control group (23.34 ± 5.84 vs. 11.64 ± 3.50 nmol MDA/mg protein respectively, $p=0.0003$). In the 5/6 Nx study, KO 5/6 Nx exhibited significantly higher SOD activity compared to WT 5/6 Nx (45.89 ± 16.63 vs. 20.57 ± 8.88 U/mg protein respectively, $p=0.0019$) and increased protein carbonyl content (1.87 ± 0.09 vs. 1.66 ± 0.13 mmol carbonyl/mg protein respectively, $p=0.0079$). A similar response was observed in KO sham vs. WT sham (1.74 ± 0.09 vs. 1.51 ± 0.14 respectively, $p=0.0039$). We found no differences between genotypes in kidney TBARS concentrations. TBARS levels in plasma were significantly elevated in KO 5/6 Nx compared to WT 5/6 Nx (1.87 ± 0.09 vs. 1.66 ± 0.13 nmol/mL plasma respectively, $p=0.0013$). KO sham rats exhibited a markedly reduced Cin compared to WT sham (0.465 ± 0.080 vs. 0.574 ± 0.104 mL/min/100g respectively, $p=0.085$).

CONCLUSION: The absence of endogenous carnosine affects redox balance in both skeletal muscle and renal tissue. We identified a crucial role of endogenous carnosine in maintaining renal homeostasis.

ACUTE AND CHRONIC CELLULAR MECHANISMS DRIVING CHEMOTHERAPY-INDUCED SKELETAL MUSCLE ATROPHY IN BREAST CANCER PATIENTS: THE PIVOTAL ROLE OF NF-KB

MALLARD, J., DEBRUT, L., HUCTEAU, E., SOMME-BENDER, L., BISCHOFF, H., MOINARD-BUTOT, F., SCHOTT, R., COLIAT, P., BENDJAMA, A., WELTZER, L., SHARIFI TAFRESHI, A., BOUTONNET, L., LAVERNY, G., KEIME, C., FAVRET, F., PIVOT, X., HUREAU, T.J., PAGANO, A.F.

INSTITUT DE CANCÉROLOGIE STRASBOURG EUROPE / UR 3072

INTRODUCTION: Early breast cancer patients frequently receive (neo)adjuvant chemotherapy (CT), commonly involving sequential administrations of epirubicin–cyclophosphamide (EC) followed by paclitaxel (TAX). While this treatment improves survival rates, it also induces severe skeletal muscle atrophy with underlying mechanisms that remain poorly understood. This study aimed to investigate acute and chronic mechanisms of chemotherapy-induced skeletal muscle atrophy by distinguishing the specific effects of EC and TAX.

METHODS: Vastus lateralis muscle biopsies were collected from breast cancer patients before and 4 days after the first administration of EC (N=10) or TAX (N=10), or before and after the entire CT treatment (N=11). Histological analyses, western blotting, and RNA sequencing were performed. Cell culture experiments were conducted on human skeletal muscle myotubes (LHCN-M2) treated with EC or TAX, with or without sulfasalazine, a specific NF-kB inhibitor.

RESULTS: Muscle fibers cross-sectional area decreased post-EC (-33%; $p<0.001$) with no further reduction observed post-TAX or post-CT, suggesting that muscle atrophy at the end of treatment is primarily driven by EC administrations. RNA sequencing revealed a strong upregulation of NF-kB signaling, confirmed by increased p-NF-kB Ser536/NF-kB protein levels post-EC (+110%; $p=0.016$), post-TAX (+136%; $p=0.033$), and post-CT (+11%; $p=0.042$), along with increased p-IkBa Ser32/IkBa post-EC (+174%; $p=0.049$) and post-TAX (+360%; $p=0.051$). RNA sequencing also indicated an upregulation of proteasome-mediated degradation, supported by increased protein levels of MuRF1 and MAFbx post-EC (+176% and +29%; $p=0.004$ and $p=0.016$), post-TAX (+138% and +136%; $p=0.026$ and $p=0.048$) and post-CT (only MuRF1, +103%; $p=0.019$). Cell culture experiments showed that both EC and TAX induced myotube atrophy (-34% and -36%; $p<0.001$), increased proteasome activity (+335% and +263%; $p<0.05$), decreased protein synthesis flux (-80% and -26%; $p<0.05$),

and elevated the Bax/Bcl-2 protein levels ratio (+306% and +237%; $p < 0.01$ and $p < 0.05$), indicating apoptosis initiation. Notably, sulfasalazine fully prevented chemotherapy-induced myotube atrophy by attenuating proteasome activity and apoptosis but failed to restore protein synthesis.

CONCLUSION: By combining acute and chronic muscle biopsies with in vitro experiments, we provided a comprehensive analysis using histological, transcriptomic, and targeted protein expression analyses by Western Blot. Our findings highlight the pivotal role of NF- κ B signaling and subsequent proteasome activation in driving muscle atrophy, while demonstrating that its inhibition fully prevents chemotherapy-induced atrophy. Further research is warranted to develop muscle-specific NF- κ B inhibition strategies that preserve skeletal muscle function in chemotherapy-treated patients without interfering with the antineoplastic effects of the chemotherapy treatment.

MUSCLE ABNORMALITIES IN NON-HOSPITALIZED PATIENTS WITH POST-COVID-19 CONDITION

TRYFONOS, A., JÖRNÅKER, G., RUNDQVIST, H., LARSEN, F., MUTVEI, P., FERNANDEZ-GONZALO, R., RULLMAN, E., STÅL, P., GUSTAFSSON, T., RUNDQVIST, T., LUNDBERG, T.

EUROPEAN UNIVERSITY OF CYPRUS, KAROLINSKA INSTITUTET, KAROLINSKA UNIVERSITY HOSPITAL, SWEDISH SCHOOL OF SPORT AND HEALTH SCIENCES, UMEÅ UNIVERSITY

INTRODUCTION: Post-COVID condition (PCC) affects ~10% of SARS-CoV-2-infected individuals and manifests as persistent symptoms such as fatigue, exercise intolerance, and muscle weakness. Our group has previously shown that >60% of non-hospitalized PCC patients show myopathic signs on needle electromyography. Therefore, the aim of the current study was to assess the skeletal muscle of this cohort, including changes in muscle histology, mitochondrial respiration, and global gene expression.

METHODS: Biopsies were obtained from the vastus lateralis muscle of 28 non-hospitalized PCC patients without concomitant diseases (75% women, mean age 46.4 ± 10.4 years) and 28 age- and sex-matched healthy controls (79% women, mean age 46.6 ± 8.7). The analysis included morphological and pathological alterations, fiber type composition, fiber cross-sectional area, capillarization, number of myonuclei, presence of developmental myosin, CD68+ cells, macroautophagy markers, mitochondrial respiration and RNA sequencing.

RESULTS: PCC patients, compared to controls, had a higher percentage of angulated fibers, (median (IQR) 0.43 (0.00-3.20) vs. 0.00 (0.00-0.00); $P < 0.001$), small, rounded fibers (0.21 (0.00-1.20) vs. 0.00 (0.00-0.00); $P < 0.001$), fibers expressing fetal myosin (0.26 (0.00-1.15; vs. 0.00 (0.00-0.17); $P = 0.015$), and signs of fibrosis. Fiber cross-sectional area was significantly lower in PCC patients compared to controls (4031 ± 1365 vs. $4982 \pm 1463 \mu\text{m}^2$; $P = 0.018$), largely driven by differences in type 2 fiber size. There was a significantly lower number of myonuclei per fiber in PCC compared to controls (3.4 ± 1.1 vs. 4.1 ± 1.0 ; $P = 0.012$). There was no difference in presence of CD68 per fiber (0.28 ± 0.15 vs. 0.22 ± 1.0 ; $P = 0.115$), but there was a lower number of CD68 per muscle area in PCC compared to controls ($P = 0.004$). No difference was observed in macroautophagy markers LC3B ($P = 0.232$) or p62 ($P = 0.814$) between the groups. Capillary-to-fiber ratio in PCC patients was lower for both type 1 (2.2 ± 0.7 vs. 2.6 ± 0.9 ; $P = 0.044$) and type 2 fibers (1.8 ± 0.6 , vs. 2.2 ± 0.8 ; $P = 0.022$). The NADH-TR activity was generally lower in type 2 fibers in PCC patients, and the mitochondrial respiration was 11–28% lower in PCC patients, although not statistically significant. RNA sequencing revealed downregulation of 8 metabolic pathways, primarily related to oxidative phosphorylation ($\text{FDR} < 0.05$).

CONCLUSION: Non-hospitalized PCC patients show signs of morphological and pathological muscle changes that indicate processes of degeneration and regeneration. The smaller overall fiber size, lower mitochondrial oxidative capacity, and lower capillarization in PCC patients may be a consequence of reduced physical activity levels. The presence of clusters of atrophied angular and round-shaped fibers, signs of inflammation and fibrosis, and increased expression of fetal myosin may reflect myopathic and neurogenic post-viral effects.

INFLUENCE OF THE MENSTRUAL CYCLE ON FAT METABOLISM DURING SUBMAXIMAL ENDURANCE EXERCISE IN ACTIVE, EUMENORRHEIC WOMEN.

LAUXTERMANN, L., TRISKA, C.1,2, MATHY, A.1,2, PIRKER, V.1, SCHARHAG, J.1,3, WESSNER, B.1

1 UNIVERSITY OF VIENNA; 2 LEISTUNGSSPORT AUSTRIA; 3 AUSTRIAN INSTITUTE OF SPORTS MEDICINE

INTRODUCTION: Almost 42% of female athletes report subjective impairments in various phases of the menstrual cycle (MC), but there is limited evidence for objective performance declines [1,2]. Fluctuations in oestrogen and progesterone may affect performance via changes in substrate metabolism [3]. Therefore, this study investigates the impact of the MC on oxygen uptake and fat metabolism in active, eumenorrheic women during submaximal endurance exercise.

METHODS: The study lasted three full natural MCs (1 observation, 2 test MCs), during which six submaximal cycling tests were completed (two per menstrual phase (MP), late follicular phase (LFP), and mid-luteal phase (MLP)). The tests consisted of a square-wave step-transition protocol (25% (transition 1) and 65% (transition 2) of the difference between VT1 and maximal power; 6 min each; 20 W baseline). Breath-by-breath data, oxygen uptake kinetics, substrate utilization and total

energy expenditure (TEE) were measured in both low-intensity (IL) and high-intensity (IH) intervals. Twenty-three of 27 interested women fulfilled the inclusion criteria with 18 completing the study. Finally, only 11 women (age: 26.9 ± 4.7 yrs; BMI: 22.7 ± 2.6 kg/m²; VO_2max : 45.7 ± 4.9 mL/min/kg) showed a regular MC with ovulation and were included in the statistical analyses (means of the data from two MP, LFP or MLP measurements subjected to repeated-measures ANOVA).

RESULTS: Blood oestrogen levels differed significantly between MC phases ($p < 0.001$, $\eta^2 p = 0.800$), with the highest levels in LFP, followed by MLP and MP (all $p < 0.05$). Progesterone levels ($p < 0.001$, $\eta^2 p = 0.919$) were higher in MLP compared to LFP and MP ($p < 0.001$). However, fat ($p = 0.478$, $\eta^2 p = 0.071$) and carbohydrate metabolism ($p = 0.430$, $\eta^2 p = 0.081$), respiratory exchange ratio rate (ΔRER : $p = 0.367$, $\eta^2 p = 0.095$), and lactate ($\Delta\text{lactate}$: $p = 0.088$, $\eta^2 p = 0.216$) did not differ between cycle phases (MP, LFP, MLP). In addition, oxygen uptake kinetics (IL: $p = 0.401$, $\eta^2 p = 0.079$; IH: $p = 0.378$, $\eta^2 p = 0.093$), TTE (IL: $p = 0.338$, $\eta^2 p = 0.094$; IH: $p = 0.382$, $\eta^2 p = 0.080$), heart rate (IL: $p = 0.647$, $\eta^2 p = 0.027$; IH: $p = 0.727$, $\eta^2 p = 0.017$), gross efficiency ($p = 0.789$, $\eta^2 p = 0.023$), and RPE (IL: $p = 0.147$, $\eta^2 p = 0.175$; IH: $p = 0.103$, $\eta^2 p = 0.203$) did not differ between phases at both intensities.

CONCLUSION: Although hormone levels varied, performance and substrate metabolism did not differ significantly. The study's three-month observation period was a strength; however, excluding irregular cycles (52%) resulted in a small sample size insufficient to detect small- to medium-effect differences. We suggest that, in addition to hormone levels, personalized (even subjective) measures should be considered to clarify the complex relationship between the MC and performance.

IS OBESITY A CONDITION ASSOCIATED TO OVERACTIVE BLADDER?: A COMPREHENSIVE ANALYSIS

LÓPEZ-SEOANE PUENTE, J., GESTEIRO, E., PANTOJA-ARÉVALO, L., QUESADA-GONZÁLEZ, C., PORTALS-RIOMAO, A., CASTRO-ALIJA, M.J., PÉREZ-RUIZ, M., GONZÁLEZ-GROSS, M.

UNIVERSIDAD POLITÉCNICA DE MADRID

INTRODUCTION: Overactive bladder (OAB) is a common syndrome causing urgency, frequent urination, and nocturia, significantly affecting quality of life (QoL). Obesity worsens symptoms by increasing intra-abdominal pressure and bladder sensitivity, while OAB-related inactivity can lead to weight gain, creating a vicious cycle. Addressing weight management is crucial for improving symptoms and well-being in OAB patients. This study analyzes the relationship between obesity, physical activity (PA), sedentarism, and sarcopenia with OAB symptoms and QoL.

METHODS: This observational study is nested in a randomized controlled trial (ClinicalTrials.gov NCT04357223). OAB symptoms and QoL were analyzed by the International Prostate Symptom Score (IPSS). Obesity indicators included body mass index (BMI), categorized as normal weight, overweight, and obese, measured by stadiometer (SECA 217, Hamburg, Germany) and bioimpedance analysis (MC780MA, Tanita, Tokyo); and waist-to-hip ratio (WHR), classified as normal or increased metabolic risk, calculated from waist and hip circumferences, measured by anthropometric tape, using standard procedures. According to European consensus, sarcopenia cut-off points when measured by handgrip strength dynamometer are <27 kg for men and <16 kg for women. Handgrip strength was measured by digital dynamometer (TKK 5401, Takei, Niigata) and sarcopenia was assessed according to European consensus. PA and sedentarism were measured by International Physical Activity Questionnaire-long form (IPAQ). The criterion for establishing physical activity and sedentarism cut-off points is that established by the World Health Organization. Statistical analyses were performed with Python 3.13 ($\alpha = 0.05$).

RESULTS: 181 adults were recruited (34.8% women). Among all participants, 24.9% were sedentary and 3.9% had sarcopenia, while 28.9% were physically inactive. These results contrast with 54.5% who were overweight (32.6%) or obese (21.9%) and 52.8% who had an elevated WHR. Men showed high BMI and WHR (26.7 ± 4.1 kg/m² and 0.92 ± 0.08 , respectively), while women had BMI and WHR close to the upper limit, but within the normal range (24.8 ± 4.8 kg/m² and 0.79 ± 0.07 , respectively). No relationship with OAB symptoms and QoL were found between sarcopenia, PA and sedentarism. Nevertheless, BMI and WHR were significantly correlated to nocturia ($\tau = 0.24$; $p < 0.001$ and $\tau = 0.17$; $p = 0.027$, respectively) and QoL ($\tau = 0.15$; $p = 0.029$ and $\tau = 0.17$; $p = 0.027$, respectively). Nocturia and QoL were significantly different according to BMI ($H = 12.87$; $p = 0.001$; $\epsilon_2 = 0.06$ and $H = 6.16$; $p = 0.046$; $\epsilon_2 = 0.02$, respectively) and WHR ($U = 1881.5$; $p = 0.027$; $r = 0.19$ and $U = 1862$; $p = 0.028$; $r = 0.19$, respectively), showing those who had higher BMI or WHR worse scores in both questions. No differences were found for daytime voids or urgency symptoms.

CONCLUSION: Obesity and a high WHR were associated with lower QoL and more nocturia episodes but not with daytime voids and urgency. No relationship was found between sarcopenia, PA, or sedentarism with OAB symptoms.

MULTISESSION TDCS AND AEROBIC EXERCISE SYNERGISTICALLY IMPROVES FOOD CRAVING, IMPULSIVITY, AND COGNITIVE FLEXIBILITY IN OVERWEIGHT AND OBESE WOMEN WITH FOOD CRAVING

AMIRI, E., MALEK KHATAEI, S., MACHADO, D.G.D.S., GRUBER, M.

RAZI UNIVERSITY / UNIVERSITY OF KONSTANZ

INTRODUCTION: Overweight and obesity are rapidly becoming a global epidemic, and the WHO Acceleration Plan to Stop Obesity highlights the major global concern in this regard. Food craving is a strong desire to consume specific types of

food, identified as a major factor contributing to overweight and obesity (1). Evidence suggests that exercise induces beneficial psycho-cognitive changes, reducing food cravings and enhancing cognitive control over appetite (2). Alternatively, Transcranial Direct Current Stimulation (tDCS) has also targeted food craving and related neural mechanisms (3). Thus, incorporating a tDCS protocol into a physical activity program may yield synergistic effects, potentially leading to greater reductions in food craving. Therefore, we explored the effects of five sessions of tDCS followed by four weeks of aerobic exercise (AE) on food craving (FC), impulsivity (IMP), risky decision-making (RDM), and cognitive flexibility (CF) in overweight and obese women with food cravings.

METHODS: Thirty-six participants were randomly assigned to three groups (n=12 per group): 1) a-tDCS+AE; 2) Sham+AE; and 3) Control. In Phase 1, the a-tDCS+AE and Sham+AE groups received 5 consecutive sessions of anodal and sham tDCS, respectively. In Phase 2, both groups engaged in 3 sessions of moderate-intensity continuous AE per week for 4 weeks, while the control group received no interventions. Outcome variables were measured at baseline, after 5 days of tDCS, and after 4 weeks of AE. One month after the interventions concluded, FC and CF were also reported.

RESULTS: In Phase 1, FC decreased only in the a-tDCS+AE group. In Phase 2, FC decreased in both the a-tDCS+AE and Sham+AE groups; however, it returned to baseline levels for the Sham+AE group at follow-up, while it remained reduced for the a-tDCS+AE group. CF was higher in the a-tDCS+AE compared to the other groups and sham+AE compared to control after Phase 2. At follow-up, CF remained significantly increased only in the a-tDCS+AE group. IMP improved over time in the a-tDCS+AE group compared to the other groups. RDM significantly improved only in Phase 2 in a-tDCS+AE compared to the control.

CONCLUSION: We concluded that multisession anodal tDCS followed by four weeks of moderate AE could provoke synergistic effects causing greater and more lasting effects on food craving and its associated variables in overweight and obese females with food craving.

REGULATION OF FATMAX EXERCISE COMBINED WITH DIFFERENT MENSTRUAL CYCLE ON LIPID METABOLISM IN RECESSIVE OBESE WOMEN

ZHANG, P.

BEIJING SPORT UNIVERSITY

INTRODUCTION: According to recent survey and supervision of health condition, at present the physical constitution of young people in our country came down, proportion of overweight and obesity increased significantly, especially in females. Since blood concentrations of ovarian hormones fluctuate according to the phase of the menstrual cycle and affect the utilization of energy substrates during exercise, this paper probes into the effect of a long-term intervention combining maximal fat oxidizing intensity exercise with different phases of the menstrual cycle on lipid metabolism in recessive obese women, to guide them to do exercise scientifically and prevent cardiovascular disease.

METHODS: Forty-eight eligible recessive obese women (21.0 ± 2.3 yrs) without training experience were recruited and screened, then participated in the study that was approved by IRB at Beijing Sport University. They were randomized into follicular group, luteal group and control group. There were sixteen women in each group. Baseline testing were performed for all participants, including body morphology, fasting blood markers, body composition (DXA), maximal oxygen uptake test and maximal fat oxidation (Fatmax) test. Then, an eight-week exercise intervention was initiated for all participants at a participant-individualized Fatmax intensity for 45 min per intervention. The control group exercised four times per week, and the follicular and luteal groups added three additional exercises to the control group in the late follicular phase and middle luteal phase of each menstrual cycle, respectively. The same indicators as at baseline were measured again after the intervention.

RESULTS: 1) After intervention, participants in the follicular group had a very significant decrease in waist circumference, hip circumference, percentage of body fat ($2.34 \pm 1.88\%$) and fat mass ($P < 0.01$), and significant decreases in body weight and body mass index (BMI) ($P < 0.05$). 2) Participants in the luteal group had a very significant decrease in hip circumference ($P < 0.01$), significant decreases in waist circumference, body fat percentage ($1.12 \pm 1.56\%$) and fat mass ($P < 0.05$), and ApoA I to ApoB ratio (0.21 ± 0.33) were statistically significantly higher ($P < 0.05$). 3) In the control group, there was a very significant decrease in hip circumference, body fat percentage ($1.79 \pm 1.16\%$) and fat mass ($P < 0.01$), and significant decreases in waist circumference, body weight and BMI ($P < 0.05$). The amount of change in body weight, waist circumference, body fat percentage and fat mass of participants in the follicular group was significantly superior to the change in the other two groups ($P < 0.05$).

CONCLUSION: An eight-week personalized Fatmax exercise intervention is effective in improving the lipid metabolism of recessive obese young women. Increasing the amount of exercise during the follicular phase of the female menstrual cycle may have more beneficial effects on lipid metabolism than the luteal phase.

CHANGES IN EXERCISE ECONOMY AFTER SLEEVE GASTRECTOMY IN WOMEN

IBACACHE-SAAVEDRA, P., CANO-CAPPELLACCI, M.

UNIVERSIDAD ANDRÉS BELLO

INTRODUCTION: Sleeve gastrectomy (SG) has emerged as the most prevalent bariatric surgery for obesity, offering significant weight loss and improvements in comorbidities. However, an often-overlooked consequence of such procedures is the alteration in physical fitness and exercise economy (EE), which refers to the energy demand for a given intensity of physical activity. These changes can lead to a barrier to increasing physical activity levels post SG, undermining the long-term success of weight management and overall health post-surgery. Understanding the underlying mechanisms that contribute to the loss of EE after SG is essential for developing targeted rehabilitation strategies and enhancing recovery outcomes. This study aims to describe some physiological changes following SG. We will explore how these adaptations impact exercise performance.

METHODS: 24 women with obesity, mean age of 36 years old and BMI of 35 kg/m² were evaluated preoperatively and three months after SG. Patients performed a submaximal cardiopulmonary test on a cyclo-ergometer to obtain peak oxygen consumption (VO₂peak). Gas exchange was measured using a Cortex Metalyzer 3B. A gradual protocol was used, cycling at 60 rpm, starting at 0.5 Watts/kg of body weight with an increase of 20 Watts/2 min until the stopping criteria. EE was calculated dividing the peak work achieved (in Watts) by the absolute VO₂ (ml/min). The paired T-test was used to detect statistical significance for changes in the studied variables and the Spearman correlation coefficient (Rho) for the association between variables. Data was analyzed using SPSS 24.0 software and this project was approved by the ethics committee of Universidad de Chile (149-2014).

RESULTS: Three months after SG there were significant changes in weight (-17.5±4.2 kg), waist circumference (-14.3±4.6 cm), absolute VO₂ (-0.28±0.29 l/min), peak work achieved (-18.8±24.3 W) and EE (-0.012±0.014 W/ml O₂) (p<0.001 in all cases) with no differences in peak VO₂ relative to weight.

The change in EE had no statistical association with loss of weight (Rho:0.072, p:0.739).

CONCLUSION: The decrease in EE after bariatric surgery implies a deterioration in the ability of skeletal muscle to produce mechanical work (from a bioenergetic perspective). This suggests the need to implement physical training programs both before and after surgery to avoid the loss of EE.

SPORT FANTASY AND PSYCHOLOGICAL DISTRESS: ATHLETES' PERCEPTION OF DEFLATED REALITY MATTERS

ZHANG, S., PAN, Z., LI, J., FAN, Z.

HUNAN UNIVERSITY OF TECHNOLOGY / UNIVERSITY OF SHEFFIELD

Background: Fantasy-prone individuals tend to engage in conscious but immersive and imaginative experiences of fantasies, of which the fantasies are real as life and could suspend their disbelief in the nonreality associated with the fantasies (e.g., seeing imaginative experience as real despite knowing it is not). Excessive fantasy use contributes to one's overly inflated self-concept, addictive daydreaming, obsessive-compulsive behaviours and even psychopathology. However, little is known regarding the role of sport fantasy engagement and athlete mental illness.

Methods: Among 397 British University and College Sports (BUCS) athletes (aged 22.27 on average, 196 males, from 4 individual and 7 team sports), we examined the hypothesis that the magnitude of the relationship between sport fantasy proneness and psychological distress increases as athletes' perception of deflated reality in sport (i.e., pessimistic feelings towards one's sporting career involving training and competition) increase. Besides, we also hypothesised that increased sense of deflated reality underpins the relationship between sport fantasy and psychological distress (i.e., an indirect effect). We therefore assessed participating athletes' sport fantasy and perceived deflated reality as the exposure variables and measured psychological distress as the outcome variable. In order to adjust for the confound of sport-specific stress on psychological distress, we also assessed athletes' psychological strain in sport as a covariate in our analysis. Clustered mediated moderated analyses were performed to test our hypothesis whilst adjusting for the nested nature of the data to control for between-person differences in each sport (i.e., sport type as the cluster).

Results: Sport fantasy demonstrated a significant indirect effect on greater psychological distress via increased sense of deflated reality. However, the moderation of deflated reality on the relationship between sport fantasy and psychological distress was a mitigating rather amplifying effect, thus contrasting our moderation hypothesis. The nature of the moderation suggested that, after controlled for sport-specific strain, sport fantasy was not related to psychological distress when

perceived deflated reality was low but reduced psychological distress when perceived deflated reality was high. The significant and positive main effect of deflated reality on psychological distress was expected and noteworthy. The findings suggest that sport fantasy is not necessarily a bad thing and could even offer mental health protection especially for those high in deflated reality.

Conclusion: Sport fantasy is not as bad as one's impression. How engaging fantasy experience in sport may intervene with athletes' mental health is likely dependent on how the athletes perceive the 'reality' in their sport career. Researchers and practitioners would do well to tackle athletes' sense of deflated reality for promoting mental health.

SELF-PRESENTATION CONCERNS AMONG INJURED CANADIAN AND FRENCH ADOLESCENT ATHLETES: A QUALITATIVE INVESTIGATION

DEMERS, N., FORTÉ, L., CARON, J.G., NAULT, M.L., PODLOG, L.
UNIVERSITY OF MONTREAL

INTRODUCTION: A growing body of evidence highlights the psychological impact of injuries on athletes. One psychological challenge that may be particularly salient, but which remains poorly understood, relates to self-presentation concerns. Self-presentation refers to individuals' efforts to shape or influence how others perceive them. Although such preoccupations may be heightened during absences from sport participation – such as during an injury – this contention requires further empirical scrutiny. The purpose of this qualitative study was to explore the nature, antecedents, and implications of injured athletes' self-presentation concerns.

Method: The first author conducted semi-structured interviews with five competitive adolescent athletes (Mage = 15.6 years) who experienced a variety of serious injuries (e.g., anterior cruciate ligament tear, labrum tear) as a result of competing in judo, cycling, basketball, ice hockey and acrobatic skiing. Thematic analysis of transcript data was undertaken using the 6-step analysis procedures outlined by Braun and Clark (2021).

RESULTS: Participants articulated concerns about being perceived as "acting" or "faking" their injury when relevant others (e.g., coaches, parents) doubted the presence of their injury. Additionally, adolescents lacking in self-confidence to return to pre-injury levels, reported concerns about being perceived as "useless" or "unreliable" when eventually performing in front of coaches or teammates. Furthermore, some participants who did not have a long-standing relationship with their coach, were worried that coaches felt they were using their injury as an excuse to avoid training or returning to competition. Such concerns led to subsequent apprehensions about the implications of negative coach evaluations for athletes' future sport participation (e.g., playing time). Finally, adolescents remarked that the aforementioned concerns often led to negative emotions such as anger and frustration. Despite experiencing self-presentation concerns, several participants indicated that they did not have specific strategies for managing such concerns.

Discussion: Building on past research, adolescents highlighted novel factors (self-confidence, the length or quality of the coach-athlete relationship) influencing self-presentation concerns, as well as implications for psychological functioning during rehabilitation (negative emotions). These concerns can be targeted in cognitive-behavioral interventions aimed at optimizing injured adolescent's rehabilitation and return to sport.

Braun, V., & Clarke, V. (2021). Thematic analysis: a practical guide. Sage.

EVALUATING A MENTAL HEALTH LITERACY WORKSHOP FOR ATHLETES: A CROSS-NATIONAL QUALITATIVE STUDY

USENIK, J., KEGELAERS, J., DE BRANDT, K., DOOMS, M., GROBBELAAR, H.
UNIVERSITY OF MARIBOR

Objectives. Studies have consistently shown that athletes are as likely as the general population to experience mental health issues (Poucher et al., 2021). Approximately half of all elite athletes report symptoms of at least one mental health disorder during their careers (Gouttebarger et al., 2019; Åkesdotter et al., 2020). Mental health literacy (MHL) plays a crucial role in determining whether athletes seek help when facing mental health difficulties (Bu et al., 2020). Effective MHL interventions can enhance athletes' ability to recognize symptoms, access support services, and increase their intentions to seek help (Diamond et al., 2022). This study aimed to design and evaluate a culturally adaptable MHL intervention for athletes, implement it across diverse contexts, and explore its effectiveness through qualitative feedback. **Methods.** A workshop titled "Mental Health Matters" was developed to enhance athletes' understanding of mental health, the impact of sport- and personal factors on mental health and well-being, and to promote self-care strategies through diverse pedagogical approaches and techniques. A total of 253 athletes from Slovenia, Belgium, and South Africa participated in the workshop. Post-intervention, six focus groups with 37 athletes (two per country) and semi-structured interviews with educators were conducted to gather qualitative feedback. Data were analyzed thematically to identify patterns and differences across cultural contexts. **Results.** Participants reported an increased awareness of mental health and a clearer understanding of how their athletic careers impact their mental health and well-being. They valued the self-care practices introduced during the workshop. Educators emphasized the importance of considering athletes' age when implementing such interventions and highlighted the value of interactive components, particularly role-play exercises and group discussions. Cross-national analysis identified both shared themes, such as reduced stigma, and culturally specific differences, including variations in perceived barriers to seeking help. **Conclusion.** The intervention workshop proved to be an effective and well-received intervention for improving athletes' mental health literacy across diverse cultural settings. The findings contribute to the broader discourse on mental health literacy programs for athletes and highlight strategies for enhancing their impact across different national contexts.

THE PROVISION OF MENTAL HEALTH SERVICES FOR CHINESE NATIONAL TEAMS

GE, Y., SUN, T., WANG, Y.H.

BEIJING SPORT UNIVERSITY

China has consistently prioritized the advancement of competitive sports. In recent years, particularly with the International Olympic Committees increased focus on athletes mental health (Reardon et al., 2019), there has been a growing emphasis on mental health services for Chinese elite athletes. This study, conducted through a five-year field study during which the authors were involved in providing psychological services to multiple Chinese national teams, documented observations and interviews with participants. Grounded in critical realist epistemology (Bhaskar, 1998) and adopting both etic and emic perspectives, the researchers combined self-reflexivity with Grounded Theory (Charmaz, 2006) to propose a socio-cultural model for understanding elite athletes mental health challenges and development.

The authors identified a cultural environment within Chinese sports teams characterized by three key features: (1) "internal division and external harmony" (i.e., national teams were divided by fierce competition among athletes from different provinces, except during international competitions); (2) "action over words" (i.e., athletes and coaches prioritize actions and results over verbal expressions or plans); and (3) "hierarchy and rank" (i.e., team members were ranked based on secular values and collective interests, which significantly influenced their thoughts and behaviors). Within this cultural context, the study revealed several critical mental health challenges faced by Chinese elite athletes: (1) stigmatization and stealthiness in seeking help, (2) intrapersonal suffering, (3) complex historical roots of mental health issues, and (4) intricate interpersonal dynamics. Based on these findings, the researchers developed a comprehensive mental health management model for Chinese sports teams. This model encompasses four key components: (1) regular mental health assessments, (2) systematic mental health education, (3) accessible mental health counseling services, and (4) effective crisis intervention strategies. Recognizing the interconnected nature of team dynamics, the proposed mental health services are designed to benefit not only athletes but also coaches and all supporting personnel within the sports teams.

This study contributes to the growing body of literature on athlete mental health by providing a culturally-specific framework for understanding and addressing mental health challenges in the unique context of Chinese elite sports. The proposed model offers practical implications for sports organizations seeking to enhance their mental health support systems while considering the complex socio-cultural dynamics within elite sports teams.

RESEARCH ON THE MECHANISM OF IMPROVING HEMODYNAMICS BY HIGH-INTENSITY INTERVAL TRAINING

ZHAO, Y.

UNIVERSITY OF WESTMINSTER

INTRODUCTION: This study examines the influence of high-intensity interval training (HIIT) on hemodynamics, a critical factor in cardiovascular health. Given that arterial stiffness, significantly influenced by hemodynamics, is a major risk factor for cardiovascular disease, the study employs color Doppler ultrasound technology to assess the effects of both acute and long-term HIIT on hemodynamics in healthy male subjects. In addition to this, the research explores the relationship between HIIT and hemodynamics, which encompasses blood flow and shear force, and is essential for maintaining arterial integrity. Regular physical activity, particularly HIIT, can enhance cardiovascular function by inducing arterial remodeling and optimizing blood flow dynamics.

METHODS: Pre-experiment: Twenty male undergraduate students from the University of Westminster participated in a strength-oriented high-intensity interval training (HIIT) protocol to ascertain the optimal exercise loads for subsequent acute and long-term interventions.

Acute Experiment: The identical cohort of 20 male undergraduate students from the University of Westminster underwent pre- and post-HIIT assessments to quantify carotid artery hemodynamic parameters, utilizing color Doppler ultrasound technology.

Long-term Experiment: A total of 40 male undergraduate students from the University of Westminster were randomly assigned to either the experimental group (undergoing an 8-week HIIT program, three sessions per week) or the control group (sedentary). Comprehensive hemodynamic and cardiac function indices were measured in both groups prior to and following the intervention period.

RESULTS: Acute HIIT: Acute high-intensity interval training (HIIT) induced a substantial increase in end-systolic and end-diastolic blood flow velocities, blood flow shear force, and blood flow rate. Concurrently, it led to a significant decrease in the resistance index and common carotid artery diameter.

After 8 weeks of HIIT: Following an 8-week HIIT regimen, there was a notable increase in the E/A value, stroke volume, and cardiac output. However, no significant alterations were observed in the dimensions of the left ventricle. The HIIT group exhibited more pronounced improvements compared to the control group.

Long-term HIIT: Prolonged HIIT enhanced hemodynamics by improving left ventricular diastolic function and augmenting common carotid blood flow and diastolic blood flow velocity.

CONCLUSION: Acute HIIT: Acute high-intensity interval training (HIIT) elicits prompt favorable alterations in the hemodynamics of the carotid artery, such as an elevation in blood flow velocities and a reduction in the resistance index.

Long-term HIIT: Prolonged high-intensity interval training (HIIT) substantially augments cardiovascular function through the enhancement of hemodynamic parameters and left ventricular function, thereby establishing a foundation for its application in cardiovascular rehabilitation.

RESTORING HEMOGLOBIN MASS TO PRE-TRAINING LEVELS DOES NOT ELIMINATE VO₂MAX GAINS FROM ENDURANCE TRAINING

MØLMEN, K., ODDEN, O., MØLMSHAUG, E., URIANSTAD, T., ROGNEFLÅTEN, T., HAMARSLAND, H., RØNNESTAD, B., NYGAARD, H., LUNDBY, C.

UNIVERSITY OF INLAND NORWAY

INTRODUCTION: Maximal oxygen consumption (VO₂max) is strongly associated with total hemoglobin mass (Hbmass), red blood cell volume (RBCV) and blood volume (BV) in cross-sectional studies [1]. However, the extent to which hematological adaptations contribute to endurance training-induced VO₂max increase remains debated. Montero et al. [2] and Bonne et al. [3] demonstrated that reverting RBCV and BV, respectively, to pre-training levels restored VO₂max to baseline. In contrast, Skattebo et al. [4] observed that VO₂max did not change despite the removal of training-induced Hbmass gains. These discrepancies may stem from variations in study design, including differences in the specific hematological component manipulated, training interventions, and notably, small sample sizes. To address the limitation of previous studies with small cohorts (n=9-16), the present study examined whether normalizing Hbmass to pre-training levels eliminates the VO₂max increase following an 8-week endurance training program in a substantially larger cohort.

METHODS: Forty-nine middle-aged untrained adults (52±10 years; VO₂max, 33±7 mL/min/kg; 24 females) completed an 8-week supervised endurance training program. Participants trained three 45 min sessions per week, which included intervals of high-intensity (4×5 min and 4×8 min) and moderate-intensity (6×6 min) cycling. After the training period, Hbmass was restored to pre-training levels using phlebotomy, during which a BV equivalent to the increase in Hbmass was removed, resulting in a hypovolemic state. VO₂max was measured pre-training, post-training, and immediately after the phlebotomy procedure.

RESULTS: Ten participants did not increase Hbmass following the training period, leaving 39 for phlebotomy procedure. These participants exhibited increases in Hbmass (23±12 g, 3%), BV (221±217 mL, 5%), and VO₂max (299±157 mL/min, 12%) from pre- to post-training (all p<0.05). Following phlebotomy, during which 154±81 mL of BV was removed to restore Hbmass to pre-training levels, VO₂max decreased by 75±100 mL/min (2%; p<0.05) compared to post-training levels. However, VO₂max remained 224±166 mL/min (9%, p<0.05) above pre-training levels. Notably, even participants who did not increase Hbmass during the training period experienced a VO₂max increase (263±159 mL/min, 9%, p<0.05).

CONCLUSION: Restoring Hbmass to pre-training levels through phlebotomy reduces VO₂max but does not fully return VO₂max to pre-training levels. These findings indicate that adaptations beyond Hbmass contribute to the VO₂max increase observed in middle-aged adults following the training intervention. Moreover, the VO₂max increase in participants without Hbmass gains underscores the training program's effectiveness in enhancing VO₂max independently of Hbmass changes.

DYNAMIC CEREBRAL AUTOREGULATION REMAINS INTACT FOLLOWING MAXIMAL SPRINT EXERCISE IN YOUNG MEN AND WOMEN

WESTON, M., CURTIN, E., BUYS, P., GILDEA, N., EGANA, M.

TRINITY COLLEGE DUBLIN

INTRODUCTION: Recent evidence suggests that the cerebrovasculature is better able to buffer acute increases, compared to decreases, in mean arterial pressure (MAP), and that dynamic cerebral autoregulation (dCA) may also be attenuated in females. Maximal sprint exercise induces large changes in systemic and cerebral hemodynamics, both during and following exercise. This may challenge dCA post-exercise, particularly during acute hypotension and in females, but this has not been studied. Therefore, the aim of this study was to 1) investigate the acute effect of maximal sprint exercise on dCA in healthy young adults, and 2) explore sex differences in dCA pre- and post-exercise.

METHODS: Twenty-one healthy adults (12 males (mean ± SD): 23.4±3.5 years, 177.7±5.5 cm and 73.3±9.7 kg; 9 females: 22.2±2.1 years, 166.9±5.9 cm and 63.1±9.9 kg) volunteered to participate in this study. During a single experimental visit, dCA was assessed at rest and 25 minutes following a maximal, 30 second Wingate test on a cycle ergometer. dCA was determined by forced oscillations in MAP during 5 minutes of repeated sit-stand manoeuvres, performed at 0.05 Hz. Middle cerebral artery blood velocity (MCAv) was measured using transcranial Doppler ultrasonography, and beat-to-beat blood pressure was measured using finger plethysmography. dCA was analysed using a multimetrics approach: 1) transfer function analysis (TFA), and 2) using a novel directional sensitivity metric, expressing the average time-adjusted (T, s-1) change in MCAv relative to MAP ($\Delta\text{MCAvT}/\Delta\text{MAPT}$) separately for each MAP direction. Two- and three-way ANOVAs explored the effects of exercise, sex and MAP direction on dCA.

RESULTS: There was no effect of sex on any TFA outcome ($P>0.05$), so all participants were subsequently pooled together to investigate the effect of the Wingate on dCA. There were no pre versus post-exercise differences in gain (0.74 ± 0.30 vs 0.70 ± 0.20 cm.s-1/mmHg, $P=0.51$), normalised gain (1.12 ± 0.41 vs 1.21 ± 0.33 %/mmHg, $P=0.22$) or phase (0.97 ± 0.23 vs 1.05 ± 0.24 rad, $P=0.17$), but coherence was significantly greater following the Wingate (0.83 ± 0.12 vs 0.90 ± 0.12 , $P=0.042$). $\Delta\text{MCAvT}/\Delta\text{MAPT}$ did not differ by sex in either MAP direction or at any time point ($P=0.64$). Pre-exercise, $\Delta\text{MCAvT}/\Delta\text{MAPT}$ was significantly higher during acute hypotension versus hypertension (1.0 ± 0.4 vs 0.9 ± 0.3 cm.s-1/mmHg, $P=0.034$), and this persisted post-exercise (0.9 ± 0.2 vs 0.8 ± 0.2 cm.s-1/mmHg, $P=0.017$). Wingate exercise had no effect on $\Delta\text{MCAvT}/\Delta\text{MAPT}$ in either MAP direction ($P=0.15$).

CONCLUSION: These novel findings: 1) Provide further support for hysteresis in the cerebral pressure-flow relationship, and show for the first time that these persist post-exercise, 2) Suggest that dCA remains intact following maximal sprint exercise in healthy young adults, and 3) Indicate males and females have comparable dCA, which are not differentially altered by acute maximal sprint exercise.

MODIFYING INTERVAL EXERCISE INTENSITY AND DURATION TO OPTIMISE CEREBRAL BLOOD VELOCITY

TENNANT, J., WEAVER, S., LUCAS, S.

UNIVERSITY OF BIRMINGHAM

INTRODUCTION: Cerebral blood flow (CBF) preservation is of fundamental physiological importance for brain health and function longevity (1). As humans age, CBF declines, but these reductions are offset by regular physical activity (2). The acute exercise-induced adjustment of CBF has been suggested as a key neuroprotective mechanism linked to improved brain vascular health (3). CBF (and by proxy, velocity (CBv)), has therefore been examined in different models of exercise, including moderate continuous and time-efficient interval exercise (4). High intensity interval (HIIT) and sprint interval training (SIT) elicit distinct acute responses – greater absolute CBv and active recovery CBv rebound, respectively (4). This study aimed to examine this rebound at lower intensities, akin to HIIT, at similar durations to SIT, and hence attempt to establish an optimal CBv enhancement combination – a HIIT and SIT hybrid.

METHODS: 7 healthy participants (4 female, 22 ± 4 yrs) completed 4 interval exercise sessions of varied intensity and duration in a randomised, cross-over manner. Sessions involved 4 exercise bouts with participants cycling at either 80% or 120% of maximal workload (W_{max}) for 30 s or 60 s, interspersed with 4.5 minutes active recovery bouts. CBv was determined as an index of CBF via measures of middle cerebral artery velocity (MCAv). Corresponding partial pressure of end tidal carbon dioxide (PETCO_2) was recorded by continuous breath-by-breath gas analysis. The CBv rebound response was calculated using MCAv within the final 30 s of exercise and first 30 s of recovery.

RESULTS: MCAv change across time was significantly different for the 120% W_{max} for 30 and 60 s sessions compared to their 80% W_{max} duration match ($p<0.05$). In 120% W_{max} for 60s, MCAv was lower ($p<0.05$) in exercise bouts 2, 3 and 4 compared to bout 1. Similarly, recovery bouts 2 and 4 were lower ($p<0.05$) than recovery bout 1. MCAv reduced between exercise bout 1 and 2 ($p=.02$) at 80% W_{max} for 60 s, before recovering in exercise bouts 3 and 4 ($p>0.05$ vs bout 1). MCAv increase was elevated ($p<0.05$) compared to pre-exercise resting values in 80% for 30 s at recovery bouts 1, 3 and 4. However, in 120% W_{max} for 30 s, MCAv was only greater in recovery bout 2 ($p<0.05$). Rebound response magnitudes were not significantly different between the 4 conditions ($p=.070$); with an absolute MCAv rebound observed at each recovery bout except for bout 1 in 120% W_{max} for 60 s (-1.2 ± 7.0 cm/s).

CONCLUSION: These pilot data indicate that 80% W_{max} interval protocols produce an optimal combination for exercise-induced changes in MCAv, with greater elevation throughout the session and comparable rebound responses. Thus, lower intensity hybrid protocols may have greater potential to enhance acute exercise-induced CBv elevations.

ENDURANCE TRAINING REDUCES METABOREFLEX ACTIVATION AND CENTRAL DRIVE AT SUBMAXIMAL EXERCISE

LOUKAS, I., KOSKOLOU, K., GELADAS, N.

NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS

INTRODUCTION: Cardiovascular response and regional blood flow during aerobic exercise are under the regulation of central command, muscle metaboreflex and functional sympatholysis. It is supposed that these mechanisms act to match oxygen delivery with metabolic demands and to increase arterial blood pressure to assure adequate blood perfusion to the working muscles. Regular endurance training is known to induce lower cardiovascular activation under a given exercise intensity. The purpose of this study was to examine whether endurance training and the subsequent increase in aerobic capacity attenuates metaboreflex activation and central command during aerobic exercise, thus contributing to a lower cardiovascular response.

METHODS: Sixteen male distance runners (age: 34.1 ± 5.1 yrs, weight: 70.8 ± 4.1 kg) participated in the study. Training consisted of two high-intensity interval sessions (90-100% $\text{VO}_{2\text{max}}$) and three continuous sessions (70-80% $\text{VO}_{2\text{max}}$) per week for two months. Pre and post training measurements of $\text{VO}_{2\text{max}}$ in running and cycling took place to assess aero-

bic capacity. Then, a 10-min submaximal cycling at an intensity 5% under the individual anaerobic threshold was executed to measure respiratory and cardiovascular response, as well as the EMG activity of the vastus lateralis. At the end of exercise, total blood flow occlusion was applied for 5 min in both legs using pressure cuffs (250mmHg) to measure blood pressure as an index of metaboreflex activation.

RESULTS: Weekly running volume was 80.4 ± 3 km. Training increased running $\dot{V}O_{2\max}$ (PRE: 55.2 ± 1.2 vs POST: 58.8 ± 1.8 ml/kg/min, $p < 0.01$) and maximal aerobic velocity ($v\dot{V}O_{2\max}$) (PRE: 18.3 ± 0.9 vs POST: 19.3 ± 0.9 km/h, $p < 0.01$). Cycling $\dot{V}O_{2\max}$ (PRE: 51.1 ± 2 vs POST: 54.3 ± 2.2 ml/kg/min, $p < 0.01$), as well as peak power output (PRE: 290 ± 12 vs POST: 307 ± 15 watt, $p < 0.05$), also increased after training. Throughout the 10-min submaximal cycling exercise, there was a significant decrease ($p < 0.05$) in cardiac output, stroke volume, heart rate and systolic blood pressure, while systemic vascular resistance increased ($p < 0.05$). EMG decreased ($p < 0.05$) during exercise, while arterio-venous oxygen difference and exercise economy (Watt/L) increased ($p < 0.05$). Post-exercise blood lactate levels were lower after training (PRE: 4.3 ± 0.9 vs POST: 3.1 ± 0.7 mmol/L, $p < 0.05$). Finally, systolic blood pressure, throughout the occlusion period, was lower by 10 mmHg ($p < 0.05$) after training.

CONCLUSION: As the aerobic capacity improves with training, a given exercise intensity elicits lesser perturbation to the system, leading to attenuated cardiovascular response via decreases in metaboreflex activation and central drive.

OP-PN21 Gut and Microbiome

TWELVE WEEKS OF MULTI-MINERAL RED ALGAE SUPPLEMENTATION REDUCES EXERCISE-INDUCED GASTROINTESTINAL SYNDROME AND ENHANCES EXERCISE ECONOMY IN RECREATIONALLY ACTIVE RUNNERS.

AITKENHEAD, R., WALDRON, M., CONWAY, G.E., HORNER, K., HEFFERNAN, S.M.

SWANSEA UNIVERSITY; UNIVERSITY COLLEGE DUBLIN

INTRODUCTION: Endurance exercise is commonly associated with gut disturbances and barrier dysfunction, which can negatively impact performance. Dietary supplementation is one potential therapeutic strategy to alleviate these effects. Aquamin (Aq), a marine-derived multi-mineral complex, rich in bioavailable calcium and trace minerals, may support gut integrity (1) and attenuate exercise-induced gastrointestinal syndrome (EIGS) due to its mineral content and prebiotic potential (2), though its effects remain largely unexplored. This study investigated whether 12 weeks of Aq supplementation could improve the physiological response to endurance exercise and enhance exercise tolerance, improve gastrointestinal symptoms, and blood biomarkers of intestinal integrity in active individuals.

METHODS: Thirty-six healthy, recreationally active participants (30.5 ± 7.3 yrs; peak oxygen uptake ($\dot{V}O_{2\text{peak}}$): 52.1 ± 6.7 mL/kg/min) completed a 12-week double-blind, randomised placebo-controlled trial. Participants received either multi-mineral marine red algae, *Lithothamnion* species (Aq, 2.66g; 800 mg/day calcium) or placebo and were assessed pre-intervention (wk 0), mid-intervention (wk 6) and post-intervention (wk 12). Participants' cardiopulmonary and perceptual responses to a 60-min moderate-intensity treadmill run (90% gas exchange threshold; GET) were monitored and immediately followed by a time-to-exhaustion (TTE) test at 50% of the difference between the GET and $\dot{V}O_{2\text{peak}}$ ($\Delta 50\%$), with venous blood-samples collected pre- and post-exercise.

RESULTS: Linear mixed models revealed a trial by group interaction for heart rate and oxygen consumption ($\dot{V}O_2$) during the moderate-intensity run with Aq supplementation eliciting a lower heart rate at post-intervention compared to placebo (3.4%; $p < 0.001$), and at post-intervention compared to mid-intervention in the Aq group ($p = 0.006$). Post-intervention $\dot{V}O_2$ was lower in the Aq group compared to placebo (6%; $p = 0.002$), and at post compared to mid-intervention ($p = 0.01$). Gastrointestinal symptoms improved across time in the Aq group ($p = 0.05$), with reductions in both upper and lower symptoms ($p = 0.03$) at post-intervention, while no changes were observed in the placebo group across time ($p > 0.05$). Gut damage biomarkers were lower post-exercise in the Aq group, with reductions in soluble cluster of differentiation 14 (sCD14) from mid- to post-intervention ($p = 0.002$) and group by time effects for intestinal fatty-acid binding protein (i-FABP; $p < 0.001$).

CONCLUSION: Aq reduced heart rate and $\dot{V}O_2$ during a 60-min moderate-intensity run, indicating a potential improvement in exercise economy. Aq also reduced gastrointestinal symptoms and post-exercise levels of sCD14 and i-FABP (markers of gut damage), supporting its role in mitigating EIGS. Future research should focus on elucidating the mechanisms behind these effects to better understand Aq's role as a therapeutic strategy for supporting gut health (1,2) and exercise performance.

PROBIOTICS IN FOOTBALL (SOCCER): A SURVEY ON PRACTITIONER'S CURRENT PERCEPTIONS AND PRACTICES

BONGIOVANNI, T., PAPPOUS, A., CLARKE, G., MUNUSWAMY, R., MOLONEY, G., CRYAN, J., MARCORA, S.

UNIVERSITY OF BOLOGNA

INTRODUCTION: Probiotic supplementation is attracting attention of the sports community to promote good health, training and exercise performance. Probiotics, when administered in adequate amounts, are widely considered to be health-promoting microorganisms. However, investigation of perceptions and practices is still lacking.

Purpose: To gain knowledge on the beliefs and practices of football practitioners applying probiotics supplementation in elite soccer players.

METHODS: Forty football practitioners (30 performance nutritionists, 4 head of performance, 1 physician, 3 sport scientists, and 2 strength & conditioning coach) from 5 different countries participated in a study consisting of a survey including 5 domains: demographic and professional characteristics (Who); perceptions about probiotics for health and performance (Why); real-life practices about probiotics supplementation (When); methodological procedures about probiotics (What); and effectiveness of common supplementation strategies (How). Survey's Inclusion criteria were: voluntary participation, > 18 years old, adequate experience working in an elite sporting environment (>2 years), be physician, nutritionist, head of performance, sport scientist or Strength & conditioning coach, currently working in elite professional level (First league or second league during season 24-25), currently working with the first team Men or Women or both.

Data were analyzed using a combination of descriptive statistics, generalized mixed effects, and multinomial logistic regression models.

RESULTS: Data revealed 5 main findings: (1) overall agreement on the importance of probiotics for soccer players (63.2%) and on the consumption under the practitioner's supervision (84.2%); (2) lack of consensus about the effects on athletic performance and recovery; (3) strong agreement on the use of probiotics to treat diarrhea (65%) and gastrointestinal symptoms (70%); (4) choice of multi-strain and specie probiotics supplements (86.5%); and (5) frequency of probiotics supplementation of 1 dose every day (77.8%) and in capsules formulations (77.8%).

CONCLUSION: This study provides actionable insights into the implementation of probiotics supplementation in elite soccer players. While practitioners recognize the importance of probiotics for soccer players on gut health, further research and professional debate are warranted to develop empirical knowledge and provide pragmatic recommendations about the effects of probiotics and athletic performance, sleep and recovery.

THE CYCLISTS' GUT: IMPACT OF A TRAINING CAMP ON THE GUT MICROBIOME OF FEMALE, WORLD TOUR CYCLISTS

AMPE, T., DECROIX, L., DE PAUW, K., MEEUSEN, R., ROELANDS, B.

VRIJE UNIVERSITEIT BRUSSEL

INTRODUCTION: The gut microbiome has emerged as a potential factor influencing endurance performance, yet its interaction with elite-level training and racing remains largely unexplored. This study investigates the impact of a World Tour cycling season on the gut microbiome of elite female cyclists. With, in this first study, focus on the effect of a two-week training camp after the off-season. It is hypothesised that the changed training volume and intensity, combined with an altered diet during the training camp will affect the gut microbiome composition and function.

METHODS: 14 elite female cyclists (26.4±4.0 yrs, 56.7±2.9kg, Functional Threshold Power 4.71±0.35 Watt/kg), from a World Tour team participated in this quasi-experimental study. Faecal samples, dietary intake, training data and physiological markers were collected at baseline and after the training camp (POST). Gut microbiome composition and function are being analysed using 16S rRNA sequencing and metabolic profiling. Mixed effects regressions were used to assess differences between baseline and POST.

RESULTS: Due to laboratory issues, only the metadata could be included in the current abstract. During training camp, training volume and intensity on the bike significantly increased from 13.3±4.1 to 22.5±1.86 hours/week ($p<0.001$), with an average Training Stress Score of 98.3±35.8 before and 133.4±42.7 POST ($p=0.018$). The amount of strength training (2.5±1.1 to 0.7±0.5 hours/week) was decreased during the training camp. The amount of sleep was not significantly different during the training camp (7.8±0.5 hours to 7.6±0.6 hours ($p=0.356$)). Their average heart rate variability was also not significantly different ($p=0.367$) during the training camp (85.8±31.1msec) compared to before (98.2±40.1msec). No significant changes were reported concerning faecal sample composition, as well as for gastrointestinal symptoms. The average caloric intake increased significantly during the training camp, with an average intake of 2835±411kcal/day, compared to before the training camp, with an intake of 2440±248kcal/day. The amount of carbohydrates increased from 309.0±53.0g to 394.0±68.0g ($p=0.006$). Within carbohydrates, sugar intake increased from 120.8±39.7g to 169.6±40.9g ($p=0.013$), however, no significant decrease in absolute fibre intake was found (27.8±7.3g to 25.2±9.59g). Lastly, protein intake increased from 105.9±13.8g to 130.5±21.0g ($p=0.001$).

CONCLUSION: This study provides a first insight into the training load, physiological responses and dietary adaptations of elite female cyclists during a two-week training camp after the off-season. With significant increases in training volume, intensity and caloric intake, effects on the gut microbiome are expected. Future studies should follow up longitudinally on the effects of a World Tour season (i.e. one-day races, grand tours, altitude camps) on the gut microbiome of female cyclists.

GUT MICROBIOTA ENHANCES SUPPRESSION OF INNATE IMMUNE RESPONSE AFTER EXHAUSTIVE EXERCISE

HIROMI, Y., FUJII, R., TAHARA, R., WATANABE, C., AOKI, T., HAMADA, H., KONO, T., KREMENIK, M.J., OYANAGI, E.
KAWASAKI UNIVERSITY OF MEDICAL WELFARE

INTRODUCTION: Temporary immunosuppression occurs immediately after high-intensity exercise, increasing the risk of upper respiratory tract infections (URTI) and other infectious diseases. The effect of gut microbiota on this phenomenon remains unclear, however. The aim of this study was to investigate the effect of gut microbiota on lipopolysaccharide (LPS)-induced tumor necrosis factor (TNF)- α production immediately after the exhaustive exercise.

METHODS: In this study, we conducted two experiments. In the first experiment, C3H/HeN male mice were divided into 4 groups: sedentary control (SC, n=10), antibiotic treatment & S (ABS, n=10), exercise (Ex, n=10), and AB & Ex (ABEx, n=12). The antibiotic cocktail consisted of ampicillin 1 g/L, neomycin 1 g/L, metronidazole 1 g/L, vancomycin 0.5 g/L, and artificial sweetener Splendor 2.5 g/L. The cocktail was given ad libitum for 7 days. Then, Ex and ABEx mice were run on the treadmill until exhaustion. Exhaustion was defined as the point at which a mouse refused to run despite being given mild touches. Electric shock was not used during the treadmill run. Immediately after the exhaustive exercise or sedentary condition, mice were stimulated by LPS (1mg/kg, i.v.). Blood samples were collected before exercise, and at 1, 3, and 6 h after LPS injection in mice under Isoflurane anesthesia, and plasma TNF- α concentrations were analyzed using an ELISA kit. In the second experiment, partially hydrolyzed guar-gum (PHGG) fed mice were stimulated with LPS after exhaustive exercise, in order to investigate the effect of gut microbiota, which were stimulated by dietary fibers, on exercise-induced TNF- α response to LPS. The mice were divided into 3 groups: non-fiber diet (NF, n=12), control diet (CD, n=11) and 5% PHGG diet (PHGG, n=14).

RESULTS: After the exhaustive exercise, plasma TNF- α concentration in AB mice prior response to LPS was significantly higher than that in control mice ($p < 0.01$). PHGG intake, moreover, attenuated to increase in plasma TNF- α concentration in response to LPS compared with both non-fiber and control diet intakes ($p < 0.01$).

CONCLUSION: In this study, we observed that AB accelerated and PHGG attenuated the LPS-induced TNF- α production after exhaustive exercise. Thus, it was suggested that stimulation of gut microbiota induces the changes in the innate immune system after exhaustive exercise in mice. We previously showed that PHGG treatment attenuated plasma TNF- α concentration after LPS stimulation, compared with control diet intake, and then this phenomenon was deleted by AB treatment before PHGG intake. Although this was just an experiment in the sedentary condition, that might strongly support our results. Conclusion: These results suggest that LPS-induced TNF- α production immediately after the exhaustive exercise is regulated by gut microbiota.

COMPARABLE AMINO ACID PROFILE AND INTRAMUSCULAR SIGNALLING RESPONSES FOLLOWING CONSUMPTION OF MICROFLORA COMPARED WITH WHEY PROTEIN POST-RESISTANCE EXERCISE IN YOUNG ADULTS

MORGAN, P., PRATT, J., ACHESON, J., LAZARATOU, A., GREENHALGH, E., WITARD, O., SALE, C., HANNAIAN, S., GRITSAS, A., CHURCHWARD-VENNE, T., HEARRIS, M., HODSON, N., MORGAN, P.
MANCHESTER METROPOLITAN UNIVERSITY

INTRODUCTION: Microflora refers to a group of micro-organisms including bacteria and fungi. Microflora protein (MIC) has been marketed as an 'environmentally friendly dairy-identical' protein. Hence, MIC is suggested to represent an innovative source of dietary protein to closely mimic the amino acid (AA) composition of high-quality proteins, whilst potentially mitigating some environmental and ethical consequences and limitations purportedly associated with large-scale intensive agriculture, and ultimately support the increasing global demand for food. Therefore, the aim of this study was to compare the AA composition of MIC to a high-quality whey protein (WHEY) and assess the efficacy of MIC in supporting skeletal muscle anabolism.

METHODS: In a double-blind, crossover, randomised and counter-balanced trial, we investigated the anabolic potential of MIC designed to mimic 'high-quality' WHEY. Twelve, physically-active young adults (sex: M=6, F=6; age: 21.1 ± 3.0 years; body fat: $21.1 \pm 7.3\%$; fasting glucose: 4.3 ± 0.4 mmol/L) consumed $0.3 \text{ g}\cdot\text{kg}^{-1}$ (of body mass) of MIC (dose: $29.8 \pm 7.3 \text{ g}$) or WHEY (dose: $27.7 \pm 7.5 \text{ g}$) protein concentrate in an overnight postabsorptive state immediately following single-leg resistance exercise (~80% of 1 repetition maximum). The AA compositions of MIC and WHEY were analysed in accordance with food industry standards. Postprandial plasma AA concentrations (0-4 h, by liquid chromatography-mass spectrometry) and intramuscular signalling responses (1 h postprandial, by immunoblot) to exercise were determined. Diet and physical activity were monitored and replicated prior to each experimental visit.

RESULTS: A comparable pattern of AA composition was observed between protein sources (Sum of determined Essential-AAs: 30.5 vs. 34.8 g/100g for MIC and WHEY, respectively). Leucine content was, however, notably higher in MIC compared with WHEY (9.1 vs. 7.8 g/100g). Postprandial plasma AA, glucose and insulin concentrations and intramuscular signalling (i.e., p-mTOR, p-4E-BP1, p-Akt, p-RPS6, p-eEF2, p-ERK1/2) significantly increased from baseline but responses were largely comparable between WHEY and MIC across the postprandial period with the exception of plasma leucine, whereby significantly higher plasma concentrations were observed with MIC compared with WHEY across the postprandial period (Area under curve: +39%, $P=0.002$).

CONCLUSION: These data provide preliminary evidence suggesting that MIC could be a viable alternative protein source with a comparable quality to WHEY, potentially supporting skeletal muscle remodelling in young, healthy, active individuals. Further research is, however, needed to assess the broader efficacy and applicability of MIC.

GENDER DIFFERENCES IN RESPONSE TO A HOME-BASED BODYWEIGHT RESISTANCE TRAINING PROGRAM FOR SARCOPE-NIA.

MARMONDI, F., GALLI, L., CERIZZA, C., ANNICCHIARICO, G., BAGLIVI, A., DELLA TORRE, L., CASTAGNA, A., BANFI, G., CINQUE, P., FAELLI, E., BONATO, M.

UNIVERSITY OF GENOA

INTRODUCTION: Sarcopenia is a geriatric pathology associated with an increased risk of disability and adverse health outcomes. The study aim was to investigate the effects of a 48-weeks, app-monitored, home-based, bodyweight resistance training program in improving muscle health in sarcopenic persons, both in general population (GP) and in persons with HIV (PWH). We here investigate gender-specific responses of physical tests, body composition, and cognitive parameters after 12 weeks (W12).

METHODS: Subjects, aged >50 years (PWH) and >60 years (GP), with sarcopenia, defined by low appendicular skeletal muscle mass index (ASMMI) by bioimpedentiometry and/or low muscle strength by handgrip strength (HGS), were randomized (1:1) into an Experimental Group (EG), performing 4 training session/week with increasing number of repetitions and sets every 6 weeks, or a Control Group (CG), without specific exercise prescription. Assessments were conducted at baseline, after 12 weeks (W12), and after 48 week, including HGS, chair stand test (CST), 6-minute walking test (6MWT), Mini-BESTest, right and left leg maximal isometric strength (RLE, LLE), ASMMI, fat mass (FM), fat-free mass (FFM), and cognitive outcomes [Trail Making A (TMA), and B (TMB), and Digit Symbol (DS)]. Within-group changes were assessed using Wilcoxon signed-rank tests. Comparisons between genders and between the EG and CG were conducted using Mann-Whitney U tests.

RESULTS: A total of 165/196 participants [98 males (EG:49, CG:49) and 67 females (EG:34, CG:33)] completed W12. In males, significant differences were observed in physical tests [HGS: EG ($P=0.0124$); CST: EG ($P<0.0001$), EG vs CG ($P=0.0066$); 6MWT: EG ($P=0.0068$), CG ($P=0.0025$); Mini-BESTest: EG ($P=0.0089$), CG ($P=0.0276$); LLE: EG ($P=0.0085$)], in body composition [ASMMI: EG ($P=0.0044$); FFM: EG ($P=0.0038$), EG vs CG ($P=0.0422$); FM: EG ($P=0.0011$)], and in cognitive outcomes [TMA: EG ($P=0.0020$), CG ($P=0.0124$); TMB: EG ($P=0.0198$); DS: EG ($P=0.0088$), CG ($P=0.0124$)]. In females, significant differences were observed in physical tests [HGS: EG ($P=0.0064$); CST: EG ($P=0.0004$), EG vs CG ($P=0.0359$); Mini-BESTest: EG ($P=0.0359$); RLE: EG ($P=0.0176$), EG vs CG ($P=0.0497$)], and in cognitive outcomes [TMB: EG ($P=0.0153$); DS: EG ($P<0.0001$), CG ($P=0.0168$)]. In gender-differences, significant changes were observed in EG in body composition [FM ($P=0.0011$)], and in CG in physical test [6MWT ($P=0.0071$)]. No other gender-differences were observed.

CONCLUSION: At W12, significant improvements were found in physical tests, body composition, and cognitive function in both males and females. While both genders benefited, males showed greater improvements in body composition and some physical performance measures. No gender differences were observed in cognitive outcomes.

EVALUATING THE ASSOCIATIONS BETWEEN MUSCLE, PHYSICAL ACTIVITY, AND PERFORMANCE-RELATED FACTORS AND BONE STRENGTH IN ENDURANCE-TRAINED INDIVIDUALS

FERREIRA, S., LEVEE, J., SEVINC, A., GARDY, S., LINARDATOS, J., AMATO, A., CHURCHWARD-VENNE, T., GIBBS, J.

MCGILL UNIVERSITY

INTRODUCTION: Bone fragility is pervasive in endurance athletes due to their high-volume training and elevated nutritional demands. Muscle size and quality has been shown to positively influence bone strength in various populations, however, few studies have investigated this relationship in endurance athletes. Further, there is limited research on the association between endurance sport-specific factors (e.g., physical activity/training, performance) and peripheral quantitative computed tomography (pQCT) measures of bone strength. Our primary objective was to evaluate the relationships between calf muscle size and density and tibial bone strength and volumetric bone mineral density (vBMD) in male and female endurance-trained individuals. We also explored whether physical activity and performance-based tests of muscle strength and cardiorespiratory fitness were associated with bone outcomes.

METHODS: 50 participants (31 males/19 females) aged 18-35 years running >3 hours/week for the past 6 months completed one-time measures. Total, trabecular, and cortical vBMD, bone compressive strength (BSI) and stress-strain indices (SSI) at the tibia (4%, 38%, 66% sites), and calf muscle density and cross-sectional area (MSCA) were measured using pQCT. Body composition was measured using dual-energy X-ray absorptiometry. Upper and lower body muscle strength were determined by handgrip and knee extensor isometric tests. Aerobic capacity (VO_{2peak}) was measured via an incremental cardiorespiratory fitness test to volitional exhaustion. Physical activity levels were assessed using accelerometers (i.e., moderate-to-vigorous physical activity (MVPA)) and the Bone-specific Physical Activity Questionnaire (BPAQ). Multivariable linear regression analyses between muscle (MSCA and muscle density), physical activity (MVPA, total, current and past BPAQ), and performance (VO_{2peak}, muscle strength) variables and bone parameters were adjusted for age, sex, and body weight.

RESULTS: Participants had a mean (95% CI) age of 26.0 years (24.6 – 27.4), body fat of 19.9% (18.0 – 21.9), VO_{2peak} of 55.9 ml/kg/min (53.1 – 58.7), and maximum knee extensor and handgrip strength of 262.3 N*m (232.0 – 292.7) and 43.5 kg

(40.2 – 46.8), respectively. Mean MVPA and total BPAQ scores were 12 hours/week (10.9 – 13.1) and 24.0 (19.0 – 29.1), respectively. Multivariable linear regression analyses revealed weak-to-moderate associations between MCSA and BSI 4% ($B=0.285$, $p=0.044$, $R^2=0.606$), BSI 66% ($B=0.426$, $p=0.018$, $R^2=0.372$), and cortical area 66% ($B=0.339$, $p=0.009$, $R^2=0.674$). Muscle density and strength, VO₂peak, MVPA, and BPAQ scores were not significantly associated with bone parameters after adjusting for confounding variables.

CONCLUSION: In endurance-trained individuals, calf muscle size was positively correlated with tibial bone strength independent of age, sex, and body weight, particularly at proximal sites. Muscle size may represent an important modifiable target to improve bone strength in endurance athletes.

PROGRESSIVE RESISTANCE TRAINING TO VOLITIONAL MUSCULAR FAILURE IMPROVES MUSCLE STRENGTH IN FRAIL COMMUNITY-DWELLING OLDER ADULTS REGARDLESS OF TRAINING INTENSITY: A RANDOMIZED CONTROLLED TRIAL

BENALI, M., BIERSTEKER, E.J.M., VAN DEN HELDER, J., TIELAND, M., SCHOUFOUR, J.D., WEIJS, P.J.M.

AMSTERDAM UNIVERSITY OF APPLIED SCIENCES

INTRODUCTION: Progressive resistance training is effective against the age-related decline in muscle strength and physical limitations in older adults. However, the optimal resistance training intensity for frail community-dwelling older adults remains unclear, with concerns about high-intensity exercise limiting participation. Emerging evidence suggests that training to volitional muscular failure may achieve similar benefits across various intensities. This study aimed to assess the optimum level of progressive resistance training intensity for enhancement of muscle strength in frail community-dwelling older adults.

METHODS: This 12-week randomized controlled trial included 295 frail community-dwelling older adults (≥ 65 years) and were randomized into 12 training intensity groups, categorized into four clusters: low (25-35%), low-medium (40-50%), medium-high (55-65%), and high intensity (70-80% of one-repetition maximum). Twice-weekly, one-on-one progressive resistance training sessions were conducted, with all participants training to volitional muscular failure. The outcome was lower-extremity muscle strength, assessed using the leg press. Linear mixed models were used to examine overall improvements in muscle strength, and to analyse if there were linear or quadratic relationships between training intensity and improved strength, as well as between the training intensity clusters and improved strength.

RESULTS: All participants demonstrated significant improvements in lower extremity muscle strength following the 12-week progressive resistance training, increasing from 101 ± 27 kg at baseline to 126 ± 35 kg at follow-up ($+25$ kg, $p < 0.001$). No linear or quadratic relationship was observed between training intensity and improvements in muscle strength. Compared to the high intensity cluster, muscle strength improvements were $+7 \pm 4$ kg ($p=0.045$), $+4 \pm 3$ kg ($p=0.222$), and $+9 \pm 3$ kg ($p=0.010$) in the low intensity cluster, in the low-medium intensity cluster, in the medium-high intensity cluster, respectively.

CONCLUSION: Progressive resistance training to volitional muscular failure effectively improves muscle strength in frail community-dwelling older adults. In this randomized study we did not find a clear optimum level of training intensity for improvement of muscle strength. The high intensity training appeared suboptimal compared to lower levels of training intensity.

CAN VIRTUAL REALITY ENHANCE KINESTHETIC MOTOR IMAGERY? PRELIMINARY RESULTS FROM A 10-DAY BEDREST STUDY

ŠLOŠAR, L., PIŠOT, S., CIKAC, A., PIŠOT, R., ŠIMUNIC, B., BIOLO, G., NARICI, M.V., MARUSIC, U.

SCIENCE AND RESEARCH CENTRE KOPER

INTRODUCTION: Physical inactivity has profound detrimental effects on the human body, impacting multiple subsystems, including the musculoskeletal, cardiovascular, and respiratory systems, as well as motor control, perception, and overall well-being. These effects are particularly pronounced in older individuals, where recovery is often slower and more challenging. Understanding the mechanisms driving these changes is critical, as is the development of effective interventions to mitigate deterioration and enhance recovery of functional abilities. Recent advancements in virtual reality (VR) offer innovative, non-physical strategies to counteract bedrest-induced effects (1). While motor imagery (MI) has shown promise in addressing these challenges (2), its integration into VR-based interventions for functional decline remains underexplored. This study investigates the potential of VR to enhance non-physical strategies, specifically its impact on MI ability. Using the Movement Imagery Questionnaire-3 (MIQ-3), we evaluated changes in internal, external, and kinaesthetic imagery to determine VRs efficacy in supporting cognitive-motor recovery during bedrest.

METHODS: Twenty healthy older adult males (68 ± 3 years) participated in a 10-day horizontal bedrest study. Participants were randomized into an intervention (INT) group and a control (CON) group. The INT group engaged in daily 25–30 min VR sessions using an Oculus Quest 2 headset, combined with 30 days of exercise prehabilitation and a leucine-rich, high-protein diet. The VR protocol simulated resistance training in a fully immersive environment, providing cognitive and sensory engagement without physical exertion. The CON group passively observed the same VR environment. MI efficiency was assessed in both groups before and after the intervention using the MIQ-3.

RESULTS: A significant time*group interaction effect ($p < 0.001$) was observed for kinaesthetic imagery, with no significant changes in internal or external visual imagery. Post-hoc tests revealed the INT group improved in kinaesthetic feeling ($p=0.007$), while the CON group experienced a decline in performance ($p=0.016$).

CONCLUSION: These preliminary findings indicate that the VR intervention enhanced specific cognitive functions, particularly the perception of body movements, by effectively engaging kinaesthetic MI. Future research will determine whether the combined intervention also mitigated other bedrest-related declines or produced similar effects across different functional domains.

RESISTANCE VIBRATION EXERCISE IN ARTIFICIAL GRAVITY: A POTENTIAL COUNTERMEASURE FOR DEEP SPACE MISSIONS

SORRENTINO, R.G.1,2, SUPEJ, M.3, VOVK, A.4, MEKJAVIC, I.B.1

1 DEPARTMENT OF AUTOMATICS, BIOCYBERNETICS AND ROBOTICS, JOZEF STEFAN INSTITUTE; 2 JOZEF STEFAN INTERNATIONAL POSTGRADUATE SCHOOL; 3 FACULTY OF PHYSICAL EDUCATION, UNIVERSITY OF LJUBLJANA; 4 FACULTY OF MEDICINE, UNIVERSITY OF LJUBLJANA, LJUBLJANA, SLOVENIA

INTRODUCTION: Prolonged exposure to weightlessness induces loss of musculoskeletal mass in the lower limbs. Current exercise countermeasures do not fully prevent these adaptations, which has instigated a programme of research coordinated by the European Space Agency to explore alternative exercise strategies. We are currently investigating the efficacy of a novel countermeasure combining artificial gravity (AG) with resistance vibration exercise (RVE). In this regard, the objectives of the present study were: 1) Compare the activation of thigh and calf muscles during upright triple extension squat exercise without (URE) and with vibration (URVE); 2) Assess vibration transmission (VT) during supine RVE conducted without (RVE) and with artificial gravity (AGRVE); 3) compare the effectiveness of URVE, HRVE and AGRVE on the basis of a 2-wk training programme.

METHODS: A total of 54 healthy active males participated in the study. The activation of thigh and calf muscles during URE and URVE was determined with magnetic resonance imaging (MRI) using T2 relaxation time (N=15). VT was determined during RVE and AGRVE with accelerometers attached to the vibration plate, pelvis and forehead (N=15). The efficacy of a 2-wk training programme (N=24) with upright and supine RVE was compared to AGRVE on the basis of muscle strength (isokinetic dynamometry), power (jump test) and volume (MRI) and body composition (DEXA). The rotational vibration/force platform allowed the ground reaction force to be maintained at similar levels in all trials. The vibration frequency was 20 Hz and the displacement was between 3 and 4 mm.

RESULTS: Muscle water and metabolite accumulation increased ($p < 0.0001$) following RE and RVE, with no difference between them. Vibrations were attenuated in the lower limbs in RVE and AGRVE ($p < 0.0001$), with greater attenuation occurring in the latter ($p = 0.001$). A 2-wk training programme resulted in greater muscle volume ($p = 0.01$) and strength gains ($p = 0.001$) during AGRVE compared to upright and supine RVE with no differences in muscle power and body composition.

CONCLUSION: Vibration did not enhance muscle activation during the squat exercise and its transmission to the upper body was significantly attenuated. AG enhanced the outcome of RVE training (AGRVE), demonstrating that it is a promising modality and exercise strategy for mitigating loss of muscle and bone mass during deep space mission.

LOCOMOTOR EFFICIENCY REDUCES DURING MATCHES IN HIGH LEVEL MALE AND FEMALE SOCCER PLAYERS

MARTIN, M., BLANCHFIELD, A.W., OWEN, J.A., OLIVER, S.J., RAMPININI, E., BOSIO, A.
SPORT SERVICE MAPEI S.R.L.

INTRODUCTION: Many authors reported changes in Total Distance (TD, measured by GPS) and Dynamic Stress Load (DSL, measured by accelerometry) at the end of soccer matches, suggesting the possible influence of fatigue (Bradley PS et al., 2009). Fatigue induces many changes in the pattern of movement, such as increased ground contact time and stride frequency, reduced stride length and a flatter centre of mass trajectory (Small K et al., 2013). Some authors reported reductions in Locomotor Efficiency (LE), calculated as the ratio between DSL and TD (Barrett S et al., 2016), at the end of basketball matches (Vazquez-Guerrero J et al., 2019) and Oliva-Lozano et al. (2020) also reported lower LE in the second half compared to the first half. It was suggested that LE might be able to capture some of the fatigue-induced changes in the bio-

mechanics of movement, due to the higher reductions in accelerometer-derived load compared to TD. Thus, the aims were to investigate: the within-match changes in LE and the differences in LE between starters and substitutes.

METHODS: Under 19 male ($n=35$, 17.8 ± 0.4 yrs, 72.1 ± 4.9 kg, 179.7 ± 6.7 cm) and adult female ($n=33$, 24.3 ± 5.6 yrs, 61.4 ± 5.8 kg, 168.5 ± 6.0 cm) players from a professional Serie A soccer club participated in this study. Using a GPS that included an accelerometer on board (Apex model, STATSports Technologies, USA), TD, DSL and LE were measured in 60 matches of the 2022–23 season (34 U19 and 26 senior female matches) collecting 639 individual match data. Mixed models were used to analyse differences between the six 15-minute time frames (T1 to T6). Tactical role, match location, opponent's rank and soccer match result were included in models to control for contextual variables.

RESULTS: For males and females, TD and DSL were higher in Q1 than all other time frames (all $p<0.015$) and were higher in Q2, Q3 and Q4 than Q5 and Q6 (all $p<0.004$). For males and females, LE was higher in Q1 than Q3, Q5 and Q6 (all $p<0.021$) and was higher in Q4 than Q5 and Q6 (all $p<0.001$). These results indicate that the reduction in DSL was higher compared to the reduction in TD. LE of substitutes in Q6 was higher than starters ($p=0.005$), suggesting that LE might reduce under fatigue.

CONCLUSION: Compared with the beginning, LE was reduced at the end of the soccer match, suggesting a biomechanical running pattern change (Buchheit M et al., 2015) which might be partially related to the development of players' fatigue during games. In comparison with substitutes, starters players showed lower LE at the end of matches, which might indicate that they alter their biomechanical running pattern, possibly due to fatigue, not experienced by substitutes due to their reduced match time exposure.

IS THE OMNI-RATING OF PERCEIVED EXERTION SCALE USEFUL IN DETERMINING TRAINING LOAD IN NON-ELITE ADOLESCENT TEAM SPORT?

SAINSBURY, D., DOWNS, J., MCKENNA, L., NETTO, K.

CURTIN UNIVERSITY

INTRODUCTION: High training load (TL) is a potential risk factor for injury in non-elite adolescent team sport. A valid, easily applied measure of TL in this population is required where access to more sophisticated measures may be limited. TL may be calculated from the product of a rating of perceived exertion (RPE) score from a Borg CR-10 or CR-100 and session duration. There is limited research into the validity of this approach to determine TL in adolescent populations in field settings using paediatric specific scales of RPE. This study aimed to investigate the validity of the paediatric OMNI-RPE scale as a tool to calculate TL when compared to heart rate (HR) and velocity derived measures of TL in non-elite adolescent team sport athletes.

METHODS: Part A involved completion of both an easy and hard version of a simulated team game circuit (each consisting of warm up, two sets of 5-minute intermittent running circuits and a cool down). Part B involved observations during usual team games. An OMNI-RPE (0 "not tired at all" to 10 "very very tired") was taken 30 minutes post session. An OMNI TL, expressed in arbitrary units, was calculated as a product of the OMNI-RPE and session duration. This score was compared against other measures of TL namely, Edwards' Training Impulse (TRIMP), time spent in heart rate (HR) zones 4 and 5 (80-100% HR peak) and time spent in 0-25%, 25-50%, 50-70% and >70% velocity peak (VP). Heart rate and velocity were measured using Catapult Optimeye S5 units and compatible Polar T31 heart rate units.

RESULTS: Twenty (age 14.2 ± 1.7 years; eight female) team sport athletes participated in Part A. For both the easy(E) and hard(H) versions of the circuit, low to moderate correlations were observed between OMNI TL and Edwards TRIMP (E $r=0.2$, H $r=0.18$) time in HR zones 4 and 5 (E $r=0.33$, H $r=0.19$), time spent in 25-100% VP (E $r=0.46$, H $r=0.37$), 50-100% VP (E $r=0.39$, H $r=0.37$) and 70-100% VP (E $r=0.05$, H $r=-0.23$). 34 different athletes (age 15.2 ± 1.5 years; 16 female) participated in Part B. Moderate to large correlations were observed between OMNI TL and Edwards TRIMP ($r=0.53$) time spent in HR zone 4/5 ($r=0.45$) time spent in 25-100% VP ($r=0.42$) and time spent in 50-100% VP ($r=0.51$). A low correlation was observed between OMNI TL and time in 70-100% VP ($r=0.28$).

CONCLUSION: The larger correlations between OMNI TL and the HR and velocity derived measures of TL in the team game suggest OMNI TL may have greater utility in monitoring TL in a naturalistic setting rather than simulations. Compared to similar studies using Borg CR-10 or CR-100 RPE scales (perceived exertion from extremely weak to extremely strong), lower correlations between OMNI TL and HR derived measures of TL were observed in this study. This may be because the OMNI-RPE scale is anchored in perceptions of tiredness making it sensitive to weariness or fatigue, so may be influenced by other physical and psychosocial factors such as poor sleep and performance stressors.

THE POWER OF BELIEF: INVESTIGATING THE PLACEBO EFFECT IN POST-EXERCISE RECOVERY STRATEGIES FOR FOOTBALL PLAYERS

PERNIGONI, M.1, ALFIERI, A.O.1, KNIUBAITE, A.1, KAMANDULIS, S.1, CONTE, D.2,1, LUKONAITIENE, I.1

1, LITHUANIAN SPORTS UNIVERSITY; 2, UNIVERSITY OF ROME FORO ITALICO.

INTRODUCTION: The demanding nature of team sports can generate substantial fatigue, with recovery strategies being widely employed by practitioners to counteract fatigue accumulation during the competitive season [1]. However, the effectiveness of such strategies may partly stem from the placebo effect, which has been shown to produce moderate-to-large benefits on measures of performance (e.g., strength, aerobic/anaerobic capacity) [2,3] and well-being (e.g., muscle soreness) [4]. Despite the evidence linking the placebo effect to performance improvements, limited research is available regarding its role in post-exercise recovery strategies. Therefore, the aim of this study was to compare measures of per-

formance, physiological and perceptual recovery between a placebo (PLA) and passive rest intervention (CON) after football matches.

METHODS: Using a crossover design, 18 high-level, youth (i.e., under-16) male players completed two full-length (2x45-min halves) friendly football matches, followed by either PLA or CON. Specifically, PLA involved the use of a non-invasive vagus nerve stimulation device (Pulsetto, Vilnius, Lithuania) as a sham intervention, where no actual stimulation was delivered. To assess between-intervention differences, countermovement jump height (CMJ), 10 and 20-m sprint times, heart rate variability (Ln-rMSSD), perceived fatigue, static and dynamic (i.e., measured during a squat) muscle soreness were recorded at pre-match, post-match, post-recovery (i.e., shortly after PLA/CON) and 24 h post-match. Two goalkeepers participated in each match, but were not included in the analyses.

RESULTS: Match-play induced substantial fatigue, with our main findings revealing significant deteriorations ($p < 0.003$) in CMJ (small-to-large effect size [ES]), 10- (moderate ES) and 20-m sprinting (moderate-to-large ES), Ln-rMSSD (moderate ES), perceived fatigue, static and dynamic soreness (large ES for all perceptual measures) in both interventions at post-match and post-recovery, compared to pre-match. Although no significant between-intervention differences were found for any variable at any time point ($p > 0.05$), perceived fatigue [ES ($r = 0.40$)] and dynamic soreness [ES ($r = 0.32$)] were moderately lower in PLA than CON at post-recovery.

CONCLUSION: Our findings suggest that the placebo intervention did not directly affect the recovery of performance or heart rate variability. It did, however, show moderate benefits in reducing perceived fatigue and dynamic muscle soreness at post-recovery, compared to passive rest. While caution is warranted – due to the lack of statistically significant differences – these results highlight the importance of considering the placebo effect when designing research on recovery strategies and when employing them in applied settings, as even small effect sizes may offer meaningful benefits for athletes using placebo interventions [2].

EFFECTS OF A SLEEP HYGIENE INTERVENTION PERIOD ON THE PHYSICAL PERFORMANCE INDICATORS OF MALE UNIVERSITY-LEVEL FOOTBALL PLAYERS DURING A TOURNAMENT

BROODRYK, A., PREVOO, G., KRAMER, M.

PHYSICAL ACTIVITY, SPORT AND RECREATION RESEARCH FOCUS AREA

INTRODUCTION: In football, performance indicators (PIs) are frequently utilized to give coaches and players clear information to maximize performance. Sleep is said to be the most crucial recuperation tool for peak performance. Unfortunately, due to multiple factors, football players frequently experience sleep deprivation, which affects these crucial performance indicators and game results.

METHODS: This study aimed to determine the effect of a sleep hygiene protocol (SHP) on various football match PIs. Sixteen male university-level football players (average age: 22.2 ± 3 y; stature: 167.6 ± 6.4 cm; mass: 62 ± 6.6 kg) participated in the study. Their matches were recorded and analyzed according to various offensive and defensive key performance indicators over 14 matches, consisting of five games (no-sleep intervention - nSHP), four matches (sleep intervention - SHP), and again five matches of nSHP. They also completed the Pittsburgh Sleep Quality Index (PSQI) before and after the SHP. During the intervention period, players had to adhere to at least ten sleep hygiene requirements daily, for four weeks.

RESULTS: Following the sleep extension phase, the PSQI results revealed a significant improvement in global PSQI scores (Meandiff = 2.00, $p = 0.028$, $g = 0.58$), which was driven by the sub scores of sleep latency ($p = 0.05$, $g = 0.51$) and hours slept ($p < 0.001$, $g = 0.96$). Those completing the SHP would complete 1.89 more dribbles ($p = 0.004$, ES = 1.89) compared to the nSHP condition. Similarly, under the SHP condition, 1.61 times more network passes ($p < 0.001$, ES = 1.61), 1.4 times more offensive crosses ($p = 0.02$, ES = 1.4), and 1.28 times more successful passes ($p < 0.001$, ES = 1.28) were completed compared to the nSHP condition. The SHP also demonstrated significantly more positive relationships between PIs compared to the nSHP. Firstly, between successful passes and 1.) successful passes in the opposition half ($r = 0.97$, $p = 0.02$), 2.) more network passes ($r = 0.99$, $p = 0.004$), and 3.) shots on target ($r = 0.99$, $p = 0.006$). Furthermore, a strong relationship was observed between successful passes in the opposition half and 1.) more network passes ($r = 0.99$, $p = 0.01$), and 2.) shots on target ($r = 0.99$, $p = 0.005$). In addition, the number of network passes also demonstrated a strong relationship with the number of shots on target ($r = 0.99$ and $p = 0.001$).

CONCLUSION: Inadequate sleep can impact visual-spatial intelligence (VSI) and visual perception. Therefore, cognitive tasks (looking where the pass comes from and knowing where to pass the ball) that involve the frontal-parietal network, such as VSI (to scan for information in the context of a football match), can be influenced by sleep or a lack thereof. Although the acute SHP did not appear to influence the match outcomes, it did influence key factors that may increase the probability of a favorable outcome, such as the number of dribbles, network passes, successful passes, and offensive crosses during matches.

CRITERION VALIDITY OF SLEEP QUALITY SCALES IN YOUNG ELITE SOCCER PLAYERS

BENEDETTI, L., DI MICHELE, R., NIGRO, F., AIELLO, P., MARCORA, S.

UNIVERSITY OF BOLOGNA

INTRODUCTION: Sleep is essential for cognitive function, recovery, and athletic performance. Sleep deprivation negatively affects performance and overall health, with athletes sleeping less than 8 hours per night exhibiting a 70% higher injury risk (1). To evaluate sleep quality and disturbances, the General Sleep Disturbance Scale (GSDS) has been recently validated against the Pittsburgh Sleep Quality Index (PSQI)(2, 3). For the same purpose, a daily wellness questionnaire is often used in the field (4). To assess the validity of the GSDS and the wellness score in competitive soccer players, this study aimed to analyze the relationships between the actigraphy and the PSQI questionnaires (objective and subjective criterion measures) compared with the wellness scores and the GSDS score.

METHODS: 35 elite soccer players (age 17.7 ± 0.8 y, stature 184.7 ± 5.2 cm, body mass 82.9 ± 6.8 kg) voluntarily participated in the present study. Athletes wore an actigraphy accelerometer (Actigraph Spectrum Plus, Philips, Pittsburgh, USA) for seven consecutive days to track selected sleep parameters and completed a daily wellness questionnaire. The GSDS and PSQI questionnaires were administered at the end of the same monitored week. The parameters collected with the actigraphy accelerometer were: total sleep period, total activity counts, sleep onset latency, sleep efficiency, wake time, and sleep time. Spearman's correlation coefficients were calculated to determine the relationships between the objective (Actigraphy) and the subjective (PSQI) criterion measures and the GSDS and the wellness questionnaire. Significance was set at $p < 0.05$.

RESULTS: The GSDS questionnaire score showed a positive relationship with sleep onset latency ($r_s(34) = 0.376$, 95% CI [0.049, 0.630], $p = 0.026$), and a negative relationship with sleep efficiency ($r_s(34) = -0.447$, 95% CI [-0.679, -0.133], $p = 0.007$) of the actigraphy accelerometer. Furthermore, The GSDS questionnaire score showed a positive relationship with PSQI scores $r_s(34) = 0.590$, 95% CI [0.319, 0.771], $p < 0.001$). Conversely, the sleep item in the wellness questionnaire showed no correlation with any actigraphy parameters ($r_s(34) = -0.145 - 0.206$, $p > 0.05$) or the PSQI questionnaire scores ($r_s(34) = 0.100$, 95% CI [-0.242, 0.419], $p = 0.569$).

CONCLUSION: These findings support the weekly use of the GSDS questionnaire for assessing sleep quality in elite soccer players. However, despite its widespread use in field settings, the use of wellness questionnaires is not supported for measuring athletes' sleep quality based on these results. Further research is needed to determine the validity and reliability of these sleep monitoring tools in athletes

Invited Symposium

IS-BM02 The power of eccentric contractions on muscle adaptation, remodeling, and function in old age: The positives of negatives

MOLECULAR RESPONSES TO ECCENTRIC EXERCISE ACROSS AGE

DEANE, C.

UNIVERSITY OF NOTTINGHAM/ BOURNEMOUTH UNIVERSITY

Traditional resistance exercise involves both shortening (concentric) and lengthening (eccentric) contractions. Compared to concentric contractions, isolated lengthening eccentric contractions represent a potential therapeutic intervention for combating muscle decline in ageing as they are the least metabolically demanding for a given load and produce the most force. However, the safety and efficacy of eccentric exercise as a training mode is often questioned, especially for ageing populations, due to the associated muscle "damage". This talk will describe the physiological and molecular responses to eccentric exercise across age drawing upon both animal and human evidence. This first part of this talk will describe, with high temporal resolution, the physiological and targeted molecular responses to a bout of eccentric exercise in young and older exercise naïve males. Unpublished observations from our lab demonstrate that functional decline and recovery trajectories are similar across age, yet there was a general pattern of blunted anabolic signaling in older versus younger adults, which might provide the molecular basis for impaired functional adaptations over repeated eccentric exercise bouts. The second part of this talk will explore the application and utility of omics for gaining deeper insight into the age-related molecular responses to eccentric exercise. Using a transcriptional approach, we identified contraction 'responsive' modules (related to 'cell adhesion' and 'transcription factor' processes) that correlated with the magnitude of post-eccentric exercise muscle strength decline, and thus may be novel molecular candidates of functional relevance to ageing muscle adaptation. The third and final part of this talk will explore the impaired adaptability of ageing muscle to eccentric exercise training. Using a mouse model, we found 5 weeks of eccentric training increased strength in younger but not older mice, which was associated with downregulated cellular respiration/oxidative phosphorylation, and upregulated extracellular matrix organization, gene responses in older mice. These molecular signatures may reveal, in part, why older muscles do not appear to be as adaptive to eccentric exercise training as young muscles. Combined, our data detail physiological and molecular responses to acute and chronic eccentric exercise, highlighting several potential molecular candidates worthy of further research as potential therapeutics for optimising adaptation to eccentric exercise.

HUMAN MUSCLE ADAPTATIONS TO ECCENTRIC EXERCISE THROUGH AN INTEGRATIVE PHYSIOLOGY APPROACH: MATCHING MORPHOLOGY TO CONTRACTILE PERFORMANCE

FRANCHI, M.

UNIVERSITY OF PADOVA

Eccentric exercise is regarded as one of the most potent stimuli for muscle remodelling owing to the marked tension produced during eccentric contractions. Nevertheless, within the last decades, a limited number of studies have focused on eccentric contraction-induced remodelling with an integrative physiological approach (from the macro-to-the-micro), trying to unravel either with models or in humans the possible connections between changes in structure and function. The first part of this talk will provide an up-to-date description of evidence for the mechanisms responsible for regulating muscle structural and molecular adaptations to different modalities of eccentric training, where I discuss the role of mechanotransduction in muscle remodelling in young and older age. The second part of the talk will present unpublished data on muscle morphological, functional and molecular response to concentric vs. eccentric loading in young vs. older age. This part will be linked to the first talk by Dr Colleen Deane, as data in older males on downregulation of cellular respiration/oxidative phosphorylation to eccentric training will be presented in support of Dr Deane's data in animal models. In fact, skeletal muscle aging is not only characterized by loss of muscle mass and power but also by mitochondrial impairments and reduced oxidative function. Despite the positive effect on muscle mass and strength, our data point towards dampened mitochondrial biogenesis, reduced mitochondrial content, and promoted fission in older males in response to moderate-load eccentric training. This is of particular interest, as eccentric training often shows positive neuromuscular adaptations in elderly populations but may not be entirely suitable for counteracting reductions in oxidative function. I will conclude with unpublished data related to muscle structural and functional adaptations to 6 weeks of conventional resistance training (concentric + eccentric phase) performed with or without the use of eccentric overload. Using ad hoc ultrasound protocols during ramped isometric contractions and synchronized High-Density EMG, I will discuss changes in architectural behaviour of fascicles at rest and during contraction, and their relation to motor unit properties and muscle function. From our pilot data, it appears that distinct structural adaptations provided by eccentric overload match differences in muscle fascicle behaviour and mechanical function. This topic is of broad interest for sport scientists, kinesiologists, biomechanics professionals and researchers, physiologists, and will complement Dr Deane's talk, while laying the ground for Dr Geoff Power's work on how sarcomerogenesis can influence muscle mechanical function in older age. Our intention is to provide the most updated view on eccentric loading in skeletal muscle.

IMPLICATIONS OF ECCENTRIC EXERCISE-INDUCED SERIAL SARCOMEROGENESIS IN OLD AGE ON MUSCLE MECHANICAL FUNCTION

POWER, G.

COLLEGE OF BIOLOGICAL SCIENCES, UNIVERSITY OF GUELPH

My Lab is interested in the effects of chronic changes to muscle fascicle length on mechanical function in old age. Here we use a F344BN aged rodent model (~32 month) to explore how eccentric exercise may stimulate sarcomerogenesis - the addition of sarcomeres in series - for improvement of muscle mechanical function. Understanding muscle design helps predict functional changes and counteract effects of aging. Muscle fascicle length gets shorter with age due to the loss of sarcomeres aligned in series. This loss of serial sarcomere number (SSN) contributes to declining muscle mechanical function including reduced active force, power, and increased passive stiffness. Due to the relationship between SSN and biomechanical properties of muscle, interventions promoting the addition of sarcomeres in series have been suggested to mitigate age-related impairments in muscle mechanical function. A common intervention for serial sarcomerogenesis is resistance training biased to active lengthening (i.e., eccentric) contractions. In young healthy rats and rabbits, eccentric training has increased SSN by up to 8%, and in humans SSN adaptations have been mostly assumed by increases in FL as measured by ultrasound. Through a series of studies, we investigated the ability for aged muscle to add sarcomeres in series and improve muscle mechanical function during re-ambulation after casting and following eccentric training. In 3 studies age-related differences in sarcomerogenesis and mechanical function were investigated following: (1) 2 weeks of plantar flexor immobilization then 4 weeks of ambulatory recovery; (2) 4 weeks of maximal eccentric plantar flexion training; and (3) 4 weeks of submaximal eccentric training. The soleus was assessed for SSN via laser diffraction. In-vivo measures of strength, passive stiffness, and power assessed changes in mechanical function. (1) Immobilization induced similar losses of SSN (~20%) and isometric strength (~40%) in young and old. Both young and old recovered SSN following immobilization, however, old took twice as long as young, and only young recovered strength. (2) Following maximal eccentric training, young exhibited increased SSN and strength, however, old exhibited no changes in SSN and became 35% weaker, 63% less powerful, and 51% stiffer. (3) Following submaximal eccentric training SSN increased 11%. Training also shifted optimal torque production towards longer muscle lengths, reduced passive torque 42%, and increased peak isotonic power 23%. Our results indicate that old retain the ability to re-add SSN following disuse, but did not increase SSN following maximal eccentric training. Impressively, submaximal eccentric training brought SSN in old back to the level of young rats and improved muscle function. Our results show, for the first time, that aged muscle retains the ability for serial sarcomerogenesis, making SSN an appealing target to improve mechanical function in older adults. Invited Symposium

IS-MH04 Why is elite athlete oral health so poor and what can we do to reverse the performance impacts?

ORAL HEALTH, INFLAMMATION, ELITE ATHLETES AND PERFORMANCE MEDICINE

NEEDLEMAN, I.

UCL EASTMAN DENTAL INSTITUTE

Our studies across Olympic games, elite squads and sports federations show a remarkably consistent pattern; elite athletes have high levels of oral diseases which are higher than non-athlete populations despite being easily preventable. Importantly, we have also shown that oral health negatively affects self-reported athlete performance with new data indicating impacts on objective laboratory parameters such as VO₂max. These observations are consistent with other effects of oral health such as impairment of glycaemic control. This presentation will summarise what we know about oral health in elite athletes and its determinants. It will also review what we know about the mechanisms linking oral health with systemic health and performance. Finally, the presentation will review what we know about how best to promote oral health within high performance sport including interventions developed in partnership with athletes. The topic is directly relevant to the health, daily wellbeing and performance of athletes. The target audience includes not only sports medicine clinicians and scientists but also athletes and their support staff.

EXERCISE, ORAL MICROBES, AND PERFORMANCE: A COMPLEX INTERPLAY

BURLEIGH, M.

THE UNIVERSITY OF THE WEST OF SCOTLAND

Emerging research demonstrates the complex relationship between exercise and the oral microbiome, revealing that exercise can influence oral health both positively and negatively. Oral health is closely tied to microbial composition and function and is an often overlooked, yet critical, component of an athlete's performance and overall well-being. While factors such as high-carbohydrate diets, frequent energy drink consumption, dehydration, and immune suppression following intense training can compromise oral health, recent data from our laboratory, suggest that physically active individuals—those habitually meeting the minimum exercise recommendations—tend to have healthier oral microbiome profiles compared to sedentary individuals. Active individuals exhibit a balanced microbial environment, which may contribute to improved oral and systemic health. This stands in contrast to previous research that shows elite athletes, particularly those involved in high-intensity training, often suffer from poorer oral health outcomes, likely due to the cumulative effects of dietary choices, reduced salivary flow, and the heightened physical demands of their training regimens. The oral microbiome is highly sensitive to changes in diet, hydration, and immune function—all of which are influenced by exercise. Regular, moderate exercise appears to promote microbial diversity, supporting a healthier balance of bacteria in the mouth. However, in elite athletes, the stress of demanding training, coupled with other risk factors, can lead to an environment that fosters pathogenic bacteria, increasing susceptibility to oral diseases such as dental caries, gingivitis, and periodontitis. This dual impact of exercise on the oral microbiome underscores the need for a nuanced understanding of the relationship between exercise and oral health. While the focus of this lecture is on the general athlete population, female athletes present a compelling area for future research. Hormonal fluctuations related to menstruation, pregnancy, and menopause may further influence the composition and health of the oral microbiome. Female athletes, especially those at risk of relative energy deficiency in sport (RED-S), may experience compounded oral health challenges due to nutritional deficiencies and compromised immune function, warranting further investigation. This talk will detail the current understanding of how exercise affects the oral microbiome, examining both the positive and negative outcomes associated with different levels of physical activity. We will explore the implications for athlete oral health management and suggest areas for future research, particularly in understanding female-specific factors that could influence oral microbial balance. The session will be of interest to athletes, sports scientists, oral health professionals, the athlete support team and anyone involved in athlete support and well-being.

NO LIMITS? THE POTENTIAL OF DIETARY NITRATE SUPPLEMENTATION TO IMPROVE ORAL HEALTH IN ATHLETES

EASTON, C.

UNIVERSITY OF THE WEST OF SCOTLAND

Nitric oxide is a key signalling molecule that regulates a multitude of physiological processes, including immune function, vascular tone, and neurotransmission. Nitric oxide is generated endogenously via nitric oxide synthase enzymes, but this process is downregulated with ageing and underpins progressive endothelial dysfunction and a range of other age-related disorders. However, circulating nitric oxide levels can be enhanced via the ingestion of nitrate-rich vegetables, including beetroot. The nitrate is converted to nitrite by certain species of bacteria in the mouth and further reduced to nitric oxide when certain physiological conditions prevail. There is now a plethora of research which demonstrates that increasing nitric oxide levels through dietary nitrate supplementation can improve cardiovascular health and exercise performance. There is also emerging evidence to suggest that nitrate supplementation can improve markers of oral health. Data from our lab, for example, has shown that nitrate-rich beetroot juice can increase the pH of saliva and significantly alter the composition of the oral microbiome in favour of oral health. We have also shown that beetroot juice atten-

uates the decline in salivary pH following the ingestion of sugar-rich and acidic sports supplements. Dietary nitrate, therefore, may provide athletes with both an ergogenic advantage and an effective means to protect their oral health. This presentation will discuss the role of the oral microbiome in the regulation of nitric oxide availability and will review the emerging evidence on the potential of dietary nitrate supplementation to reduce the incidence of oral health issues in athletes or treat those where oral disease is already present. This talk will be of interest to athletes, support teams, and sporting bodies with a commitment to athlete well-being in addition to academics with research interests in immune function, sport nutrition, and nitric oxide physiology.

Oral Presentations

OP-PN03 Endurance Physiology I

HABITUAL EXPOSURE TO EXERCISE-INDUCED HYPOHYDRATION ATTENUATES THE DECLINE IN RUNNING PERFORMANCE WHILST HYPOHYDRATED IN MALE ENDURANCE RUNNERS

CABLE, T., FUNNELL, M., MEARS, S., JAMES, L.

LOUGHBOROUGH UNIVERSITY

INTRODUCTION: Exercise-induced hypohydration (EIH) impairs endurance performance, with field data suggesting well-trained runners regularly experience EIH during training and competition. It is unclear if habitual exposure to EIH in such athletes attenuates the hypohydration-induced performance decline. Thus, this study assessed the impact of habitual exposure to EIH on performance and physiology responses whilst hypohydrated in runners habituated (H) and non-habituated (NH) to EIH.

METHODS: 11 habituated (H: $\text{VO}_{2\text{peak}} 63 \pm 9 \text{ mL/kg/min}$) and 10 non-habituated (NH: $\text{VO}_{2\text{peak}} 60 \pm 7 \text{ mL/kg/min}$) athletes completed familiarisation (ad-libitum water intake) and 2 experimental trials, involving a treadmill preload (PL; 8-11 x 6 min at 70% $\text{VO}_{2\text{peak}}$, 1 min rest; standardised within participant) and a 3 km time-trial (TT) in 28°C. Water replacement (80% mass loss; EU) or minimal water intake (100 mL; HH) was provided during PL, aiming for ~3% total body water (TBW; via bioelectrical impedance) loss in HH. Venous blood and nude mass measures were made pre-PL, post-PL and post-TT, with gastrointestinal (GI)/skin temperature, heart rate, perceptual responses and oxygen uptake measured throughout. 3 km TT performance was the primary outcome.

RESULTS: Post-PL relative TBW loss in EU (H $-1.1 \pm 0.4\%$; NH $-1.0 \pm 0.2\%$) and HH (H $-3.4 \pm 0.8\%$; NH $-3.2 \pm 0.2\%$) was not different between groups ($P \geq 0.227$). Hypohydration increased heart rate, RPE and thirst ($P \leq 0.046$), decreased body mass and plasma volume ($P \leq 0.003$), but did not alter GI or skin temperature, oxygen uptake, running economy, GI comfort or thermal sensation ($P \geq 0.129$). However, there were no trial*time*group interactions for any physiological or perceptual variables during PL ($P \geq 0.198$). There was a trial*group interaction for 3 km TT performance ($P = 0.041$), with NH athletes 4.2% slower in HH (EU $817 \pm 43 \text{ s}$; HH $855 \pm 60 \text{ s}$; $P = 0.013$), but H athletes not different between trials (EU $703 \pm 83 \text{ s}$; HH $708 \pm 78 \text{ s}$; $P = 0.658$). During TT, there was a mean effect of group where NH had a 0.4°C greater GI temperature compared to H ($P = 0.004$). During familiarisation, NH drank more water ad-libitum (H $0.50 \pm 0.24 \text{ L}$; NH $0.85 \pm 0.42 \text{ L}$; $P = 0.031$), meaning hypohydration was greater in H athletes (H $-1.6 \pm 0.4\%$; NH $-1.1 \pm 0.4\%$; $P = 0.021$).

CONCLUSION: These data demonstrate that EIH impairs endurance performance in non-habituated athletes only, but no differences were observed between groups for physiological or perceptual variables. Interestingly, during TT, NH athletes had a greater GI temperature, indicating impaired thermoregulation during running performance, potentially exacerbating the effects of hypohydration. The greater ad-libitum water intake and lower hypohydration in NH runners indicates differences in hydration behaviour that might explain some of the observed performance effects. These results suggest that regular exposure to and familiarisation with EIH may attenuate the expected decline in performance whilst hypohydrated.

EFFECT OF HYPOXIC EXPOSURE AT DIFFERENT TIMINGS ON IRON REGULATION AND HEMATOPOIESIS AFTER ENDURANCE EXERCISE

LIN, C., NATSUI, T., TOMIISHI, C., TSUYUKI, M., GOTO, K.

RITSUMEIKAN UNIVERSITY

INTRODUCTION: Strenuous exercise increases circulating hepcidin levels during post-exercise, potentially contributing to the reduced iron storage in individuals who engage in regular physical activity. While prolonged exposure to hypoxia, lasting days to weeks, suppresses hepcidin levels and enhances iron absorption, interest is growing in short-term exposure to hypoxia that can be integrated into athletes' training routines. The present study aimed to examine the effects of acute hypoxic exposure at different timings on exercise-induced hepcidin responses.

METHODS: Twelve healthy individuals (5 women, 7 men; age: 23 ± 2 years; height: $169.9 \pm 8.3 \text{ cm}$; body mass: $62.4 \pm 8.1 \text{ kg}$) participated in a single-blind, randomized, cross-over design study. They completed high-intensity interval running under three different conditions on separate days: (1) normoxic control (CON; resting in normoxia before and after exercise), (2) pre-exercise hypoxic exposure (Pre-HYPO; 2-hour exposure to hypoxia before exercise), and (3) post-exercise hypoxic exposure (Post-HYPO; 2-hour exposure to hypoxia after exercise). The fraction of inspired oxygen was 12.5% in the hypoxic environment and 20.9% in the normoxic control environment. The exercise protocol consisted of eight sets of 4-

minute running intervals at 85% of maximal oxygen uptake in a normoxic environment. Venous blood samples were collected at 2 hours before exercise (baseline), immediately before, immediately after exercise, and 3 hours post-exercise. Blood analyses included measurements of serum iron, ferritin, erythropoietin (EPO), and hepcidin levels.

RESULTS: Serum EPO levels increased significantly immediately after exercise and 3 hours post-exercise in both Pre-HYPO and Post-HYPO trials ($p < 0.05$ vs. baseline). The immediate post-exercise EPO response was greater in Pre-HYPO trial ($45.7 \pm 15.9\%$ increase from baseline) than in the CON trial ($3.4 \pm 17.5\%$, $p < 0.05$). At 3 hours post-exercise, EPO was still higher in both Pre-HYPO trial ($53.0 \pm 31.5\%$ increase from baseline) and Post-HYPO trial ($50.0 \pm 24.1\%$) than in CON trial ($11.9 \pm 16.8\%$, $p < 0.05$). Serum hepcidin elevated at immediately after exercise and 3 hours post-exercise compared to baseline ($p < 0.05$). However, the serum hepcidin level did not differ significantly among the three trials at any time points ($p > 0.05$). No significant differences among the trials were observed for serum iron or ferritin ($p > 0.05$).

CONCLUSION: Both “pre-exercise hypoxic exposure” and “post-exercise hypoxic exposure” enhanced EPO secretions in young women and men. However, despite the increased erythropoietic responses, exercise-induced elevations in serum hepcidin were not suppressed with pre-exercise hypoxic exposure or post-exercise hypoxic exposure.

INDIVIDUAL RESPONSES TO 8 WEEKS OF AEROBIC INTERVAL TRAINING ARE PARTIALLY REPRODUCIBLE

ODDEN, I., HAMARSLAND, H., URIANSTAD, T., HAMMARSTRÖM, D., ROGNEFLÅTEN, T., HANSEN, J., ELLEFSEN, S., RUSTADEN, A.M., NYGAARD, H., RØNNESTAD, B.R., LUNDBY, C., MØLMEN, K.S.

INLAND NORWAY UNIVERSITY OF APPLIED SCIENCES LILLEHAMMER

INTRODUCTION: The ability to adapt to exercise training varies among individuals, raising concerns about the uniformity of health benefits derived from training interventions [1]. Central to this issue is the concept of high- and low-responders to exercise training, which assumes that the ability to adapt to a specific exercise prescription is a fixed trait of individuals [2]. However, when small groups ($n=10-19$) of young, moderately trained individuals are repeatedly exposed to identical aerobic training programs, individual training responses are not consistent [3-6]. Whether these observations extend to other populations and larger sample sizes are currently unknown. Hence, the present study examined whether individual responses to two identical aerobic training interventions are reproducible in middle-aged, untrained males and females.

METHODS: Forty-two untrained but healthy men and women ($\bar{x} \pm \text{SD}$; age, 54 ± 9 years; maximal oxygen uptake ($\text{VO}_{2\text{max}}$), 32 ± 7 mL/min/kg) underwent two identical 8-week aerobic training interventions (ET-1 and ET-2), separated by an 8-week wash-out period. ET-1 and ET-2 included 24 supervised 45-min interval sessions, alternating between high-intensity (4×5 min and 4×8 min) and moderate-intensity (6×6 min) cycling exercise. Participants' $\text{VO}_{2\text{max}}$, maximal 1-min power output during the $\text{VO}_{2\text{max}}$ test ($\text{MPOVO}_{2\text{max}}$), and maximal 15-min mean power output ($\text{MMPO}_{15\text{min}}$) were determined before and after each intervention period. The reproducibility of pre-test values and change scores across ET-1 and ET-2 was determined using intraclass correlation coefficients (ICC). Pearson correlation coefficients (r) were used to evaluate the strength and direction of the relationships between scores. 95% confidence intervals (CIs) were calculated to interpret the results.

RESULTS: At the onset of ET-1 and ET-2, $\text{VO}_{2\text{max}}$, $\text{MPOVO}_{2\text{max}}$, and $\text{MMPO}_{15\text{min}}$ demonstrated excellent reproducibility and very strong associations between training interventions ($\text{ICC} = 0.96-0.98$, $r = 0.97-0.98$, 95% CIs not including zero). Changes in $\text{MPOVO}_{2\text{max}}$ and $\text{MMPO}_{15\text{min}}$ during ET-1 and ET-2 exhibited some level of reproducibility ($\text{ICC} = 0.35$ and 0.29 , respectively) and weak associations ($r = 0.38$ and 0.32 , respectively), with 95% CIs not including zero. In contrast, changes in $\text{VO}_{2\text{max}}$ were neither reproducible nor correlated (95% CIs including zero).

CONCLUSION: When exposed to two identical aerobic training interventions, individual changes in $\text{MPOVO}_{2\text{max}}$ and $\text{MMPO}_{15\text{min}}$ were partially reproducible in middle-aged, untrained males and females. In contrast, $\text{VO}_{2\text{max}}$ changes were not. These findings challenge the notion of fixed high- and low-responders to exercise training and question the predictability of individual responses to exercise training prescriptions based on the observed response to a single training period.

SIX WEEKS OF LOW INTENSITY ENDURANCE RUNNING TRAINING IMPROVE TRADITIONAL PERFORMANCE MARKERS BUT NOT VASTUS LATERALIS OXYGEN SATURATION

SKOTZKE, P., SCHWINDLING, S., VOLKAMER-KIEN, B., ZWIENER, L., RICHRATH, O., MEYER, T.

SAARLAND UNIVERSITY

INTRODUCTION: Recent technological developments have enabled measuring local muscle oxygen saturation (SmO_2) non-invasively during exercise. Changes in traditional performance markers following endurance training like the first and second lactate threshold (LT_1 , LT_2), maximal velocity (v_{max}), running economy (RE) and $\text{VO}_{2\text{peak}}$ during a graded exercise test (GXT) are well documented. The Bohr effect provides a physiological link between lactate and SmO_2 . Still, it remains unclear how submaximal SmO_2 and muscle deoxygenation ($\text{SmO}_{2\text{min}}$) at the end of a GXT change following endurance training.

METHODS: In a within-subject repeated-measures design, $n = 46$ healthy sport science students (26 m, 20 f, 21.8 ± 1.5 yrs, 71 ± 10 kg, $\text{VO}_{2\text{peak}}$ 48.3 ± 5.6 mL/min/kg, recreationally active to trained) completed a 6-weeks running training pro-

gram (END) after a control period of normal training (CON). During END, participants performed 18 ± 3 45 min runs (90% compliance) at the heart rate corresponding to their first lactate threshold (± 5 bpm) in addition to their normal training. Training diaries were used to document training load as duration $\times$ sRPE (in arbitrary units, AU). GXTs ($6 + 2$ km/h every 3 min) were performed before (T1) and after CON (T2) as well as after END (T3). SmO₂ at the vastus lateralis muscle (VL) was measured using continuous-wave near-infrared spectroscopy (NIRS, Moxy Monitor) as well as capillary lactate concentration and VO₂.

RESULTS: Weekly training load during END increased significantly by 24% compared to CON ($+280$ AU/wk, $p < 0.01$). Repeated measures ANOVA showed significant ($p < 0.01$) overall effects of time for LT1, LT2 and v_{max}, but not VO_{2peak} ($p = 0.06$). Post hoc analysis revealed significant differences between T2 and T3 for LT1 ($+0.6$ km/h, $p < 0.01$, $d = 0.88$), LT2 ($+0.8$ km/h, $p < 0.01$, $d = 0.95$) and v_{max} ($+0.7$ km/h, $p < 0.01$, $d = 0.68$). No differences were found between T1 and T2 ($p > 0.05$). A linear mixed model revealed a significant fixed effect for timepoint: RE increased for all submaximal stages from T1 to T2 (-1.5 ml/min/kg, $p < 0.01$) and from T2 to T3 (-1.6 ml/min/kg, $p < 0.01$). Neither submaximal SmO₂ ($p = 0.61$, T1 = 53.6 ± 12.9 %, T2 = 55.1 ± 14.8 %, T3 = 56.0 ± 12.3 %) nor SmO_{2min} ($p = 0.054$, T1 = 37.3 ± 18.6 %, T2 = 33.6 ± 16.3 %, T3 = 28.6 ± 17.4 %) showed a significant change.

CONCLUSION: The intervention was sufficient to induce adaptations in classical performance markers, but SmO₂ parameters remained unchanged. This suggests that SmO₂ – unlike lactate kinetics – might not be altered by 6 weeks of low intensity endurance training in moderately trained sport students. Whether SmO₂ shows no changes following endurance training or if a longer intervention duration or higher training intensity are necessary to elicit adaptations requires further research and should consider the influence of adipose tissue thickness on SmO₂. The improvement in v_{max} despite lacking changes in VO_{2peak} can be explained by an improved running economy.

CONCURRENT STRENGTH AND ENDURANCE TRAINING IMPROVES CYCLING POWER OUTPUT IN YOUNG MALE CYCLISTS WITHOUT AFFECTING VO₂MAX OR STRENGTH MEASURES

ŽITNIK, J., ŠARKO, P., SMAJLA, D.

UNIVERSITY OF PRIMORSKA - FACULTY OF HEALTH SCIENCES

INTRODUCTION: Concurrent training involves combining resistance and endurance exercises within a structured training program (1). While some studies have investigated its effects in children (2,3), to our knowledge, no studies have explored concurrent training in young cyclists. Our aim was to evaluate the effects of a 7-week concurrent training intervention on endurance performance, body composition, and lower-body strength and power in young male cyclists.

METHODS: Fourteen young male cyclists (11–14 years; intervention: $n = 8$, control: $n = 6$) with ≥ 2 years of regular training (≥ 2 days/week) participated (age: 12.3 ± 0.4 vs. 12.7 ± 1.0 years; height: 151.8 ± 7.0 vs. 162.7 ± 7.7 cm; body mass: 40.6 ± 4.9 vs. 48.8 ± 7.7 kg; maximal oxygen uptake [VO_{2max}]: 56.3 ± 6.2 vs. 57.2 ± 6.9 mL/kg/min, control vs. intervention). Baseline assessments included body composition (bioelectrical impedance), lower-body strength (maximal voluntary contraction [MVC] for knee extension and flexion), lower-body power (countermovement jump [CMJ] and squat jump [SJ] height), and an incremental cycling test to determine maximal power output (P_{max}), time to exhaustion (T_{lim}), and VO_{2max} (indirect calorimetry). The 7-week intervention consisted of concurrent endurance and strength training (intervention: 2×1 h strength + 2×1.5 h endurance sessions/week; control: endurance training-only with matched duration and intensity). Post-intervention, all tests were repeated. Linear mixed models were used to assess changes over time, with baseline values included as covariates. Relative change score differences between groups were also evaluated. Data are presented as mean $\pm$ SD. Significance was set at $p < 0.05$.

RESULTS: The 7-week concurrent training intervention resulted in significant improvements in maximal power output P_{max} ($+7.3$ %, $p = 0.027$, $d = 1.33$, 95% CI [0.99, 13.68]) and P_{maxRel} ($+6.2$ %, $p = 0.044$, $d = 1.19$, 95% CI [0.20, 12.19]) in the intervention group compared to controls. No changes were observed in T_{lim} ($+9.5$ %, $p = 0.075$, $d = 1.03$, 95% CI [-1.13, 20.11]) in the incremental test. VO_{2max} showed no significant changes between groups over time ($p = 0.394$). No significant group $\times$ time interactions were observed for body composition (fat mass, $p = 0.127$; fat percentage, $p = 0.322$; fat-free mass, $p = 0.774$) or lower-body strength (knee extension MVC, $p = 0.397$; knee flexion MVC, $p = 0.979$). Similarly, lower-body power (CMJ height, $p = 0.805$; SJ height, $p = 0.101$) showed no significant changes between groups over time.

CONCLUSION: Concurrent strength and endurance training intervention in young cyclists demonstrated significant improvements in relative and maximal power output without concomitant increases in maximal oxygen uptake or other strength measures. Future studies with larger sample sizes and longer intervention durations are needed to verify these findings and further explore the potential benefits of concurrent training in this population.

INHERITABLE TRAITS: MUSCLE FIBRE TYPOLOGY OF ELITE FEMALE ATHLETES

MINAHAN, C., BELLINGER, P., KENNEDY, B., ROBERTS, L., MCLAREN, A., WACKWITZ, T., LIEVENS, E., DERAIVE, W.

GRIFFITH UNIVERSITY

INTRODUCTION: Elite performance in sports is closely linked to an athlete's muscle fibre composition, with endurance specialists typically exhibiting a predominance of type I (slow-twitch) fibres, while power and sprint athletes tend to have a higher proportion of type II (fast-twitch) fibres. A precise understanding of muscle fibre typology is valuable for guiding athlete development, refining training programs, and optimizing race strategies. However, much of these data are based on studies of male athletes and little is known about the muscle fibre typology of elite female athletes. This gap likely stems from both the historically low representation of elite female athletes in sports performance research [1] and the reliance on invasive muscle biopsies as the primary assessment method.

METHODS: This study utilized proton magnetic resonance spectroscopy (¹H-MRS), a non-invasive imaging technique that estimates muscle fibre typology by measuring muscle carnosine levels [2]. More than 110 elite female athletes from diverse sports—such as athletics, swimming, cycling, kayaking, rugby league, and Australian football—underwent assessments. Carnosine concentrations were recorded in the soleus, gastrocnemius, and deltoid muscles and analysed as Z-scores against a reference population. Athletes were categorized as type I or type II dominant if their Z-scores exceeded ± 0.5 .

RESULTS: Athletes specializing in explosive, power-based disciplines—including sprinting (across multiple sports), weightlifting, jumping, and throwing—had an average Z-score of +0.71, reflecting a strong type II fibre predominance. In contrast, those competing in middle-distance events or team sports exhibited more balanced muscle fibre typology, with an average Z-score of +0.15. Meanwhile, endurance athletes participating in distance events in athletics, cycling, and swimming displayed a Z-score of -0.75, consistent with a higher proportion of type I fibres.

CONCLUSION: Muscle fibre typology varies significantly among elite female athletes, not only across sports but also between event specializations within the same discipline. These findings underscore the usefulness of non-invasive muscle fibre estimation for identifying athletic potential, refining talent development strategies, and tailoring training programs to maximize performance outcomes.

FACTORS RELATED TO PULL-UP PERFORMANCE: SMALL RELATIONSHIP BETWEEN BRACHIAL INDEX AND PULL-UP ONE REPETITION MAXIMUM IN CANADIAN RECREATIONAL TO COMPETITIVE CALISTHENICS ATHLETES

LAWSON, E., COTTRELL, T.

SHERIDAN COLLEGE

INTRODUCTION: Pull-ups (PU) are a popular exercise used in resistance training programs. Anthropometrics like total body mass, and fat mass generally affect PU performance.[1,2] However, the relationships of arm lengths or length-ratios on sport and exercise performance varies.[3,4,5,6,7] The brachial index (BI) is defined as the quotient of forearm length (radiale to stylium) and upper arm length (acromiale to radiale). The aim of this study was to investigate the relationship between BI and PU performance and determine differences between high and low performing groups.

METHODS: Thirty male recreational to competitive calisthenics athletes, age 26 ± 5.2 years, body mass 75.5 ± 10.85 kg, fat mass 14.2 ± 4.8 kg, and height 173 ± 5.38 cm, reported to the testing location on a single occasion for anthropometric and performance testing. Participants completed a survey to determine eligibility and provided informed written consent. The protocol was approved by the Sheridan Research Ethics Board prior to commencement. Anthropometric testing included measurement of body mass (BM), height, selected arm lengths, girths, and skinfolds. Performance testing consisted of a one repetition maximum (1RM) PU test which was equal to 1RM load and BM, and mean velocity (MV) at 1RM, 80% 1RM, and BM loads. Pearson's product moment correlation coefficients were used to investigate the relationship between variables, and two-tailed, homoscedastic students t-tests were performed to compare differences between groups.

RESULTS: A small positive relationship was found with BI and all variables of performance. No significant differences were found between high and low BI groups for any variable. However, significant differences ($p < 0.05$) were found between groups, with the high strength group (> 122.4 kg 1RM, $n=15$), having greater body mass, flexed upper arm, chest, and thigh girth, as well as bicep, waist, and thigh corrected girth, lean body mass, body mass index, Brugsch index, and Takai's equation than the low strength group (< 122.4 kg 1RM, $n=15$). The high MV at BM load group (> 0.905 m/s, $n=15$) had non-significant lower chest skinfold ($p=0.06$), abdominal skinfold ($p=0.08$), sum of skinfolds ($p=0.09$), and hip girth ($p=0.1$), while having a greater BI ($p=0.08$), flexed upper arm to thigh girth ratio ($p=0.051$), and significantly greater measures of performance than the low MV at BM load group (< 0.905 m/s, $n=15$). Lastly, a positive medium correlation ($r=+0.42$, $n=30$) was found with total 1RM load and BM PU MV, which is similar to prior data on first repetition concentric velocity and PU repetitions.[7]

CONCLUSION: BI should not be used for talent selection in the sport of street-lifting. Athletes wishing to maximize 1RM strength and MV in the PU exercise should focus on the accrual of lean mass in the PU prime movers and decreasing excess fat mass.

AEROBIC ENDURANCE, AGILITY, AND STRENGTH: KEY FITNESS PREDICTORS OF SUCCESS IN ELITE JUNIOR TENNIS PLAYERS

ZHAO, Z., YANG, W., CUI, Y., ZHU, Q., QI, B.

BEIJING SPORT UNIVERSITY

INTRODUCTION: The relationship between physical fitness and tennis performance in elite junior players remains a significant area of interest. Specifically, understanding how various fitness components influence on-court performance can provide valuable insights for optimizing training regimens. This study aims to investigate how fitness characteristics correlate with the competitive success of elite junior tennis players in China, focusing on differences between players with high and low semi-final list rates across different age groups (U12, U14, U16).

METHODS: A total of 600 fitness test data points were collected throughout 2024 from elite junior tennis players (U12, U14, U16). Players were categorized into high (HSR) and low (LSR) semi-finalist rate groups using K-means clustering, based on the percentage of times they reached the semi-finals relative to the total number of tournaments they participated in during the competitive season. The dataset includes multiple testing instances for each player, as athletes who did not pass a fitness test were required to retake it. The players underwent a comprehensive battery of fitness tests, assessing strength, power, endurance, agility, flexibility, and balance. Performance was quantified using a points system derived from players' tournament rankings. A generalized linear model (GLM) was used to compare the fitness characteristics between the HSR and LSR groups. Additionally, bivariate correlation analyses were conducted to examine the relationship between fitness test results and performance scores.

RESULTS: Significant differences were found in fitness characteristics between HSR and LSR groups across various age and gender categories.

- U12 female: double jump rope (183 ± 63.3 vs 261 ± 41.5 , $ES=1.46^{**}$), medicine ball throw (7.82 ± 1.26 vs 8.65 ± 0.947 , $ES=0.74^{*}$), and shuttle run (1251 ± 387 vs 1576 ± 254 , $ES=0.99^{**}$).
- U12 male: double jump rope (186 ± 69.7 vs 248 ± 38.9 , $ES=1.10^{**}$) and shuttle run (1405 ± 355 vs 1810 ± 215 , $ES=1.38^{**}$).
- U14 female: double jump rope (204 ± 61 vs 250 ± 42.4 , $ES=0.88^{**}$), medicine ball throw (8.84 ± 1.27 vs 10.5 ± 0.786 , $ES=1.57^{***}$), and shuttle run (1428 ± 328 vs 1700 ± 233 , $ES=0.96^{*}$).
- U14 male: push-ups (24.7 ± 6.89 vs 27.4 ± 5.47 , $ES=0.43^{*}$).
- U16 female: double jump rope (223 ± 80 vs 292 ± 39 , $ES=1.10^{*}$).
- U16 male: no significant differences in any fitness tests.

Bivariate correlation analyses revealed moderate to strong positive correlations between aerobic endurance ($r=0.40-0.50$), agility ($r=0.29-0.50$), while strength had moderate correlations ($r=0.23-0.41$). Balance and muscular endurance showed weaker correlations ($r=0.20-0.30$).

CONCLUSION: Aerobic endurance, agility, and strength play significant roles in determining competitive success in junior tennis players. The findings suggest that players with a higher semi-final list rate exhibit superior fitness levels in endurance and agility. Coaches and sports scientists should emphasize these key attributes when designing training programs to optimize the performance and success of young tennis athletes.

DIFFERENCES IN ISOMETRIC STRENGTH AND SPRINTING SPEED OF ACADEMY SOCCER PLAYERS: A SPECIAL FOCUS ON TRANSITION BETWEEN AGE GROUPS

SKALA, F., CHOLP, J., NAGY, N., MIKULIC, M.

COMENIUS UNIVERSITY IN BRATISLAVA

INTRODUCTION: Physical and psychosocial development of athletes fluctuates within the various age groups [1]. Despite their minor chronological age, soccer players frequently advance to the superior age groups. However, the neuromuscular development of these athletes must not be neglected, as later maturation and advanced chronological age are potential risk factors for injury in youth soccer [2]. This study compares the isometric strength and sprinting speed of elite academy soccer players. Highlighting differences among age groups may help with the talent identification procedures and injury prevention of players in soccer academies.

METHODS: This cross-sectional study compared a total of 83 academy players from five age groups (U14, U15, U16, U17, and U19) in absolute (N) and relative (N/kg) isometric peak force production in a bilateral 30-degree knee flexion test (ISO 30°), 60-degree abduction and adduction tests (ABD and ADD 60°). Their sprinting speed was compared by a 30-meter sprint test with a 10-meter split time and the 505 change of direction test (COD 180°). Isometric strength was measured by VALD NordBord and ForceFrame (Vald Performance, Newstead, Australia). Sprinting speed was assessed by photocells Witty GATE (Microgate, Bolzano, Italy). A one-way analysis of variance (ANOVA) with Tukey's post hoc test analysed strength and speed differences among age groups. The effect size (ES) was determined by calculating eta-square (η^2) while pairwise effects were expressed by Cohen's d.

RESULTS: Significant strength differences among the age groups were observed for ISO 30° ($p < 0.001$; $\eta^2 = 0.40$ [U14 < U16, U17, and U19; U15 < U17 and U19]), ABD 60° ($p < 0.001$; $\eta^2 = 0.41$ [U14 < U16, U17, and U19; U15 < U17 and U19]), and ADD 60° ($p < 0.001$; $\eta^2 = 0.43$; U14 < U15 to U19). The relative strength differences occurred only between U15 and U19 groups in ISO 30° ($p = 0.043$; $ES = 1.04$). The U14 players were slower in speed tests compared to U16, U17, and U19 ($ES = 0.95 - 3.68$) while the same pattern occurred for the U15 players ($ES = 1.07 - 2.37$). The U17 players were faster than U19 players in COD 180° ($p = 0.019$; $ES = 0.22$).

CONCLUSION: The major differences in isometric strength are visible between U14 and U16 academy soccer players. The most sensitive period for neuromuscular demands is their transition from the U15 to the U16 age group. We recommend placing a special focus on the analysis of the isometric adduction strength, linear speed, and COD speed in these age groups. There is a plateau in isometric strength and speed performance from U16 to U19 groups. In this period, other methods or factors must be considered when transitioning players to the superior age groups. Lastly, the COD speed should not be considered to analyse age-related differences between U17 and U19 players.

INHERITABLE TRAITS: PROFILING ELITE FEMALE SPRINT KAYAKERS

MCLAREN, A., ROBERTS, L., BELLINGER, P., OSBORNE, M., KENNEDY, B., LEIVENS, E., DRAVE, W., JANG, C., BULLOCK, N., PRETORIUS, C., MCWHINNEY, B., NEUMANN, D., MINAHAN, C.

GRIFFITH UNIVERSITY

INTRODUCTION: Athlete profiling is widely used in elite sport and commonly focuses on physical, physiological and psychological characteristics; however, this method of profiling can be limited due to modifiable factors such as health and training status, stage of maturation and task familiarity [1]. Alternatively, 65% of athlete performance is influenced by inherited traits and therefore profiling these traits may provide a more accurate assessment of performance potential [2]. This study aimed to profile 'inHERitable TRAITS' (i.e., muscle fibre typology; MFT, sex hormones and personality attributes) in a group of elite female sprint kayakers.

METHODS: Fourteen female sprint kayakers (KAY; international – world class status) and 64 recreationally active women (CON) were recruited. Proton magnetic resonance spectroscopy was used to estimate MFT in the upper and lower body. The concentration of sex hormones was determined following the collection of a venous blood sample. Personality attributes which have been previously correlated with sex hormones (i.e., competitiveness and willingness to take risks) were determined. Strength and K1 500-m event performances were also recorded to assess the interaction of 'inHERitable TRAITS' with performance metrics.

RESULTS: KAY were estimated to have a significantly greater proportion of type II fibres in the lower body ($p=0.020$) than the CON. Although MFT was not related to strength or K1 500-m performance, the most successful athletes in the 200 and 1000-m events possessed the most extreme MFT. There was no significant difference in hormonal profiles between KAY and the CON, however athletes who displayed an irregular menstrual cycle (>35 -d) had significantly lower concentrations of sex hormones ($p>0.05$). Some sex hormones, most notably free testosterone, were significantly related to strength metrics ($p>0.05$). KAY reported a significantly higher enjoyment of sport experiences such as competition, risk taking and making progress ($p=0.016$). In these athletes' willingness to take risks and consistency of interest were significantly related to some sex hormones ($p>0.05$).

CONCLUSION: Despite there being no single inherent physiological profile for a successful female KAY, inHERitable TRAITS may be useful for performance support staff in predicting performance potential in a certain event and individualising training approaches for each athlete.

PREDICTIVE VALUE OF PRESEASON STRENGTH TEST IMPROVEMENT ON ALPINE SKIING PERFORMANCE

CUNIBERTI, G., PARENZAN, S., TODESCO, B., SAVOLDELLI, A., BORTOLAN, L.

UNIVERSITY OF VERONA

INTRODUCTION: Alpine skiing performance needs strength, power, and balance, and high external forces and specific neuromuscular demands influence it. Traditional fitness assessments such as squat jump (SJ) and countermovement jump (CMJ) evaluate explosive power but may poorly address skiing's strength requirements due to high-force outputs occurring at low angular velocities [1]. While anaerobic and aerobic capacities have been explored, their relationship with performance is ambiguous [2]. This study examines whether preseason strength test enhancements correlate with FIS point progression in slalom (SL) and giant slalom (GS), providing insight into strength tests predictive value for skiing.

METHODS: Twenty-one alpine skiers were evaluated. Testing occurred at the preseason beginning (PRE) and conclusion (POST). The assessment battery comprised CMJ, SJ, and loaded squats at different body weight (BW) percentages. Peak force (PF), power, jump height, and velocity were quantified using a force platform [3]. Isometric strength was measured via belt isometric squat at 90°, 110°, and 130° knee angles, focusing on PF, early and late rate of force development (RFD), and maximum RFD. Pre-post differences were analyzed, and deltas between preseason tests were assessed. Competitive performance was quantified by the delta of FIS points between the seasons start and the best result achieved. Data were normalized via Z-score transformation. Statistical tools included Principal Component Analysis (PCA) to identify critical performance variables and multivariate regression to explore the relationships between predictor variables and competitive performance.

RESULTS: The PCA revealed nine components accounting for over 90% of the total variance, with the initial three components explaining 54%. The first principal component was peak power and velocity in loaded squats and CMJ PF. The second one is related to body composition and PF in SJ and isometric squat at 90°. Finally, the third component encompassed power and velocity at the highest squat load alongside various RFD metrics. Multivariate regression revealed that peak power during squat at 150% BW is the primary predictor of performance improvements in SL and GS, with positive coefficients indicating strong explanatory power for the enhancements in both disciplines ($R^2 = 0.67$ and 0.66 , respectively).

CONCLUSION: Results underscore the significance of lower-limb power output and high-load strength as pivotal factors in alpine skiing performance. Similar outcomes for SL and GS regression models suggest that enhancing maximum force production at slow movement velocities is more pertinent than augmenting fast, explosive movements. This indicates that conventional jump-based evaluations, which predominantly assess explosive power at elevated velocities, may inadequately capture the crucial strength attributes for skiing.

SELECTION OF THE EXTREMES IN ELITE TEAMS: UNCOVERING THE INTERACTION BETWEEN THE RELATIVE AGE EFFECT AND BIOLOGICAL MATURITY TIMING IN SWEDISH ICE HOCKEY PLAYERS

NIKlasson, E., RIETZ, M., LINDHOLM, O., LIND, J., JOHNSON, D., LUNDBERG, T.

KAROLINSKA INSTITUTET

INTRODUCTION: In youth sports, differences in biological maturation and relative age (RA) may lead to selection biases favouring early-born and early-maturing players due to advantages in psychological development and physique, respectively (1). However, no previous study has investigated the interaction of RA and biological maturity timing in ice hockey, considering elite junior and adult success.

METHODS: Between 1998 and 2017, longitudinal anthropometrical data was collected in certified Swedish high school ice hockey programmes. For 2211 players, biological maturity timing was computed as z-scores of % adult height (z%AH) at term 1, compared to a Swedish reference (2). Birth dates for these players were used to calculate numerical relative age. Retrospective data on selection to the Swedish U16 national team (Team 16) and the National Hockey League (NHL) were retrieved from open databases. Next, absolute counts and proportions of players selected for Team 16 and the NHL were tabulated across quartiles of RA and z%AH. Generalized logistic regression models (GLM) including the predictors RA, z%AH, and their interaction, as well as other relevant confounders, were used to analyse selection probabilities.

RESULTS: Distributions in RA and biological maturity timing differed significantly between Team 16 and the NHL. Considering Team 16, the group with the highest proportion of selected players was individuals born late in the year with early biological maturity timing (22%), although absolute counts in this group ($n=13$) were markedly less than in early-born players at any maturity timing, ranging from 21–28 selected players (10.8%–15.3%). In a GLM, RA and z%AH were independently identified as significant predictors of being selected for Team 16, and a significant interaction between RAE and z%AH was observed ($P < 0.05$). Considering adult success, players with late biological maturation timing ($z\%AH < -0.03$) presented the highest proportion of players reaching the NHL, regardless of RA. Next, z%AH ($P < 0.01$), but not RA ($P = 0.24$), was significantly associated with NHL selection probabilities (favoring players who matured later than average), but there was no significant interaction between RA and z%AH ($P = 0.44$) in the employed GLM.

CONCLUSION: Overall, there were independent and joint associations between RA and biological maturity timing considering the national Team 16 selection. Here, early maturity timing may cancel out disadvantages due to low RA. In contrast, late biological maturity timing was positively associated with NHL selection, but there was no interaction with RA.

ISCHEMIC PRECONDITIONING DURING A CONCURRENT TRAINING MICROCYCLE: EFFECTS ON PERFORMANCE IN SHORT-TRACK SPEED SKATING ATHLETES

FURNO PUGLIA, V., PARADIS-DESCHÊNES, P., BERRYMAN, N.
UNIVERSITÉ DU QUÉBEC À MONTRÉAL

INTRODUCTION: Concurrent training is necessary for short-track speed skating performance. To optimize the benefits of these sessions in a context where athletes might face a diminishing return phenomenon [1], ischemic preconditioning (IPC) may be a promising strategy [2,3].

METHODS: Tier 3 and 4 [4] short track speed skaters ($n=21$) participated in this randomized crossover study with 2 micro-cycles including 1 strength session (3 sets of 6 reps and 1 set to failure of trap bar squats at $\sim 85\%$ of 1 RM, with 90 seconds of rest between series) and 1 sprint interval (SIT) session 48 hours later (2 sets of 6 all-out sprints of 15 seconds on a bike, with 2 min of rest between sprints and 4 min between sets). During the strength sessions, mean velocity for each repetition was recorded with a Gym Aware device (Kinetic Performance Technology, Australia). During SIT sessions, power outputs were recorded using a Kickr trainer (Wahoo, United States of America). In a random order (AB or BA), athletes performed a microcycle during which strength and SIT sessions were preceded by IPC (week A; 3 x 5 min at 220 mmHg followed by 5 min at 0 mmHg, on each thigh) or a placebo condition (week B; 3 x 5 min at 20 mmHg). For strength sessions, the outcome of interest was the number of repetitions completed during the 4th set while for SIT, a percent decrement score (PDecr) was calculated for each set. Furthermore, 24 or 48 hours after SIT, an on ice 4-laps time-trial (TT) was performed. Athletes had 2 or 3 days of recovery between microcycles. During both microcycles, the load of on-ice training was equivalent and the sequence of experimental sessions was the same. Paired-sample T-tests compared performance during IPC and Placebo weeks. Repeated measures ANOVA (Condition*Sex) verified if the effects of IPC varied depending on the sex. Effects sizes were calculated using Hedges' g (rm).

RESULTS: Due to injuries unrelated to the protocol and equipment malfunction, the final sample size was 19 for strength outcomes (9F) and 20 for SIT and TT (10F). IPC improved significantly the mean number of repetitions to failure during the last set ($+2.84$ reps; $p = 0.015$; $g = 0.21$). No significant differences were observed for mean velocity maintained during this set ($p = 0.126$; $g = 0.07$). During the SIT sessions, for both sets, no significant differences were observed for PDecr (Set 1: $p = 0.556$; $g = 0.17$; Set 2: $p = 0.070$; $g = 0.52$). Similar TT performance has been observed between experimental conditions ($p = 0.294$; $g = -0.05$). No interactions were found between sex and performance outcomes.

CONCLUSION: IPC improves the total volume of repetitions performed to failure in short track speed skaters, which might indicate better resistance to fatigue. Furthermore, contrary to previous reports, adaptations were similar among males and females.

A PRACTICAL METHOD FOR ANALYSING ON-ICE DRAFTING SKILLS IN LONG-TRACK SPEED SKATERS.

VAN DEN BRANDT, F., HARMSSEN, D., ROETE, A., MENTING, S., HETTINGA, F., ELFERINK-GEMSER, M.
UNIVERSITY OF GRONINGEN

INTRODUCTION: Drafting occurs when athletes closely follow behind one or more competitors to reduce aerodynamic resistive forces. Wind tunnel research has shown that with better drafting skills, the reduction in aerodynamic drag increases, resulting in lower energy expenditure (1). Although athletes and coaches are aware of the benefits of drafting, they do not specifically train to improve their drafting skills (2). A hurdle for training is the fact that measuring drafting skills in a practical setting is still a challenge and there is need for a feasible, reliable and valid method. Therefore, this study aims to develop a practical method for quantifying on-ice drafting skills in long-track speed skaters.

METHODS: A protocol has been developed to analyse video footage based on three key components of drafting skills: distance between the skaters, following in a straight line and takeover in the corners. Two independent raters evaluated the drafting skills of experienced skaters ($n=29$) using Dartfish. Additionally, an expert speed skating coach reviewed the video footage. Relative and absolute intra- and inter-rater reliability was determined by Intraclass Correlation Coefficients (9) and One-Sample T-tests (9). Concurrent validity was assessed using Spearman's rank correlation. Discriminative validity was assessed by categorizing the participants into three groups (good, moderate, poor drafters) based on expert opinion scores, and evaluated using a one-way ANOVA. Statistical significance was set at $p < 0.05$.

RESULTS: Relative reliability was high with ICCs $> .95$ ($p < 0.05$). Absolute reliability was good with 8 out of 9 One-Sample T-tests being non-significant ($p > 0.05$). Concurrent validity was supported for following in a straight line ($\rho = 0.89$, $p < 0.001$) and distance between the skaters ($\rho = -0.66$, $p < 0.05$). A significant between-group difference was found for following in a straight line ($F(2,11) = 8.15$, $p < 0.05$) and for distance between the skaters ($F(2,13) = 3.38$, $p < 0.05$), with better scores for good drafters compared to poor drafters.

CONCLUSION: The method for analysing on-ice drafting skills in long-track speed skaters using video footage is feasible, reliable and valid. This innovative method is a useful and practical tool for analysing drafting skills, and may be used to evaluate and monitor skaters' drafting skills. Establishing a practical method to assess the benefits of drafting skills enables for targeted training and improvement, ultimately enhancing performance in long-track speed skating.

TRACKING EXERCISE INTENSITY: INSIGHTS FROM THREE DIFFERENT ANALYSIS METHODS IN BIATHLON SPRINT RACING

PALUMBO, M., BORTOLAN, L.1,3, MODENA, R.1, VISCIONI, G.1,2, BETTEGA, S.1,2, SCHENA, F.1,2, ZOPPIROLI, C.1,3
UNIVERSITY OF VERONA

INTRODUCTION: Biathlon is an Olympic endurance sport that combines cross-country skiing with precision shooting. Due to the undulating terrain with multiple uphill and downhill and to the shooting series, the skiing part of biathlon is characterized by an intermittent load profile which is reflected in heart rate fluctuations.⁽¹⁾ When monitoring their training biathletes, often use a five-zone intensity scale based on HRmax or a five-zone scale based on laboratory-determined thresholds, while most scientific literature relies on a three-zone model. The aim of this study is to analyze race intensity distribution with the three methods, with the hypothesis that noteworthy differences will be found between them.

METHODS: Four biathlon sprint races were analysed, with 53 (28 females, 25 males) athletes participating, some across multiple events. They were asked to wear a heart rate monitor during the race. Maximum heart rate (HRmax) and lactate thresholds (LT) were determined through a preliminary laboratory test conducted on roller skis. The percentage of race time spent in 5 intensity zones based on HRmax (5STA), LT (5IND), and in 3 based on LT (3Z) were determined. Friedman test with pairwise Durbin-Conover comparisons and Bonferroni correction and the Wilcoxon test were used to compare intensity distribution within the three and when using different methods.

RESULTS: When considering a 5IND intensity distribution model, athletes spent most of the time in Z3 during lap 1 (40%) but progressively shifted to Z5 across the three laps (17% → 37% → 50%; $p < 0,001$), while Z4 remained stable (all $p > 0,05$). 5STA showed a different pattern, with most time spent in Z4 in lap 1 (46%), increasing time in Z5 (28% → 59% → 70% $p < 0,001$), while Z3 decreased early and remained low (17%, 4% and 3%). In 3Z, time in Z3 increased (42% → 76% → 85%, all $p < 0,001$), while Z2 decreased (40% → 20% → 13% all $p < 0,001$). Compared to 5IND, 5STA had significantly more time in Z5 with Z4 showing smaller differences between methods.

CONCLUSION: These findings highlight how different classification methods influence the interpretation of intensity distribution. We suggest that researchers and coaches should be cautious when using different exercise intensity distribution methods interchangeably. As 3Z categorized most of the effort within Z3, is potentially overlooking fluctuations in higher intensity zones and should therefore be avoided when differentiating those is important. Regarding the five-zone models, smaller differences were found in Z4, with 5IND showing less time spent in Z5 and more time in Z3 compared to 5STA. 5STA, despite being accurate for many athletes, may overestimate exercise intensity, making it unsuitable for the uniqueness of each individual. 1 Laaksonen et al, 2018

OP-BM03 Sports Injury

EFFECTS OF COGNITIVE DEMANDS ON BIOMECHANICS DURING CHANGES-OF-DIRECTION IN FEMALE ATHLETES

EBNER, C., GRANACHER, U., GEHRING, D.
UNIVERSITY OF FREIBURG

INTRODUCTION: A substantial proportion of anterior cruciate ligament (ACL) injuries occur in football during defensive actions involving change-of-direction (COD). Recent research has highlighted the role of cognitive demands in this movement type [1]. While previous studies have mainly focused on simple decision-making tasks using artificial stimuli (e.g., light signals), the influence of more complex and ecologically valid conditions remain largely unexplored. Thus, this study aimed (i) to determine the effects of increasing cognitive demands on biomechanical parameters during COD tasks in females and (ii) to examine the moderating role of football expertise.

METHODS: Biomechanical data were obtained from 15 female participants with high football expertise (age = 22.9 ± 3.8 yrs, 14.7 ± 3.8 yrs expertise) and 14 female participants with < 1 year football expertise (age = 22.5 ± 1.8 yrs). Participants performed an approach run at 4.0 ± 0.3 m/s, followed by 90° CODs to the left or the right in response to a real opponent, who determined the direction by kicking a ball. Participants performed CODs under four conditions with increasing cognitive demand: (i) anticipated, only one option, (ii) unanticipated, two options, i.e. left or right, (iii) unanticipated, three options including a stop, and (iv) unanticipated, four options including a stop or a feint of the opponent. Knee joint mechanics, trunk and pelvis kinematics were recorded using 3D-motion analysis. A mixed 2x4 ANOVA was performed to analyze the effects of the factors expertise (between-subjects) and cognitive condition (within-subjects) on biomechanical outcomes.

RESULTS: No significant main effects were observed for maximum knee abduction moment and knee abduction angle as well as knee flexion angle at initial contact (IC). However, significant condition effects were observed at IC for trunk rotation ($p < 0.001$, $d = 0.54$) and pelvis kinematics in frontal ($p = 0.004$, $d = 0.42$) and transverse planes ($p = 0.006$, $d = 0.40$). Post-hoc analyses revealed significantly less trunk rotation towards the cutting leg in all cognitive conditions compared to the anticipated condition. The pelvis was significantly more tilted and rotated to the contralateral leg in the anticipated condition compared to condition (iv). No effects of the factor expertise were observed. No significant effects were found for the control variables approach speed and available time to react.

CONCLUSION: This study revealed that increasing cognitive demands significantly influenced trunk and pelvis kinematics but not knee joint mechanics during CODs in both high- and low expertise female football players. Given the established

link between altered trunk and pelvis mechanics and ACL injury risk [2], our findings imply that whole-body kinematics, especially in CODs with increased cognitive demands, should be considered in ACL injury risk evaluations.

IN VIVO ANTERIOR TALOFIBULAR LIGAMENT STRAIN IN LATERAL ANKLE INJURY AND HEALTHY-MATCHED CONTROLS ASSESSED VIA STRESS IMAGING ARTHROMETRY

DEISTER, F., HARPUT, S.1, POTTHAST, W.2, KARAMANIDIS, K.1,3, JAMES, D.1

1 LONDON SOUTH BANK UNIVERSITY; 2 GERMAN SPORT UNIVERSITY COLOGNE, GERMANY; 3 UNIVERSITY OF KOBLENZ, GERMANY

INTRODUCTION: A lateral ankle sprain (LAS) typically involves trauma to the anterior talofibular ligament (ATFL). Ex vivo, ATFL has a relatively low yield and ultimate force response (1) so understanding its capacity to tolerate mechanical loading in vivo may be beneficial for injury prevention and rehabilitation. The aim of this study was to assess ATFL strain and changes in its elastic material property to passive ankle inversion rotations in participants with a history of LAS and healthy-matched controls.

METHODS: Bilateral ATFLs were imaged in 34 young adults: 17 with a previous unilateral LAS (12f/5m, 25±6 years) and 17 healthy-matched controls (12f/5m, 25±6 years) using a custom-made arthrometer (2) designed to passively invert the ankle joint from 0° to 5°, 10° and 20° and thereby elongating ATFL. ATFL length and strain were assessed via B-mode ultrasonography (15 MHz, 2cm depth) taking the curved path of the ligament into account, and strain referenced to 0° inversion. Shear-wave velocity (SWV; 15MHz, 4cm depth) - as an index of the ligament's elastic material property, was measured via a 25mm region-of-interest within the mid-part of the ligament with the probe stabilised with a mechanical arm over a 2cm gel-pad.

RESULTS: ATFL length, strain and SWV increased with increasing inversion angle ($P<0.001$) independent of the analysed group and limb. ATFL length and strain increased more in the involved limb vs. non-involved limb of injured participants ($P<0.001$), but did not differ between limbs in the control group. As such, the involved and non-involved measurements were compared separately to the average ATFL data from the control group and the involved limb showed a greater length at 0° ($21.8\pm2.5\text{mm}$ vs $19.5\pm2.5\text{mm}$, respectively; $P<0.01$) and remained longer through to 20° inversion ($25.2\pm2.7\text{mm}$ vs $20.7\pm2.6\text{mm}$, $P<0.001$), reaching a factor of 2.2 compared to the control group strain ($15.9\pm7.0\%$ vs $7.3\pm2.9\%$; $P<0.001$). SWV was only different at 5° ($2.43\pm0.26\text{m/s}$ vs $2.33\pm0.30\text{m/s}$ $P<0.05$) and 10° ($2.64\pm0.24\text{m/s}$ vs $2.56\pm0.25\text{m/s}$ $P<0.05$) inversion. There were no differences in ATFL properties between the non-involved and control limbs ($P>0.05$).

CONCLUSION: The maximum ATFL strain reported in the involved limb of participants with a history of LAS are above yield threshold (~13%, 1) and close to ultimate strain (~20%, 3) values reported during ex vivo mechanical testing. This suggests maladaptive changes in ligament biomechanical properties following LAS injury. Our non-congruent findings between strain and SWV measurements further suggest that tensile are more affected than transient properties in response to the injury. Thus, interventions that increase tensile stiffness of the ATFL following injury are required.

SOUNDING THE FINAL DEATH KNELL INTO THE USE OF ISOKINETIC PEAK TORQUE AS A MEASURE OF RECOVERY AFTER SEMITENDINOSUS TENDON HARVEST

KOSITSKY, A., BARRETT, R., STENROTH, L., VERTULLO, C., KORHONEN, R., DIAMOND, L., SAXBY, D.

UNIVERSITY OF EASTERN FINLAND AND GRIFFITH UNIVERSITY

INTRODUCTION: The semitendinosus (ST) is important for actions such as sprint performance [1]. Distal ST tendon harvesting for anterior cruciate ligament reconstruction (ACLR) substantially alters ST morphology and induces knee flexion (KF) weakness. As individual muscles within a synergist group specialize in different tasks [2], ST function cannot be compensated for by the other hamstrings [3]. Between-leg differences in isometric strength at 90° of KF strongly relate to ST muscle changes after ACLR [3,4]. Angle-specific strength decrements are also evident during concentric strength testing [5]. Nonetheless, isokinetic peak torque is still used as a clinical measure following ACLR. Here, we compared KF torque metrics from isometric and isokinetic tests in individuals post-ACLR with an ST autograft, hypothesizing that isokinetic peak torque would not relate to angle-specific strength losses.

METHODS: Ten individuals (6 female, 27.2 ± 4.9 y, 1.72 ± 0.10 m, 72.6 ± 13.4 kg, 13.9 ± 3.4 months post-ST autograft ACLR) performed unilateral strength tests (System 4 Pro, Biodex) in the prone position. Maximal voluntary isometric contractions (MVIC) were performed at 15°, 45°, 60°, and 90° of KF [3]. Maximal concentric and eccentric contractions were preloaded at 10-20 Nm (depending on participant MVIC) and performed at 60°/s between 5°-95° of KF. For each contraction type, peak instantaneous torque was obtained from a minimum of three separate efforts. To obtain angle-specific metrics (15°,

45°, 60°, 90°) from isokinetic actions, torque-angle curves were averaged across the two best maximal efforts. Repeated measures ANOVAs and Pearson's correlation coefficients were used to compare torques between legs, angles, and contraction types.

RESULTS: For all contractions, ACLR legs were weaker than contralateral legs at 45°, 60°, and 90° ($p < 0.001$), but not at 15° ($p = 0.097$). Between-leg differences in torque were larger at 90° than at 15°, 45°, and 60° ($p \leq 0.004$). Although peak torques (~20°) were lower (~9%) for both isokinetic modes on the ACLR compared to contralateral leg (main effect: $p = 0.018$), magnitudes were substantially less than at 90°, and between-leg differences in isokinetic peak torque did not significantly correlate with differences at 90°, regardless of contraction mode ($r \leq 0.539$; $p \geq 0.108$). Some individuals who had "recovered" (e.g., <5% difference in isokinetic peak torque) had large between-leg differences in KF torque at 90° (>30%).

CONCLUSION: Between-leg differences in isokinetic KF peak torque are not related to important angle-specific torque metrics. As ST substantially contributes to 90° KF torque [3], we conclude isokinetic peak torque does not provide information on the recovery of ST. Thus, isokinetic peak torque should not be used to inform clinical decisions and treatments, particularly for athletes requiring high-velocity actions such as sprints, where ST is important [1].

NO INSTRUCTION, NO PROBLEM: PARKOUR ATHLETES HABITUAL LANDING TECHNIQUE OPTIMIZES LOWER EXTREMITY JOINT CONTRIBUTION TO ENERGY DISSIPATION IN 2-METER DROP LANDINGS

SOTER, K.1,2, ZANONI, M.3, BABIEL, S.2

1: UNIVERSITÀ DEGLI STUDI DI MILANO-BICOCCA, ITALY; 2: RUHR UNIVERSITY BOCHUM, GERMANY; 3: BRUNEL UNIVERSITY LONDON, UXBRIDGE, UNITED KINGDOM

INTRODUCTION: Parkour is a highly dynamic sport involving frequent high-impact landings. 67% of injuries in Parkour occur during landings [1]. Previously, rapid, high ground reaction forces, as recorded during landings, have been linked to increased injury risk [2]. Interestingly, in comparison to untrained individuals Parkour athletes tend to execute softer, knee-dominant landings [3], potentially reducing injury risk. Furthermore, while Parkour often involves landings from considerable heights, research has not yet examined impact loads at heights that reflect real-world scenarios in Parkour. This study is the first to assess the effects of different landing instructions on landing biomechanics following drop landings from a 2-meter platform, simulating conditions closer to the environments found in Parkour.

METHODS: Six male Parkour athletes (age: 22.7 ± 1.5 y, training: 8.5 ± 2.0 y) performed drop landings from a 2-meter platform under three different landing instructions: habitual, soft, and stiff. Soft and stiff landings respectively emphasized and resisted knee flexion upon impact. Sagittal plane video and ground reaction forces, expressed as multiples of bodyweight (BW), were recorded. Inverse dynamics were performed to obtain joint kinetics for the ankle, knee, and hip joints. One-way repeated measures ANOVAs with Bonferroni post-hoc tests were carried-out ($\alpha = .05$).

RESULTS: Peak vertical ground reaction forces were the highest in stiff landings at 10.9 BW (soft: 8.6 BW, habitual: 7.9 BW, $p < .001$). Total eccentric joint work was similar (9.5 J/kg, $p = .201$), however, its distribution varied across landing instructions: The plantarflexors contributed less in habitual (30%) than in soft (39%) or stiff (41%) landings ($p < .001$), while the knee extensors contributed more work in habitual (46%) than in soft (36%) or stiff (37%) landings ($p = .010$). Hip extensor contributions remained constant (22-25%, $p = .446$). Peak joint moments at the ankle (5.1 Nm/kg), knee (5.4 Nm/kg), and hip (9.0 Nm/kg) did not differ across instructions (all $p > .054$). Peak knee eccentric power was found to be greater in habitual landings ($p = .009$), while peak ankle power was lower ($p = .038$).

CONCLUSION: As previously observed, Parkour athletes' habitual landing strategy resulted in knee-dominant energy absorption [3], a pattern maintained even in 2-meter drop landings. Conversely, soft and stiff instructions shifted this energy absorption toward the ankle plantarflexors. The reliance on the larger quadriceps muscles may be crucial for efficiently dissipating the high vertical forces and preventing injury. Importantly, habitual landings did not expose the knee extensors to higher peak loads but rather optimized muscle engagement, displaying better movement control as indicated by the increased eccentric peak power despite similar peak joint moments.

PELVIC KINEMATICS IN FEMALE RUNNING - TOWARDS AI-ASSISTED INJURY PREVENTION

KOVSE, J., VERDEL, N., DROBNIC, M., PAPUGA, I., STROJNIK, V., SUPEJ, M.

UNIVERSITY OF LJUBLJANA

INTRODUCTION: Running is a common physical activity with significant health benefits but a high injury risk, influenced by strength, anthropometrics, and kinematics (1). Pelvic kinematics are key in running biomechanics, impacting both the lower back (2) and distal limb structures (3). This research is a component of the "AICoachU: Artificial Intelligence in Coaching" project, which utilizes artificial intelligence to forecast kinematic changes in the lower extremities and pelvis that may signify an elevated risk of injury. This study aims to utilize biomechanical data obtained from high-precision kinematic measurements to train neural networks for the analysis of the effects of running speed and incline on pelvic kinematics in female runners, addressing the current limitations in the investigation of pelvic motion.

METHODS: Twenty-five female heel-strike runners participated in a laboratory-based study, undergoing a structured treadmill running protocol. Participants ran at speeds of 10 km/h, 12 km/h, and 14 km/h, as well as at 10 km/h while facing 5% and 10% inclines. Kinematic data were captured using a 12-camera motion capture system, and key parameters of pelvic rotation, tilt, and obliquity were examined. A mixed-effects model was applied to evaluate the effects of speed and incline on pelvic kinematics.

RESULTS: The maximum pelvic rotation exhibited a significant increase with increasing speed ($p < 0.001$). The range of motion for pelvic rotation also demonstrated a significant enhancement with speed ($p < 0.001$). Pelvic tilt at the moment of heel contact was elevated at higher speeds ($p < 0.001$), and maximum pelvic tilt followed a comparable pattern ($p < 0.001$). Incline running was shown to affect pelvic motion, with maximum pelvic rotation increasing at both 5% and 10% inclines ($p < 0.012$). The rotation range of motion was significantly greater at a 10% incline ($p = 0.0016$). Pelvic obliquity increased at a 10% incline, with both maximum obliquity ($p = 0.002$) and obliquity range of motion ($p < 0.001$) exhibiting significant increases.

CONCLUSION: Speed and incline are significant factors affecting pelvic kinematics, which may have important implications for injury prevention. The biomechanical changes observed in this study highlight the need for personalized running strategies and suggest that AI-driven gait analysis has the potential to optimize performance while mitigating injury risks. Future research should focus on developing AI algorithms that adapt to individual biomechanics, potentially guiding runners toward safer training regimens.

OP-BM14 Gait

THE ROLE OF PHYSICAL ACTIVITY IN MITIGATING AGE-RELATED CHANGES IN GAIT NEUROMUSCULAR CONTROL

NUNEZ-LISBOA, M., DEWOLF, A.H.

UNIVERSIDAD FINIS TERRAE

INTRODUCTION: Aging is associated with a reorganization of neuromuscular control, reflected in changes in spinal motor output (1). The Center of Activity (CoA), an EMG-derived measure of spinal activation, represents the temporal distribution of neuromuscular activity throughout the gait cycle (2). Evidence suggests that aging is linked to a posterior shift in lumbar CoA, reflecting delayed neuromuscular activation compared to younger adults (2). This delay in spinal motor output may contribute to an increase in external work and power of the center of mass (Wext & PCOM) during walking in older adults (3). While strength is often considered a determinant of gait mechanics, differences in motor strategies can occur independently of maximal force capacity. Physical activity (PA) may mitigate these effects by preserving neuromuscular coordination. This study examines the impact of PA level on spinal motor output and gait biomechanics in young and older adults.

METHODS: Fifty-nine participants (31 young, 29 older adults) were categorized as more or less active via the Global Physical Activity Questionnaire (GPAQ). Gait analysis was conducted at $1.11 \text{ m} \cdot \text{s}^{-1}$ on an instrumented treadmill, measuring kinematics, kinetics, and EMG of 12 lower-limb muscles. Wext and PCOM were computed. Isometric maximal voluntary torque (IMVT) of the knee and ankle extensors was assessed, and spinal motor output analyzed using EMG-based spinal maps. A mixed-effects model evaluated age and activity level effects.

RESULTS: Spinal maps showed a lower lumbar CoA ($p < 0.001$) and a reduced lumbar-sacral CoA difference ($p < 0.01$) in less active older adults, suggesting altered neuromuscular coordination. While older adults exhibited reduced IMVT in the knee and ankle extensors ($p < 0.001$), no significant differences were observed in IMVT based on PA level. Despite these neuromuscular differences, Wext was higher ($p < 0.001$) in less active older adults, indicating increased mechanical demand. Additionally, W_1^+ , the first peak of PCOM corresponding to weight acceptance, was higher in this group ($p < 0.001$).

CONCLUSION: Less active older adults exhibit a posterior lumbar CoA shift, reflecting delayed spinal motor output compared to more active older adults and both young groups. These neuromuscular changes coincide with higher Wext and altered PCOM (W_1^+), indicating greater mechanical demand. Interestingly, despite differences in motor strategy, IMVT of the knee and ankle extensors did not differ across PA groups, suggesting that strength alone does not dictate gait adaptations. Physical activity may help preserve neuromuscular efficiency and reduce the mechanical cost of walking in aging.

NORMAL GAIT PATTERN IN PATIENTS SUFFERING FROM BRAIN TUMORS IS DISTURBED WHEN APPLYING ADDITIONAL COGNITIVE LOAD DURING WALKING IN A REAL-TIME VIRTUAL ENVIRONMENT– A PILOT STUDY

EILS, E., HEINZE, A., BRAUN, R., HANSEL, N., RÖSENER, J., WIEWRODT, D.

INSTITUTE OF SPORT AND EXERCISE SCIENCES

INTRODUCTION: Exercise interventions have the potential to enhance quality of life and to improve physical fitness and balance in brain tumor patients (1-3). Cognitive complaints commonly occur in brain tumor patients (4). However, direct effects of exercise interventions and/or cognitive impairment on gait cycle characteristics have not been reported, yet. This pilot-study is part of a broader investigation to evaluate effects of exercise on balance and gait and examines how additional cognitive load while walking in a real-time virtual environment impacts gait characteristics in brain tumor patients and their caregivers.

METHODS: 7 patients (4f/3m 50±15y, 175±8cm, 72±14kg) and 5 caregivers (4f/1m 44±18y, 169±5cm, 81±16kg) participated performing a walking test on the GRAIL-system. Ground reaction forces were measured separately for both feet as well as kinematics of two markers attached to each foot. Two different conditions were used, a normal gait (NG) with and without an additional cognitive task (CT-Stroop-test with color-denoting words) while walking on a treadmill with constant speed. Step length and width (SL, SW) as well as ground contact time (GCT), swing phase time (SP) were derived for analysis. Statistical analysis for within subject condition (NG vs. CT) was performed using the Wilcoxon tests ($\alpha=.05$). Effect sizes were interpreted using Cliff's's delta (negligible <0.15; 0.15<small<medium<large).

RESULTS: Under Stroop-condition, SL was significantly reduced, and SW was significantly increased compared to normal walking-condition (SL: 1403±143mm vs. 1424±140mm, $p<.001$; $\delta=.94$ and SW: 126±36mm vs. 117±34mm, $p=.003$; $\delta=.72$) for all subjects. Group analysis revealed significant SL reduction in patients (1384±158mm vs. 1410±151mm, $p=.002$; $\delta=.1$) but not in caregivers. Similarly, GCT and SP were significantly reduced under Stroop-condition compared to normal walking-condition (603±47ms vs. 612±43ms, $p=.02$; $\delta=.74$ and 359±24ms vs. 368±24ms, $p=.003$; $\delta=.90$) for all subjects. This reduction was significant in patients (593±45ms vs. 605±39ms, $p=.03$; $\delta=.93$ and 356±23ms vs. 368±19ms, $p=.016$; $\delta=.1$) but not in caregivers. Effect sizes were large for measured parameters (SL, SW, GCT, SP).

CONCLUSION: Additional cognitive load during gait seems to be compensated differently by patients and caregivers. It manifests itself in the gait pattern through a changed step cycle and thus might offer the possibility of a differentiated diagnosis to specifically evaluate effects of training interventions in these patients.

ASSOCIATION BETWEEN SELF-SELECTED AND MAXIMUM WALKING SPEED, STRENGTH, BALANCE AND GAIT CHARACTERISTICS AMONG MALES WITH TYPE 2 DIABETES

BIRGISDÓTTIR, B., GÍSLADÓTTIR, T., PETROVIC, M.

UNIVERSITY OF ICELAND, SCHOOL OF EDUCATION, RESEARCH CENTER FOR SPORT AND HEALTH SCIENCES

INTRODUCTION: The prevalence of type 2 diabetes (T2D) is increasing, placing a burden on both individuals and healthcare systems. T2D accounts for approximately 90% of all diabetes cases, making it a priority for improved prevention and management. T2D is associated with various pathological complications, including those affecting the neuromuscular system. Previous research suggests that individuals with T2D often exhibit slower walking speeds, altered gait patterns, decreased muscle strength and impaired mobility compared to non-diabetic individuals. The aim of this study was to examine how strength, balance, ankle range of motion and step length are associated with self-selected (SS) and maximum (MS) walking speeds among males with T2D.

METHODS: The study design was cross-sectional, with 18 males (age 62.5 ± 10.6 , body height 177.1 ± 5.4 cm, body weight 94.7 ± 16.7 kg), diagnosed with T2D. Participants were recruited from the Department of endocrinology at the University Hospital, Reykjavik, Iceland. Gait speed was assessed for both SS and MS. Maximum voluntary contraction (MVC) of plantar flexors was measured in a seated position using VALD ForceFrame and MVC of knee extensors with VALD Dynamo. Balance was evaluated during a 15 second single leg stance on VALD ForceDecks. Step length and ankle angles at heel

strike and toe-off were determined using video recordings analyzed with the Dartfish software while walking on a treadmill. Jamovi software was used for statistical analysis. Pearson's correlation coefficient was used to assess the association between SS and MS with plantar flexor strength, knee extensor strength, single leg balance, step length and ankle angles at heel strike and toe-off. A significance level of $\alpha = 0.05$ was set for all analyses.

RESULTS: Among males with T2D, SS was strongly and significantly correlated with MS ($r = 0.86$, $p < 0.001$). Additionally, SS was significantly correlated with step length at SS ($r = 0.69$, $p = 0.004$) and the strength of plantar flexors ($r = 0.63$, $p = 0.009$). A moderate, but non-significant ($p = 0.060$) correlation was found between knee extensor strength and SS. No significant correlations were found between SS and single leg balance or ankle angles at heel strike and toe-off. For MS, significant positive correlations were found with plantar flexor strength ($r = 0.662$, $p = 0.005$), knee extensor strength ($r = 0.579$, $p = 0.015$), step length at MS ($r = 0.562$, $p = 0.046$) and ankle angle at toe-off ($r = 0.612$, $p = 0.026$). However, MS was not significantly correlated with single leg balance or ankle angle at heel strike.

CONCLUSION: The results of this ongoing study indicate that among males with T2D, greater plantar flexor strength and step length are associated with faster SS and MS. Achieving higher MS may be further influenced by plantar flexion at toe-off and knee extensor strength. These findings suggest a possible beneficial effect of targeted strength training to improve walking speed in this population.

THE IMMEDIATE EFFECTS OF WEDGE-SHAPED INSOLES ON GAIT AND JOINT LOADING IN PATIENTS WITH THE KNEE OSTEOARTHRITIS: A CASE STUDY

HUANG, Z., HUANG, Q., LI, Y.

GUANGZHOU SPORT UNIVERSITY

INTRODUCTION: Knee osteoarthritis (OA) is a prevalent degenerative joint disease, often leading to pain and functional limitations in older adults. Traditional treatments, such as pharmacological interventions and surgery, have limitations in terms of efficacy and invasiveness. Wedge-shaped insoles have emerged as a non-invasive intervention to redistribute mechanical loads and alleviate symptoms. This study investigates the effects of different wedge angles on knee joint mechanics in a patient with knee OA, aiming to optimize insole design for improved clinical outcomes.

METHODS: A 65-year-old female with knee OA participated in this case study. Seven wedge insoles (0° , 3° , 6° , and 9° in both medial and lateral directions) were tested. Data collection included 3D motion capture (Vicon system), ground reaction forces (AMTI force plate), plantar pressure distribution (Zebris pressure plate), and MRI scans for finite element (FE) modeling. Knee joint angles and meniscal stress distribution were analyzed using FE analysis. Each condition involved five gait trials to ensure data reliability.

RESULTS: Significant changes in knee joint angles were observed across wedge angles. The 6° lateral wedge showed a 12% reduction in peak knee extension compared to the 0° condition ($p < 0.05$). Finite element analysis revealed that the 6° lateral wedge redistributed meniscal stress more evenly, with a 15% decrease in peak medial meniscus stress ($p < 0.01$). Plantar pressure distribution shifted laterally by 8% with the 6° lateral wedge, indicating effective load redistribution. The 3° lateral wedge demonstrated a smaller but significant reduction in knee extension (8%, $p < 0.05$) and a 10% decrease in medial meniscus stress ($p < 0.05$), with a 5% lateral shift in plantar pressure. Conversely, the 9° lateral wedge caused a 20% reduction in knee extension ($p < 0.01$) but also induced a 25% increase in lateral meniscus stress ($p < 0.01$), with a 12% lateral shift in plantar pressure. For the medial wedges, the 3° and 9° conditions increased knee flexion by 6% and 10%, respectively ($p < 0.05$), with corresponding increases in medial meniscus stress of 8% and 12% ($p < 0.05$). These findings suggest that while the 6° lateral wedge provides a balanced mechanical environment for the knee joint, other wedge angles may either under- or over-correct knee mechanics, highlighting the importance of angle optimization.

CONCLUSION: The results highlight the potential of lateral wedge insoles in managing knee OA, particularly the 6° configuration, which demonstrated improved stress distribution and reduced joint loading. However, individual variability in response to different wedge angles warrants further investigation. This study provides valuable insights for optimizing insole design and personalized treatment strategies for knee OA patients. Future research should explore long-term clinical outcomes and patient-specific factors influencing wedge angle efficacy.

MULTI-MODAL ANALYSIS OF GAIT, BALANCE AND INFRARED THERMOGRAPHY FOR KNEE OSTEOARTHRITIS PREDICTION WITH MACHINE LEARNING

ROGGIO, F., TROVATO, B., SORTINO, M., TESTA, G., PAVONE, V., VECCHIO, M., BIANCO, A., TRIMARCHI, F., MUSUMECI, G.

UNIVERSITY OF CATANIA

INTRODUCTION: Knee osteoarthritis (KOA) is a degenerative joint disease characterized by biomechanical alterations and inflammatory processes that can affect an individual's mobility and balance. Wearable inertial measurement units (IMUs) provide a portable and cost-effective method to capture detailed gait kinematics, revealing alterations such as reduced walking speed or asymmetry that are often present in individuals with KOA. Force platforms offer precise measurements of postural sway, indicating impaired balance in KOA patients. Additionally, infrared thermography (IRT) represents a non-invasive approach to identify thermal anomalies of the body, reflective of underlying inflammatory processes.

METHODS: In this study, we integrated data from IMUs for gait analysis, force platforms for balance assessment, and IRT for detecting knee joint inflammation, followed by advanced machine learning (ML) techniques. A cohort of 16 individuals with clinically diagnosed KOA, along with 16 matched healthy controls, was recruited to undergo comprehensive evaluations across these modalities. The objective was to identify differences in spatiotemporal parameters, balance, and knee

thermal ratios between the osteoarthritic group (OG) and the healthy group (HG). Various statistical methods, including Student's t-tests with Bonferroni-Holm adjustments, were employed to compare the OG and HG. Furthermore, the resulting multi-modal dataset was analyzed using a support vector machine (SVM) classifier with cross-validation to ensure robust model performance.

RESULTS: Our analyses revealed several significant differences between the groups. Notably, compared to the HG, gait symmetry ($p < 0.001$), cadence ($p = 0.019$), left stance ($p < 0.001$), right stance ($p < 0.001$), and swing phase for both legs ($p < 0.001$) were significantly altered in the OG. Additionally, IRT measures indicated pronounced thermal differences around the knee in the medial and lateral patella, medial and lateral knee areas, sovrapatella, and popliteal fossae (all $p < 0.001$), between the OG and HG. Finally, the SVM classifier with a radial basis function kernel was trained using 26 predictors derived from these modalities on 32 samples. Employing 10-fold cross-validation, the optimal model ($C = 0.25$, $\sigma = 0.0263$) achieved an accuracy of 97.5% and a kappa of 0.95.

CONCLUSION: These findings reveal distinct patterns in gait, balance, and knee thermal profiles that not only facilitate early KOA detection but also lay the foundation for timely, personalized intervention strategies tailored to individual biomechanical and inflammatory characteristics.

The work was carried out as part of the PRIN 2022 project entitled "Predictive model of osteoarthritis through the use of inertial knee brace and thermography applied to movement analysis. Get back to move!" announcement D.D. n. 104, 2nd of February 2022, financed by the European Union – NextGenerationEU".

THE IMPACT OF SIMULATED FLIGHTS ON EXTERNAL TRAINING LOAD, IMMUNE RESPONSE, AND COGNITIVE PERFORMANCE IN FOOTBALL PLAYERS

STERGIOPOULOS, D., BOTONIS, P., MILIOTIS, P., ZAVVOS, A., NTALAPERAS, S., PAPALEONTIOU, G., SOUKARA, E., GELADAS, N.
NATIONAL AND KAPODISTRIAN OF ATHENS

INTRODUCTION: Mild hypoxia, restricted activity, and disruption of individual routines may affect health and performance following short-haul air travel (SHAT)¹. However, the extent to which SHAT affects physiological responses and performance indices of high-level football players remains unknown². This study aimed to investigate the impact of two simulated SHAT of different duration (4-h and 2-h) on cortisol and immunoglobulin-A (IgA) responses, external training load, and cognitive performance of high-level football players.

METHODS: Nineteen high-level football players completed, in a randomized order, two SHAT, one week apart, each one lasting 4-h and 2-h, followed by a control condition (CON). Oxygen saturation (SpO₂%) and heart rate (HR) were continuously recorded during CON and simulated flights. Salivary cortisol and IgA, were measured and wearable GPS trackers and the Flanker test were used to evaluate physiological responses, training-related external load metrics, and cognitive performance (i.e., reaction time), respectively, one day before (D-1), the day of the flight (DF), one-day after the travel (D+1).

RESULTS: A notable decline in SpO₂% accompanied by a rise in HR was observed during SHAT in comparison to the CON ($p < 0.01$). IgA was decreased at D+1 compared to D-1 only following the 4-h flight ($p < 0.05$). No significant differences were observed for cortisol among conditions ($p > 0.05$). Total distance covered, very high-speed running distance, and number of accelerations were decreased at D+1 compared to CON after the 2-h SHAT ($p < 0.05$). Similarly, high-speed running distance and number of decelerations were decreased at D-1 compared to CON after the 2-h SHAT ($p < 0.05$). Reaction time was slower at D+1 compared to CON after the 4-h SHAT ($p = 0.04$).

CONCLUSION: This study showed impaired immunological responses and reaction time after the 4-h SHAT. However, the extent to which external load metrics are affected by SHAT warrants further investigation.

IMPACT OF HYPOXIA ON CEREBROVASCULAR RESPONSES TO EXERCISE IN YOUNG HEALTHY MALES AND FEMALES

FAISAL, A., TAYLOR, M., PURANIK, S.V., ROSSETTI, G.M.K., MORSE, C.I.
MANCHESTER METROPOLITAN UNIVERSITY

INTRODUCTION: Cerebral function is critically dependent upon the adequate and continuous delivery of oxygen to the brain through the active regulation of cerebral blood flow (CBF) (Powers et al., 1985). Hypoxia and exercise result in competing vasoactive stimuli, which in turn influences CBF, therefore the cerebrovascular response to exercise in hypoxia remains unclear (Nobrega et al., 2014). Moreover, males and females had similar CBF responses during incremental exercise in normoxia (Chamoun et al., 2023), but sex-specific differences in cerebrovascular regulation during exercise in hypoxia remain unknown. Aim: This study aimed to i) examine the impact of moderate hypobaric hypoxia on CBF during

incremental cardiopulmonary cycle exercise test (CPET) to volitional exhaustion; ii) examine the effect of sex on cerebrovascular response during exercise in hypoxia and normoxia.

METHODS: In a randomised cross over study, 24 healthy active participants (25 ± 3 years, 12 males and 12 females) completed two separate incremental CPET in normoxia ($FiO_2=0.21$) and moderate hypobaric hypoxia ($FiO_2=0.14$). Middle cerebral artery mean blood velocity (MCAv-mean), an estimate for CBF, was measured continuously throughout exercise using Transcranial Doppler Ultrasound. Breath-by-breath metabolic data, heart rate, oxygen saturation, and blood pressure were measured continuously throughout exercise. Blood lactate (BLa) was measured at the end of each exercise stage.

RESULTS: In comparison to normoxia, hypoxia induced significant increase in MCAv-mean, ventilation (VE), BLa with lower partial pressure of end-tidal carbon dioxide ($PetCO_2$) during submaximal exercise (e.g. at the highest equivalent work rate of 140 watts, MCAv-mean: 68.3 ± 13.5 vs. 59.8 ± 14.6 cm/sec; VE: 69.4 ± 9.8 vs. 59.0 ± 11.8 L/min; BLa: 4.1 ± 1.0 vs. 3.5 ± 0.9 mmol/L; $PetCO_2$: 35.0 ± 3.5 vs. 39.6 ± 5.3 mmHg, $P < 0.01$ for all). Females exhibited higher MCAv-mean and VE, and lower $PetCO_2$ than males during submaximal work rates (80-140 watts) in both normoxia and hypoxia. At 140 watts, MCAv-mean was higher in females than males in both normoxia (64.7 ± 13.0 vs. 54.4 ± 14.8 cm/sec) and hypoxia (69.7 ± 13.2 vs. 60.17 ± 12.6 cm/sec, $P < 0.01$). Hypoxia induced similar relative changes in MCAv-mean across sexes.

CONCLUSION: In hypoxic condition, an increase in MCAv-mean during exercise acts as a compensatory mechanism to preserve cerebral oxygen delivery in response to reduced oxygen saturation levels. Females showed consistently higher CBF compared to males in both normoxia and hypoxia, but hypoxia affected MCAv-mean in both sexes similarly. These findings suggest intrinsic sex differences in cerebrovascular regulation during exercise, independent of oxygen availability.

COGNITIVE AND CEREBRAL OXYGENATION RESPONSES TO GRADED NORMOBARIC HYPOXIA IN MIDDLE-AGED ADULTS: A SINGLE-BLIND RANDOMIZED CROSSOVER STUDY

BOULARES, A., PICHON, A., FAUCHER, C., THEUROT, D., GIMENES, M., DUPUY, O.

POITIERS UNIVERSITY

INTRODUCTION: Approximately 81.6 million individuals reside permanently at altitudes above 2,500 meters, with many more intermittently exposed to high-altitude environments through travel, work, or recreation. Hypoxia, a reduction in available oxygen, can adversely affect human physiology and cognitive performance. While younger adults often exhibit resilience to moderate hypoxia[1], the extent to which middle-aged adults experience cognitive changes remains less established. Age-related declines in neurovascular coupling and cerebral autoregulation may increase susceptibility to hypoxia-induced impairments, underscoring the importance of focused research in middle-aged adults.

METHODS: Sixteen healthy participants (aged 45–65 years) were recruited to investigate the impact of acute normobaric hypoxia on cognitive performance and cerebral oxygenation. Each participant attended four separate sessions in a hypoxia chamber, simulating altitudes of 0 m (normoxia, $FiO_2 \approx 20.9\%$), 1,500 m (low altitude, $FiO_2 \approx 17.3\%$), 3,000 m (moderate altitude, $FiO_2 \approx 14.5\%$), and 4,500 m (high altitude, $FiO_2 \approx 12\%$). At each session, participants completed a cognitive test battery comprising the Stroop test, N-back task, Corsi block-tapping test, and Operation Span Task. Cerebral oxygenation was assessed continuously using near-infrared spectroscopy, measuring tissue saturation index (TSI), total hemoglobin (tHb), deoxyhemoglobin (HHb), and oxyhemoglobin (O2Hb). Changes in these parameters ($\Delta TSI\%$, ΔtHb , ΔHHb , and $\Delta O2Hb$) were determined by subtracting normoxic resting values from those obtained during each hypoxia level. Perceived exertion was evaluated after each cognitive task using the DP15 rating scale.

RESULTS: Exposure to graded hypoxia significantly impaired cognitive performance in middle-aged adults, particularly at moderate to high altitudes (3,000–4,500 m). Compared with normoxia, participants exhibited slower reaction times and decreased accuracy on the Stroop test ($p < 0.05$), reduced accuracy on the N-back task ($p < 0.05$), as well as on the Corsi block-tapping test ($p < 0.05$). These deficits were more pronounced under high-altitude conditions (4,500 m). Correlation analyses indicated a strong positive relationship between reduced oxygen availability (SpO_2) and heightened perceived exertion ($p < 0.05$), suggesting that lower oxygen levels may directly contribute to cognitive performance decrements.

CONCLUSION: Acute normobaric hypoxia at simulated moderate to high altitudes significantly affects cognitive function in middle-aged adults, underlining a potential vulnerability in this demographic. These findings emphasize the importance of monitoring and mitigating hypoxia-related risks for individuals exposed to lower oxygen environments and warrant further research into interventions that could preserve cognitive performance at altitude.

THE ACUTE EFFECTS OF MODERATE-INTENSITY CONTINUOUS, RESISTANCE, AND CONCURRENT EXERCISE ON CEREBRO-VASCULAR REACTIVITY TO HYPOCAPNIA IN HEALTHY YOUNG ADULTS.

BUYS, P., WESTON, M.E., CURTIN, E., GILDEA, N., EGAÑA, M.

TRINITY COLLEGE DUBLIN

INTRODUCTION: Exercise promotes cerebrovascular health. However, the impact of different exercise modes on cerebrovascular function in the post-exercise period remains underexplored. In particular, how acute exercise influences cerebrovascular reactivity (CVR) during recovery is not well understood. Therefore, this study explored the acute effect of moderate-intensity continuous (MOD), resistance (RE), and concurrent (CE) exercise on CVR.

METHODS: Twenty-four healthy young adults (12 males, 12 females; mean $\pm$ SD age: 23.8 $\pm$ 2.9 years) volunteered to participate in this study. Each participant completed a total of six visits. During visits one and two, participants performed a ramp incremental exercise test to exhaustion on a cycle ergometer and a 1 repetition maximum (1RM) protocol to assess maximal strength, respectively. The remaining visits involved four 30-minute, time-matched experimental sessions, including a seated control trial (CON), MOD cycling at 90% gas exchange threshold, four sets of 10 repetitions of RE at 70% of 1RM, and CE consisting of 15 minutes of RE followed by 15 minutes of MOD, completed in a randomized order. CVR of the middle cerebral artery to hypocapnia was determined through one minute of voluntary hyperventilation, performed at 25 breaths.min⁻¹. Middle cerebral artery blood velocity (MCAv) was measured using transcranial Doppler ultrasonography, and the partial pressure of end-tidal carbon dioxide (PETCO₂) was measured breath-by-breath using a gas analyser. Participants completed the CVR protocol before, and 20 minutes following exercise. CVR was quantified as both the absolute (cm.s⁻¹) and relative (%) change in MCAv from baseline per 1 mmHg change in PETCO₂, derived from the final 10 s of hyperventilation. A two-way repeated-measures ANOVA assessed the effects of condition and time on MCAv, PETCO₂, and CVR.

RESULTS: Baseline MCAv was unchanged following each condition ($P>0.05$), while baseline PETCO₂ was significantly lower following the RE and CE trials ($P<0.05$). Following exercise, absolute CVR was lower in the RE trial compared to CON (1.53 $\pm$ 0.35 vs 1.70 $\pm$ 0.44 cm s⁻¹.mmHg⁻¹, $P=0.024$) and CE (1.73 $\pm$ 0.44 cm s⁻¹.mmHg⁻¹, $P=0.012$) trials. Additionally, absolute CVR was lower in the MOD trial (1.54 $\pm$ 0.47 cm s⁻¹.mmHg⁻¹) than the CE trial ($P=0.040$). Relative CVR was also reduced post-exercise in the RE trial compared to CON ($P<0.001$) and CE ($P<0.001$) trials, and was lower in the MOD trial than the CE trial ($P=0.012$).

CONCLUSION: These findings demonstrate that CVR is attenuated during recovery following RE, and that MOD results in a greater reduction in CVR compared to CE. This suggests that exercise mode influences post-exercise cerebrovascular function and offers insight into the time course of cerebrovascular recovery.

CEREBROVASCULAR FUNCTION DURING 24-HOURS OF HYPOXIA, COLD, AND COLD HYPOXIA EXPOSURE IN HUMANS

HOWE, C., CARR, J., DENEKE, J., BRUCE, C., PERKINS, D., RIEMER, K., MUGELE, H., LAWLEY, J.

UNIVERSITY OF INNSBRUCK

INTRODUCTION: High-altitude environments are commonly frequented by recreational enthusiasts, elite athletes, and inhabitants local to the region. Individuals traveling to, and residing in these regions, can be exposed to a range of environmental stimuli, most notably hypoxia and cold stress. Despite these two environmental conditions often occurring simultaneously, they are rarely studied this way. Impairments in cognition have been described to occur both during hypoxia and cold exposure and may be related to the pattern of cerebral blood flow (CBF) and cerebral oxygen delivery (CDO₂) that is observed during these individual and combined environmental stressors. Thus, the aim of this study was to investigate the individual and combined effects of cold and hypoxic exposure on cerebrovascular function over a 24-hour period in humans.

METHODS: Participants ($n=11$; 4 female) were exposed to three 24-hour environmental conditions inside the TerraXcube chamber (Bolzano, Italy) in a single blinded, non-randomized crossover study. Participants were exposed to 1) room-temperature normobaric hypoxia (23°C and FiO₂=13%); 2) cold normoxia (10°C and FiO₂=20.93%); and 3) cold normobaric hypoxia (10°C and FiO₂=13%) with sessions separated by ~1 week. Participants were dressed in identical base layer clothing and food and water intake was standardized. Measurements of regional and global cerebral blood flow (gCBF) were assessed using duplex ultrasound of the internal carotid and vertebral arteries. Peripheral oxygen saturation, end-tidal gases, and hemoglobin concentration were measured to estimate arterial oxygen content (CaO₂) and CDO₂. Skin temperature was assessed using multi-site skin thermocouples to calculate total body skin temperature while core temperature was assessed using a rectal thermistor. All measurements were obtained during a room-temperature normoxic baseline (23°C and FiO₂=20.93%) and following 6, 12, and 24 hours of environmental exposure.

RESULTS: No differences in gCBF were observed in any condition following 6 and 12-hours of exposure compared to room-temperature normoxic baseline (all $P>0.05$). Following 24-hours of exposure, gCBF was reduced with cold ($P=0.009$), but was not different during hypoxia ($P=0.760$) or cold-hypoxia ($P=0.670$) compared to baseline. During all three conditions, hemoglobin concentration was similarly increased compared to baseline at 24-hours (all $P<0.001$). CaO₂ was reduced with hypoxia ($P=0.009$), and increased with cold ($P=0.001$), but was not different during cold hypoxia ($P=0.186$) compared to baseline. Under all conditions, at all timepoints, CDO₂ was unaltered compared to baseline.

CONCLUSION: Hypoxia prevents the reduction in gCBF which occurs during cold exposure. The changes in CBF in all conditions are commensurate to the changes in CaO₂ whereby CDO₂ under all conditions is maintained. Previous reports of

cognitive impairment with moderate, prolonged hypoxia and cold stress are likely not related to impairments in bulk cerebral oxygen delivery.

NO EFFECT OF AGE AND OBESITY ON PEAK FAT OXIDATION

WEINREICH, C., JOHANSEN, V., BECKER, L., FILIPPAKI, K., ANDERSEN, P.F., LARSEN, S., SCHJOLDAGER, K., CLEMMENSEN, C., HELGE, J.W.

UNIVERSITY OF COPENHAGEN

INTRODUCTION: Peak fat oxidation (PFO) is one parameter contributing to metabolic flexibility and may therefore impact metabolic health. However, it remains unclear how obesity affects PFO. In addition, there is a lack of data on the obese elderly population and how the interplay of aging and obesity affect PFO. Here, we hypothesized that peak fat oxidation would be higher in obese compared to lean individuals, independent of age.

METHODS: Healthy males matched for physical activity level were recruited into four groups; Lean young (LY) BMI 23 ± 2 aged 26 ± 5 years VO_{2max} 3988 ± 704 ml/min ($n = 12$); Lean old (LO) BMI 24 ± 1 aged 65 ± 4 years VO_{2max} 3514 ± 451 ml/min ($n = 10$); Obese young (OY) BMI 34 ± 3 aged 30 ± 5 years VO_{2max} 4206 ± 675 ml/min ($n = 10$); Obese old (OO) BMI 33 ± 3 aged 65 ± 5 years VO_{2max} 2998 ± 379 ml/min ($n = 8$).

Subjects arrived overnight fasted and body composition (Dual-Energy X-Ray Absorptiometry), blood-pressure, blood sampling and hip-waist ratio were measured. After this a submaximal and maximal incremental exercise test to measure PFO and maximal oxygen consumption (VO_{2max}) were performed. Lastly, isometric handgrip strength was tested. Data were tested for normality using Shapiro-Wilk test and Q-Q plots. Data are presented as mean $\pm$ SD. Between-group differences were analyzed using two-way ANOVA with BMI (Lean/Obese) and Age (Young/Old) as independent factors, and post-hoc comparisons conducted using Tukey's multiple comparison test where appropriate (GraphPad Prism 10).

RESULTS: BMI influenced fat oxidation at rest ($P = 0.003$), with higher fat oxidation observed in OY and OO compared to LY. However, fat oxidation at rest did not differ between LY and LO. PFO (LY: 0.44 ± 0.11 ; OY: 0.58 ± 0.24 ; LO: 0.57 ± 0.23 ; OO: 0.49 ± 0.12 g/min) and PFO/Lean body mass (LY: 7.0 ± 1.3 ; OY: 7.2 ± 3.0 ; LO: 8.6 ± 4.9 ; OO: 8.5 ± 2.3 mg/min/kg LBM) were similar in all groups ($P > 0.05$). FAT_{max} , the percentage of VO_{2max} eliciting PFO, was higher in the old groups compared to the LY group ($P < 0.05$). VO_{2max} was lower in OO compared to LY and OY ($P > 0.05$). There were no differences in VO_{2max} between the other groups. Plasma free fatty acids (FFA) were not different between groups (LY: 432 ± 228 ; OY: 512 ± 222 ; LO: 542 ± 182 ; OO: 628 ± 349 μ mol/L).

CONCLUSION: In conclusion fat oxidation at rest is higher in obese compared to young lean males regardless of age. However, in contrast to our hypothesis PFO is not affected by aging or obesity when matched for habitual physical activity level, but the intensity eliciting PFO is higher in old compared to lean young males independent of BMI. These findings contribute to our understanding of the interplay between obesity, aging and fat oxidation.

EFFECTS OF AEROBIC EXERCISE ON RENAL FUNCTION ABNORMALITIES AND MITOPHAGY OF OBESE RATS

ZHANG, B., XU, J.F.

CHINA INSTITUTE OF SPORT SCIENCE

INTRODUCTION: The rising prevalence of obesity-associated kidney injury is concerning, but the full extent of the injury and its underlying mechanisms are not yet fully elucidated. This study investigates the impact of varying aerobic exercise regimens on renal dysfunction in obese rats and examines the regulatory role of aerobic exercise in mitophagy.

METHODS: Ninety male SD rats were divided into a normal diet group (CON, $n=10$) and a high-fat diet group ($n=80$). The high-fat diet group was fed for 8 weeks to induce obesity and renal function abnormality. After modeling, 40 rats were assigned to four groups: a high-fat diet control group (HFD, $n=10$) and three exercise groups (40%, 60%, and 80% VO_{2max} , $n=10$ each). Aerobic exercise was performed via treadmill training (60 min/day, 5 days/week) for 8 weeks. Post-intervention, body weight, body length, fat weights, and Lees index were measured. Blood and urine samples were collected to assess lipid profiles, serum creatinine, urinary protein, and microalbumin (mALB). Kidney pathology was examined by HE staining, and ultrastructural changes were observed using transmission electron microscopy. Western blot analysis was conducted to detect key mitophagy proteins (Beclin1 and Parkin) in kidney tissues.

RESULTS: After 8 weeks of intervention, the HFD group exhibited significantly higher body weight and Lees index compared to the CON group ($P<0.05$), whereas these parameters in all exercise groups were significantly lower than those in the HFD group ($P<0.05$). The average SCr and mALB levels in the HFD group were significantly higher compared to the CON group ($P<0.05$). Moreover, the average SCr levels in all exercise groups were significantly lower than those in the HFD group ($P<0.05$), and the average mALB levels in the 40% VO_{2max} and 60% VO_{2max} groups were also significantly lower than those in the HFD group ($P<0.05$). The renal tubular epithelial cells in the HFD group showed moderate degeneration. In contrast, the degree of glomerular hypertrophy in each exercise group was reduced compared to the HFD group, and the renal tubules of the 60% VO_{2max} group showed a clearer contour. Moreover, compared with the CON group, the

number of swollen mitochondria in the HFD group was increased, whereas the 60% VO₂max group exhibited a significant improvement compared with the HFD group. The protein expression levels of Beclin1 and Parkin were increased in the HFD group compared to those in the CON group ($P < 0.05$), and a reduction was observed in the 40% VO₂max group compared with the HFD group ($P < 0.05$).

CONCLUSION: Moderate to low intensity aerobic exercise can alleviate renal dysfunction in obese rats by reducing mitophagy in renal mitochondria, as evidenced by the downregulation of renal function biochemical indicators and the reduced degree of renal tissue damage.

COMPARATIVE EFFECTS OF MICT, HIIT, AND RESISTANCE TRAINING ON HEPATIC AND METABOLIC OUTCOMES IN NAFLD: A RANDOMIZED CONTROLLED TRIAL

HE, X.

CHINA INSTITUTE OF SPORT AND HEALTH SCIENCE

INTRODUCTION: Given the lack of pharmacological interventions, exercise remains a critical strategy for managing non-alcoholic fatty liver disease (NAFLD), with its efficacy well-established. Different exercise modalities induce distinct physiological stress profiles, potentially exerting differential effects on NAFLD. As NAFLD is considered a hepatic manifestation of systemic metabolic dysregulation, this study comprehensively compared the therapeutic effects of moderate-intensity continuous training (MICT), high-intensity interval training (HIIT), and resistance training (RT) on NAFLD across multiple metabolic dimensions: liver fat, glucose metabolism, lipid metabolism, and central obesity.

METHODS: Thirty-six adults with NAFLD (age: 51 ± 8 years) were randomized to three 8-week supervised exercise regimens: MICT (3 sessions/week, 60 minutes/session at 60-70% HRmax), HIIT (3 sessions/week, 3 sets/session alternating 4-minute intervals at 85% HRmax and 4-minute recovery at 60% HRmax), or RT (3 sessions/week, 8 exercises at 60% 1RM, 3 sets $\times$ 12 repetitions). Liver fat content was measured using MRI-PDFF, insulin resistance was assessed using HOMA-IR, insulin sensitivity was assessed using the QUICKI index, and the degree of central obesity was assessed using waist circumference.

RESULTS: After 8 weeks, both MICT (-2.13% ; 95% CI, -3.23 to -1.02 ; $p < 0.01$) and HIIT (-1.74% ; 95% CI, -3.00 to -0.48 ; $p < 0.01$) significantly reduced liver fat, with no difference between the two ($P = 0.64$). MICT also lowered fasting insulin levels ($-3.47 \mu\text{U/mL}$; 95% CI, -6.22 to -0.72 ; $p = 0.02$) and improved insulin sensitivity (QUICKI: $+0.01$; 95% CI, 0.002 – 0.02 ; $p = 0.02$). Waist circumference decreased in both MICT (-5.46 cm ; 95% CI, -8.18 to -2.74 ; $p < 0.01$) and RT (-3.25 cm ; 95% CI, -6.07 to -0.43 ; $p = 0.02$), with MICT showing a greater reduction than HIIT ($p = 0.02$). HIIT increased HDL cholesterol ($+0.118 \text{ mmol/L}$; 95% CI, 0.02 – 0.22 ; $p = 0.03$).

CONCLUSION: MICT was the most effective exercise modality for NAFLD management, achieving simultaneous improvements in hepatic steatosis, insulin resistance, and central obesity. While HIIT reduced liver fat comparably, it exhibited limitations in addressing glucose metabolism and central obesity. RT showed no direct therapeutic effect on NAFLD pathology.

EFFECTS OF HIGH INTENSITY INTERVAL TRAINING ON LEFT ATRIAL MECHANICS IN YOUNG WOMEN WITH OBESITY

LOPES, W., LOPES, W.A., SIMÕES, C.F., LOCATELLI, J.C., DE OLIVEIRA, G.H., RECK, H.B., OKAWA, R.T.P., MOTA, J.

STATE UNIVERSITY OF MARINGÁ

INTRODUCTION: High intensity interval training (HIIT) has been shown to improve body composition [1], inflammatory responses [2] and vascular function [3] in individuals with overweight and obesity. However, the effects of HIIT on cardiac parameters, particularly in left atrial (LA) mechanics remain unclear [4]. Therefore, the aim of this study was to investigate the effects of HIIT on LA mechanics in young women with obesity.

METHODS: Twenty-five young women with grade I and II obesity were randomized to receive eight weeks of HIIT (4 $\times$ 4 minutes of walking/running at intensity between 85 and 95% of HRmax, alternated by 3 minutes of active recovery at intensity between 65 and 75% of HRmax) or moderate intensity continuous training (MICT) (41 minutes of walking/running at intensity between 65 and 75% of HRmax). Body composition, cardiorespiratory fitness and LA mechanics (LA reservoir, LA conduit and LA contractile) were evaluated.

RESULTS: There were significant improvements in LA mechanics, including LA reservoir ($4.2 \pm 7.2\%$, $p=0.03$ and $7.4 \pm 4.9\%$, $p<0.01$), LA conduit ($3.0 \pm 2.4\%$, $p=0.02$ and $3.2 \pm 2.1\%$, $p<0.01$) and LA contractile ($2.4 \pm 3.4\%$, $p<0.01$ and $3.0 \pm 3.0\%$, $p<0.01$) after HIIT and MICT, respectively. In addition, both protocols reduced body fat, but only HIIT significantly increased cardiorespiratory fitness.

CONCLUSION: Both HIIT and MICT improve LA mechanics in young women with obesity, suggesting that the effects may be independent of the nature and intensity of aerobic exercise.

EFFECTS OF 12 WEEKS POL VS. HIIT TRAINING PROGRAMS IN MALES WITH OBESITY

MARI, L., D'ALLEVA, M., ZACCARON, S., ENRICO, R., STAFUZZA, J., GRANIERO, F., AZZINI, V., CIGALOTTO, A., CASASOLA, M., MOLINO, J., PASSARO, A., FIORI, F., MARINONI, M., PARPINEL, M., LAZZER, S.

UNIVERSITY OF UDINE

INTRODUCTION: Background: Obesity is primarily caused by a poor diet and low physical activity (1). Compared to normal weight individuals, people with obesity had lower cardiorespiratory fitness (CRF), lower exercise tolerance (4) and impaired lipid oxidation (2) both at rest and during exercise (3). The American College of Sports Medicine (ACSM) recommends a combination of vigorous and moderate exercise to improve body composition and physical performance (4). The aim of this study was to compare the effects of high-intensity interval training (HIIT) and polarized training (POL) on anthropometry, body composition, aerobic capacity, energy cost of transport and substrates used during walking at 5 km/h.

METHODS: Twenty-eight adult males with obesity were recruited and divided into two groups, POL (n: 14) and HIIT (n: 14). Assessments were performed at baseline (T0) and after 3 months of intervention (T3). Anthropometric data, body composition, basal metabolic rate (BMR) and a maximal aerobic capacities (VO₂max) were measured. The training programs were structured based on the participants ventilatory thresholds and distributed either interval-based or polarized.

RESULTS: Both groups reduced their weight (-3%) and BMI (-3%) (p=0.002). V̇O₂ (L min⁻¹) improved at maximum (+10%, p=0.004) and the first (+18.5%, p<0.001) and second (+12%, p=0.001) ventilatory thresholds in both groups. It also improved both maximal (+10%, p<0.001) and threshold (+10%, p<0.001) velocity. In addition, total energy expenditure did not change significantly, while carbohydrate utilization (g·min⁻¹) decreased (-38%, p<0.001) and fat utilization (g·min⁻¹) increased (+28%, p=0.002).

CONCLUSION: Both training modalities resulted in a reduction in body mass (BM) and body mass index (BMI), while improving VO₂ and velocity at maximal and ventilatory thresholds and promoting fat oxidation. These results emphasize the benefits of structured training to improve aerobic fitness, metabolic health and body composition in individuals with obesity, with each method offering different benefits.

OP-SH02 Psychology I - Mental Fatigue

EXPLORING INDIVIDUAL DIFFERENCES IN ATTENTIONAL CONTROL: THE PSYCHOPHYSIOLOGICAL IMPACT OF REWARD AND PUNISHMENT SENSITIVITY

CODD, L., BEATTIE, S., COOKE, A.

BANGOR UNIVERSITY

Background: Enhanced attentional control is linked to mentally tough behaviours and overall superior sporting performance. One potential explanation for this connection is that attentional control (AC) may help regulate psychophysiological responses to stress, such as gaze behaviour and heart rate, leading to increased focus on task demands and reduced distraction from irrelevant stimuli. Research suggests that individuals sensitive to punishment are more adept at identifying and reacting to threats early. This may help to lower anxiety and free up attentional resources, allowing for superior AC. This study aimed to investigate the impact of punishment (PS) and reward sensitivities (RS) on cognitive performance and psychophysiological responses to stress.

Methods: 83 participants completed three AC tasks targeting shifting, inhibition, and updating. Each task involved coins with varying monetary values under two conditions: gain/no gain (clicking earns money, failure to click results in no gain) and loss/non-loss (failure to click results in a loss, clicking prevents it). Tasks included a practice block, low-stress block (no carryover of earned money), and a high-stress block (where real monetary rewards were based on gains and losses). In the first task (shifting), participants were given £20 credit in the loss condition, providing them with money to lose. Eye tracking and heart rate variability were recorded throughout.

Hypothesis: Individuals with high PS focus on avoiding loss, and their early threat detection may reduce anxiety and improve AC during high-stress tasks. In contrast, those with high RS may be more distracted by gains, leaving fewer resources to manage task demands.

Results: Preliminary data shows a significant increase in self-report anxiety across conditions ($t(43) = -3.69, p = .001$). Shifting-task data shows individuals high in PS clicked more coins ($\beta = 2.83, p = .01$) than those high in RS ($\beta = 1.70, p = .18$), with PS individuals accounting for 24% of the variability in the gain, high-stress condition. Both PS and RS fixated more on the gain condition, though PS individuals demonstrated a greater increase in eye fixation duration on gain coins ($\beta = 1262.45, p = .01$), compared to their RS counterparts ($\beta = 978.02, p = .07$), with PS predicting 28% of the variability from gain to loss in high stress.

Conclusion: Individuals high in PS excel at task-switching, clicking more coins, fixating longer, and showing less distraction by losses. This may result from stress-induced recruitment of attentional resources, which blunts their stress response to loss and leads them to use strategies (such as utilising the £20 credit in the loss condition to maximize gains and prevent greater overall loss). In contrast, individuals high in RS struggled with task demands, clicking fewer coins and fixating less, for shorter periods. This suggests that the presence of rewards may impair task-switching performance, in RS individuals.

DETERMINANTS OF MENTAL FATIGUE: THE ROLES OF COGNITIVE CONTROL AND REAL-TIME TASK DIFFICULTY ADJUSTMENTS

JIAJUE, T., COOKE, A., GALLICCHIO, G.
BANGOR UNIVERSITY

INTRODUCTION: Mental fatigue impairs performance and safety. This research aims to uncover the underlying causes of mental fatigue by identifying factors that intensify and accelerate its onset. We developed computer-based protocols manipulating (a) cognitive-control demands and (b) real-time task difficulty adjustments designed to promote sustained engagement with the fatiguing activity.

METHODS: In a within-subject single-task study ($n = 36$) and a between-subject multi-task study ($n = 72$), we manipulated task parameters from three executive function domains (inhibition, switching, updating) across conditions of (a) lower vs higher cognitive-control demands without difficulty adjustments and (b) high cognitive control with vs without difficulty adjustments, where speed increased following correct responses and decreased otherwise. Subjective, behavioural, and physiological data were analysed for changes in cognitive load, task engagement, and fatigue. Statistical significance was evaluated using ANOVA planned contrasts and reported as percentage changes.

RESULTS: The within-subject study showed that higher (vs lower) cognitive control increased perceived workload by 16.25% while reducing boredom by 23.80% and sleepiness by 6.40%. It also slowed responses by 9.75%, impaired accuracy by 2.65%, and decreased blink rate by 11.50%. Difficulty adjustments (vs none) heightened workload by 34.33% and led to 7.08% less accurate but 32.58% faster responses, with a further 15.89% reduction in blink rate.

The between-subject study extended these findings to mental fatigue. Higher (vs lower) cognitive control did not consistently elevate perceived workload but led to 11.01% lower accuracy and 58.98% slower response times. Difficulty adjustments (vs none) increased workload by 37.22% across all executive function domains and impaired accuracy by 23.85% while speeding up responses by 20.24%. Mental fatigue was 60.87% larger at the end than the beginning of the study on average across all conditions but emerged 28.69% faster under higher cognitive-control demands with (vs without) difficulty speed adjustments. A 15.22% reduction in parasympathetic activity and 78.98% more blink flurries were observed immediately after (vs before) completing the high cognitive-control condition with difficulty adjustments, possibly reflecting compensatory responses to elevated cognitive workload.

CONCLUSION: These findings reveal how prolonged exertion of cognitive control and task difficulty adjustments can intensify cognitive load and fatigue. While the former can create additional cognitive load, the latter promotes task engagement and accelerates fatigue onset. Beyond identifying contributors to mental fatigue, this research introduces an innovative, time-efficient approach that addresses limitations of previous one-size-fits-all fatiguing protocols, promising to reduce opportunity for disengagement and therefore variability in individual responses in mental fatigue.

BRAIN ENDURANCE TRAINING (BET) IMPROVES UPPER BODY RESISTANCE EXERCISE

MORTIMER, H., RING, C.
UNIVERSITY OF BIRMINGHAM

INTRODUCTION: It is well established that mental fatigue (MF) limits various forms of physical performance. Brain Endurance Training (BET) is a MF countermeasure that combines demanding cognitive tasks that systematically induce elevated levels of MF through engaging higher order executive functions alongside regular physical training. BET has been proven to be effective in improving running, cycling, rhythmic handgrip, and bodyweight calisthenic exercise performance. However, its application to strength and resistance training is less well understood. This study explored the effects of BET on sub-maximal strength training and potential underlying mechanisms that may explain training-related changes in performance.

Method: Forty-two resistance-trained student athletes were randomly assigned to either high cognitive load (high BET group) or low cognitive load (low BET group) conditions and completed 12 training sessions over 4 weeks. In pre- and post-testing, they completed sets to failure at 60% of one repetition maximum for bench press (compound) and preacher curl (isolation) exercise when "fresh" and when mentally and physically "fatigued". Performance (number of exercise repe-

titions to failure), perceived exertion, and mental fatigue were assessed. Linear displacement transducers recorded lifting kinematics (including velocity) while surface electromyography (sEMG) transducers recorded muscle activation patterns.

RESULTS: In pre-testing, exercise performance did not differ between groups. Performance improved in post-testing for both groups as a result of training. In post-testing, the high BET group performed more bench press repetitions than the low BET group both in a 'fresh' and 'fatigued' state. No group differences were observed for preacher curl repetitions. Ratings of perceived exertion (reported after five repetitions) were lower for the high BET group than the low BET group suggesting that increased cognitive demands during training recalibrated the effort-exercise relationship. The high BET group also reported less mental fatigue despite completing more repetitions before failure.

Discussion: The findings show that BET enhances resistance exercise performance and confirm its applicability to strength and conditioning. They also reveal that exercise performance enhancement requires sufficient cognitive load during training to recalibrate the relationship between perceived effort and actual effort. Finally, differences in performance enhancement between the compound and isolated exercises suggest that BET may help improve neuromuscular control.

MOTOR LEARNING UNDER MENTAL FATIGUE: THE COMPENSATORY ROLE OF REST PERIODS

RUFFINO, C., JACQUET, T., LEPERS, R., PAPAXANTHIS, C., TRUONG, C.

LABORATORY C35, UNIVERSITY OF FRANCHE-COMTÉ, BESANÇON, FRANCE

INTRODUCTION: Mental fatigue (MF) is a psychobiological state induced by the realization of prolonged and/or intensive cognitive tasks and characterized by a subjective feeling of tiredness¹. It is well established that MF negatively impacts both cognitive and physical performances. Recent research has shown that MF affects motor adaptation², mainly due to difficulties in engaging explicit strategies. However, its impact on motor learning remains unclear.

METHODS: To address this gap, we used a finger-tapping-task (FTT) and divided 28 participants into one of two groups: an MF group (n=14), which completed a 30-min modified Stroop task, and a Control group (n=14), which watched a documentary of equivalent duration. Following these tasks, both groups trained on the FTT, which required tapping a pre-determined sequence as quickly as possible. The training consisted of 48 trials, divided into 12 blocks of 4 trials, with 5-s rest intervals between trials and 30-s rest intervals between blocks. Movement duration and accuracy of each trial were recorded to calculate a composite ratio to characterize motor skill³. We analyzed motor skill improvement between the beginning (T1) and the end (T2) of the training, the learning curve across all trials, and the online and offline processes. The online process represents motor skill evolution within each block, while the micro-offline process reflects changes during the rest periods between blocks. Additionally, to assess the impact of the Stroop task and documentary viewing, MF was evaluated using a visual analog scale (100mm).

RESULTS: MF significantly differed between groups ($p < .001$), with a higher level of MF after the Stroop (61/100) task than after the control task (26/100). Concerning motor skill improvement, the rmANOVA revealed a significant increase in motor skill in both groups between T1 and T2 ($p < .001$) without difference between them ($p = .53$). Similarly, the analysis of the learning curve showed no difference in the learning rate between groups ($p = .82$). However, motor skill deterioration during online process and motor skill improvement during micro-offline process were greater in the MF group (for both, $p = .02$). Interestingly, a strong negative correlation ($r = -0.96$, $p < .001$) was observed between the online and micro-offline processes, meaning that a greater decrease in motor skill during online process is associated with a greater increase during the micro-offline process, and vice versa.

CONCLUSION: While the total motor skill improvement was similar between groups after MF, the dynamic of motor learning differs. The deterioration observed during the online process was compensated by the offline period between blocks with greater motor skill regain in the MF group. These results highlight the potential role of rest periods in optimizing motor learning under MF.

MENTAL FATIGUE MONITORING IN ELITE FENCING TRAINING AND COMPETITION

BIAN, C., RUSSELL, S.2, BOGATAJ, S.3, ROELANDS, B.1

1. Vrije Universiteit Brussel; 2. Australian Catholic University; 3. University of Ljubljana

INTRODUCTION: Mental fatigue (MF) is increasingly implicated in elite sports. This is strengthened by results from lab studies indicating performance decrements after MF, and by athletes and coaches' self-reported experiences in the field. Fencing, an open-skilled combat sport, demands perceptual-cognitive skills and mental resource allocation for performance optimization and success. The gradual onset of fatigue in simulated fencing competitions is closely linked to increased mental demand. However, to date, MF is not sufficiently addressed in fencing. To optimize performance there is a need to understand the impact of fencing training and competition periods on MF. This would enable coaches and athletes to better manage MF throughout the season.

METHODS: A four-week longitudinal, single-blind monitoring of 31 (7 Epee, 13 Foil, 11 Sabre; 15 Female) elite fencers daily MF was conducted subjectively and behaviorally across phases before, during, and after the national championship (i.e., tapering, competition, recovery training, and normal training week). Subjective MF from a Visual Analogue Scale (MVAS) and reaction time (RT) from the 3-min Psychomotor Vigilance Test (PVT-B) were collected every morning (baseline) and

after the last training session or competition of the day (post). Self-reported individualized training variables (Rating of Perceived Exertion (RPE), duration, contributions of physical, technical, tactical, psychological, and external demands) were also recorded post-training. One-way repeated measure ANOVAs analyzed daily changes (post vs. baseline) in MVAS and RT across phases. Linear mixed-effect models analyzed training days to examine the fixed effects of calculated training load (session-RPE * duration) and specific training demand contributions on daily MVAS changes.

RESULTS: In total, 93 match days and 440 training days were analyzed. MVAS increased after all training and competition compared to baseline, peaking on match days (+19.34 AU, $p < 0.001$), which also aligned with an impaired RT (+76.43 ms, $p < 0.01$). On training days, general training load ($\beta = 0.02$, $p < 0.001$), and the contributions of tactical ($\beta = 0.26$, $p < 0.001$) and physical ($\beta = 0.12$, $p < 0.001$) demands in training activities, showed significant positive effects on daily MF increase. In contrast, external demand ($\beta = -0.13$, $p = 0.022$) substantially mitigated the elevation of MF.

CONCLUSION: Athletes and coaches should recognize the prevalence of MF in fencing and its subsequent impact on reaction performance, particularly on match days. The effects of training variables on daily MF changes suggest the potential of individually tailoring training load and content for active MF management. The focus could be switched between tactical, physical, and external demands in training activities. Finally, field-based MF monitoring should combine daily subjective perceptions with practical, individualized behavioral indicators for an optimal assessment in elite fencing athletes.

OP-MH42 Sedentary Behaviour

THE EFFECTS OF REDUCING SEDENTARY BEHAVIOUR ON PERCEIVED WELL-BEING: A SIX-MONTH RANDOMISED CONTROLLED TRIAL

NORHA, J., SJÖROS, T., GARTHWAITE, T., LAINE, S., LAITINEN, K., HOUTTU, N., VÄHÄ-YPYÄ, H., SIEVÄNEN, H., LÖYTTYNIEMI, E., VASANKARI, T., KNUUTI, J., KALLIOKOSKI, K.K., HEINONEN, I.H.A.

UNIVERSITY OF TURKU

INTRODUCTION: High sedentary behaviour (SB) associates with cardiovascular risk factors, which in turn associate with poorer perceived well-being. Therefore, reducing SB could improve well-being in adults with cardiovascular risk factors. However, evidence from interventional studies is scarce. To fill this gap, this randomised controlled trial investigated whether a six-month SB-reducing intervention affects perceived well-being among adults with cardiovascular risk factors.

METHODS: Sixty-four adults with high accelerometer-measured SB (>10 h/day), overweight or obesity, physical inactivity, and metabolic syndrome (58 % women, 58 [SD 7] years old, SB 10 [I] h/day) were randomised to the intervention group ($n=33$) that aimed at reducing daily SB by 1 h for six months, or to the control group ($n=31$) that continued their usual activity behaviour. In the intervention group, the reduced SB was replaced by individually discussed non-exercise activities. All participants wore accelerometers connected to a mobile application throughout the study to monitor their daily SB and physical activity in relation to the individually set goals. Perceived well-being was measured using four questionnaires before, at the midpoint, and after the six-month intervention: RAND-36 (quality of life), PSQ (perceived stress), GHQ-12 (depressive symptoms), and workability score.

RESULTS: Compared to the control group, the intervention group reduced SB by 40 min/day. Half of the reduced SB was replaced by light physical activity and standing, and half was replaced by moderate-to-vigorous physical activity. The vitality score in RAND-36 decreased in the control group and increased in the intervention group, and the difference was significant at three months ($p=0.012$) and near-significant at six months ($p=0.079$). PSQ-measured perceived stress increased in both groups (time $p=0.033$) without statistically significant differences between groups ($p=0.143$).

CONCLUSION: A six-month intervention aimed at reducing daily SB by 1 h may improve perceived vitality among adults with metabolic syndrome, high SB, and physical inactivity. Therefore, reducing SB could be considered if fatigue or tiredness is a concern.

RANDOMIZED CROSS-OVER TRIAL OF MUSCLE ACTIVITY-MATCHED INTERRUPTIONS TO SITTING IN TYPE 2 DIABETES: GLUCOSE AND INSULIN CHANGES

LAMBERG, S., BRAKENRIDGE, C.J., GAO, Y., DEMPSEY, P., WHEELER, M., DUNSTAN, D.W., FINNI, T., HEALY, G.H., OWEN, N., PESOLA, A.J.

SOUTH-EASTERN UNIVERSITY OF APPLIED SCIENCES

INTRODUCTION: Physically active interruptions to prolonged sitting have beneficial effects on glucose and insulin metabolism, potentially through increased muscle activity. However, it remains unclear if specific movement patterns, such as standing up and moving, may be more effective. We examined the effects on glucose and insulin in those with type 2 diabetes (T2D) of prolonged sitting interrupted by standing, seated pedaling, and sit-to-stand transitions—each matched for total muscle activity.

METHODS: In a randomized crossover trial, 24 inactive overweight/obese adults with T2D (15 women, 61.3 ± 8.1 y) underwent four 6.5-h conditions on four separate days (with 3–14 days washout). Trial days included a 30-minute seated

steady-state, followed by different one-hour bout conditions repeated six times and ending in 30 minutes of sitting. Conditions were uninterrupted sitting (control; SIT), sitting 30-min and standing 30-min (STAND), sitting plus 6-13-min seated pedaling (PEDAL), and sitting plus 2-7-min sit-to-stand transitions (TRANS). Standardized meals were consumed during each condition. Total areas under the curve (tAUCs) for glucose and insulin were compared between conditions using generalized linear mixed models. Participants' total muscle activity for the active conditions was tailored to match the STAND muscle activity by modifying the duration of seated pedaling versus sitting and sit-to-stand transitions versus sitting within the one-hour bouts.

RESULTS: Compared with SIT, both PEDAL and TRANS significantly attenuated tAUCs for glucose (SIT: tAUC mean 121.8 mmol [95% CI 112.9, 131.4] vs. PEDAL: 117.1 [108.6, 126.4] and TRANS: 116.9 [108.3, 126.1]), and for insulin (SIT: tAUC 977.2 pmol [738.9, 1292.6] vs. PEDAL: 772.9 [584.5, 1022.0] and TRANS: 773.9 [584.5 to 1024.8]).

CONCLUSION: Interrupting prolonged sitting with brief bouts of seated pedaling or sit-to-stand transitions, but not with standing, can attenuate acute total areas under the curve for glucose and insulin responses in adults with T2D. These findings suggest that within periods of prolonged sitting, dynamic muscle activity, with either seated or upright posture, can be more effective than prolonged standing for reducing glucose and insulin responses.

THE SPATIAL MISMATCH BETWEEN COMMUNITY PHYSICAL ACTIVITY VULNERABILITY AND URBAN GREEN SPACE ACCESSIBILITY CHARACTERIZES HEALTH PERFORMANCE INEQUALITY

ZHANG, B., LI, X., HAO, L., HOU, Y.

NORTHEAST FORESTRY UNIVERSITY

INTRODUCTION: Physical activity is influenced by both individual and social environmental factors, and the use of urban green spaces (UGS) is closely related to health. However, urban population growth has led to an imbalance in the supply and demand of UGS, affecting the vulnerability of physical activity and health. This study evaluates the matching of UGS supply and demand and proposes green space compensation strategies to enhance residents health.

METHODS: A physical activity vulnerability index was developed to assess the ability of physical activity and the environment to counteract external pressures at the street level. Taking old communities in Harbin as an example, indicators such as population density and green space quality were selected from three dimensions—exposure, sensitivity, and adaptability—to construct an evaluation system. ArcGIS was used to calculate the indicators. Based on the index, street vulnerability was classified into four categories (low, relatively low, relatively high, and high), and the two-step floating catchment area (2SFCA) method was used to evaluate UGS accessibility.

RESULTS: Firstly, the northwestern part of the selected area has high accessibility to UGS, while residents in old communities in the central and southern parts have relatively high accessibility. Some areas in the northeastern suburbs, however, lack access to any services. Secondly, there are significant differences in accessibility among regions with varying levels of vulnerability ($p < 0.001$), with an overall trend of higher vulnerability in the northeast and lower vulnerability in the northwest. This indicates that regions with relatively high and high vulnerability are at a disadvantage in accessing UGS services. Areas with high vulnerability generally have higher population outflow rates and elderly population proportions compared to low-vulnerability areas. Finally, the community vulnerability index and UGS accessibility show significant spatial autocorrelation ($p < 0.05$, with Moran's I value close to 1).

CONCLUSION: The research findings indicate significant inequalities in the accessibility of UGS and the quality of green spaces in residential areas, leading to potential disparities in the physical activity benefits for residents. Residents of older neighborhoods face greater challenges in accessing well-equipped UGS, which may be a result of urban planning prioritizing short-term gains over the needs of residents. Future planning should prioritize increasing green spaces in areas lacking UGS, with a rational layout and diversified facilities to enhance residents physical activity and health levels. Meanwhile, the internal green space quality in low-vulnerability residential areas is generally lower, posing greater public health risks. It is recommended to prioritize the addition of UGS near these areas to ensure that different vulnerability groups equally benefit from the health-promoting services of UGS, thereby narrowing health disparities.

EVALUATION OF PHYSICAL FITNESS, BIOCHEMICAL PARAMETERS AND OXIDATIVE STRESS STATUS BEFORE AND AFTER A 24-WEEK WORKPLACE PHYSICAL ACTIVITY INTERVENTION ON ADULT WOMEN OF AN ACADEMIC COMMUNITY.

MAISTO, G., TUCCCELLA, C., SCATIGNA, M., DELLE MONACHE, S., COPPOLINO, M.F., TOLLI, E., TOBIA, L., PUGLIESE, L., BONA VOLONTÀ, V., FABIANI, L., VINCIGUERRA, M.G.

UNIVERSITY OF LAQUILA

INTRODUCTION: Workplace physical activity interventions (WPAI) are widely recognized for improving employees health, slowing down the ageing process (1) and boosting immunity through an increase in oxidative stress and antioxidant potential (2), but results remain inconsistent. The aim of this study was to evaluate the potential association between physical fitness (PF), biochemical parameters and oxidative stress status before and after a 24-week WPAI on adult women of a university community.

METHODS: Twenty-nine university female employee, aged 50 ± 13.5 years, followed a 24-week WPAI consisting of two circuit training sessions and one mobility session per week. Physical fitness was evaluated as follows: cardiorespiratory fitness (CRF) with 2-min step test (2MST), upper limb strength with Handgrip test, upper body mobility with shoulder-neck test, core endurance with sit-up test, lower limb strength with jump and reach test, balance with one-leg stand test. Total

cholesterol (TC), LDL-cholesterol (LDL-C) and glycemia were assessed before (T0), after 12 weeks (T1) and after 24 weeks (T2). Oxidative stress (d-ROMs test), PF and markers of antioxidant status (BAP test) were assessed at T0 and T2.

RESULTS: 2MST scores increased from 78.8 ± 16.6 (baseline) to 88.3 ± 20.1 (T2). At baseline, women with higher CRF values (≥ 65 steps in 2MST) showed lower d-ROMs values (378.6 ± 88.9 vs 472.6 ± 118.8 U-CARR) and higher BAP values (2729.3 ± 537.4 vs 2073.0 ± 933.4 $\mu\text{mol/L}$), compared to those with lower CRF values (< 65 steps in 2MST). TC, LDL-C and glycemia values decreased from baseline (199.5 ± 41.1 , 120.5 ± 38.7 , 90.6 ± 18.0 mg/dl) to T2 (181.2 ± 33.5 , 106.6 ± 32.5 , 82.2 ± 9.6 mg/dl) with $p < 0.05$, < 0.01 , < 0.05 , respectively. D-ROMs values ranged from 410.4 ± 104.4 at T0 to 464.0 ± 116.4 U-CARR at T2 ($p < 0.01$) while BAP values ranged from 2596.7 ± 632.3 at T0 to 2727.5 ± 569.1 $\mu\text{mol/L}$ ($p < 0.05$) at T2.

CONCLUSION: At baseline a higher CRF was positively associated with lower oxidative stress, suggesting that aerobic fitness may play a protective role. An adapted 24-week WPAI showed improvements in CRF, cholesterol and glycemia in blood samples and an improvement of the oxidative stress status. Specifically, although a significative increase of the ROMs was found, the WPAI may have led to an increase of the antioxidant potential, therefore contributing to boosting protection from absolute oxidative stress.

THE CRITERION VALIDITY OF THE ARABIC SEDENTARY BEHAVIOR QUESTIONNAIRE AGAINST ACTIGRAPHY ACCELEROMETERS AND PEDOMETERS IN ADULTS

ALAHMADI, M., FOUAD, A., ELBATTAWY, K., SHARAF, M., ALJUHANI, O., AL-DAGHRI, N.
TAIBAH UNIVERSITY

INTRODUCTION: The aim of this study was to test the criterion validity of the Arabic Sedentary Behavior Questionnaire (ASBQ) against accelerometers and pedometers in male and female university students.

METHODS: A total of 151 university students, aged 21.90 ± 1.36 years (55% female), participated in the study. Sedentary behavior (SB) was assessed using the ASBQ in a face-to-face interview. SB and physical activity (PA) were measured in 71 students using an Actigraph for 7 consecutive days. Daily steps of an additional 80 students were objectively measured using pedometers for 7 consecutive days.

RESULTS: On average, students reported 557.58 ± 178.58 minutes/day of SB using the ASBQ. A paired sample t-test revealed a significant difference between the ASBQ and Actigraph, with a mean difference of -332.45 minutes/day (95% CI: -398.44 to -266.45 ; $P < 0.001$), indicating that the ASBQ underestimated sitting time compared to the Actigraph. The mean difference for average sitting time was -332.45 minutes/day (95% limits of agreement: -878.92 to 214.03), suggesting a systematic bias between the ASBQ and Actigraph measures of sitting time. No significant correlation was found between the average sitting time estimated by the ASBQ and the average sitting time measured by the Actigraph ($r = -0.06$, $P = 0.59$). A small inverse correlation was observed between total sitting time reported by the ASBQ and the index of sedentary lifestyle ($< 6,000$ steps/day) measured by pedometers ($r = -0.26$, $P = 0.05$). The ASBQ results also showed gender differences opposite to those observed with the Actigraph. A small inverse correlation was found between total sitting time from the ASBQ and moderate-to-vigorous physical activity (MVPA) ($r = -0.26$, $P = 0.05$), though no correlation was observed with light-intensity physical activity (LIPA) ($r = -0.03$, $P = 0.79$).

CONCLUSION: The current study revealed a low correlation between the ASBQ and the reference tool (Actigraph). Although the ASBQ tended to underestimate daily sedentary time compared to accelerometry, our findings support its use as a reasonable tool for estimating sedentary time in adults in Arab-speaking countries.

SHORT-TERM UNILATERAL LOWER LIMB SUSPENSION: A VIABLE MODEL FOR INVESTIGATING EARLY MUSCLE ATROPHY RESPONSES

MANDIC, M., LOPEZ-ORTIZ, S., PEREZ-DIAZ, S., BADALI, C., TRYFONOS, A., KVIST, O., BOUMA, K., RULLMAN, E., FERNANDEZ-GONZALO, R.
KAROLINSKA INSTITUTET

INTRODUCTION: locomotor muscles such as the knee extensors and the plantar flexors. Prolonged bed rest can lead to a reduction in muscle mass of up to 30%. However, the onset of muscle atrophy is rapid, with measurable changes occurring within a few days of disuse. A 3% reduction in the cross-sectional area of the thigh muscle has been observed after only 5 days of full leg casting 1. Although the full leg cast model is frequently used for studies investigating the initial mechanisms of muscle atrophy, it has some serious drawbacks. The angle of fixation can influence the number of serial sarcomeres. Fixation also makes it difficult to adapt the model outside of clinical investigations, for example in studies investigating atrophy induced by spaceflight, as the joint is fixed in an unnatural position. One option to overcome these

limitations is the unilateral lower limb suspension (ULLS) model, in which the intervention limb is unloaded by lifting the contralateral limb with a plateau shoe. This allows the unloaded limb to assume a straight position and move passively and freely around the hip, which is closer to the situation of an astronaut in weightlessness. To date, there have been no studies investigating whether the ULLS model results in comparable changes in muscle volume to those reported for short periods of bed rest and full leg casting. Therefore, this study aimed to investigate the changes in muscle volume induced by 5 days of ULLS.

METHODS: At the time of abstract submission, a total of 11 subjects have completed the 5-day ULLS protocol, 8 men and 3 women. At the congress we will have data from 20 participants, equally divided between the sexes. The volume of the quadriceps muscle was measured by MRI before and after the five-day unloading. All subjects wore a thermometer patch on the gastrocnemius muscle on both legs, which recorded the skin temperature every minute during the unloading phase.

RESULTS: The intervention resulted in a significant decrease ($2.35 \pm 1.45\%$) in m. quadriceps in the unloaded leg ($894.7 \pm 323.8 \text{ cm}^3$ vs $873.7 \pm 319.5 \text{ cm}^3$, $p < 0.05$). The control leg was unaffected ($917.5 \pm 323.5 \text{ cm}^3$ vs $920.0 \pm 327.1 \text{ cm}^3$, $p > 0.05$). The magnitude of muscle loss was similar between the sexes (females; $-2.35 \pm 1.57\%$, men; $-2.36 \pm 1.52\%$). The skin temperature in the unloaded leg was on average $4.2 \pm 1.3 \text{ }^\circ\text{C}$ lower than in the control leg during daily activities.

CONCLUSION: Our preliminary data shows that short-term ULLS produces similar changes in m. quadriceps to those previously reported for bed rest and full leg casting protocols of the same length. This means that the method is suitable for interventions aiming to investigate the early responses of muscle atrophy. We also show that men and women respond similarly, and that continuous temperature monitoring can serve as a tool for protocol compliance.

THE EFFECT OF DIETARY BRANCHED CHAIN AMINO ACID RESTRICTION ON FOREARM MUSCLE PROTEIN SYNTHESIS AND AMINO ACID KINETICS DURING DISUSE IN YOUNG, HEALTHY INDIVIDUALS

OAKLEY, S., JAMESON, T., DOMINGOS, L., MONTEYNE, A., ANDREWS, R., ABDELRAHMAN, D., MURTON, A., WALL, B., STEPHENS, F., DIRKS, M.

UNIVERSITY OF EXETER

INTRODUCTION: Skeletal muscle loss occurs during short-term muscle disuse, e.g. immobilisation following injury. Muscle disuse is accompanied by a decrease in muscle protein synthesis (MPS) rates and branched-chain amino acid (BCAA) accumulation. However, the relevance of BCAAs in disuse atrophy remains unclear. Thus, we aimed to manipulate muscle BCAA availability via a BCAA restricted diet to assess its impact on MPS and amino acid kinetics during forearm immobilisation.

METHODS: Twenty healthy participants (15/5 M/F; 22 ± 1 yrs, BMI $22.7 \pm 0.5 \text{ kg}\cdot\text{m}^{-2}$) attended two metabolic test days before (PRE) and after (POST) 48 h forearm immobilisation, during which they were randomly allocated to a control (CON; $n=10$) or BCAA restricted diet (BCAA-; $n=9$). During immobilisation, CON consumed a fully controlled diet (50-55 en% carbohydrates, 25-30 en% fat, and $1.5 \text{ g}\cdot\text{kg}^{-1}\cdot\text{day}^{-1}$ protein [15-20 en%]) containing $20.0 \pm 0.7 \text{ g}\cdot\text{d}^{-1}$ BCAA, whilst BCAA- consumed the same macronutrient matched diet but with $0.9 \pm 0.1 \text{ g}\cdot\text{d}^{-1}$ BCAA. An intravenous infusion of L-[ring-2H5]phenylalanine with repeated arterialed-venous forearm balance samples and m. brachioradialis forearm muscle biopsies in fasted and clamped (hyperinsulinaemic [$50 \text{ mU}\cdot\text{m}^{-2}\cdot\text{min}^{-1}$]-hyperaminoacidaemic [$0.11 \text{ g}\cdot\text{kg}^{-1}\cdot\text{h}^{-1}$]-euglycaemic [$5.0 \text{ mmol}\cdot\text{L}^{-1}$]) conditions was used to explore the flux of amino acids between 3-pools (arterialised, venous, and intracellular [IC] pools) and mixed muscle fractional synthesis rate (FSR). Data (mean $\pm$ SEM) were analysed via a 3-way repeated measures ANOVA with clamp, immobilisation and diet as factors.

RESULTS: BCAA- reduced fasted arterialised plasma leucine concentrations (PRE: 125.1 ± 6.5 to POST: $108.6 \pm 8.1 \text{ } \mu\text{mol}\cdot\text{L}^{-1}$; $P < 0.05$), resulting in lower concentrations POST compared to CON ($135.6 \pm 6.4 \text{ } \mu\text{mol}\cdot\text{L}^{-1}$; $P < 0.05$). Fasted IC pool phenylalanine and leucine concentrations increased by $26 \pm 9\%$ and $24 \pm 9\%$ POST in CON, respectively (both $P < 0.05$), but remained unchanged in BCAA- ($P > 0.05$). Phenylalanine net balance (NB) decreased by $56 \pm 6\%$ (fasted) and $67 \pm 6\%$ (clamp) from PRE to POST ($P < 0.05$), with no effect of diet ($P > 0.05$). Three-pool amino acid fluxes increased after clamp ($P < 0.05$) but were not affected by immobilisation or diet ($P > 0.05$). Forearm FSR increased from PRE to POST ($P < 0.05$) but was not affected by diet (PRE: CON 0.052 ± 0.008 , BCAA- $0.041 \pm 0.007 \cdot \text{h}^{-1}$; POST: CON 0.103 ± 0.027 , BCAA- $0.058 \pm 0.015 \cdot \text{h}^{-1}$; $P > 0.05$).

CONCLUSION: Dietary BCAA- decreases plasma leucine concentrations and suppresses intracellular amino acid accumulation but does not affect three-pool amino acid kinetics or MPS during short-term immobilisation. Forearm immobilisation decreases forearm phenylalanine NB, indicating early muscle protein loss, but does not affect 3-pool modelled amino acid fluxes. The rise in MPS after immobilisation may be attributed to intracellular amino acid accumulation, providing leads for future research on the role of extra- and intracellular amino acid availability in muscle disuse atrophy.

EFFECT OF COMBINED BETA-LACTOGLOBULIN SUPPLEMENTATION PLUS RESISTANCE TRAINING PREHABILITATION ON MUSCLE PROTEIN SYNTHESIS RATES FOLLOWING LIMB IMMOBILISATION IN HEALTHY YOUNG MALES AND FEMALES

HUGHES, A., FRANCIS, T., MARJORAM, L., ROONEY, J.H., ELLISON-HUGHES, G., POLLOCK, R., CURTIS, M.J., CAPE, A., LARSEN, M., PHILLIPS, B.E., ATHERTON, P.J., SMITH, K., WELSH, B., LAI, Y.C., WITARD, O.C.

KINGS COLLEGE LONDON

INTRODUCTION: Periods of muscle disuse occur across the lifespan due to illness, injury, and hospitalisation, suppressing muscle protein synthesis (MPS) rates and leading to muscle atrophy and a reduction in physical performance and quality of life. To date, no studies have investigated use of a combined exercise and nutrition prehabilitation regimen to mitigate declines in MPS or muscle mass during a period of disuse. This study aims to investigate the effect of beta-lactoglobulin (BLG), a leucine rich protein, supplementation combined with resistance exercise training before 5-days of unilateral limb immobilisation on muscle mass, strength, and MPS rates.

METHODS: We conducted a randomised, placebo-controlled trial whereby healthy young adults ($n=11$) ingested a BLG supplement or a dextrose monohydrate placebo (PLA) thrice daily for 1-wk prior to, and during, 5-d of unilateral limb immobilisation. Participants completed four sessions of resistance training during the week prior to immobilisation. Deuterium oxide tracer methodology was used to measure free-living MPS rates in response to prehabilitation and muscle disuse. Measurements of thigh lean mass by dual energy x-ray absorptiometry and muscle strength by isokinetic dynamometry were conducted at baseline, pre-immobilisation (post-exercise training), and post-immobilisation.

RESULTS: Thigh lean mass remained unchanged for BLG ($3.1 \pm 12.9\%$ pre-immobilisation, $1.7 \pm 12.5\%$ post-immobilisation) and PLA ($2.2 \pm 5.4\%$ pre-immobilisation, $0.4 \pm 6.6\%$ post-immobilisation) in response to prehabilitation and muscle disuse. Isometric strength increased in BLG ($12.7 \pm 16.9\%$) and PLA ($12.6 \pm 13.9\%$) with exercise training, but declined to below baseline in BLG ($-3.0 \pm 17.4\%$) and baseline levels in PLA ($0.6 \pm 16.2\%$) following immobilisation. Isokinetic strength appeared to decline to a greater extent in BLG than PLA (BLG: $-4.7 \pm 19.0\%$ pre-immobilisation, $-19.5 \pm 22.8\%$ post-immobilisation, PLA: $25.7 \pm 9.9\%$ pre-immobilisation, $-1.5 \pm 13.2\%$ post-immobilisation). However, the decline in MPS in response to disuse was attenuated in BLG compared with PLA (change pre- to post-immobilisation, BLG: $-23.7 \pm 7.4\%$, PLA: $-41.2 \pm 12.7\%$). Protein expression of muscle protein breakdown (MPB) markers indicated a pre-post immobilisation increase in MuRF1 (BLG: $60.7 \pm 51.3\%$, PLA: $57.1 \pm 39.5\%$) and Atrogin-1 (BLG: $55.9 \pm 26.6\%$, PLA: $43.8 \pm 31.4\%$) in both groups.

CONCLUSION: To conclude, BLG supplementation combined with resistance exercise as a prehabilitation strategy may attenuate the decline in MPS following 5-d of immobilisation. However, the improvements in MPS in BLG did not appear to translate to the better preservation of muscle mass and strength compared with PLA, of which the PLA group achieved better outcomes. An increased expression of MPB markers in both groups may be explained by the novel resistance exercise training stimulus, although immobilisation also elicited elevations in MuRF1 and Atrogin-1 levels above baseline.

SKELETAL MUSCLE MEMORY OF REPEATED DISUSE-INDUCED ATROPHY

TURNER, D., RAASTAD, T., SEYNES, O., ULLRICH, M., CHRISTIANSEN, S., HALLÉN, J., SUTHERLAND, H., TREEBAK, J., KELLEZI, E., OWENS, D., HUGHES, D., BODINE, S., JARVIS, J., SHARPLES, A.

UNIVERSITY OF PAVIA

INTRODUCTION: Skeletal muscle (SkM) possesses a positive memory of hypertrophic stimuli. However, it is unknown whether SkM has a negative memory of disuse-induced atrophy. The present study therefore investigated the physiological and genome-wide transcriptional response to repeated disuse in young adult human and aged animal SkM.

METHODS: Ten healthy young adult humans (27 ± 4 yrs) underwent 2 wks of lower limb immobilization, 7 wks recovery and 2 wks repeated disuse. Aged rats (F344, 22-24 months, $n = 3/\text{condition}$) underwent 1 wk of tetrodotoxin-induced disuse of the dorsiflexors, 1.5 wks recovery and 1 wk repeated disuse. Before and after each period of disuse, SkM tissue was obtained, and SkM mass, size and strength were assessed. Subsequent transcriptomic analysis (RNA-seq) was performed on human vastus lateralis (VL) and rat tibialis anterior (TA) muscles. A one-way ANOVA with Tukey post-hoc comparisons detected significant physiological changes ($p < 0.05$). Differentially expressed genes (DEGs) were detected via FDR < 0.05 with $\geq 20\%$ change. Data presented as mean $\pm$ SD.

RESULTS: In young humans, leg lean mass, VL muscle cross-sectional area (CSA) and quadriceps strength were significantly reduced after disuse (-4% , -9% , -12 - 14% , respectively) that were fully restored following recovery. Repeated disuse induced comparable reductions in lean mass, CSA and strength to those seen during earlier atrophy. In aged rats, there was a progressive loss of SkM mass following disuse (-4%), recovery (-18%) and repeated disuse (-30%). Transcriptomic analysis revealed that a larger number of DEGs were downregulated than upregulated after disuse and repeated disuse in adult and aged SkM. In young SkM, disuse evoked 4-fold more DEGs (384) vs. repeated disuse (104), with no DEGs post-recovery. Conversely, a 2-fold greater number of DEGs were identified after repeated disuse (3948) than during earlier disuse (2115) and recovery (2058) in aged SkM. Energy sensing, oxidative metabolism and mitochondrial-related pathways were most enriched after both periods of disuse in both young human and aged rat SkM. Temporal mRNA profiling in young SkM suggested most genes recovered and did not show greater reductions after repeated disuse. In contrast, genes that were altered with disuse in aged SkM were more susceptible to larger, exaggerated changes after repeated disuse. Many genes demonstrated a retained memory profile into recovery following earlier disuse in aged rats or displayed enhanced regulation following repeated disuse relative to young humans.

CONCLUSION: Repeated disuse evokes comparable physiological responses associated with reduced transcriptional perturbations following repeated disuse-induced atrophy in young adult humans. Conversely, SkM wasting is exacerbated

ed upon repeated disuse in aged rats that is associated with retained or exaggerated transcriptional changes. Further analysis will confirm whether the transcriptional profiles are underpinned by epigenetic mechanisms.

EFFECTS OF DISUSE ON MITOCHONDRIA AND NEUROMUSCULAR JUNCTIONS IN YOUNG AND OLDER ADULTS

MOTANOVA, E., NEGRO, S., ZUCCARELLI, L., PIRAZZINI, M., ROSSETTO, O., GRASSI, B., NARICI, M.V.

UNIVERSITY OF PADOVA

INTRODUCTION: Physical activity is essential for muscle health, improving strength, metabolic functions, and cardiovascular health. In contrast, inactivity reduces muscle mass, strength, and overall functionality (Narici & M. D. de Boer, Eur J Appl Physiol, 2010).

Skeletal muscle is a highly innervated tissue and relies on the neuromuscular junction (NMJ) for contraction. Mitochondria are vital for both NMJ and muscle function, supplying energy for neurotransmission and contraction. Evidence indicates that prolonged inactivity disrupts both mitochondrial function and NMJ stability (Sarto et al., J Physiol, 2022; Eggelbusch M et al., Cell Rep Med, 2024). In this study, we hypothesised that inactivity would provoke mitochondrial changes in skeletal muscle, potentially leading to NMJ alterations.

METHODS: To test our hypothesis, we investigated the relationship between mitochondrial function and NMJ morphology following chronic inactivity in both young and older adults. Specifically, we analysed mitochondrial respiratory capacity, ROS production, mitochondrial complexes and supercomplexes abundance, mitochondrial dynamics, and morphology in relation to NMJ integrity.

9 young (18-29 years) and 10 older (65+ years) participants underwent bed rest—10 and 21 days for the younger group and 10 days for the older group—with vastus lateralis muscle biopsies collected before and after bed rest.

RESULTS: In the older group, inactivity decreased the overlap between the motor axon terminal and the post-synaptic specialisations and led to an increase in C-terminal agrin fragment (CAF), a marker of NMJ instability. These changes were also linked with increased ROS production and altered mitochondrial dynamics. Although no visible changes in mitochondrial fission or fusion were observed, there was a reduction in mitochondrial volume density.

In the younger group, after 10 days of bed rest, mitochondrial changes occurred without a corresponding increase in CAF. These changes included shifts in mitochondrial dynamics and reduced volume density. However, after 21 days, both mitochondrial alterations and increased CAF were observed, suggesting that mitochondrial dysfunction may precede NMJ remodelling.

CONCLUSION: In conclusion, our results suggest that inactivity-induced mitochondrial changes in skeletal muscle could be an early driver of NMJ instability. However, the specific role of mitochondria in presynaptic terminal deterioration remains uncertain, requiring further research, especially in the context of ageing and inactivity.

OP-SH03 Philosophy and Ethics

DISCRIMINATION OR PROTECTION? INVESTIGATING THE ETHICS OF LIMITING PARTICIPATION IN SPORTS ON PUBLIC HEALTH AND INDIVIDUAL WELL-BEING GROUNDS

SESA, G., BORRY, P., LOLAND, S., CAMPORESI, S.

KU LEUVEN & NORWEGIAN SCHOOL OF SPORT SCIENCES

Inclusivity is a core value in sports, yet athletes with health conditions are often excluded from participation. Over the past decade, various restrictions have been imposed by governments and sports federations, from limiting sports participation for controlling infectious disease outbreaks to barring athletes with chronic or infectious conditions from participating in sports (Michelini et al., 2021; Magavern et al., 2017). The boundary between unjustly discriminating individuals with a health condition from accessing and participating in sports and justifiably excluding them to safeguard their health or that of others is ambiguous and requires further investigation. This paper seeks to investigate whether and when such exclusions are ethically justified. In doing so, we adopt a collective reflective equilibrium approach, first specifying well-established public health ethical principles and frameworks, next discussing the application of such principles and frameworks to real-world cases, and ultimately developing a framework based on the balancing of the principles and frameworks (Savulescu, 2025). Specifically, we analyze and draw conclusions from four distinct cases: a professional boxer living with HIV, a professional soccer player with a cardiovascular condition, an athlete struggling with an eating disorder, and the exclusion of a 12-year-old from grassroots sports due to mandatory vaccination policies. We conclude that several key factors must be considered when evaluating the ethical justification for sports participation restrictions. Established public health ethics principles—such as beneficence, utility, fairness, respect for human dignity, justice, and transparency—must be operationalized within the sports context. Additionally, novel dimensions—including the nature of the disease, the type of sport, and individual health status—influence how these ethical principles are weighted in deci-

sion-making. We also acknowledge and emphasize the critical role of education and ongoing health monitoring for athletes, to promote safe participation in sports. Together, these considerations provide a foundation for guiding justifiable decisions in sports eligibility and in distinguishing between justifiable and unjustifiable discrimination. Future research should engage a diverse range of stakeholders to gather insights on the practical applicability of the proposed framework.

SCIENTIFIC THINKING ON SPORTS AND HEALTH ETHICS IN THE ERA OF DIGITAL INTELLIGENCE CIVILIZATION

JIA, Y., GONG, Z.

SHANGHAI UNIVERSITY OF SPORT

Scientific Thinking on sports and Health ethics in the Era of Digital Intelligence Civilization

Jia Yuzhen Gong Zhengwei

Shanghai University of Sport

INTRODUCTION: The rapid development and widespread application of technologies such as big data, artificial intelligence, the Internet of Things, and cloud computing are fundamentally reshaping the practices, decision-making mechanisms, and social structures in the fields of sports and health, leading humanity into the digital intelligence era. In the digital intelligence era, the connotations of sports ethics are undergoing profound changes. This change is not only reflected in the application of traditional ethical principles but also involves ethical considerations brought about by emerging technologies.

METHODS: The research adopts various methodologies such as literature, logical analysis, interdisciplinary research, case analysis, etc.

RESULTS: (1) The core issues of sports and health ethics in the digital era. First, data privacy and security issues. When early wearable devices and health data acquisition systems first emerged, people were concerned about how data helps individuals optimize their health without fully considering the risk of data abuse. Second, algorithm fairness and discrimination. AI is increasingly used in sports training, injury prediction, event referees, etc., but the scientificity, fairness and transparency of its decisions are controversial. Third, the fairness of sports is impaired. the emergence of technologies such as gene editing, AI-assisted training, and brain-computer interfaces has enabled athletes to improve their abilities to break through the boundaries of traditional "natural person" competition and challenge the fairness and ethical bottom line of sports.

(3) The normative construction of sports and health ethics in the digital era. In the construction of normative construction of sports technology ethics, we often face the "Collingridge Dilemma". The Colingridge dilemma needs to be solved by introducing ethical factors in the process of technological development. There are two main paths for ethical intervention: constructive technology evaluation and technical moral design. The ethical design of technology and constructive technology evaluation should form a continuous ethical monitoring mechanism to ensure the ethical compliance of the technology during the application process.

CONCLUSION: The application of digital intelligence technology is not only a technical issue, but also a social issue, involving values, rights distribution and social fairness. The core of the scientific thinking of the digital era for sports and health ethics is how to find a balance between technological innovation and ethical constraints, ensure that technology serves the comprehensive development of mankind, and at the same time maintains basic values such as fairness, privacy and dignity.

COMPARATIVE ANALYSIS OF FOOTBALL COACH EDUCATION: EVOLUTION, STRATEGIES, AND DEVELOPMENT IN ENGLAND AND CHINA

WU, Y., REN, D.

BEIJING SPORT UNIVERSITY

INTRODUCTION: Coaches play an important role in athletes' learning and development, as their coaching philosophy, competencies, and effectiveness are vital to improving their performance. Since 1997, The Football Association (FA) has implemented its "A Charter for Quality," which has significantly influenced how coaches think and deliver, expanded the coaching workforce, and laid a solid foundation for talent identification and development.

METHODS: This study employed documentary and comparative analysis to systematically examine the developmental trajectories of football coach education in England and China. The search was conducted across multiple databases,

yielding 126 relevant articles and books(e.g. *Advances in Coach Education and Development*(2016) and coach education materials).

RESULTS: The historical trajectory of England's football coach education is categorized into four stages—Enlightenment (1863–1901), Development (1902–1966), Reform (1967–1999), and Takeoff (2000–present). Crucial milestones include sustained government policy support, collaborative societal supervision of qualifications, innovative pedagogical frameworks, and a structured coaching course curriculum.

In contrast, China's formal football coach training originated in 1979 and aligned with the Asian Football Confederation (AFC) certification system between 1994 and 2001.

Discussion: Formal football coach education in England originated in the 19th century during clashes between the ideals of amateurism and professionalism. Regularization began in the early 20th century when the FA introduced standardized coaching courses with professional certification. Mid-20th-century reforms, driven by the National Vocational Qualifications (NVQs) framework and sustained funding, accelerated the expansion of coach education. In the 21st century, a pedagogical paradigm shift embraced social constructivism, prioritizing learner-centered approaches and collaborative knowledge-building.

Policy continuity has underpinned England's coach education system. The 2002 reports by the Department for Culture, Media and Sport (DCMS) pledged nearly £30 million in funding for coaching. Its tiered certification system expands access (Levels 1–2 for grassroots) while maintaining high standards (Levels 3–5 aligning with UEFA B, A, and Pro licenses). The FA also considers the needs of ethnic minority and disabled coaches. Following a shift in pedagogical methodology, this program emphasizes reflection and critical thinking.

For China, the study underscores the need for long-term strategic planning to expand coach education by leveraging centralized resource mobilization. Cross-sector collaboration between sports departments, educational organizations, and social institutions is critical for reforming certification systems, lowering entry barriers, streamlining administration, and delegating power.

A COMPARATIVE STUDY ON THE DEVELOPING TRENDS OF CIVIC SPORTS IN CHINESE AND EUROPEAN FEUDAL SOCIETIES

ZHANG, A., YU, C.

BEIJING SPORT UNIVERSITY

INTRODUCTION: The rise of civic sports took place in both Chinese and European feudal cities, but they followed different paths. By comparing the two types of civic sports, this study tends to explore their differences and underlying reasons.

METHODS: Utilizing the methods of literature review and historical comparative, this paper sorts out the different developing trends of civic sports in Chinese and European feudal societies.

RESULTS: Although civic sports and their organizations emerged in feudal China and Europe, the developing trajectory of them differed largely.

Firstly, different relationships between civic sports and military led to different degree of confrontation of the bodies of the participants. Because the strong centralization of power in China's feudal society opposed the practice of martial arts among the people, Chinese civic sports emphasized the aesthetic effect of physical technology but not the intense of the physical actions. While in Europe, served both of the self-defense of the city and needs of entertainment of the citizens, civic sports pursued the competitiveness of proceed and the fairness of the results.

Secondly, different relationship between civic sports and education led to different historical trends. The civic sports was rejected by Chinese feudal education system which valued morality over physical movement, so that it could only develop along the traditional path with the rise and fall of the feudal economy. In the late medieval Europe, educators modified sports into education to cultivate "the whole people". Civic sports were standardized and scientific and got the foundation of modernization.

Lastly, different relationship between civic sports and royal power led to different social status. The feudal lord class in feudal China regarded civic sports as inferior peoples games and prohibited the nobles to participate. Civic sports in feudal European cities were protected by communes and guilds, even the king, and accepted by the bourgeoisie following the cities' industrialization.

CONCLUSION: The feudal centralized system and the concept of "emphasizing intelligence over body" narrowed the survival space of civic sports in China and making it impossible to get rid of the traditional trajectory. While in feudal Europe, monarchy allied with the city, encouraged the development of civic sport and its economic base, which enabled civic sport to modernize with the city's industrialization.

BODY POLITICS AND TRANSFORMATION OF CITIZENSHIP IN THE HANKOW HORSE RACING (1861-1949)

YU, C., ZHANG, A.

BEIJING SPORT UNIVERSITY

INTRODUCTION: Horse racing, as a symbol of colonial modernity, served as a tool for colonists to enforce bodily discipline through discipline, competition, and health. It also became a key field for shaping the body recognition and identity of Hankow's citizens. During urban modernization, Hankow citizens used this activity to reconstruct local modernity, creating a unique path that both echoed and conflicted with European humanistic notions of the body. This study aims to reveal how Horse racing acted as a tool of colonial power and how it was transformed by locals into a practice of identity reconstruction in pursuit of modern citizenship.

METHODS: This study uses historical and comparative research methods, analyzing texts on Horse racing management and events from the Hankow Concession Gazette and Customs Reports. A comparison with 15th-century Florentine Palio Races reveals the role of sports in shaping civil society across cultures.

RESULTS: The Horse racing in Hankow epitomizes the intersection of colonial modernity and local modernization. As a colonial tool, it reinforces racial and class distinction through bodily discipline; on the other hand, the civic class adapts it as a cultural resource to construct modern identities. This duality highlights the complex interactions of "being disciplined" and "self-enlightenment" in China's modernization. Compared to European Renaissance civic sports, Hankow's experience offers a critical perspective on non-Western societies' passive yet creative roles in the transformation of modernity, and provides a case study for the multiple paths of global modernity.

Discussion: 1. Colonial logic of physical discipline:

Horse racing in Hankow imposed Western "civilized body" standards on local citizens through strict schedules, spatial segregation, and behavior codes. The Hankow Club Regulations required Chinese attendees to dress appropriately and behave decorously, or they would be expelled, reflecting the colonial powers' intention to divide social hierarchy through bodily control.

2. Reconstructing civic identity:

In the 1920s, Hankow women began attending horse races and even participated in equestrian performances, provoking debate about the "new woman's" body. Women's Magazine recorded ethical criticism of women in Western riding attire, highlighting the conflict between traditional morality and modern body ideals. Local elites transformed horse racing into a symbol of national revitalization by organizing the Chinese Businessmen's Racing Association.

3. Dialogue with the Renaissance:

Florence's Renaissance Palio horse racing centered on city-state honor, with citizens displaying courage and loyalty. In contrast, Hankow's horse racing was intertwined with colonial modernity, with civic identity construction constantly navigating the tension between "Westernization" and "localization". Both sports activities shaped public life, but Hankow's case more strongly exemplifies active resistance within passive modernity.

IS-EX03 ACSM-ECSS exchange symposium: Lactate metabolism

LACTATE METABOLISM: FROM HYPOXIA TO SHUTTLES

GLADDEN, G.

AUBURN UNIVERSITY

Lactate (La-) stands at the crossroads of glycolytic and oxidative energy metabolism. Studies of exercise and muscle metabolism from the 1700s to the mid-twentieth century asserted that La- is the product of anaerobic glycolysis, with "anaerobic" implying a lack or absence of oxygen (O₂) availability for mitochondria. However, it is now appreciated that healthy mitochondria function well, even at low O₂ levels such that dysoxia (O₂ levels so low that mitochondrial oxidative phosphorylation is inhibited) is rare and low O₂ is often a minor factor in the increasing concentrations of La- typically observed with exercise or even many acute critical care situations. Instead the basic mechanisms underlying La- production, removal, and accumulation emphasize stimulation of key glycolytic enzyme activities, limitations to lactate removal, and the distribution of La- among cells throughout the body and even within tumors. From its role in coordinating whole-body metabolism as a fuel to its role as a signaling molecule in tumors, the study of La- metabolism continues to expand and holds potential for multiple clinical applications. Various aspects of the history of La- metabolism, as well as the structures, processes and mechanism of La- appearance, disappearance, and exchange will be examined.

LACTATE: ITS USE (AND MISUSE) IN SPORT

JONES, A.

EXETER UNIVERSITY

Measurement of blood [La-] during exercise is a mainstay of fitness assessment, performance estimation and training prescription in athletes. However, the application and interpretation of such measurements has been mired in controversy. This presentation will outline several misunderstandings regarding the role of La- in exercise performance, particularly in relation to its role, or otherwise, in fatigue development. Despite these misconceptions, blood La- measurements continue to be valuable if used appropriately. Blood La- dynamics during exercise typically reflect changes in other muscle metabolites that might be more directly involved in fatigue development and help identify exercise intensity domains within which broader physiological responses are manifest - with implications for adaptations to training. While the La-threshold, or its pulmonary gas exchange counterpart, continues to find application in clinical settings, the highest exercise speed that can be sustained in a metabolic (including La-) 'steady state' is of particular importance in endurance sports. New approaches for defining this transition point will be described and the future directions for La- monitoring in athlete evaluation, training intensity assessment and exercise prescription will be considered.

Invited Symposium

IS-BM03 Biomechanical and physiological trade-offs in sprint and endurance performance: lessons from the animal kingdom to human athletes

HOW HUMAN ATHLETES MOVE: TRADE-OFFS IN ANATOMICAL AND PHYSIOLOGICAL DESIGN

BLAZEVICH, A.

EDITH COWAN UNIVERSITY

Animals including human athletes move using energy generated (work done) by muscles, which are activated by the nervous system. Optimum movement performance can occur when muscle activation is maximal and coordination optimal (if maximum strength or speed are required) or when the energy cost of activation is minimized (if movement economy is required), so a trade-off between speed/strength and endurance is apparent. Peak muscle force is proportional to the muscle's physiological cross-sectional area (PCSA) while its maximum shortening speed is set by the length of its longest fibers. Yet, inertial masses increase with PCSA and fiber length, reducing limb (and whole body) acceleration and increasing energy cost, thus facilitating "fatigue". So, unless maximal force is primarily required, a balance must be struck between PCSA and fiber length to minimize mass. Thus, no single design allows force, speed, and efficiency (economy) to be optimized, and some balance must be achieved. And this balance must be achieved with consideration of muscle fiber types and fiber pennation angles (the latter influencing fiber rotation, and thus gearing during contraction), which also influence maximal muscle power. In human athletes (and nonathletes), fatigue manifests in the nervous system and muscles, and is affected by muscle coordination (efficiency) and muscle fiber type as well as muscle oxygen delivery (e.g. cardiac output) and utilization (e.g. capillarization). Here too there are trade-offs that affect the physiologic make-up of single individuals (and different animal species) while also governing the types of exercise training done by athletes. Finally, muscles suffer from velocity-related force limitations, impacting high-speed actions and imposing energy-related work limitations (i.e., fatigue). Long tendons can alleviate these problems by momentarily storing the energy of muscles and then releasing it rapidly – the rate of work is increased so power is amplified. Tendon action also reduces (or mitigates) the need for muscles to stretch and shorten, thereby reducing muscle damage (imposed during lengthening) and muscle work and thus energy cost (expensive during shortening), in turn reducing fatigue and improving endurance. Yet, tendon stiffness must vary with the force-time requirements of the task, dictating tendon properties to vary between muscles, between animals (incl. athletes in different disciplines), and over time as physical activity patterns change, imposing a dynamic stiffness-compliance trade-off. Utilizing this framework, the aim of this presentation is to explore trade-offs created by the need for muscle-tendon units to produce forces and power of different magnitudes, at different lengthening-shortening speeds, and over different overall durations. The presentation will investigate the impact of these trade-offs in animal design and on the training of human athletes.

TRADE-OFFS IN ANIMAL MOVEMENT: SPEED AND AGILITY VS ENDURANCE

MCGUIGAN, P.

UNIVERSITY OF BATH

Investigating performance through an animal lens provides examples of where specialization has evolved due to one particular area of performance being key to the survival of an individual; and thus natural selection rather than training has been the driver of adaptations favoring speed and agility or endurance. Exploring these examples at both the organismal and muscle-tendon unit level provides insight into the potential trade offs of this specialization, which are not always as obvious as they might seem. This is because, even in what would be considered the most extreme examples of specialization, there are rarely only two traits that trade-off against each other and it is necessary to consider them within the more complex survival needs of the single animal. This presentation will explore these trade-offs through some examples

of animals using cursorial (running) and saltatorial (hopping) locomotion. The highly specialized digital flexor muscles of the horse enable highly efficient locomotion at slower speeds, but what constraints do their very short muscle fascicles and long tendons place on speed and agility and how would a change in the properties of those tendons, due to injury or age, impact their function? The fastest land mammals (eg the cheetah) are undoubtedly extreme in terms of their speed and agility, with high peak power output of their hindlimb muscles compared to other large mammals, and about 20% higher than their prey species. But maximum muscle fiber stress (F/CSA) and power alone do not explain the differences between the large predators such as the cheetah and the lion, and in exploring the other factors that determine their remarkable speed and agility we can learn how trade-offs can be optimized to maximize hunting (i.e. survival) success. Finally, by also looking at a more generalist animal, the goat, we will demonstrate how trade-offs in the architecture of different muscles allows plasticity of function to adapt to highly different locomotion conditions (i.e. running, jumping and climbing).

NEUROMUSCULAR ADAPTATIONS TO RESISTANCE TRAINING IN HUMAN ATHLETES: DO THEY HINDER OR HELP SPRINT AND ENDURANCE PERFORMANCE?

BAS, VAN H.

MAASTRICHT UNIVERSITY

Resistance training results in numerous morphological and physiological adaptations. These adaptations are broadly considered beneficial for athletic performance as well as for reducing the risk of musculoskeletal injury. However, some practitioners believe that resistance training triggers morphological and physiological adaptations that may impair physical performance and increase injury risk. However, the morphological and physiological adaptations by which resistance training might impair physical performance, the likelihood of these being evoked, and the training program specifications that might promote such impairments, remain largely undefined. This presentation will discuss how selected adaptations evoked by resistance training may not only enhance but could also impair sprint and endurance performance, or lead to increased injury risk. The presentation will address specific resistance training program variables under which such beneficial or maladaptive adaptations may be likely to occur. Specifically, it will be demonstrated that high volumes of resistance training can lead to macro- and microscopic adaptations such as increases in internal moment arms, changes in muscle architecture, and alterations in fiber typology, myocellular morphology, and intra- and intermuscular coordination, that may maximize strength at the expense of speed, or maximize speed at the expense of endurance. Finally, the implications for athletic performance and the design of optimized training protocols also will be discussed.

HMATOLOGICAL AND BLOOD RHEOLOGICAL RESPONSES TO TEN DAILY 1-H ACTIVE HEAT ACCLIMATION SESSIONS IN WOMEN: A RANDOMIZED CONTROLLED TRIAL

NARANG, B., BONCA, E.2, REMEC, K.2, TOMINEC, D.2, RABERIN, A.3, BOUTEN, J.4,5, MCDONNELL, A.C.1, CIUHA, U.1, BROCHERIE, F.4, MEKJAVIC, I.B.1, MILLET, G.P.3, DEBEVEC, T.1,2

1 JOŽEF STEFAN INSTITUTE, SLOVENIA; 2 UNIVERSITY OF LJUBLJANA, SLOVENIA; 3 UNIVERSITY OF LAUSANNE, SWITZERLAND; 4 INSEP, FRANCE; 5 GHENT UNIVERSITY, BELGIUM

INTRODUCTION: Heat acclimation (HA) has been shown to induce plasma volume expansion, which may stimulate compensatory erythropoiesis and increase hemoglobin mass (Hbmass) [1,2]. However, findings are inconsistent, and most studies have focused exclusively on men, despite possible sex-specific differences in thermoregulatory physiology [3,4]. Additionally, these hematological adaptations may modulate blood viscosity, but this has not been explored with heat acclimation in humans. The aim of this study was to examine the effects of a short-term (10-day) active heat acclimation, compared to equivalent thermoneutral training, on hematological and blood rheological parameters in active women.

METHODS: Twenty-eight healthy, active women were randomized into a 10-day HA (n = 15) or thermoneutral (CON; n = 13) training group. Participants cycled for 1 h per day at 40% maximal aerobic power in either 35°C (HA) or 20°C (CON), with 50% relative humidity. Hbmass, along with blood and plasma volumes, were measured in duplicate at baseline and after the intervention using the carbon monoxide rebreathing method. Venous blood samples were also collected for viscosity analysis at varying shear rates. Data were analyzed using a 2x2 (time*group) mixed-effects ANOVA, with statistical significance set at $p < 0.05$. Data are presented as Mean $\pm$ SD.

RESULTS: Blood volume increased similarly in both groups (HA, 4.53 ± 0.67 L vs. 4.91 ± 0.84 L; CON, 4.53 ± 0.81 L vs. 4.66 ± 0.44 L; interaction $p = 0.197$; time $p = 0.012$), underpinned by plasma volume expansion (HA, 2.73 ± 0.38 L vs. 2.96 ± 0.59 L; CON, 2.67 ± 0.52 L vs. 2.87 ± 0.24 L; interaction $p = 0.853$; time $p = 0.011$). Hbmass remained unchanged in both groups (HA, 9.1 ± 1.1 g/kg vs. 9.3 ± 0.9 g/kg; CON, 9.4 ± 0.7 g/kg vs. 9.4 ± 0.8 g/kg; interaction $p = 0.112$; time $p = 0.147$). Native blood viscosity decreased in both groups across increasing shear rates (time $p = 0.063, 0.008, 0.002, 0.006, 0.019$ for 11.25/s, 22.50/s, 45.00/s, 90.00/s, 225.00/s, respectively). This reduction appeared more pronounced in CON, though a significant time*group interaction was only observed at a shear rate of 90.00/s ($p = 0.040$).

CONCLUSION: The addition of a heat stimulus (35°C) to ten consecutive daily 1-h moderate-intensity cycling sessions did not elicit additional hematological benefits compared to equivalent thermoneutral (20°C) training. In particular, both groups exhibited plasma volume expansion with no change in Hbmass. Blood viscosity may be marginally preserved by HA at higher shear rates, though notable decreases were observed in both groups. Overall, these data suggest that short-term HA is insufficient to enhance the hematological response to daily exercise training in healthy, active women, compared to an equivalent thermoneutral training intervention.

PHYSIOLOGICAL DEMANDS AND MODULATORS OF CORE TEMPERATURE DURING MASS PARTICIPATION DISTANCE RUNNING IN A WARM-HUMID ENVIRONMENT

ALHADAD, S., SAKAMOTO, Y., XIAOHAN, Z., TAN, B.Y., ANG, W.H., LAW, L., PRAKAASH, S., RACINAIS, S., MUNIZ-PARDOS, B., BANDIERA, D., COMADRAN, E., IGLESIAS, D.P., PITSILADIS, Y., LEE, J.K.W.

NATIONAL UNIVERSITY OF SINGAPORE

INTRODUCTION: Increased sports participation and global warming are posing a greater heat-related risk to individuals. Sensors assessing physiological parameters (e.g. heart rate (HR) and core temperature (T_{cl}) offer insights into the cardiovascular and thermal demands of individuals exercising in the heat. However, few studies have characterised both cardiovascular and thermal responses in field-based events, with only one study characterising skin temperature (T_{sk}) during a mass participation event, albeit in elite populations rather than in recreational populations who may be more poorly informed [1, 2]. Therefore, we utilised a real-time monitoring system to profile HR, T_{cl} and T_{sk} during mass participation distance running in a warm-humid environment and investigated potential modulators of T_{cl} in a tropical and recreational population.

METHODS: 162 recreational tropical natives participated in a 21km (n=84) or 10km (n=78) run. Real-time continuous monitoring of HR (n=115) and T_{cl} (n=102) was conducted via a multi-user dashboard. Continuous T_{sk} (n=34) was assessed using iButtons at four sites. Splits and finishing times were extracted from official results. Multiple linear regression (MLR) analyses were performed across various parameters and peak T_{cl}.

RESULTS: Participants achieved peak HR, T_{cl} and T_{sk} as high as 209bpm, 40.8°C, and 35.4°C during 21km and 204bpm, 41.1°C and 35.3°C during 10km, respectively. Mean HR (21km: 163±10 (139-188) bpm, 10km: 163±11 (133-180) bpm; p=0.516) and T_{sk} (21km: 32.9±0.9 (31.6-34.9) °C, 10km: 33.0±0.8 (30.9-34.6) °C; p=0.735) were similar between races. Mean T_{cl} was higher in the 21km (38.7±0.5 (37.9-39.8) °C) than the 10km (38.5±0.4 (37.7-39.9) °C; p<0.05). T_{sk} exhibited an inverted-U profile in the 21km but plateaued in the 10km. MLR analysis revealed that starting T_{cl} (16%), mean HR (11%), body surface area (11%), and average speed (7%) significantly contributed to peak T_{cl}.

CONCLUSION: This study is the first to integrate T_{sk} with T_{cl} and HR to provide continuous time-profiles of the cardiovascular and thermal demands of recreational tropical runners, adding to literature that typically focuses on elite populations. The inverted-U T_{sk} profile in the 21km contradicts the plateau seen in laboratory-based findings and may be explained by air velocity fluctuations and/or differences in pacing in longer distance runs. Real-time monitoring and incorporation of modulators of peak T_{cl} can be used to inform targeted interventions to optimise safety of heat-exposed exercising individuals.

THERMOREGULATORY RESPONSES TO A SIMULATED HEAT WAVE ACROSS THE HUMAN LIFESPAN

BROWN, H., JOHN, K., ELLIOTT, J., DESHAYES, T., GAGNON, D., JAY, O., CLARK, B., PÉRIARD, J.

UNIVERSITY OF CANBERRA

INTRODUCTION: Global population ageing, the rising prevalence of non-communicable diseases (e.g. obesity, type 2 diabetes) and sedentary behaviour suggest that humans are becoming less resilient to hotter climates. Personal cooling strategies, such as electric fans or self-dousing, have been shown to attenuate the adverse effects of environmental heat stress in a range of conditions. However, these acute strategies fail to provide individualised long-term benefits, such as those afforded by regular physical activity and high aerobic fitness (VO₂peak). Therefore, this study aimed to determine the relationship between aerobic fitness and thermoregulatory and heart rate responses to a simulated heat wave across the human adult lifespan (18 – 80 y).

METHODS: Sixty-one (27 females) participants (median [IQR]: age 44 y [30, 66], body mass 71.9 kg [63.2, 80.6], VO₂peak 42 ml·kg⁻¹·min⁻¹ [31, 49]) completed an incremental treadmill test, dual x-ray absorptiometry scan, and a six-hour heat

wave simulation (43°C, 25% relative humidity). Rectal temperature (Tre) and heart rate (HR) were measured throughout the heat wave simulation. Whole-body sweat rate (WBSR) and physiological strain index (PSI) were calculated at the end of the exposure. Age and either VO₂peak or body fat (%) were used as predictor variables in Bayesian regression models. Data are presented as posterior means, [95% credible intervals] and probability of direction (%).

RESULTS: Mean Δ Tre during the heat wave simulation was 0.89°C [0.83, 0.95]. An increase in age from 35 to 65 y led to a greater Δ Tre of 0.36°C [0.23, 0.49; >99%], whereas a 20 ml·kg⁻¹·min⁻¹ increase in VO₂peak had little effect (-0.00°C [-0.14, 0.13; 55%]). Mean WBSR was 142 g·m⁻²·h⁻¹ [134, 150] and increasing age from 35 to 65 y lowered WBSR by 13 g·m⁻²·h⁻¹ [-26, 0; 97%], whilst a 20 ml·kg⁻¹·min⁻¹ increase in VO₂peak increased WBSR by 21 g·m⁻²·h⁻¹ [6, 35; >99%]. On average, the percentage of maximum HR (%HRmax) during the last hour of the heat wave simulation was 48% [46, 49]. Increasing age from 35 to 65 y led to a predicted change in %HRmax of -1% [-4, 2; 73%], whereas increasing VO₂peak by 20 ml·kg⁻¹·min⁻¹ changed %HRmax by -5% [-8, -2; >99%]. Mean PSI was low [2.2 [2.0, 2.5]]. Increasing age from 35 to 65 y increased the PSI by 0.6 [0.2, 1.0; >99%], whilst a 20 ml·kg⁻¹·min⁻¹ increase in VO₂peak had no effect (-0.0 [-0.5, 0.4; 59%]). When body fat percentage was included in the models instead of VO₂peak, a 15% increase in body fat reduced WBSR (18 g·m⁻²·h⁻¹ [5, 31; >99%]) and increased %HRmax (5% [2, 7; >99%]) but had no effect on PSI or Δ Tre.

CONCLUSION: Ageing increases thermal and physiological strain during a six-hour heat wave simulation in 43°C and 25% relative humidity. A greater VO₂peak attenuates cardiovascular strain (i.e. %HRmax), likely facilitated by a greater WBSR, but has little effect on Δ Tre or PSI.

A SIX-SESSION HIGH-INTENSITY, INTERMITTENT HEAT ACCLIMATION PROTOCOL IN FEMALES: PHYSIOLOGICAL AND PERCEPTUAL ADAPTATIONS AND SLEEP RESPONSES.

KELLY, M., SNOW, R.J., BROWN, H.A., CONDO, D., GUY, J.H., CHALMERS, S., BROATCH, J.R., ROBERTS, S.R., PÉRIARD, J.D., BOWE, S.J., CARR, A.J.

DEAKIN UNIVERSITY

INTRODUCTION: High-intensity, intermittent exercise heat acclimation (HA) is rarely utilised compared to sub-maximal continuous exercise in the heat. However, high-intensity, intermittent exercise HA is likely more specific and perhaps beneficial for team sport athletes when preparing for competition in hot environments [1]. In females, the precise time course for heat adaptation when using a high-intensity, intermittent HA protocol is unknown, including its effect on sleep outcomes as an important marker of recovery. The aim of this study was to investigate, in female participants, the effects of six sessions of high-intensity, intermittent exercise in the heat conducted over seven days on the time course of the thermophysiological (rectal temperature (Tre), skin temperature (Tsk), heart rate (HR), sweat rate), and perceptual adaptations (thermal discomfort, rating of perceived exertion), and the effect on objective sleep measures (sleep duration, wake after sleep onset).

METHODS: Eleven non-heat acclimatised females (mean $\pm$ SEM: age 27 $\pm$ 2 yr; body mass 69.63 $\pm$ 2.64 kg; body surface area 1.78 $\pm$ 0.04 m²) of recreationally active to highly trained status [2], completed six, 60-min cycling sessions over seven days in the follicular phase of the menstrual cycle. The intermittent exercise protocol alternated work periods of 30 s at ~90% VO₂peak and 30 s active recovery at ~30% VO₂peak (mean work rate ~60% VO₂peak) in the heat (~40°C, ~40% relative humidity). Tre, Tsk, HR, Tre at onset of sweating, rating of perceived exertion, thermal discomfort, and objective sleep were measured. Linear mixed models were used to compare outcomes measures at the third (HA3), fourth (HA4) and sixth (HA6) compared to the first HA session (HA1). Bonferroni post-hoc procedures were used to locate differences where appropriate. Results were considered statistically significant when $p < 0.05$.

RESULTS: In the final HA session (HA6), resting Tre was lower (-0.18°C; $p = 0.001$) compared to the first session (HA1: 37.2 $\pm$ 0.1°C). Mean Tre was lower on HA6 than HA1 (-0.21°C; $p < 0.001$), HA3 (-0.16°C; $p < 0.001$), and HA4 (-0.12°C; $p = 0.001$). Mean Tsk was lower on HA6 than HA1 (-0.20°C; $p < 0.001$). Tre at the onset of sweating was lower on HA6 than HA3 (-0.17°C; $p = 0.035$). Mean HR was lowest in HA6 than HA1 (-9 beats.min⁻¹; $p < 0.001$), HA3 (-3 beats.min⁻¹; $p < 0.001$), and HA4 (-5 beats.min⁻¹; $p < 0.001$). TD was lower on HA6 than HA1 (-242 mm; $p < 0.001$), and RPE lower on HA6 than HA1 (-0.9; $p = 0.003$). There were no significant effects on measures of sleep ($p \geq 0.208$) during the HA protocol.

CONCLUSION: In females, high-intensity, intermittent exercise presents an effective HA protocol that induces rapid thermophysiological and perceptual adaptations, without inducing disturbances in sleep.

PRELIMINARY EVIDENCE OF THE ADDITIVE EFFECT OF ISCHEMIC PRECONDITIONING ON THE TIME-COURSE OF PHYSIOLOGICAL ADAPTATIONS TO HEAT ACCLIMATION

FELSTEAD, A., AGGETT, J., HEFFERNAN, S.M., KILDING, A., MAUNDER, E., NEVOLA, R., PALLISTER, I., WALKER, E., WALDRON, M.

SWANSEA UNIVERSITY

INTRODUCTION: Heat acclimation (HA) is a common strategy to prepare military personnel for heat exposure. Combining HA with ischemic preconditioning (IPC) can enhance physical performance and vascular function, which may have an additive effect on thermo-physiological adaptations, yet this has not been investigated. We evaluated the effects of HA or HA+IPC vs. Control (CON) on the time-course of thermo-physiological adaptations among trained participants.

METHODS: Nineteen participants (5 females, 14 males) were randomly assigned to one of three groups: HA+IPC (n = 7; heat acclimation+ischemic pre-conditioning), HA (n = 7; heat acclimation with sham IPC), or CON (n = 5; Control with Sham IPC). Participants received 8 exercise sessions, interspersed by 4 heat stress tests (HST) at baseline (HST1) and after 3 (HST2), 8 (HST3) and 11 days (HST4) of training. Groups exercised for 60 min at a heart rate ~65% maximum, with HA+IPC and HA in 38°C & 40% relative humidity (RH) and CON in 20°C & 40% RH, following 40 min of repeated bi-lateral lower-limb occlusions or sham. HSTs comprised 35 min of cycling at a heat production (Hprod) of 6 W/kg, followed by an incremental test to exhaustion, with thermo-physiological responses recorded.

RESULTS: Linear mixed models, with control for baseline covariance, revealed group by time interaction effects, with post-hoc tests demonstrating HA+IPC and HA groups to have greater ($P < 0.05$) skin blood perfusion compared to CON during fixed Hprod exercise at both HST2 (~33 & ~8%max, respectively) and HST4 (~20 & ~7%max, respectively), with HA+IPC also greater than HA at HST2 and HST4 (~25 and ~13%max, respectively). HA+IPC also had greater ($P < 0.05$: ~18%max) skin blood perfusion compared to CON in the incremental test of HST2. Group by time interaction effects were also found for heart rate during fixed Hprod exercise, with HA+IPC ~7% lower ($P < 0.05$) between HST1 and HST4. Following group by time interaction effects for local sweat rate, HA (~15%) and HA+IPC (~14%) were found to increase ($P < 0.05$) between HST1 and HST4, which was not found for CON (~3%; $P > 0.05$).

CONCLUSION: These preliminary data demonstrate that HA+IPC and HA enhanced two key thermoeffectors (skin blood flow and local sweating) in response to heat exposure more than exercise alone. The addition of IPC accelerated the improvements in skin blood perfusion after only three days of heat exposure and resulted in greater perfusion at higher exercise intensities. Despite reductions in exercising heart rate in HA+IPC, this did not translate to changes in body temperature or exhaustive performance in the heat. These preliminary findings suggest that IPC could be a useful intervention to accelerate the adaptation of the heat-acclimated phenotype, which has potential use in military settings.

INLAND NORWAY UNIVERSITY OF APPLIED SCIENCES

INTRODUCTION: Exercise training is an effective tool for preventing lifestyle-related diseases [1]. However, individuals exhibit considerable variability in their responses to standardized exercise training programs [2,4]. Sex-based differences may contribute to this variability in adaptive capacity [2,3], but this remains a topic of debate. Studies examining VO₂max changes indicate conflicting results regarding sex differences, both in long-duration (39-52 weeks; [2,4]) and short-duration (≤8 weeks; [3]) training interventions. A recent meta-regression study reported that females demonstrated greater percentage changes in VO₂max compared to males, while absolute changes (mL/min/kg) were comparable between sexes [5]. However, it is still unclear whether long-term aerobic exercise training leads to similar VO₂max changes in females and males. Hence, this study examined whether 11 months of aerobic exercise training induce similar percentage and absolute changes in VO₂max in middle-aged females and males.

METHODS: Untrained but healthy middle-aged females (59±6 years; VO₂max, 27.3±7.5 mL/min/kg; n=12) and males (52±8 years; VO₂max, 38.8±5.3 mL/min/kg; n=15) underwent 48 weeks of aerobic exercise training. The program included 100 cycling sessions (45min each), of which 87 sessions were supervised. Training sessions alternated between high-intensity intervals (4x5min, 5x5min, and 5x8min) and moderate-intensity sessions (6x6min or 45min of continuous exercise). VO₂max was determined before the intervention period, and after 8, 22, 32, 40, and 48 weeks of training. Values were normalized to body mass, and both absolute and percentage changes were analyzed longitudinally using a linear mixed-effects model with repeated measures. Time points and sex were treated as fixed effects, with individual participants modeled as random effects. 95% confidence intervals (CIs) were calculated to interpret the results.

RESULTS: Eleven months of aerobic exercise training increased VO₂max in both females (4.8±1.4 mL/min/kg; 18.4±6.7%) and males (4.6±3.1 mL/min/kg; 12.8±9.3%). No sex differences were observed in absolute VO₂max changes (mL/min/kg) at any time point (95% CIs including zero). However, females demonstrated greater percentage increases in VO₂max compared to males after 32, 40, and 48 weeks of training (4.7, 5.2, and 5.6%-points difference, respectively; 95% CIs not including zero).

CONCLUSION: When middle-aged females and males undergo the same 11-month aerobic exercise training program, absolute VO₂max increases (scaled to body mass) are comparable between sexes. However, females exhibit greater percentage increases in VO₂max compared to males. These findings demonstrate that middle-aged females do not have a reduced capacity to increase VO₂max through aerobic exercise training compared to males.

“LIVE HIGH-TRAIN LOW” INDUCED CHANGES IN THE ERYTHROPOIETIN-ERYTHROFERRONE-HEPCIDIN AXIS AND HEMOGLOBIN MASS IN FEMALE ENDURANCE ATHLETES

KUORELAHTI, T., IHALAINEN, J.K., LINNAMO, V., BADENHORST, C., KETTUNEN, O., MIKKONEN, R.S.

UNIVERSITY OF JYVÄSKYLÄ

INTRODUCTION: Iron availability has been proposed as one of the main factors explaining the high variability in hemoglobin mass (Hbmass) adaptation to hypoxia (1), however, little is known about hypoxia-induced changes in the iron regulatory pathways. In sustained hypoxia, iron availability is supported by the down-regulation of the systemic iron regulator hepcidin via hormones erythroferrone (ERFE) and erythropoietin (EPO). (2) This study investigated the effects of a 21-day live high-train low (LHTL) on iron availability in female endurance athletes by determining the changes in EPO-ERFE-hepcidin axis and routine iron markers serum ferritin and serum transferrin receptor (sTfR) and whether these changes are associated with Hbmass adaptations.

METHODS: 15 participants completed either a 21-day LHTL period in normobaric hypoxia (2500 m, ~18 h·day⁻¹) (INT, n=8) or lived and trained at sea level for the same duration (CON, n=7). All participants conducted PRE and POST tests one to two days before and after the intervention. The tests included Hbmass assessment via the carbon monoxide rebreathing method and resting venous blood samples to test for changes in EPO, ERFE, hepcidin, ferritin, and sTfR. For INT an additional venous blood sample was collected on the 6th morning in hypoxia (MID, 111 ± 5 h in hypoxia) to investigate short-term changes in blood biomarkers.

RESULTS: Normobaric hypoxia increased Hbmass (3.8 ± 2.0 %, p<0.001) in INT, while no changes were detected in CON. In INT, serum EPO increased 35.6 % (p=0.037) from PRE to MID, followed by a -42.4 % decrease from MID to POST (p=0.019). In INT there were no changes in ERFE, hepcidin, or ferritin from PRE to MID or POST but sTfR increased 13.9 % (p=0.013) from PRE to POST. In CON there were no changes in any of the iron markers at all time points. Changes in Hbmass were not associated with changes in ERFE or hepcidin in either group. However, a higher Hbmass was associated with a smaller reduction in ferritin during the first 5 days of hypoxia in INT (r=0.87, p=0.005).

CONCLUSION: The results of the present study suggest that hepcidin and ERFE may not provide additional information regarding changes in iron demand and availability during and within the few days following prolonged hypoxic exposure compared to routine iron markers. The association between Hbmass and serum ferritin, in turn, underlines the necessity of maintaining adequate ferritin levels during hypoxia to support hematological adaptations, thereby supporting the current practical recommendations of dietary and supplementary iron use prior to and during prolonged hypoxia. NO DIFFERENCE IN MYOFIBRILLAR PROTEIN SYNTHESIS RATES OR WHOLE-BODY PROTEIN TURNOVER DURING THE EARLY FOLLICULAR AND MID-LUTEAL PHASES OF THE MENSTRUAL CYCLE

APICELLA, M., PAVIS, G., ABDELRAHMAN, D., MURTON, A., ALAMDARI, N., DIRKS, M., WALL, B., STEPHENS, F.

UNIVERSITY OF EXETER

INTRODUCTION: Research using ovariectomy models in rats and hormone replacement therapy in postmenopausal females suggest, that the female sex hormones oestrogen (O) and progesterone (P) may influence rates of myofibrillar protein synthesis (MyoPS) and, therefore muscle growth/remodelling. However, limited data are available on how fluctuating low and high endogenous O and P concentrations across phases of the menstrual cycle (MC) impact MyoPS in young females. This study aimed to investigate MyoPS in a postabsorptive state and in response to exercise and nutrition, when O and P concentrations are low and high, during the early follicular (EF) and mid-luteal (ML) phases of the MC, respectively. To provide further insight into the effect of sex hormones on MyoPS, whole-body protein turnover and expression of genes involved in muscle mass regulation were also measured.

METHODS: Fourteen healthy females (age: 25±7 y; BMI: 24±2 kg/m²) were recruited to this randomised cross-over study. Following two months of menstrual cycle tracking, participants completed two experimental trials during EF (4±2 d following menses; O 160±60 pmol/L, P 1.3±0.7 nmol/L) and ML phases (7±1 d following luteinising hormone surge; O 729±332 pmol/L, P 40.5±17.7 nmol/L), using best practice methodologies to confirm MC phases. On each visit, participants received a primed continuous infusion of L-[ring-2H5]phenylalanine and L-[3,3-2H2]-tyrosine for 6.5 h. Following a bout of resistance exercise, participants ingested a drink containing 1.5 g of essential amino acids. Muscle biopsies were collected before and during the 3 h postexercise postprandial period to assess MyoPS and gene expression. Blood samples were collected to assess amino acid concentrations and whole-body protein turnover. Two-way ANOVAs were performed to detect changes across MC phases. Data are expressed as means±SD.

RESULTS: Total plasma amino acid concentrations were lower overall in the ML compared to the EF phase (P<0.001). Exercise and drink ingestion increased basal (0.035±0.023 and 0.036±0.013 %·h⁻¹) MyoPS rates between 0-3 h to 0.066±0.028 and 0.060±0.020 %·h⁻¹ (P<0.001), for EF and ML, respectively, with no differences between phases at either time point (P=0.329). Exercise and drink ingestion decreased whole-body protein synthesis below basal rates by 18±5% (P<0.0001), suppressed protein breakdown by 31±6% (P<0.0001), which resulted in whole-body net protein balance shift-

ing from negative to positive ($P < 0.0001$), with no differences between EF and ML phases (all $P > 0.050$). Expression of several genes associated with protein synthesis, muscle remodelling and sex hormone signalling were increased in ML vs EF phase, whereas protein breakdown associated genes were decreased.

CONCLUSION: Despite decreased circulating amino acid concentrations and a gene expression profile consistent with muscle growth, MyoPS, whole-body protein turnover and hence muscle growth/remodelling do not appear to be affected by increased O and P during the ML phase of the MC.

THE IMPACT OF MATERNAL EXERCISE ON PLACENTAL MINERAL TRANSPORT

MARTÍNEZ-ROSALES, E., ACOSTA-MANZANO, P., BAENA-GARCÍA, L., SÁNCHEZ, C., APARICIO, V.A.

UNIVERSITY OF GRANADA

INTRODUCTION: Exercise during pregnancy is associated with improved maternal-fetal outcomes, yet the biological mechanisms linking exercise to placental health remain poorly understood. Emerging evidence suggests that exercise may modulate placental inflammation, oxidative stress, and nutrient transport, potentially influencing levels of minerals. However, the interplay between prenatal exercise, placental mineral homeostasis, and angiogenic protein expression has not been explored. We aimed to investigate the effects of a supervised concurrent exercise program on placental levels of minerals.

METHODS: For the present study specific aims, 45 placentas were randomly selected from women who participated in the GESTAFIT project into exercise ($n=22$) and control ($n=23$) groups. The exercise group followed a concurrent aerobic and strength training program, three 60-minute sessions per week, from the 17th gestational week until birth. Placental levels of toxic minerals (cadmium [Cd], lead [Pb], arsenic [As], cobalt [Co]) and essential elements (copper [Cu], manganese [Mn], zinc [Zn], selenium [Se]) were quantified via inductively coupled plasma mass spectrometry. Statistical analysis was conducted in RStudio v.4.2, with significance set at $p < 0.05$.

RESULTS: After adjusting for confounders such as maternal age and pre-gestational body mass index, the placenta of the mothers who participated in the exercise group presented higher values of Mn [mean difference: 0.18 mg/kg, 95% Confidence Interval (CI)=0.04 to 0.29, $p < 0.01$] and Pb (mean difference= 0.01 mg/kg, 95% CI=0.00 to 0.02, $p = 0.033$) compared to the placentas from the control group, while no significant differences were observed in the other minerals explored.

CONCLUSION: This study highlights the significant role of physical exercise during pregnancy in modulating placental nutrient and protein levels. Women in the exercise group exhibited higher placental manganese (Mn), an essential nutrient for fetal neurodevelopment. These findings suggest that maternal exercise may positively influence placental function and fetal development. However, the unexpected rise in placental lead (Pb), a known neurotoxicant, warrants further investigation. Previous studies suggest that increased bone turnover and calcium metabolism during pregnancy may contribute to lead mobilization, although the mechanisms underlying exercise-induced changes in Pb accumulation remain unclear. Future research should explore the interplay between maternal physical activity, environmental exposures, and placental mineral transport to determine whether these findings have clinical implications.

ANABOLIC AND CATABOLIC HORMONE LEVELS DURING THE MENSTRUATION PHASE IN HIGHLY TRAINED FEMALE ATHLETES

COLLOMP, K., TEULIER, C., OLIVIER, A., BONNIGAL, J., BUISSON, C., CRÉPIN, N., ERICSSON, M., MONGONGU, C., DURON, E., FAVORY, E., ZIMMERMANN, M., AMIOT, V., CASTANIER, C.

PÔLE STAPS, UFR ST, UNIVERSITÉ ORLÉANS

INTRODUCTION: Fluctuations in sex hormones during the normal menstrual cycle (NMC) may significantly affect women's performance and well-being, particularly during the menstrual phase when estradiol (E2) concentrations are lowest (Carmichael et al., 2021). However, there is little literature on anabolic and catabolic hormone levels during this phase in a highly trained population.

METHODS: Therefore we tested hormonal levels in fourteen NMC highly trained female athletes, during the early follicular, with low estradiol concentrations (Low E2) vs. the end follicular/peri-ovulatory phase, with high estradiol concentrations (High E2). We examined the concentration of E2, testosterone (T), sex hormone-binding globulin (SHBG), free estrogen and androgen indexes (i.e., $FEI = E2/SHBG$ and $FAI = T/SHBG$, respectively), dehydroepiandrosterone (DHEA) and cortisol (Cor) basal hormone levels as well as $E2/T$, $DHEA/T$, and Cor/T ratios. Body weight and composition were assessed in parallel by impedancemeter.

RESULTS: In Low E2 vs. High E2 phase, there were significantly lower T concentrations ($p < 0.01$) as well as a significant decrease in FEI, FAI and $E2/T$ ratios ($p < 0.05$), without any change in SHBG, DHEA, cortisol concentrations or in body weight and composition. In addition, no significant difference in $DHEA/T$ or Cor/T ratio was found between Low E2 and High E2 phases.

CONCLUSION: As previously described in the literature on healthy active women (Knutsson et al., 2023), there was a significant change in T across the menstrual cycle, with higher values around the ovulation phase vs. the menstruation phase. While both free estrogen and androgen indexes decreased during the early follicular phase, there did not seem to be any significant modification in the endogenous anabolic/catabolic balance during this phase. Further studies are necessary to

determine whether the fluctuation of E2/T ratio across the menstrual cycle, used as an overtraining biomarker in male subjects (Cadegiani & Kater, 2019), may have performance and/or well-being repercussions in female athletes.

OP-AP12 Training and Testing II - Maturity, Relative Age and Performance

BIOLOGICAL MATURITY, PHYSICAL PERFORMANCE, AND FORCE-VELOCITY MEASURES: A MIXED-LONGITUDINAL ANALYSIS

VOLK, N., RUF, L., FERRAUTI, A.
RUHR UNIVERSITY BOCHUM

INTRODUCTION: Adolescence is marked by significant variability in biological maturation, leading to differences in physical performance among youth athletes despite sharing the same chronological age (CA). These differences influence the timing and magnitude of peak height velocity (PHV), which varies between males (M) and females (F) but also within sexes (1), resulting in different development rates in physical performance qualities (2). Frequent assessment and long-term physical performance monitoring are crucial along the talent pathway. However, there is a lack of normative data on high-level youth athletes, especially considering the varying stages of maturation in both sexes. The study aimed to examine the impact of maturation and gender on physical performance.

METHODS: A mixed-longitudinal study design was used, including 6171 data points from 1478 elite junior tennis players (3633 M: 14.0±2.1yrs; 2538 F: 13.8±1.9yrs) over the last 10 years. Athletes were categorized based on their biological maturity using the maturity offset method into pre-, mid-, and post-PHV. Physical performance was assessed via standardized tests, including anthropometrics, jumping, sprinting, handgrip strength, and endurance. A subsample (n=36) underwent repeated assessments for longitudinal force-velocity (Fv) profile tracking. Correlation and generalized additive model analyses were applied to examine performance differences across maturity stages.

RESULTS: Early matured athletes had superior results relative to their peers at similar CA. Strength and speed-related tasks exhibited the strongest correlations to age, followed by endurance, with M showing higher correlations than F (e.g., CMJ: M: $r=0.74$; F: $r=0.32$). Improvements in 20m sprint times nearly doubled from pre- to post-PHV in M (M:11%; F:6%). F demonstrate greater relative changes during pre-PHV, while M exhibit larger relative increases during mid-PHV (e.g., Yo-Yo IR1; F est. 134m, 37%; M est. 228m, 21%). Longitudinal analysis revealed no significant changes in F0 and v0 over three consecutive times, although individual variations were present.

CONCLUSION: The results indicate that performance improves with age and maturity, though the progression differs between sexes in both rate and magnitude. M exhibit a steep performance incline in mid- and partly post-PHV, especially in strength- and speed-based metrics, likely due to testosterone, increasing muscle mass, and neuromuscular efficiency. F enhance performance the most during pre-PHV before estrogen might restrict the minimal but gradual progression. Fv analysis generally aligns with M increasing values post-PHV, and F do not, although lacking significance. Especially F should start maturation-independent individualized training with the onset of PHV, focusing on plyometrics, speed, and endurance to maximize performance in adulthood. Males should prioritize neuromuscular performance post-PHV and its transfer to sports performance, e.g., sprinting.

CHRONOLOGICAL AGE VS. MATURITY STATUS : WHAT BETTER INFLUENCES YOUNG FEMALE SOCCER PLAYERS' PERFORMANCE ?

GERUS, P.
UNIVERSITE COTE D'AZUR

INTRODUCTION: Young female soccer players are typically grouped by chronological age, but this method ignores the substantial differences in biological maturity that can impact critical performance factors like strength, speed, and coordination. Although studies have examined the influence of age and maturity on male youth athletes, research focusing on female players is still limited. As a result, there is insufficient knowledge about how chronological age and biological maturity interact to influence physical performance and development in young female soccer players. This study aims to

address this gap by analyzing the effects of age groups and biological maturity on physical performance, including speed, jumping ability, change-of-direction (COD) ability, and endurance in young female soccer players.

METHODS: Eighty-two young female soccer players from the same club academy squad participated in this study and were classified into four age groups based on their birth years: U11, U13, U15, and U18. Maturity offset (YPHV) was estimated using anthropometric measurements [Mirwald et al. 2002]. Each subject was categorized into one of three maturity group (i.e, PRE (YPHV <-1); MI (-1≤YPHV≤1) and POST (YPHV > 1)).The assessment of physical performance took place over four separate sessions, during which players underwent a series of standardized tests. These included the 30-15 intermittent fitness test, a 40-meter sprint, the COD 505 test, a countermovement jump (CMJ), and a repeated sprint test consisting of six 20-meter sprints.

RESULTS: Players in the U11 age group consistently demonstrated lower performance across all tests compared to their older counterparts. Similarly, the PRE maturity group, predominantly composed of U11 players along with two U13 players, also exhibited reduced performance levels. U13 players performed worse than those in the U18 category, while U15 players achieved lower results in CMJ, sprint, and COD tests compared to the U18 group. Furthermore, the MI maturity group underperformed in all tests relative to the POST maturity group, which included half of the U15 players and all U18 players.

The correlation between chronological age (AGE) and years from peak height velocity (YPHV) with performance was significant, ranging from 0.59 (YPHV) and 0.58 (AGE) for CMJ to 0.78 (YPHV) and 0.75 (AGE) for the 40-meter sprint time. Correlation coefficients for height and body mass were lower compared to those for AGE and YPHV, further highlighting the stronger influence of biological maturity and age on performance outcomes.

CONCLUSION: This study shows that biological maturity (YPHV) influences performance slightly more than chronological age, particularly in speed, jumping, and change of direction. Grouping players solely by age may overlook key developmental differences. Integrating maturity status into training and talent identification could better optimize player development.

LONGITUDINAL PERFORMANCE TRAJECTORIES FOR YOUTH FEMALE AND MALE SOCCER PLAYERS: 10M-SPRINT PERCENTILE CURVES ADAPTED TO BIOLOGICAL AGE

HERNANDEZ, J., WIDMER, C., COBLEY, S., BORN, D., TAUBE, W., ROMANN, M.

FEDERAL OFFICE OF SPORT

INTRODUCTION: Longitudinal monitoring of performance development could help improve talent identification accuracy in sport, including soccer (1). However, during adolescence, the capability to evaluate performance is confounded by sex-specific inter-individual maturational growth differences which do not necessarily align with chronological age-based evaluation methods. To better consider the influence of maturational growth in performance development data and reduce selection bias, the purpose of the study was to illustrate differences performance percentile curves when evaluated according to maturational age v chronological age. Using this information, a predictive model was generated to develop realistic performance benchmarks and support athlete development.

METHODS: 10m-sprint and anthropometric data were extracted from the Swiss Football Association's online database, ranging from 2014 - 2024. Initially, data from 5115 soccer players (f = 223, m = 4892), aged 9-19 years, with corresponding maturity status (Mirwald) estimates were examined to generate percentile curves, using Lambda-Mu-Sigma (LMS). Then, following screening for longitudinal (3+ measures) only, data on 1881 (f = 63, m = 1818) were examined to identify performance trajectories, generate predictions, and illustrate individualized trajectories, applying Linear Mixed-effects Models (LMMs).

RESULTS: LMS percentile curves based on chronological and biological age were compared and showed significant differences ($t(1013) = 1.21$, $p < 0.001$, $d = 0.39$) in percentile rank improvement for late (v earlier) maturing male players; illustrating differences in performance percentile curves according to maturational age. Similar results were not observed in females, likely due to sample limitations. LMMs identified individualized longitudinal performance trajectories and generated future performance estimates according to chronological and biological age. Finally, a web-based Shiny-App development facilitated evaluation of current performance and predicted future performance relative to others.

CONCLUSION: Percentile ranking improvement of later developing males based on biological v chronological age provides added value in 10m-sprint time assessment. LMMs deployed on longitudinal 10m-sprint data, facilitated the establishment of performance benchmarks and future performance trajectories. Incorporating biological age into modelling allowed individual maturational differences to be better considered, potentially improving predictive accuracy during adolescence. Shiny-App development based on data could provide coaches with maturational considered training objectives, identify likely performance trajectories, and offering a more individualized and maturation-sensitive approach to athlete development and talent identification.

BEHIND BEFORE YOUVE STARTED? LONGITUDINAL CHANGING DEVELOPMENT TRAJECTORIES IN EARLY AND LATE MATURING SWIMMERS.

ABBOTT, S., HOGAN, C., WOOLDRIDGE, J., BARCLAY, G., SALTER, J., COBLEY, S.
THE UNIVERSITY OF SYDNEY

INTRODUCTION: The path to athletic success in many sport contexts is predicated on the development of multiple, interacting, factors over time. For instance, anthropometric, physiological, technical skill, psychological, and training structure potentially all contribute toward optimised development. At youth competition stages, maturational growth has substantial influences upon multiple indices, subsequently affecting performance. In swimming, this is somewhat reflected by maturity biases in participation and performance data (Abbott et al., 2021). Thus, examining and understanding the longitudinal influence of maturational growth on performance would be valuable, identifying hypothesised differing early, normative, and late maturational developmental patterns. Such study findings would also justify the benefit of strategies which could account for maturational differences. This study examined longitudinal trajectories in male and female data in 50 and 200-metre (m) Freestyle events.

METHODS: Participants were male (N= 923; N= 364) and female (N= 725; N= 267) youth 50 and 200m Freestyle swimmers respectively, aged 10–18 years (yrs), who completed anthropometric assessment and competed at sanctioned age-group swim events between 2016–2025. To identify longitudinal trajectories, repeated annual best performance times on 4 or more occasions were examined. To test for maturational influences, participants maturity timing (age at Peak Height Velocity; APHV) was calculated from estimates within 1.5 yrs from PHV (M= 0.66 yrs) and included. Following data screening, trajectories were quantified using longitudinal growth curves. Curves were sequentially modelled using a Linear Mixed Models (LMMs) framework with fixed (age and APHV) and random effects (individual repeated measures) added. To assess maturity influences on longitudinal development, interaction terms were added.

RESULTS: In males and females, LMMs identified maturity timing was influential on nonlinear 50 and 200m performance development. Interaction and model-fit statistics indicated earlier maturation was associated with earlier age and more accelerated performance development. Meanwhile, later maturation reflected slower performance at younger ages; but with sustained, steadier, performance trajectories. By 15 yrs (females) and 17 yrs (males), maturational influences upon rates of performance development had diminished and performance differences dissipated or reversed.

CONCLUSION: Consistently differing performance trajectories according to maturity timing were apparent for male and female 50 and 200m Freestyle. Relative to early-maturing trajectories, normative and later-maturing swimmers had correspondingly slower performance times across age ranges. However, post-PHV, trajectories either converged or reversed, illustrating further dynamics for consideration.

Abbott, S., et al. (2021). Maturity-related developmental inequalities in age-group swimming: The testing of 'Mat-CAPS' for their removal. *Journal of Science and Medicine in Sport*, 24(4), 397-404.

A SURVIVAL ANALYSIS OF DROPOUT AMONG FRENCH SWIMMERS

DIFERNAND, A., MALLET, A., DE LAROCHELAMBERT, Q., PLA, R., MARC, A., BARLIER, K., ANTERO, J., TOUSSAINT, J.F., SE-DEAUD, A.
INSEP

INTRODUCTION: This study examines the dropout rates among French swimmers based on performance levels, sex, and relative age.

METHODS: Using data from 160,861 swimmers under the age of 21, we analyzed the distribution of birth quarters and dropout rates across performance levels. Chi-squared tests were conducted to confirm the significant effect of birth quarter on performance. Kaplan-Meier Survival (KMS) curves were used to evaluate and interpret the impact of sex and relative age on dropout trends.

RESULTS: The results show that dropout peaks occur at 13.16 years for girls and 17.50 years for boys. Analyzing by age year, at 13 years, the top 10% of female swimmers exhibit a dropout rate of 8.7% (9.9% for males), while the bottom 10% show a much higher rate of 78.1% (69.3% for males). By 17 years, the dropout rate rises to 39.6% (28.6% for males) for the top 10% and 91.7% (83.4% for males) for the bottom 10%. KMS curves, stratified by age, reveal similar dropout trends for both sexes below the age of 13. However, after this age, the dropout rate increases more sharply among females, reaching a maximum difference of 4.8% at 17.9 years. Disparities in dropout rates based on birth quarters are most pronounced at 12.7 years for girls (10%) and at 14.7 years for boys (8.1%).

CONCLUSION: This study underscores the significant influence of sex, relative age, and performance level on dropout rates among French swimmers. Higher performance levels are associated with lower dropout rates, and female swimmers display consistently higher dropout rates than their male counterparts.

OP-AP05 Resistance Training

ATHLETES PHYSICAL FITNESS CHANGES AFTER FLYWHEEL CLUSTER-SET AND FLYWHEEL STRAIGHT-SET RESISTANCE TRAINING PROTOCOLS

RYAN, S., RAMIREZ-CAMPILLO, R., BROWNE, D., MOODY, J., BYRNE, P.J.

SOUTH EAST TECHNOLOGICAL UNIVERSITY CARLOW

INTRODUCTION: The aims of this study were to (i) compare the acute physical fitness changes after 6-weeks of flywheel resistance training when using a flywheel cluster-set (FCS) and flywheel straight-set (FSS) protocol and (ii) to monitor the effect of set configuration on flywheel training variable (mean/ peak power outputs and eccentric overload) progression during the intervention period.

METHODS: Twenty-four amateur male field sport athletes ($n=24$) were randomly allocated into one of two groups (FCS and FSS). Participants underwent pre- and post-intervention testing for 20m linear sprints (including a 5m sprint interval), countermovement jump (CMJ) performance (height, force and velocity), change of direction (5-10-5) time, and maximal isometric mid-thigh pull (IMTP) strength (peak vertical force (N)). During the intervention, both FCS and FSS groups performed two weekly sessions of quarter-squats and Romanian deadlifts using 0.050 kg.m² inertial load. The FCS group employed cluster set blocks of three repetitions (3x3x3), with 30-second intra-set rest periods allocated between cluster blocks per session (Ryan et al., 2024b) whereas the FSS group performed four sets of nine repetitions per session. The kmeter apparatus was used to record training variables within sessions and monitor progression of flywheel training performance during the intervention period.

RESULTS: Performance measures were found to be reliable (ICC= 0.876-0.985; CV%= 0.98%-4.82%). A group by time interaction showed a significant ($p=0.043$) difference for the 5m linear sprint distance in favour of the FCS group. Within group analysis for pre- to post-testing for the FCS group showed improvements for 5m ($p=0.016$; effect size [ES]=0.82) and 20m sprint time ($p=0.016$; ES=0.74); COD time ($p<0.001$; ES=0.34-0.75) and CMJ performance (height; $p<0.001$, force; $p=0.012$, velocity; $p=0.025$; ES=0.25-0.45). Similarly, the FSS group reported improvements in COD time ($p\leq 0.050$; ES=0.47-0.49) and CMJ performance (height; $p<0.001$, force; $p=0.030$; ES=0.35-0.53). Additionally, both intervention groups observed no significant improvements in IMTP strength (ES=0.045-0.19).

CONCLUSION: The findings support the usability of both flywheel training protocols to enhance field sport athletic performance. However, the FCS group experienced greater improvements in performance, providing an alternative option for flywheel training through the use of cluster sets.

TIME TO PEAK VELOCITY AS AN INDIRECT MEASURE OF DYNAMIC RATE OF TORQUE DEVELOPMENT

GROSSIO, L., SALVAGGIO, F., BRUSTIO, P.R., RAINOLDI, A., SAMOZINO, P., BOCCIA, G.

UNIVERSITY OF TURIN

INTRODUCTION: The measurement of velocity through accelerometers or linear encoders has become a common practice in resistance training. As peak velocity is dependent to the total impulse expressed during a contraction, practitioners have recently focused on time to peak velocity as a complementary measure, which is thought to better reflect dynamic rate of torque development (RTD). Consequently, the aim of this work is to understand the behavior of this metric at different velocity conditions and its relationship with dynamic RTD and muscle activation.

METHODS: Sixty-four young adults performed two isometric maximal voluntary contractions (MVC) and an incremental load test on a single-leg isoinertial leg extension to obtain their individual torque-velocity relationship and to measure peak torque, peak velocity, time to peak velocity and RTD for each load. The root mean square (RMS) of high-density surface electromyography (HDsEMG) recorded from the vastus lateralis and medialis was quantified in the first 50 ms of each contraction. Torque and EMG signals of dynamic contractions were normalised by the corresponding values obtained during MVC.

Linear hierarchical regression analysis was used to assess the relationship between time to peak velocity (dependent variable), peak velocity and peak RTD as fixed factors. A second model was performed using peak velocity and RMS as fixed factors. Each analysis was performed accounting for repetition's peak torque and considering the intercept and slope of peak velocity of each subject as a random effect.

RESULTS: As expected, time to peak velocity was principally affected by peak velocity ($F = 461.6$, $\beta = -7.4 \times 10^{-1}$, $\eta^2 = 0.80$, $p < 0.001$) but also influenced by peak RTD ($F = 141.3$, $\beta = -1.3 \times 10^{-3}$, $\eta^2 = 0.18$, $p < 0.001$). In the second model, peak velocity retained its primary role in determining time to peak velocity ($F = 475.2$, $\beta = -7.5 \times 10^{-1}$, $\eta^2 = 0.77$, $p < 0.001$) with a significant effect of RMS ($F = 91.9$, $\beta = -9.7 \times 10^{-3}$, $\eta^2 = 0.13$, $p < 0.001$). In each analysis, the independent influence of peak torque was minimal ($\eta^2 \leq 0.01$).

CONCLUSION: We support the theoretical basis for using time to peak velocity as an indirect indicator of the rate of torque development during dynamic resistance training contractions. This is further reinforced by the correlation between early muscle excitation (first 50 ms), which is widely recognized as a key factor influencing explosive contractions, and time to peak velocity.

EFFECT OF DETRAINING ON MUSCLE STRENGTH AND MASS OF LOWER EXTREMITIES AFTER SYSTEMATIC RESISTANCE TRAINING WITH MULTI-JOINT OR SINGLE-JOINT EXERCISES

MPAMPOULIS, T., METHENITIS, S., STASINAKI, A.N., TERZIS, G.

NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS

INTRODUCTION: The use of multi-joint or single-joint resistance exercises is an effective method to increase muscle strength and mass. Yet, it remains unclear if the use of a multi-joint or a single-joint exercise, might result in different loss rates of these adaptations during a detraining period. The purpose of this study was to investigate the effect of 8 weeks detraining on muscle strength and mass of lower extremities after 8 weeks systematic resistance training with either multi-joint or single-joint exercises.

METHODS: Fourteen young moderately trained women (height 173 ± 6 cm, mass 62 ± 10 kg), with no experience in systematic resistance training, followed 8 weeks of unilateral lower extremities' strength training, in which one leg trained with multi-joint exercise (leg press; LP) and the other with single joint exercise (knee extension; KE). The training protocol involved 2 sessions per week, 4 sets X 6 repetitions at 80% of maximal strength for both training interventions. After 8 weeks of training, participants completely abstained from training for another 8 weeks. Unilateral maximum strength (1-RM) in LP and KE, quadriceps' muscle cross sectional area (CSA) at 2 different sites of the thigh length (40%, 60%) and vastus lateralis (VL) thickness (via ultrasonography) were evaluated before training (T1), at the end of systematic training (T2) and at the end of detraining (T3).

RESULTS: Unilateral 1-RM strength increased significantly (LP: $36.5 \pm 11.5\%$ and KE: $28.3 \pm 14.8\%$, respectively, $p < 0.05$) after training, with no difference between interventions ($p > 0.05$). Quadriceps muscle CSA increased at 40% (LP: $10.2 \pm 3.6\%$ and KE: $8.2 \pm 3.4\%$, $p < 0.05$) and at 60% of thigh length (LP: $11.2 \pm 4.5\%$ and KE: $7.1 \pm 3.2\%$, $p < 0.05$) with significant differences between interventions, $p < 0.05$). VL thickness increased significantly (LP: $8.4 \pm 4.5\%$ and KE: $5.6 \pm 5.4\%$, $p < 0.05$) with significant differences between interventions, $p < 0.05$) after systematic training. Unilateral 1RM strength decreased between T2-T3 (LP: $-11.2 \pm 6.3\%$ and KE: $-16.8 \pm 6.5\%$, $p < 0.05$) with significant difference between interventions, $p < 0.05$). Quadriceps' muscle CSA at 40% of thigh length (LP: $-5.9 \pm 2.1\%$ and KE: $-6.3 \pm 3.4\%$, $p < 0.05$) and at 60% of thigh length (LP: $-7.0 \pm 2.8\%$ and KE: $-4.8 \pm 2.1\%$, $p < 0.05$), as well as VL thickness (LP: $-4.9 \pm 3.0\%$ and KE: $-3.2 \pm 3.6\%$, $p < 0.05$) decreased significantly between T2-T3, but with no difference between interventions.

CONCLUSION: These findings indicate that leg press and knee extension resulted in similar increases in 1-RM. On the contrary, the LP led to larger increases in quadriceps muscle mass in comparison to the KE. However, after 8 weeks of detraining, a comparable reduction in muscle mass is anticipated regardless of the type of exercise that was previously implemented. Therefore, the use of a multi-joint resistance exercise is a more effective way to increase muscle mass, yet detraining has a similar effect in muscle mass reduction regardless of the type of exercise used.

THE EFFECT OF POST-ACTIVATION POTENTIATION ENHANCEMENT (PAPE) INDUCED BY ISOMETRIC CONTRACTIONS ON VERTICAL JUMP PERFORMANCE: A SYSTEMATIC REVIEW, THREE-LEVEL META-ANALYSIS AND META-REGRESSION

HE, Z., XUE, Z., QIANG, L., LU, Z., LI, W., WANG, Q., ZHANG, R., XU, Y., TU, J., BAO, D.

LANZHOU UNIVERSITY

INTRODUCTION: There is increasing interest in the post-activation potentiation enhancement (PAPE) effect of isometric contractions, which differ from dynamic isotonic contractions in the factors that influence PAPE and may offer unique advantages for practical applications. However, the complexity and inconsistencies in existing studies present challenges for effectively applying PAPE in training and pre-competition settings. This study aimed to assess the impact of isometric contractions on subsequent vertical jump performance and explore the moderating variables that influence the PAPE effect of isometric contractions.

METHODS: Literature up to December 10, 2024 was searched in five electronic databases. Studies were assessed for eligibility using the PICOS protocol. Risk of bias and study quality were evaluated using a modified Cochrane Collaboration tool and the PEDro scale. A three-level meta-analysis and moderator analysis were conducted using R software and the metafor package. Meta-regression examined the relationship between PAPE effects and factors such as total contraction duration, volume, and measurement timing. Dose-response relationships for different intensity groups were analyzed. Sensitivity analysis and publication bias assessment were performed.

RESULTS: A total of 18 studies were included. For comparison within the isometric group, the three-level model indicated a significant effect favoring post-test ($ES = 0.180$, $p = 0.001$), with all moderators showing significance (significant levels including male individuals, strength training experience ≥ 2 years, moderate volume, moderate duration, short and moderate interval, multi reps, knee angle of $90-140^\circ$). Compared with control group, the effect size significantly favored the isometric group ($ES = 0.349$, $p = 0.003$), with all moderators except volume showing significance. A similar effect was found when compared with dynamic isotonic resistance training ($ES = -0.061$, $p = 0.642$). For comparison within the isometric group, a significant risk of bias at level 2 was found, but no significant risk at level 3. No significant publication bias was detected in the isometric vs control group comparison. Meta-regression analyses revealed inverted U-shaped relationships between vertical jump improvement and time of measurement, total contraction duration, and volume (with optimal improvement at 7.7 min, 7.3 sec, and 7.4 units, respectively). Dose-response relationships showed greater improvements at later time points (> 8 minutes) for maximal intensity and earlier improvements (< 4 minutes) for submaximal intensity. Submaximal intensity favored longer contraction durations (≥ 12 seconds), while maximal intensity benefited from shorter to moderate durations (< 12 seconds). Similar trends were observed for volume.

CONCLUSION: isometric contractions can serve as an effective tool for inducing the PAPE effect on vertical jump, which might be most pronounced with a moderate recovery interval (4-8min), moderate total contraction duration (8-12sec), and moderate volume (6-10 unit). However, the optimal recovery time, total contraction duration may vary when using different intensities. Individuals of male, or with at least two years of strength training may benefit greater from it. When prescribing isometric contractions for PAPE effect, multiple repetitions, holding isometric muscle actions, and maintaining joint angles of 90°~140° are also recommended for better application.

THE EFFECTS OF TRADITIONAL AND AUTOREGULATION METHODS ON RESISTANCE TRAINING PERFORMANCE AND RECOVERY OUTCOMES IN RUGBY PLAYERS: A RANDOMIZED CROSS-OVER TRIAL

DELLO IACONO, A., MACDONALD, C., JUKIC, I., BUCHANAN, J., MARINKOVIC, M., KAVALIAUSKAS, M.

UNIVERSITY OF THE WEST OF SCOTLAND

INTRODUCTION: Resistance training (RT) is fundamental for performance enhancement in various sport disciplines. In team sports, effective RT programming is essential to balance the conditioning stimulus and the concurrent fatigue responses within a microcycle. This is critical during the in-season period when competitions are frequent. The current study investigated the effects of traditional (TRA) and two autoregulation resistance training methods—Objective Autoregulation Rest-Redistribution Training (O-ARRT) and Subjective Autoregulation Rest-Redistribution Training (S-ARRT)—on recovery outcomes in highly trained rugby players during competitive microcycles.

METHODS: Twelve athletes completed a randomized, crossover trial involving three sessions using the barbell back squat exercise, matched for volume (24 repetitions), load (80% of 1RM), and total rest time (540 seconds), but differing in training structure: TRA: 4 sets of 6 repetitions with 180 s of between-set rest; O-ARRT and S-ARRT: personalized structures of clusters, repetitions, and rest intervals regulated according to a velocity loss threshold or perception of the number of repetition in reserve from failure, respectively. Recovery kinetics was investigated at two timepoints, immediately after the experimental sessions and on the day of competition that followed, approximately 48 and 8 hours prior to the official match, respectively. Recovery was assessed through neuromuscular performance (session barbell velocity, countermovement jump height, net propulsive and braking impulse) and perceptual responses (rate of fatigue, perceived recovery status). The effects of the different RT methods were examined using linear mixed-effects models.

RESULTS: The O-ARRT method resulted in significantly higher mean session barbell velocity outputs compared to both TRA ($p < 0.001$, $b = 0.032$ [95% CI: 0.015, 0.049]) and S-ARRT ($p < 0.001$, $b = 0.031$ [95% CI: 0.017, 0.045]). Additionally, O-ARRT resulted in greater recovery of neuromuscular performance and perceived fatigue on match day, with the latter returning to baseline and reduced by 1 unit compared to TRA ($P = 0.033$, $b = -0.98$ [95% CI: -1.88, -0.08]), while braking impulse showed a recovery improvement of 12 N·s ($P = 0.039$, $b = 12.2$ [95% CI: 0.7, 23.7]) compared to TRA.

CONCLUSION: The O-ARRT method demonstrated greater mean velocity outputs, enhanced recovery of kinetic measures, and reduced perceived fatigue compared to the TRA and S-ARRT methods, while yielding similar perceived recovery status outcomes. These results suggest that the O-ARRT method may be a more suitable choice for strength sessions scheduled close to competition. These findings also have affective implications, as autoregulation-based RT offers a personalized approach that may enhance athletes sense of control and motivation to achieve their performance goals.

PERIPHERAL NEUROMUSCULAR FATIGUE INDUCED BY A SIMULATED BASKETBALL MATCH-PLAY

FERIOLI, D.1, FREITAS, T.T.2, MANNUCCI, C.1, CHUNG, L.H.2, MOMBELLI, A.2, ALCARAZ, P.E.2, MAFFIULETTI, N.A.3

1. UNIVERSITY OF MESSINA 2. UCAM RESEARCH CENTER FOR HIGH PERFORMANCE SPORT 3. SCHULTHESS CLINIC ZURICH

INTRODUCTION: Basketball is a high-intensity intermittent team sport that places significant demands on neuromuscular factors to execute quick accelerations, decelerations, jumps, and direction changes [1]. While match-play has been reported to negatively impact physical performance [2], less is known on muscle contractile function and the associated recovery process. Therefore, this study investigated the amount and recovery of knee extensor peripheral neuromuscular fatigue induced by a simulated basketball match-play.

METHODS: Thirteen highly-trained adult male basketball players (age: 25±4 years, stature: 185±9 cm, body mass: 86±14 kg) voluntarily participated in this study. Each player performed a simulated match-play consisting of standardized specific basketball activities. The simulated match-play lasted a total of 63 min with 32 min of activity (i.e., representing real active play time) being performed across quarters. Each quarter involved two 4-min activity bouts and standardized passive seated rest reflecting the likely occurrence of in-game stoppages. Before (PRE), immediately after (POST), 24 h (POST24) and 48 h (POST48) after the simulated match-play, neuromuscular evaluations were performed on the knee extensor muscles to determine the amount and recovery of peripheral fatigue. Electrical stimuli (single pulses and 10-Hz and 100-Hz paired pulses) were delivered in resting conditions to evoke a peak twitch (PT) response, from which maximal rate of torque development (MRTD) and relaxation (MRTR) were also determined. Furthermore, the ratio between 10-Hz and 100-Hz PT (10:100 Hz ratio) was calculated.

RESULTS: Significant time-related changes (one-way repeated measures ANOVA) were observed for single and paired pulses PT (main effect: $P < 0.001$, strong), MRTD ($P < 0.05$, moderate-to-strong), MRTR ($P < 0.05$, minimum-to-strong) and 10:100 Hz ratio ($P < 0.001$, strong). Overall, post hoc analyses revealed that all variables were significantly reduced at POST compared to PRE, but completely restored at POST24.

CONCLUSION: A simulated basketball match-play induced peripheral fatigue in the knee extensor muscles of highly-trained basketball players, that was marked immediately after the match but fully restored 24 h later. The observed decline in the 10:100 Hz ratio is indicative of low-frequency fatigue that however did not last more than 24 h.

COMPARING TRADITIONAL AND SMALL-SIDED GAME WARM-UPS: IMPACT ON WORKLOAD, PERFORMANCE, AND ENJOYMENT IN YOUTH BASKETBALL

CONTE, D.1,2, VANACORE, M.1

1. UNIVERSITY OF ROME FORO ITALICO. 2. LITHUANIAN SPORTS UNIVERSITY.

INTRODUCTION: Traditional warm-up routines (TRAD) in basketball typically involve individual dribbling and shooting drills, or pair-executed give-and-go drills. However, different warm-up typologies can be implemented during basketball training sessions, including small-sided games (SSGs), such as 1v1, 2v2, and 3v3. Although SSG warm-ups might represent a more specific and enjoyable alternative in preparing players for upcoming activities, limited research is available comparing its effects on workload, physical performance, and enjoyment (ENJ) levels with TRAD warm-up routines. Therefore, this study aimed to compare the differences in workload between TRAD and SSG warm-up routines and their effects on physical performance and ENJ in youth basketball players.

METHODS: In a counterbalanced, crossover design, 24 male young basketball players (age: 16.0 ± 0.1 years; stature: 1.82 ± 0.07 m; body mass: 73.8 ± 9.1 kg; training experience: 8.6 ± 3.1 years) completed time-matched (~12-min) SSG and TRAD warm-ups performed in groups of six players on a half-court. Before each warm-up typology, players were required to report their fatigue levels via a rating of fatigue (ROF) scale and to complete an 8-min standardized pre-warm-up performed without a ball. For each warm-up typology, players internal [i.e., rating of perceived exertion (RPE), mean heart rate (HRmean), and peak heart rate (HRpeak)] and external [i.e., movement load (ML) measured via inertial movement units] loads were monitored. Prior to and after each warm-up typology, players physical performance was measured via a 20m sprint (including a 10m split time) and a countermovement jump (CMJ) test, while the 505 test was performed only at the post-warm-up time point. After completing each warm-up, players were also required to report their enjoyment levels (ENJ) using a previously used scale.

RESULTS: No between-group differences were evident for ROF ($p=0.053$), RPE ($p=0.259$), and HRmean ($p=0.053$), while a higher HRpeak was found in SSG compared to TRAD warm-up ($p=0.001$). Conversely, ML was lower in SSG compared to TRAD ($p<0.001$). No interaction, effect of time, or warm-up typology was found in any of the physical performance tests evaluated, except for higher CMJ performance documented for TRAD compared to SSG warm-up routine ($p=0.047$). Finally, no difference was found for ENJ between TRAD and SSG ($p=0.066$).

CONCLUSION: The higher external load in TRAD compared to SSG might be explained by the more static basketball activities (e.g., screening, boxing out) performed in SSG compared to TRAD, which yet elicited a higher internal load (i.e., HRpeak). Basketball coaches should use SSG warm-ups when preparing players for specific activities encompassing basketball-specific static conditions typical of basketball match performance. Moreover, the overall lack of differences in physical performance (except for CMJ) suggests that coaches can use both modalities interchangeably to prepare players for the upcoming training session drills.

THE EFFECTS OF DIFFERENT RE-WARMING STRATEGIES ON LOWER LIMB PERFORMANCE IN COLLEGIATE BASKETBALL PLAYERS

CHONFAI, C., LIANG, J.M., WU, W.L.

KAOHSIUNG MEDICAL UNIVERSITY

INTRODUCTION: Re-warming strategies have been widely investigated as a means to mitigate performance decline following a prolonged passive recovery after warm-up[1,2]. This study hopes to compare the effects of three re-warming strategies—passive rest (PR), plyometric-based potentiation re-warming (PPR), and inertial resistance re-warming (IRR) on lower limb performance in collegiate basketball players.

METHODS: This study recruited nine collegiate basketball players, each of whom performed a 10-minute comprehensive warm-up[3] followed by one of three randomly assigned re-warming strategies: (1) PR: a 10-minute complete rest after the warm-up (control group); (2) PPR: a 3-minute rest, a 4-minute plyometric re-warm including countermovement jumps, short sprints, and lateral shifts, and another 3-minute rest (experimental group 2); and (3) IRR: a 3-minute rest, followed by a 4-minute inertial-resistance re-warm using the Exxentric kPulley Go for squats, short sprints, and lateral shifts, followed by an additional 3-minute rest. Lower limb performance was measured before and after each re-warming strategy, using the My Jump Lab mobile application, Kinvent Physios Kpull tool, and the Lane Agility Drill test to assess agility. The tests including CMJ height (cm), CMJ relative force (N/kg), maximal knee flexion/extension strength (kg), and Lane Agility Drill

Test time (seconds). A two-way repeated measures ANOVA was used to analyze performance differences across conditions and time. The post-hoc test was used for more detailed analysis of significant main effect differences and the partial eta squared values (η^2) was calculated to determine the significance of the findings of two-way repeated measures analysis.

RESULTS: This study found a statistically significant difference in CMJ height and agility over time ($p = 0.02$, $\eta^2 = 0.472$ and $p < 0.01$, $\eta^2 = 0.714$). Additionally, both plyometric-based potentiation re-warming (PPR) and inertial resistance rewarm-up (IRR) showed a significant effect on the knee extension strength of the non-dominant leg compared to the passive rest (PR) group ($p = 0.01$, $\eta^2 = 0.735$). This effect may be attributed to the superior ability of these rewarm-up methods to activate the muscles of the non-dominant leg more effectively than complete rest.

CONCLUSION: The results suggest that an appropriate rewarm-up can enhance lower limb performance and optimize bilateral muscle activation.

IS PRE-GAME NEUROMUSCULAR STATUS ASSOCIATED WITH KEY GAME-RELATED STATISTICS IN MALE BASKETBALL PLAYERS DURING OFFICIAL GAMES?

SANSONE, P., PAGLIARINI, L., POLVERARI, D.

PEGASO TELEMATIC UNIVERSITY

INTRODUCTION: One of the primary goals of the sport performance staff is to ensure athletes arrive at the day of competition in the best conditions possible to perform. This study evaluated if pre-game neuromuscular status is associated with in-game technical-tactical performance of male basketball players during the competitive season.

METHODS: 11 male semiprofessional basketball players (age: 20.1 ± 4.1 years) underwent bilateral countermovement jump testing (no arm-swing) 45 minutes before the start of official games, with jumps recorded and analysed using a valid and reliable smartphone application (MyJump Lab) to calculate the modified Reactive Strength Index (RSImod) (Bishop et al., 2022). Z-scores of RSImod were computed for each player to evaluate variations in individual players' neuromuscular status (Gallo et al., 2015). In-game performance was evaluated by monitoring the following, well-established key basketball technical-tactical indicators (Leicht et al., 2017; Gasperi et al., 2023): points; free-throw-accuracy (FT%); 2-point-shots-accuracy (2P%); 3-point-shots-accuracy (3P%); total rebounds (TREB); assists (AST); turnovers (TO); and Performance Index Rating (PIR), with all variables normalized per minute of playing time. Separate linear-mixed models were performed (using Jamovi statistical software) to evaluate the effect of pre-game RSImod on players' technical-tactical performances.

RESULTS: No effect of RSImod was found on any of the technical-tactical indicators monitored (all $p > 0.05$).

CONCLUSION: Pre-game neuromuscular status is not associated with key technical-tactical performance indicators in male semi-professional basketball, which is likely due to the different performance domains assessed. Future studies should assess more pertinent aspects, such as neuromuscular status with external load metrics, and cognitive and psychological measures with technical-tactical indicators.

SALIVARY PH AS A BIOMARKER FOR INJURY RISK AND TIME-LOSS IN YOUNG BASKETBALL PLAYERS

JÒDAR-PORTAS, A., FORT-VANMEERHAEGHE, A., LÓPEZ-ROS, V., VASILEVA, F., HOMES-AVILA, J., FONT-LLADÓ, R., ÁLVAREZ-HERMS, J., PRATS-PUIG, A.

UNIVERSITY SCHOOL OF HEALTH AND SPORT; RAMÓN LLULL UNIVERSITY; INSTITUTE OF EDUCATIONAL RESEARCH

INTRODUCTION: Studies in young basketball players indicate a high incidence of injuries, therefore accurate identification of players at risk for injury is crucial to implement prevention strategies. Salivary-based diagnostic techniques have been studied as a potential diagnostic tool due to its abundance of biomarkers, non-invasiveness, cost-effectiveness and suitability for field use.

Among all salivary biomarkers, pH levels seem to play an important role in oxygen availability through the Bohr effect, a physiological mechanism that describes in which a lower pH reduces hemoglobins affinity for oxygen facilitating greater oxygen delivery to tissues with increased demands [1]. Given the high physiological demands of basketball players and the importance of efficient oxygen transportation in the sport context, pH levels could be associated with players' injury risk and time-loss.

The aims of the present study were to (1) compare pH levels between injured and non-injured players and (2) investigate differences in total number of injuries suffered and time-loss between pH groups.

METHODS: A total of 124 elite young basketball players (68 male and 64 female) from 12 to 18 years old participated in the study. Preseason salivary pH levels were assessed using test strips. Participants were grouped into tertiles based on their salivary pH values: Acidic, Neutral and Basic. Injury-related variables were registered throughout the season following the protocol detailed in the International Olympic Committee consensus and the OSICS classification system [2].

The data collected were analyzed using IBM SPSS Statistics version 29.0. A Pearson chi-square test was used to compare the distribution of injured players according to pH levels. Non-parametric test of Kruskal Wallis was used to compare the injury-related variables between pH groups.

RESULTS: Significant differences in salivary pH level were observed between injured and non-injured players ($p = 0.042$). Differences in the total number of sport injuries ($p = 0.014$) and time-loss ($p = 0.029$) between pH groups were found. Specifically, players with the highest pH levels (Basic) sustained more sport injuries and greater time-loss due to injury

compared to those players with lower pH (Acidic and Neutral). Same trend was found in non-contact sport ligament injuries ($p = 0.024$).

CONCLUSION: In conclusion, the findings of the study point to a potential relationship between salivary pH levels and sport-related injuries and time-loss. Although further research is needed, the results suggest that salivary pH could serve as a screening tool to detect players with an increased risk of injury.

IMPROVING RISK PREDICTION FOR HEAT STROKE AND RACE DROPOUTS IN ATHLETICS: BEYOND THE WBGT

BANDIERA, D., GARRANDES, F., MATZARAKIS, A., ADAMI, P.E., RACINAIS, S., PITSILADIS, Y., TESSITORE, A., BERMON, S.
UNIVERSITY OF ROME FORO ITALICO

INTRODUCTION: Exercising under strenuous environmental conditions can lead to fatal exertional heat stroke (EHS) if not managed promptly and adequately. Also, the number of athletes who do not finish a race (DNF) is believed to be influenced by environmental stress during competition. To measure heat stress, international federations rely on thermal indices, such as the Wet Bulb Globe Temperature (WBGT) in Athletics. However, the relationship between thermal indices, EHS incidence, and DNF rates in elite endurance athletes remains unclear. The aim of this study was therefore to i) quantify the incidence of EHS and DNF events in World Athletics competitions, ii) examine their association with thermal indices, and iii) develop predictive models to estimate EHS and DNF risk before a race.

METHODS: Eighty Athletics endurance races held between 2019 and 2024 were included in the analysis, encompassing the World Championships and the Olympic Games. Environmental parameters (e.g., temperature, humidity) and WBGT were measured on-site and linked to race-specific details (e.g., distance, race time), and the number of DNF and EHS (called dependent variables) were counted. Additionally, several thermal indices (e.g., PET, mPET, UTCI) and energy expenditure were estimated for each race. To analyse the relationship between predictors and the dependent variables, a linear regression analysis was conducted, with a significance level at 0.05. Additionally, Generalized Additive Models (GAM) with k-fold cross validation were used to assess the prediction power of models on unknown races.

RESULTS: A total of 41 EHS cases were diagnosed among 4938 athletes (8/1000 athlete exposures) with 56 races (70%) reporting no EHS and 24 races (30%) recording between 1 and 5 cases. In average, each race led 6 ± 9 DNF, ranging from 0 to 60. The strongest EHS linear regression was observed for UTCI ($R^2=0.10$, $p=0.003$), while WBGT showed a lower association ($R^2=0.06$, $p=0.025$). For DNF, race distance was the strongest linear regression ($R^2=0.40$, $p<0.001$) while WBGT association was not significant ($R^2=0.01$, $p=0.58$). The best GAM for predicting EHS included temperature, WBGT, mean radiant temperature, and the days elapsed since the last spring onset, with an R^2 of 0.20 ± 0.15 . For DNF, the best GAM included WBGT, race time, and mean velocity, achieving an R^2 of 0.80 ± 0.03 .

CONCLUSION: Our analysis showed that WBGT alone has only a weak linear relationship with EHS and DNF in Athletics and that more recent thermal indices (e.g., UTCI), while improved, still do not demonstrate a sufficiently strong association. Likewise, non-linear prediction models incorporating environmental parameters and race-specific details do not provide a robust estimation of EHS. This suggests that key factors contributing to EHS were not accounted for in our analysis. However, the prediction models for DNF proved to be robust, allowing for an accurate estimation of the number of athletes who will not finish the race, before the start of the competition.

INVESTIGATING THE ASSOCIATION OF GENETIC MARKERS, PREVIOUSLY IDENTIFIED BY GENOME-WIDE ASSOCIATION STUDIES, WITH ACL RUPTURE IN MULTIPLE COHORTS

PHIPSON, C., LAGUETTE, M.J., FIRFIREY, F., SEPTEMBER, A., COLLINS, M.
UNIVERSITY OF CAPE TOWN

INTRODUCTION: Genetic variance is an important risk factor for many musculoskeletal soft-tissue injuries, including ACL rupture. Several direct-to-consumer genetic tests have emerged that claim to be able to test for susceptibility to such injuries[1]. Only a single company uses injury-specific genetic markers based on the findings of genome-wide association studies (GWAS), an arguably more robust and scientifically reliable approach than the traditional candidate gene studies. The genetic markers identified by GWAS used to determine ACL rupture risk include rs188099931 (A/G), rs186727643 (C/T) and rs144051132 (T/A)[2]. However, their viability as reliable markers of injury risk has yet to be critically and scientifically evaluated in independent cohorts. Thus, this study aimed to determine whether rs188099931, rs186727643 and rs144051132 are associated with ACL rupture across multiple population groups.

METHODS: A genetic association study, comprising cases clinically diagnosed with ACL rupture (ACL), a subset of cases who had sustained an ACL rupture via a non-contact mechanism (NON) and a control group (CON), was conducted whereby participants from four cohorts of European ancestry; South African (CON=229, ACL=242, NON=161), Australian (CON=82, ACL=330, NON=149), Polish (CON=147, ACL=142, NON=56) and Swedish (CON=116, ACL=95, NON=79), as well

as a South African mixed ancestry (MA) cohort (CON=106, ACL=99, NON=51), were genotyped for the three variants using TaqMan™ Genotyping assays. Genotype distributions were compared between ACL and CON groups, as well as NON and CON groups.

RESULTS: No significant associations between the three variants and ACL rupture were reported. Furthermore, several genotypes were either absent or rare. Specifically, the rs188099931 GG, rs186727643 TT and rs144051132 AA genotypes were not detected. Six rs188099931 AG [CON(0.2%, n=1) vs ACL(0.6%, n=5), $p=0.410$; CON vs NON(0.7%, n=3), $p=0.448$], one rs186727643 CT [ACL(0.1%, n=1), $p=1.000$; NON(0.2%, n=1), $p=0.589$] and 12 rs144051132 TA [CON(0.7%, n=4) vs ACL(1.0%, n=8), $p=0.770$; CON vs NON(0.9%, n=4), $p=0.819$] genotypes were identified across the European cohorts. In the MA cohort, one rs188099931 AG [CON(0.9%, n=1), $p=1.000$], eight rs186727643 CT [CON(2.8%, n=3) vs ACL(5.1%, n=5), $p=0.486$; NON(2.0%, n=1), $p=0.092$] and three rs144051132 TA [CON(0.9%, n=1) vs ACL(2.0%, n=2), $p=0.611$; NON(2.0%, n=1), $p=0.489$] genotypes were identified. All three heterozygote genotypes were absent from the Swedish cohort, while rs188099931 AG and rs186727643 CT were absent from the Polish cohort. The rs186727643 CT genotype was also absent from the South African cohort.

CONCLUSION: The scientific evidence is too weak to support an association between ACL rupture and rs188099931, rs186727643 or rs144051132. The observed rarity of the effect alleles suggests that the use of these variants as reliable markers of ACL rupture risk is not viable, and we do not support their inclusion as markers of ACL rupture risk in a genetic test.

SPORTS-RELATED HEAD IMPACTS AND CORTICAL AND SUB-CORTICAL BRAIN FUNCTION: DIFFERENCES BETWEEN CONTACT AND NON-CONTACT SPORT ATHLETES

ANDREW, J., DEAN, E., THOMAS, A., PLACK, C., GAFFNEY, C., NUTTALL, H.

LANCASTER UNIVERSITY

INTRODUCTION: Repetitive head impacts in contact sports may have significant effects on neural function even in the absence of a diagnosed concussion. While much attention has been given to the cognitive and motor consequences of concussive injuries, less is known about the impact of sub-concussive head impacts on auditory processing. This is an essential function for communication in dynamic sporting environments but also acts as a physiological marker for brain health. This study investigates how contact sports influence auditory neural responses by comparing cortical and sub-cortical electrophysiological markers between contact and non-contact athletes.

METHODS: We tested $n=54$ tier 2 athletes age (mean $\pm$ SD) (20.24 ± 1.99 years), height (1.76 ± 0.09 m) and body mass (77.2 ± 12.7 kg) divided into two groups of $n=28$ contact sport and $n=26$ non-contact sport athletes. Groups were matched for age (contact: 20.25 ± 1.92 years; non-contact: 20.23 ± 2.1 years, $t(52) = -0.035$, $p > 0.05$) and body mass index (BMI) (contact: 25.38 ± 3.35 ; non-contact: 24.08 ± 2.44 , $t(52) = -1.76$, $p > 0.05$). There was no significant difference in sex distribution (contact: 10 female, 18 male; non-contact: 17 female, 9 male, $\chi^2(1) = 3.63$, $p > 0.05$). Cortical (N100) and sub-cortical (auditory brainstem responses) responses were recorded using 32-channel electroencephalography (EEG) to measure auditory neural processing under two conditions: (i) low neurophysiological stress (no background noise) and (ii) high neurophysiological stress (background noise).

RESULTS: Results from a mixed-model two-way ANOVA revealed a significant main effect of group ($F(1,52) = 4.476$, $p < 0.05$) for the auditory cortical responses, where contact athletes showed a reduced neural response to sound (N100 amplitudes, $-2.07 \pm 1.7\mu V$) compared to non-contact athletes ($-2.81 \pm 1.54\mu V$). There was no significant main effect of stress condition ($F(1,52) = 2.060$, $p > 0.05$) and no significant group $\times$ stress condition interaction ($F(1,52) = 1.822$, $p > 0.05$). Sub-cortical neural responses (F0 amplitudes) showed no significant group ($F(1,52) = 1.246$, $p > 0.05$), stress condition ($F(1,52) = 2.088$, $p > 0.05$) or interaction effect ($F(1,52) = 2.181$, $p > 0.05$).

CONCLUSION: These findings show that cortical auditory processing may be more vulnerable to repetitive sub-concussive head impacts than sub-cortical responses. This suggests that cortical brain areas are more susceptible to impact-induced dysfunction than sub-cortical brain areas, indicating that sub-concussive injury is potentially damaging to cortical neural generators of the auditory N100 response.

PHYSICAL CHARACTERISTICS AND INCIDENCE OF INJURIES IN ELITE PAIR SKATERS: A RETROSPECTIVE SURVEY

CHEN, Y., BAI, Z., DUAN, Y., ZHU, F., ZHU, Y.

BEIJING SPORT UNIVERSITY

INTRODUCTION: Figure skating is a sport that combines art and athletic competition. Technical movements mainly include jumps and spins. Pair skating builds on this with some pair movements like lifts, throws, twist lifts, death spirals and so on. Firstly, due to the technical characteristics of pair skating, there are many overhead movements and also in order to be competitive the athletes have to constantly increase the difficulty, speed and power of their performance, which leads to an increased risk of sports injuries.

METHODS: As a retrospective survey, 20 elite pair skaters (10 male and 10 female) of Team China voluntarily completed a study questionnaire about general demographic information, exercise habits, and injury history from January 1, 2024 to December 31, 2024. A total of 20 questionnaires were distributed and 20 valid questionnaires were recovered, with a valid recovery rate of 100 percent. Survey data on injuries in pairs skaters as well as observational data were summarized and analyzed using SPSS 26.0 and Excel.

RESULTS: In this survey, age of male skaters is 18.1 ± 2.13 years, and training duration is 9.6 ± 2.22 years. Age of female skaters is 13.8 ± 2.15 years, and training duration is 6.6 ± 1.90 years. The age difference between male skaters and female skaters is large. The time of injury was mainly in October(35%), September(20%), November(20%), December(20%). Ranking of injury rate was ice training(100%), physical training(20%), specialized training on land(20%), warm-up exercise on land(5%). And the most common injury parts were knee(50%), ankle(45%), groin(40%), low back(35%). If it was categorized according to different genders, in male skaters, the most common injury parts were knee(50%), shoulder(40%), ankle(30%), groin(30%), low back(30%), and in female skaters, the most common injury parts were ankle(60%), knee(50%), groin(50%), low back(40%). The type of injury was mainly acute(55%).

CONCLUSION: Due to the specificity of pairs skating movement technology, the injury of male athletes and female athletes is different, but the lower limbs are the same parts with more injuries. For their different sports injuries, it is important to develop injury prevention methods to minimize injury.

CORRELATION ANALYSIS OF PATIENT-ORIENTED AND CLINICALLY-ORIENTED FUNCTIONAL ASSESSMENT IN PATIENTS WITH CHRONIC ANKLE INSTABILITY

GOU, X., RUAN, B., GE, R., YANG, Y., GAO, Q.

BEIJING SPORT UNIVERSITY

INTRODUCTION: Chronic ankle instability (CAI) affects up to 40% of individuals following initial ankle sprain. While traditional assessment primarily focuses on clinically-oriented objective measures such as muscle strength and range of motion, the International Ankle Consortium emphasizes incorporating patient-oriented subjective measures through patient-reported outcome measures (PROMs). We hypothesized that correlations exist between patient-oriented and clinically-oriented measures in CAI patients, with distinct patterns between genders. This study investigates these potential correlations and their gender-specific characteristics.

METHODS: Forty-six CAI patients (23 males, 23 females) were evaluated using patient-oriented (Cumberland Ankle Instability Tool [CAIT]) and clinically-oriented measures (Y-Balance Test [YBT] and handheld dynamometer testing for ankle and hip strength). Spearman correlation analysis examined relationships between subjective and objective measures.

RESULTS: Overall analysis: CAIT scores correlated with YBT anterior ($p=0.297$), posteromedial ($p=0.325$), posterolateral ($p=0.355$), composite ($p=0.359$), ankle dorsiflexion ($p=0.319$), eversion ($p=0.302$), and hip external rotation strength ($p=0.316$, all $P<0.05$). Gender differences: Males showed correlations between CAIT and ankle dorsiflexion ($p=0.445$, $P<0.05$) and YBT anterior ($p=0.435$, $P<0.05$), posteromedial ($p=0.491$, $P<0.05$), posterolateral ($p=0.494$, $P<0.05$), composite ($p=0.473$, $P<0.05$); In females, no significant correlations were found between CAIT scores and any clinically-oriented objective measures (all $P>0.05$).

CONCLUSION: The CAIT scores showed significant correlations with YBT performance, ankle dorsiflexion strength, eversion strength, and hip external rotation strength, indicating that the perceived instability in CAI patients is closely related to muscle strength deficits and impairments in dynamic stability. In male patients, CAIT scores were correlated with YBT performance, suggesting that the subjective feeling of instability in males is associated with deficits in dynamic stability. In contrast, no correlations were found between CAIT scores and objective measures in female patients, indicating that the source of their perceived instability requires further investigation.

EMOTIONAL MEMORY RECALL WITH HIGH AROUSAL FACILITATES CORTICOSPINAL EXCITABILITY IN LOWER LIMB MUSCLES

MASHIKI, Y., KANEKO, N., YAMASAKI, D., ISHIKAWA, K., TAKAHASHI, R., KATO, T., NAKAZAWA, K.

THE UNIVERSITY OF TOKYO

INTRODUCTION: Emotional memory refers to the recollection of emotionally significant experiences, which tend to persist longer than neutral experiences and influence behavior by modulating motor control. Previous research has shown that recalling negative emotional memories enhances corticospinal excitability (CSE), a key mechanism underlying motor control [1]. However, given the variety of daily emotions, the impact of discrete emotions (e.g., sadness, anger) on CSE is unclear and requires further investigation. Furthermore, while the effects of emotional memories on CSE have been studied in upper limb muscles, their impact on lower limb muscles remains unexplored. Thus, this study aimed to investigate the effects of discrete emotional memory recall on CSE in lower limb muscles.

METHODS: Twenty-one healthy males (18–29 years old) participated in this study. CSE was assessed using motor-evoked potential (MEP) amplitudes elicited by transcranial magnetic stimulation applied to the primary motor cortex. MEPs were recorded from the soleus, tibialis anterior, medial and lateral gastrocnemius, and rectus femoris muscles. While recalling episodes of happiness, sadness, fear, anger, and neutral (morning routine), 12 MEPs were recorded per condition. Participants rated arousal (high–low) and valence (pleasant–unpleasant) levels of their recalled episodes using the Self-

Assessment Manikin. Statistical analyses included a two-way ANOVA with an aligned rank transform to examine the effects of five muscles and five emotions on MEP amplitudes, followed by a post-hoc contrast test using the ART-C procedure. Additionally, a repeated measures correlation (rmcorr) was conducted to explore relationships between MEP amplitudes and valence/arousal levels. The level of statistical significance was set at $p < 0.05$.

RESULTS: The two-way ANOVA showed a significant main effect of emotions ($p < 0.01$) but not of muscles ($p = 0.99$) or their interaction ($p = 0.82$). Post-hoc contrast tests revealed that recalling emotional memories—whether happiness, sadness, fear, or anger—significantly increased MEP amplitudes compared to neutral (all $p < 0.05$). Given the lack of a significant main effect of muscles, the rmcorr was conducted using mean MEP amplitudes across all muscles and revealed a significant positive correlation between MEP amplitudes and arousal levels ($r = 0.34$, $p < 0.01$).

CONCLUSION: The results indicate that recalling emotional memories enhances CSE in lower limb muscles. Although no significant differences were observed among discrete emotions, MEP amplitudes were positively correlated with arousal levels. These findings suggest that subjective arousal levels rather than emotion types modulate CSE in lower limb muscles. This study advances our understanding of the interplay between emotional memories and motor control, with potential implications for sports performance and rehabilitation strategies.

AFFERENT-LIKE MODULATIONS OF RESPONSES EVOKED BY TRANSCUTANEOUS SPINAL CORD STIMULATION

SORDET, J., MARTIN, A., QUENOT, J.P., PAPAORDANIDOU, M.

INSERM U1093 CAPS

INTRODUCTION: Transcutaneous spinal cord stimulation (tSCS) is an emerging stimulation technique which has known a great interest in the neuromuscular field. It presents the advantage of evoking concomitant responses in multiple muscles of the lower limb, known as posterior root muscle (PRM) reflexes (Minassian et al., 2007). Although the nature of these last is complex, stemming from sensory and/or motor solicitation, they present some similarities with the H-reflex that is evoked by peripheral nerve stimulation (PNS). Conversely to PRM reflex, the H-reflex results mainly from Ia afferents depolarization and its amplitude is modulated by external interventions, known to activate Ia afferents, such as neuromuscular electrical stimulation (NMES) (Vitry et al., 2019), local vibration (LV, Abbruzzese et al., 2001) as well as muscle lengthening (Budini & Tilp, 2016). The aim of this study was to determine whether the modulations observed for the H-reflex are also present for the PRM reflex.

METHODS: Fourteen volunteers participated in two experimental sessions. For both sessions, tSCS electrodes were placed at the L1-L2 level of the spinal cord and under the umbilicus to evoke soleus PRM reflex, while PNS was applied to the posterior tibial nerve, to evoke soleus H-reflex. Amplitudes of H- and PRM reflexes were matched at 85% Hmax. For the first experiment, H- and PRM reflexes were delivered before, during and after 3min of Achilles tendon vibration and 1min of plantar-flexor muscles stretching (amplitude: 20°, speed: 30°/s). For the second experiment, both reflexes were delivered before and following 20-s of NMES applied at a frequency of 20 and 100Hz. The evolution of the amplitude of H- and PRM reflexes was explored before, during (for the first experiment only) and after each intervention.

RESULTS: Results showed similar modulations of the responses evoked by PNS and tSCS for the four interventions that were tested. Indeed, both H- and PRM reflexes were decreased during LV and stretching ($P < 0.001$) with a return to baseline values following the interventions. For the NMES trains, a decrease was observed following the 20-Hz train ($P < 0.02$) while no modulation was revealed for either reflex for the 100-Hz condition ($P = 0.51$).

CONCLUSION: Present results show that H- and PRM reflex are modulated in the same way by different external interventions known to solicitate Ia afferents. This suggests that similar mechanisms, most probably presynaptic inhibitory mechanisms, are responsible for both H- and PRM reflexes modulations during these different interventions. This study provides new proof of the similarities between the two types of reflexes and a better understanding of the nature of PRM reflexes.

SPINAL AND SUPRASPINAL EXCITABILITY DURING NORDIC SKIING USING V2 SKATING TECHNIQUE

LINDINGER, S., KARCZEWSKA-LINDINGER, M., PIITULAINEN, H., GIANGRANDE, A., PIIRAINEN, J.

LABIS-IIS ALBERTI I, BORMIO

INTRODUCTION: Motor control has been divided into spinal and supraspinal control, which can be measured using H-reflex and V-wave methods, respectively (Aagaard et al. 2002, Nevanperä et al. 2023). Utilizing these methods in dynamic conditions are challenging since responses are sensitive with variation on neural behavior, constance of performance (skiing) techniques and distance between stimulating electrode and the nerve. The purpose of the study was to analyze repeatability of H-reflex and V-wave methods during cross-country skiing (XCS). In addition, the role of spinal and supraspinal control was evaluated especially in the gliding phase (balance control).

METHODS: Seven experienced skiers (27-49 yrs) performed 10-15 trials (3- minutes each) using V2 skate on roller skies (treadmill; 2° incline) with a velocity corresponding 85% of their maximal skiing velocity. Soleus muscle V-wave (normalized to Mmax) was measured utilizing supramaximal stimulation intensity (150% Mmax) at 1, 255 and 455 ms after the ground contact of the roller ski to measure the effect of supraspinal output during early contact phase, early gliding phase and the late gliding phase, respectively. H-reflex responses (conditioned with 15% Mmax) were measured with identical delays to evaluate spinal level output.

RESULTS: Between day repeatability (ICC) was moderate to good for the V-wave and H-reflex 0,556-0,748 and 0,663-0,895, respectively. In both responses, there was significant main effect between the phases (V-wave $F=4,529$, $p<0.05$; H-reflex $F=9,969$, $p<0.001$) without significant interactions. V-wave responses increased significantly from contact phase to early gliding phase ($p<0.01$) with no changes between early and late gliding phases. Similarly, H-reflex increased significantly from contact to early gliding phase ($p<0.001$) with again no changes between early and late gliding phases.

CONCLUSION: Stimulation techniques may be a potential tool to investigate motor control during XCS. Spinal output was higher during the gliding phase, likely due to increased supraspinal output, although the possibility of increased reflex loop output cannot be ruled out. Possible limitations of the methods are variation of the muscle length and of the pressure of the stimulation electrodes during skiing, which may be subject dependent behavior. Weaker skiers in pilot trials also showed a tendency to lower repeatability. This is to be further investigated evaluating the method applied to XCS.

FATIGUE- AND RECOVERY-RELATED ALTERATIONS IN CORTICAL AND MOTONEURONAL EXCITABILITY WHEN ASSESSED DURING THE PERFORMANCE OF FAST MAXIMAL-EFFORT ISOKINETIC ELBOW EXTENSIONS IN FEMALES AND MALES

HA, P., BENNETT, E., PEMBERTON, N., PAISH, A., MCNEIL, C., DALTON, B.

UNIVERSITY OF BRITISH COLUMBIA

INTRODUCTION: Despite the task-dependent nature of fatigue, performance fatigability and subsequent neuronal adaptations have primarily been gleaned from isometric tasks. In the context of dynamic contractions, neural excitability is typically assessed using an isometric model prior to and following termination of the repetitive task. Because performance fatigability is also task-dependent, it is most relevant to assess cortical and motoneuronal excitability during a dynamic contraction. At present, it is unclear how neural excitability is affected by repeated, fast muscle-shortening actions. Further, reports on the influence of sex on fatigue-induced power loss after rapid concentric contractions are equivocal. Thus, the purpose of this study was to assess cortical, motoneuronal, and peripheral excitability during and after repetitive, rapid, concentric isokinetic elbow extensions in females and males.

METHODS: Twenty healthy participants (12 females: 26 ± 5 y; 8 males: 28 ± 5 y) performed 120 maximal-effort elbow extensions at an isokinetic velocity of 240 deg/s. Peak power was used to characterize performance fatigability. Neural excitability was assessed during separate elbow extensions during the first 11 (START) and last 11 (END) contractions of the fatigue task, as well as at 10-min post task termination (POSTTEN). Motor evoked potentials (MEPs) from transcranial magnetic stimulation (TMS), cervicomedullary motor evoked potentials (CMEPs) from transmastoid electrical stimulation, and maximal compound muscle action potentials (Mmax) from brachial plexus electrical stimulation were evoked during a TMS-induced silent period while performing concentric elbow extensions. All evoked potentials were induced in the triceps brachii at 90 degrees of elbow flexion. Peripheral excitability was evaluated using Mmax area. To isolate cortical and motoneuronal excitability, the CMEP and MEP area were normalized to the Mmax and CMEP area, respectively.

RESULTS: Peak power (START: 115.73 ± 37.60 W) decreased by $36.2\pm 12.2\%$ ($p<0.01$) with no sex-related differences ($p=0.90$). Compared to START (Mmax area: 0.17 ± 0.04 mV·s, CMEP/Mmax area: 0.16 ± 0.07 , MEP/CMEP area: 1.26 ± 0.54), Mmax area ($p=0.19$) was unaltered by the END, but CMEP/Mmax ($p<0.01$) and MEP/CMEP ($p<0.01$) areas decreased by 31.7 ± 25.3 and $38.3\pm 53.1\%$, respectively, for both sexes ($p\geq 0.16$). At POSTTEN, regardless of sex ($p\geq 0.32$), Mmax area was $9.6\pm 16.7\%$ less than START ($p=0.02$), whereas MEP/CMEP area recovered ($p=0.94$). Interestingly, CMEP/Mmax area was less in females compared to males ($p=0.01$) at POSTTEN, such that female CMEP/Mmax area remained blunted ($37.5\pm 22.9\%$; $p<0.01$), but males recovered ($p=0.96$) compared to START.

CONCLUSION: Taken together, fatigue-induced peak power loss was likely, in part, owing to decreased cortical and motoneuronal excitability for both sexes. Despite cortical excitability recovering fully within 10 min of task termination, motoneuronal excitability remained blunted for females, but not males.

EXPLORING THE NEURAL CORRELATES OF EFFORT PERCEPTION AND PAIN DURING A VISUO-MOTOR TASK PERFORMANCE.

MONTI, I., PICARD, M.E., MANGIN, T., GRUET, M., BAUDRY, S., OTTO, R., CHEN, J., ROY, M., RAINVILLE, P., PAGEAUX, B.

UNIVERSITY OF MONTREAL

INTRODUCTION: The perception of effort (PE) arises from voluntary actions and reflects their costs, influencing decisions to initiate, sustain, or terminate a task. However, the neural network underlying PE remains poorly understood compared with that of pain. Research suggests that pain and PE share common neural substrates, including regions such as insula, supplementary motor area (SMA) and middle cingulate cortex (MCC). This overlap suggests the possibility of an interaction between these two perceptions.

This study aims to: i) replicate the behavioral effect of pain on the PE, ii) investigate the brain mechanism underlying the interaction between pain and effort. We hypothesize that: i) executing a visuo-motor task in the presence of painful stimulations, compared to non-painful stimulations, increases the associated PE, ii) the activity in the MCC and SMA increases during a visuo-motor task in the presence of pain.

METHODS: Forty healthy participants (50% female, aged 18-40) visited the laboratory twice. During the first visit, each participant completed a thermal calibration to identify the temperatures eliciting a perception of warm and intense pain. During the second visit, participants performed a visuo-motor task in an MRI scanner in the presence of painful or warm (control) thermal stimulations. The task consisted of handgrip contractions at 5% or 30% of the participant's maximal force,

with the instruction to match as precisely as possible a line presented on the screen. After each contraction, participants rated their perceived effort and pain/warm intensity on visual analogue scales.

RESULTS: To maintain performance, PE was higher in the presence of pain, compared to the warm stimulation ($p < .001$). fMRI analyses confirm a) robust activations in several cortical regions in response to painful stimuli, including SMA/pre-SMA, MCC, and insula; b) significant activations associated with the visuo-motor task in motor cortices, including the SMA and MCC, as well as the parieto-occipital cortex. Contrary to our hypothesis, fMRI analysis revealed a decreased activation in the SMA and MCC during the visuo-motor task when performed in the presence of pain (fdr-corrected $q = .05$).

CONCLUSION: Our behavioral results confirm that maintaining performance in the presence of pain is effortful. Contrary to our hypothesis, the activity of SMA and ACC decreased. Our finding still suggests a role of these areas in effort and pain integration, offering new insights into the neural mechanisms underlying effort in painful contexts. The decreased activation in SMA and ACC may be linked to the integration of pain processing and action execution; or to the hypoalgesic effect of action execution on pain elaboration. Future studies should investigate the complex interplay between visuo-motor tasks, pain, and PE, to better understand how SMA and ACC activity is related to pain and performance regulation.

EXPLORING FACIAL ACTIONS AS INDICATORS OF AFFECTIVE RESPONSES DURING RESISTANCE EXERCISE: A NOVEL APPROACH TO UNDERSTANDING EXERCISE-RELATED PLEASURE AND DISPLEASURE

KER, T., SPACKMAN, L., KIRK, C., BRAND, R., JONES, L.
SHEFFIELD HALLAM UNIVERSITY

Feelings of pleasure and displeasure (affective valence) during exercise are considered predictors of future exercise behavior (1). Affective valence is typically measured using self-report scales such as the Feeling Scale (FS) (2). However, these measures are susceptible to biases (e.g., social desirability). Consequently, identifying alternative methods that mitigate biases could offer new insights into affective responses during exercise. Facial actions have emerged as promising objective measures, providing real-time, non-verbal indicators of affective states (3). This study examines relationships between facial actions and pleasure-displeasure during resistance exercise.

We hypothesized that FS scores would decrease over repetitions and that specific facial actions (e.g., mouth open, jaw drop) would negatively correlate with FS scores, indicating reduced pleasure.

Using a within-subjects repeated measures design, participants completed 4 sets of 10 repetitions of a seated row exercise with a 3-minute recovery period between sets. Exercise intensity was standardized using each participants 10-repetition maximum. FS responses were collected after repetitions 1, 4, 7, and 10 of each set. Facial actions were continuously recorded and analyzed at 30 frames per second using iMotions (version 8.1).

Preliminary analyses of 40 participants (19 females, 21 males; mean age = 42.8, SD = 12.1) using repeated-measures ANOVA found no significant inter-set FS differences ($p > .05$). However, a repeated-measures ANOVA with Greenhouse-Geisser correction revealed a significant intra-set effect, $F(1.35, 52.71) = 13.98$, $p < .001$, $\eta^2 = .264$, indicating a moderate-to-large effect size.

Post hoc pairwise comparisons (Bonferroni corrected) demonstrated that FS scores significantly decreased between repetitions 4 and 10 ($p < .001$), 4 and 7 ($p = .003$), and 1 and 10 ($p = .006$). No significant differences were observed between repetitions 1 and 4, and 1 and 7 ($p > .05$). The associated mean FS scores rose from repetition 1 to 4 before declining thereafter with values of $M = 2.13$ (SD = 1.28), $M = 2.24$ (SD = 1.21), $M = 1.84$ (SD = 1.41), and $M = 1.47$ (SD = 1.52) at repetitions, 1, 4, 7 and 10, respectively. Pearson correlations revealed significant negative associations between eye widen, cheek raise, and FS scores, indicating these facial actions may reflect affective responses during exercise.

These findings offer support for the use of facial actions as indicators of affective responses during resistance exercise, offering a complementary approach to self-report measures. Future studies may employ these novel methods in different protocols, such as cardiorespiratory exercise, to further validate their utility. Such research could inform the development of exercise protocols that maximize pleasure, ultimately promoting long-term engagement in physical activity.

EFFECTS OF MODERATE-TO-HIGH COMPARED TO LOW INTENSITY SHAM RESISTANCE EXERCISE ON DEPRESSED MOOD STATE AMONG YOUNG ADULT WOMEN WITH ANALOGUE GENERALIZED ANXIETY DISORDER: A RANDOMIZED CONTROLLED TRIAL

O SULLIVAN, D., RICE, J.M., LYONS, M., HERRING, M.P.

UNIVERSITY OF LIMERICK

Young adult women are at risk for Generalized Anxiety Disorder (GAD) and Major Depressive Disorder (MDD), which are highly comorbid. The antidepressant effects of regularly-performed resistance exercise training (RET) are well-established, and have high potential for impact among women. However, little is known about the effects of a single resistance exercise (RE) session on transient feelings of depressed mood, or depressed mood state.

PURPOSE: To examine the acute effects of a single moderate-to-high intensity compared to low intensity sham RE session on depressed mood state among young adult women with subclinical, or analogue GAD (AGAD), with or without comorbid subclinical, or analogue MDD (AMDD).

METHODS: Sixty-six young adult women (22.0 ± 2.8 y) with AGAD were randomized to eight weeks of moderate-to-high intensity, guidelines-based RET, or a low intensity sham RET attention control. An acute randomized controlled trial at week one investigated the effects of a single RE session on mood states. Moderate-to-high intensity participants performed two sets of 8-12 repetitions of eight exercises with loads of approximately 70-80% of their estimated one-repetition maximum (1RM). Low intensity sham RE participants completed the same RE session with lighter loads (~20% 1RM). The Depression subscale of the Profile of Mood States-Brief Form (POMS-B) measured depressed mood state pre- and 10 minutes post-RE. A two group (RE/sham) X two timepoint (pre/post) repeated measures ANOVA examined differences between moderate-to-high and low intensity RE. Sub-analyses were conducted among young adults with comorbid depressive symptoms, AMDD, and pre-exercise POMS-B ≥ 1 and ≥ 4 .

RESULTS: No significant group X time interaction was found for depressed mood state ($F(1,64)=2.40$, $p=0.127$). Significant main effects for time were found among the total sample ($F(1,64)=30.55$, $p<0.001$, $d=0.56-0.59$), and sub-samples with comorbid depressive symptoms ($F(1,56)=29.70$, $p<0.001$, $d=0.55-0.64$), AMDD ($F(1,24)=20.38$, $p<0.001$, $d=0.73-0.90$), and pre-exercise POMS-B ≥ 1 ($F(1,36)=46.23$, $p<0.001$, $d=0.76-1.16$) and ≥ 4 ($F(1,16)=34.07$, $p<0.001$, $d=1.10-1.37$), such that depressed mood state reduced following both moderate-to-high and low intensity RE.

CONCLUSION: Moderate-to-high and low intensity RE elicited similar, within-condition, moderate-to-large magnitude reductions in depressed mood state. Consequently, anxious young women may achieve similar benefits for depressed mood state by performing light intensity RE, requiring less physical effort, as they would from higher intensity, more physically-demanding RE.

BREATHING TECHNIQUES FOR STRESS REDUCTION AND COGNITIVE FUNCTION IMPROVEMENT IN 14 – 17-YEAR-OLD ADOLESCENT ATHLETES POPULATION

PELECKIS, G., SEMJONOVA, G., PLEINICA, S., SURINA, S., TANG, J., LIEPA, A.

RIGA STRADINS UNIVERSITY

INTRODUCTION: Adolescent athletes face an enormous amount of stress due to high demands in their career, and it can impact their physical performance and mental well-being. Since ancient times people have used breathing techniques to help them improve their focus and prepare for the challenges ahead. A number of these techniques have been proven to work for adults, but there is a lack of knowledge of what kind of techniques can be applied to adolescents. The aim of the study was to identify and summarize breathing techniques for stress reduction and cognitive function improvement in 14 – 17-year-old adolescent athletes.

METHODS: Following the Joanna Briggs Institute Manual for Evidence Synthesis searches covered databases: Science Direct; Scopus; Cochrane; ProQuest; PsycINFO; Google Scholar; The Web of Science; EBSCOhost Complete. A scoping review for English-language research covered the period from January 2000 to December 2023, to determine the scope of the use of breathing techniques in an adolescent sports environment.

RESULTS: The results yielded five articles that encompassed such breathing techniques as heart rate variability biofeedback, slow-paced breathing, yogic breathing techniques and relaxation breathing. Stress was a much more prevalent outcome variable as compared to cognitive function.

Discussion: The benefits of breathing techniques have been long documented for various conditions both related and unrelated to sports. The present scoping review affirmed that breathing techniques for adolescent athletes can reduce stress and enhance cognitive capacity. In sports context this can be used as a tool to gauge the nervous system and maximize the benefit of either peak activity moments or the recuperation phase thereafter. As for the adolescent population, more demand and techniques seem to be available for the calming effect.

Conclusions

Breathing techniques can reduce stress and improve cognitive function in adolescent athletes, but more research is needed to determine the most effective techniques.

SOCIAL PHYSICAL ACTIVITY, HUMOR EXPRESSION, AND LONELINESS: A CROSS-SECTIONAL STUDY OF THEIR RELATIONSHIPS

SOGA, K., UNO, A.1, KAWAMURA, T.1, KAMIJO, K.2, TAKI, Y.1

1 TOHOKU UNIVERSITY; 2 CHUKYO UNIVERSITY

INTRODUCTION: Social isolation is a growing concern among older adults. Previous studies have demonstrated that physical activity can enhance social cognitive functioning through multiple neurobiological pathways (Ludyga et al., 2022). This study used a Bayesian sparse regression model with a large-sample dataset to examine the associations among physical activity, humor expression, and loneliness.

METHODS: Older Japanese adults participated in an online survey (n=5213, 50% women, age range: 65–84 years). We used a Bayesian sparse regression model with horseshoe priors to select relevant variables related to loneliness from physical activity patterns (e.g., team/individual sports experience and physical activity), sedentary behavior, and humor outcomes (humor and humor coping styles). A Bayesian structural equation model (SEM) was used to examine how variables with a high inclusion probability (IP) affected loneliness.

RESULTS: The Bayesian sparse regression model identified the following variables with high IP: past exercise experiences with friends (IP = 0.758), present exercise experiences with friends (0.736), affiliative humor (0.899), self-deprecating humor (0.809), self-enhancing humor coping (0.829), and aggressive humor coping (0.755). Past and present exercise experiences with friends, affiliative humor, and self-enhancing humor coping were associated with reduced loneliness. In contrast, self-deprecating and aggressive humor coping was associated with increased loneliness. The Bayesian SEM revealed that both past and present exercise experiences with friends were associated with reduced loneliness through affiliative humor (past: posterior mean = -1.171 [95% Credible Interval = -1.406, -0.936]; present: -1.591 [-1.906, -1.277]) and self-enhancing humor coping (past: -0.547 [-0.700, -0.394]; present: -0.659 [-0.863, -0.455]). Additionally, an indirect pathway associated with greater loneliness was found for past exercise experiences with friends through self-deprecating humor (0.114 [0.013, 0.214]).

CONCLUSION: These findings highlight relationships between exercise experiences with friends and reduced loneliness, which were associated with utilizing affiliative humor and self-enhancing humor coping. In contrast, self-deprecating humor mediates the association between past exercise experiences with friends and increased loneliness. These results provide valuable insights into the development of interventions aimed at reducing loneliness among older adults. Specifically, promoting exercise experiences with friends may encourage positive humor expression and indirectly alleviate loneliness, with the present exercise status playing a more critical role than past exercise experiences.

EFFECTIVENESS OF PHYSICAL EXERCISE INTERVENTIONS ON MENTAL HEALTH AND WELL-BEING IN UNIVERSITY STUDENTS - A SYSTEMATIC REVIEW

PRAISAN, G., BERCHICCI, M., BERTOLLO, M.

UNIVERSITÀ DEGLI STUDI G. DANNUNZIO CHIETI-PESCARA

INTRODUCTION: University and college students might be at higher risk of developing mental health issues due to high stress levels, and depression and anxiety disorders peaking during these years. Physical Exercise Interventions (PEIs) effectively improve mental health and well-being outcomes in various populations [1]. However, existing reviews in university students solely focus on self-reported questionnaires [2]. Therefore, this review aims to investigate the effectiveness of PEIs in university students not only using validated questionnaires, but also psychophysiological measures (e.g., EEG, HRV) to decrease depressive and anxiety symptoms, and to increase well-being.

METHODS: The review followed the PRISMA guidelines. The search was conducted on Web of Science and SPORTDiscus with the following eligibility criteria: university or college students, physical activity intervention, outcomes of depression, anxiety, or well-being, psychophysiological measures, and English language. Reviews and meta-analyses were excluded. The methodological quality of included studies is assessed using the PEDro scale. A meta-analysis will be performed if feasible.

RESULTS: After removing duplicates, the search revealed 2,140 records. The screening process, methodological quality assessment, data extraction, and synthesis are ongoing. We expect that PEIs are efficient strategies to decrease depression and anxiety symptoms and improve well-being in university students [2]. We also expect to find increased HRV after PEIs and modulations of theta and alpha brain rhythms. If meta-analysis is feasible, a small-to-moderate effect size favoring the PEIs is expected [1].

CONCLUSIONS

This review will provide a comprehensive overview of the effectiveness of different PEIs (e.g., aerobic exercise, yoga), comparing the findings to existing literature. It is expected that there will be limited information about the effectiveness of PEIs combined with standard treatment (e.g., psychotherapy) in students. However, research suggests the additional benefits of combining these interventions over standard treatment alone in clinical populations [3]. The findings of this review will help to inform future intervention studies aimed at improving mental health and well-being in university students.

CHANGES OF OCULAR BIOLOGICAL PARAMETERS AND PHYSICAL HEALTH STATUS IN SCHOOL-AGE CHILDREN: A 2-YEAR COHORT STUDY

LI, F., LI, Y., LI, L.

BEIJING NORMAL UNIVERSITY

INTRODUCTION: Myopia has become a growing global health concern, with a particularly high prevalence among school-age children¹. Research has established that various ocular biometric parameters, such as axial length (AL), spherical equivalent refraction (SER), anterior chamber depth (ACD), and axial length-to-corneal radius ratio (AL/CR), are intricately linked to the onset and progression of myopia. Studies highlight a direct correlation between AL elongation and myopia severity². Physical health indicators—such as BMI, height, and cardiorespiratory fitness—also play a crucial role, influencing ocular growth and visual health outcomes. Despite the extensive body of research, there remains a significant gap in long-term longitudinal studies that examine the simultaneous relationship between multiple ocular biological parameters and physical health in school-aged children.

METHODS: This two-year longitudinal study involved a cohort of 313 children (172 boys, 141 girls) aged 8–12, drawn from two urban primary schools in Hefei, China. Annual assessments conducted from 2019 to 2021 measured various ocular biometric parameters and physical health indicators. Myopia was categorized as persistent (diagnosed in both 2019 and 2021), incident (new diagnosis in 2021), or absent (no myopia at both time points). Exclusion criteria included ocular diseases, surgeries, or significant refractive disparities. Physical health evaluations were performed in accordance with national standards, assessing height, weight, BMI, cardiorespiratory fitness, agility, and strength through tests such as the 50-meter run, sit-and-reach, rope skipping, and sit-ups. Statistical analyses, including Pearson correlations, ANOVA, and multivariate linear regression, were performed to identify relationships between ocular and physical variables over time.

RESULTS: The rate of myopia was 25.56% in 2019. By 2020, it soared to 63.90%, and reached 72.20% in 2021, by the end of the study, 226 children (127 boys, 99 girls) were classified as myopic. Consistent trends were observed across all groups, including increased AL, ACD, BMI, height, and strength-related metrics (rope skipping and sit-ups), coupled with decreased SER and flexibility scores ($p < 0.05$). The persistent myopia group exhibited the most pronounced axial elongation and myopia progression ($p < 0.001$). In this group, changes in SER correlated positively with sit-up performance ($r = 0.085, p < 0.05$), while axial length changes correlated negatively with height and positively with vital capacity ($r = -0.201, p < 0.05$; $r = 0.223, p < 0.05$). The increased myopia group showed a significant correlation between ACD changes and sit-up performance ($r = 0.138, p < 0.05$). In none myopia group, slower 50-meter run times corresponded to more stable refractive errors ($r = 0.216, p < 0.05$). Regression analyses revealed that higher BMI changes predicted greater SER shifts in increased myopia group, and improved sit-up performance was linked to higher AL/CR changes ($p < 0.05$).

CONCLUSION: This study demonstrates a significant association between physical fitness indicators—such as BMI, cardiorespiratory endurance, and strength—and ocular biometric parameters. These findings suggest a complex interaction between physical and visual development in school-age children, emphasizing the importance of integrated strategies for myopia prevention. Public health initiatives should consider the combined influence of lifestyle, physical fitness, and visual health, aiming to mitigate myopia progression through holistic interventions.

SCHOOL-BASED PHYSICAL ACTIVITY, ACADEMIC ACHIEVEMENT IN SCIENCE AND HEALTH-RELATED FITNESS: A COMPARISON OF SCHOOL-AGE CHILDREN WITH AND WITHOUT OBESITY.

HERMASSI, S., KONUKMAN, F., GHOUILI, H., DHAHBI, W., KETELHUT, S.

QATAR UNIVERSITY

INTRODUCTION: Physical inactivity among children is a significant public health concern that is becoming increasingly prevalent^{1,2}. This study compared school-based physical activity levels (PA), health-related fitness, and academic achievement (AA) in science-related courses between normal-weight and obese school-age children in Qatar.

METHODS: Fifty healthy schoolchildren were recruited (age: 11.2 ± 0.41 years; body mass: 44.36 ± 8.17 kg; height: 1.56 ± 7.79 m; body mass index (BMI): 21 ± 3.8 kg/m²). Based on age-specific BMI percentiles, the schoolchildren were classified as normal weight ($n=25$) and obese ($n=25$). Measurements included anthropometric data and health-related fitness test (T-half test for change-of-direction (CoD), 10 m sprint, medicine ball throw (MBT) and Stork test of static balance (SB)). AA was assessed through school records of grades point average (GPA) in Mathematics, and Science courses. The International Physical Activity Questionnaire Short Form (IPAQ—SF) was used to estimate the total amount of time engaged in PA per week in children classified into three intensity levels: moderate (4 METs), vigorous (8 METs), and walking. Additionally, the time spent sitting (TS) was calculated to quantify sedentary behaviors.

RESULTS: Comparative analysis showed that obese students exhibited significantly lower AA scores in Mathematics ($80.80 \pm 9.32\%$ vs $89.60 \pm 3.80\%$, $p < 0.001$, $d = 1.24$) and Science ($81.20 \pm 9.92\%$ vs $89.20 \pm 3.73\%$, $p < 0.001$, $d = 1.07$) compared to their normal-weight peers. While health-related fitness performance metrics showed no significant differences between groups. However, obese participants demonstrated significantly higher weekly TS (4.12 ± 2.13 vs 2.92 ± 1.44 hours, $p = 0.02$, $d = 0.66$) and lower engagement in moderate-intensity PA (448.00 ± 291.43 vs 611.20 ± 277.01 MET-minutes/week, $p = 0.05$, $d = 0.57$).

CONCLUSION: This study determined health-related fitness and AA in BMI-stratified obese and non-obese schoolchildren. Surprisingly, the predictor's body weight did not influence the health-related fitness of the students. Descriptive analysis revealed that obese children had lower levels of PA compared to their normal-weight peers. Conversely normal-weight students demonstrated the highest AA. Future studies are required to incorporate additional variables, such as biological maturation status, to validate our observations and enhance accuracy. Schools should consider strategies to increase PA and health-related fitness as part of their overall strategy for improving AA of science-related courses.

THE ROLE OF ACTIVE BREAKS IN ENHANCING COMPLEX PROCESSING SPEED, MATH PERFORMANCE, AND PHYSICAL ACTIVITY

DI FONZA, D., CENTORBI, M., BUONSENSO, A., MELIS, A., DI CLAUDIO, G., CARANGELO, M., BARALLA, F., CALCAGNO, G., DI CAGNO, A., FIORILLI, G.

UNIVERSITY OF MOLISE

INTRODUCTION: The World Health Organization (WHO) recommends that children and adolescents aged 5 to 17 engage in at least 60 minutes of moderate-to-vigorous physical activity (MVPA) daily. Adherence to these guidelines is low across European countries, with a notable increase in physical inactivity among children [1]. To address this concern, Active Breaks (ABs) have gained increasing attention in educational settings. ABs are short periods of physical activity integrated into the school day, aiming to enhance both academic and physical outcomes. Research indicates that ABs can improve attention levels and mathematical performance in primary school children [2]. The present study aimed to evaluate the effects of a 12-week ABs program on academic and physical outcomes in primary school children.

METHODS: This study was designed as a randomized controlled trial (RCT) to assess the effects of a 12-week ABs program, consisting of two daily sessions of 10 to 15 minutes each. A total of eighty third-grade children (aged 7.84 ± 0.37 years) were recruited from Primary School in Italy. Following baseline assessments, classes were randomly assigned to one of four conditions based on the type of AB protocol performed: Creativity-based ABs (CREAT; $n = 20$), Fitness-based ABs (FIT; $n = 20$), Combined ABs (COMB; $n = 20$), and a Control group (CON; $n = 20$). At both baseline and post-intervention, all participants underwent the MOTORFIT test, Reynolds Interference Task (RIT), and the AC-MT 6-11 Math Test.

RESULTS: RM-ANOVA showed significant improvement in mathematical performance, in particular written calculations and problem-solving, where the experimental groups showed significant improvement from pre- to post-assessment ($p < 0.001$) and a significant difference between groups, where the combined group showed better performance than the control group ($p < 0.030$). Significant improvements were found in complex processing speed, where the experimental groups showed significant improvement from pre- to post-assessment ($p < 0.001$) and a significant difference between groups, where the combined group showed better performance than the control group ($p = 0.032$). Finally, significant differences were found in the MOTORFIT test, in particular in single-leg hops, alternating single-leg hops, and hitting a ball with a tennis racket, where the experimental groups achieved better performance than the control group ($p < 0.05$). Significant improvements were found from pre- to post-assessment in the shuttle run test, in the fitness and creative groups ($p < 0.001$).

CONCLUSION: The study demonstrated that the incorporation of active breaks over 12 weeks within the school system led to improvements not only in physical skills but also in math performance and complex processing speed. These enhancements positively impacted two key academic parameters: problem-solving skills and written calculation. Therefore, physical activity promotes motor abilities and better executive functions performance.

PARAMETERIZED NEURAL ACTIVITY FOLLOWING AN ACUTE BOUT OF EXERCISE

NWAKAMMA, M., MORRIS, T., RAINE, L., HILLMAN, C.

NORTHEASTERN UNIVERSITY

INTRODUCTION: Physical exercise has been found to benefit cognitive and brain health. Reported changes in brain function using electroencephalography (EEG) following exercise have traditionally been measured via canonical frequency bands. However, previous studies have yet to investigate changes in brain function while accounting for the aperiodic component of the neural signal. The aperiodic component is a scale free metric of EEG imbedded within the neural signal and has been associated with age, cognitive function, and brain injury. Therefore, we aimed to use resting-state EEG (rs-EEG) to examine within-subject differences in parameterized frontoparietal brain function following an acute bout of high-intensity interval exercise (HIIE) in a cohort of healthy preadolescent children. We hypothesized pre-intervention cardiorespiratory fitness (CRF) would influence any observed changes in brain function following HIIE.

METHODS: Preadolescent children (N=89; 36 female; $9.51 \pm .52$; 9 – 11 years) completed one study visit, which consisted of a two-minute collection of pre-intervention eyes open (EO) rs-EEG data. Next, they performed an intervention consisting of 20 minutes of HIE (squats, high knees, jumping, etc.), followed by a two-minute collection of post-intervention EO rs-EEG (same protocol as the pre-intervention). The FOOOF algorithm was used to parameterize the collected neural signal to account for rs-EEG metrics of the aperiodic component. Power within the canonical frequency bands (e.g., alpha, beta) were also processed and analyzed. Analyses were conducted using a linear mixed effects model, with a time*CRF interaction, accounting for sex, age, body mass index, and baseline maximal heart rate.

RESULTS: A significant main effect of time was observed, which revealed a significant increase of the aperiodic exponent ($b = 3.05$, $p = 0.039$) following HIE. A significant main effect of time also revealed a significant decrease in beta2 relative power ($b = 0.022$, $p = 0.048$) following HIE. No significant effects of time*CRF were observed for either brain metric. However, CRF was associated with beta2 relative power post-exercise ($p = 0.03$) but not pre-exercise ($p = 0.17$).

CONCLUSION: Preliminary findings reveal significant differences in the aperiodic exponent and beta2 relative power following HIE. This suggests that an acute bout of exercise may influence parameterized brain function in healthy preadolescent children. Furthermore, CRF did not influence changes in brain function immediately following exercise. As such, increases in the aperiodic exponent (slope of the power spectrum) coupled with decreases in canonical beta2 activity, within the frontoparietal network, may be a plausible mechanism for the immediate effects of HIE on brain function in healthy preadolescent children. Future research should continue to explore this potential mechanism relative to its effects on cognition.

OUTDOOR PHYSICAL ACTIVITY IS MORE BENEFICIAL THAN INDOOR PHYSICAL ACTIVITY AT IMPROVING COGNITIVE FUNCTION IN YOUNG PEOPLE

WALTERS, G., DRING, K., WILLIAMS, R., NEEDHAM, R., COOPER, S.
NOTTINGHAM TRENT UNIVERSITY

INTRODUCTION: Substantial evidence demonstrates the beneficial acute effect of physical activity on cognitive function in young people. Being outdoors is also reported to improve cognition. Given that being outdoors and physical activity can independently enhance cognitive function, there is a potential synergistic effect between the two i.e. outdoor physical activity may have a larger impact on cognitive function than indoor physical activity.

METHODS: Forty-five children (aged 11-13 years) took part in an identical physical activity session (30-min basketball session) outdoors and indoors. Participants completed cognitive tests (Stroop test, Sternberg paradigm, and Flanker task) before, immediately post-, and 45-minutes post-physical activity. Outcome variables were accuracy (percentage of correct responses) and the response time of correct responses. Data were analysed using mixed effect models, using two-way (condition [indoor, outdoor] * time [pre-, immediately post-, 45-minutes post-physical activity]) repeated measures approach.

RESULTS: Outdoor physical activity improved response time more than indoor physical activity immediately post-physical activity on the 3-item level of the Sternberg Paradigm (-34 vs $+14$ ms; $P = 0.001$) and 45-minutes post-physical activity on the complex level of the Stroop test (-94 vs -20 ms; $P = 0.002$), the 1-item (-9 vs $+71$ ms; $P = 0.026$) and 3-item (-37 vs $+69$ ms; $P < 0.001$) levels of the Sternberg paradigm, and the congruent level of the Flanker test (-44 vs -14 ms; $P = 0.001$). Outdoor physical activity improved accuracy more than indoor physical activity immediately post- ($+2.0$ vs $+0.4$ %; $P = 0.036$) and 45-minutes post- ($+2.0$ vs $+0.1$ %; $P = 0.043$) physical activity on the complex level of the Stroop test and 45-minutes post-physical activity on the incongruent level of the Flanker test (0 vs -3 %; $P = 0.008$).

CONCLUSION: This is the first study to demonstrate superior cognitive benefits of outdoor vs indoor physical activity. Attention restoration theory may explain these findings; it suggests that exposure to nature captures attention in a non-taxing way, allowing cognitive processes to be restored. Young people spend a lot of time in activities requiring prolonged and focused attention (during school) and thus are more likely to experience mental fatigue and a diminished capacity for complex cognitive tasks. Exposure to nature offers an organic, practical, and cost-effective avenue to nurture and support healthy cognitive development during these critical formative years. Therefore, utilising the outdoors/ nature should be a key consideration in the design of future physical activity interventions. The findings of this investigation give support to initiatives that increase time spent outdoors during the school day, e.g., schools to incorporating outdoor physically active learning into their day, increasing the proportion of PE lessons done outdoors, and using initiatives such as the Daily Mile to ensure children get some outdoor physical activity every day.

DIFFERENT PROTEIN PROFILES DISPLAY UNEQUAL CHANGES AFTER RESISTANCE TRAINING, DETRAINING AND RETRAINING

HALONEN, E., RISSANEN, E., KELAHAARA, M., VARJOSALO, M., AHTIAINEN, J., HULMI, J.
UNIVERSITY OF JYVÄSKYLÄ

INTRODUCTION: Proteins can be fractionated in skeletal muscle into e.g. "myofibrillar" and "sarcoplasmic" fractions, but these are not pure and distinct profiles (1). Alternatively, high-end proteomics has been used to examine responses of individual proteins and pathways to exercise. It can also be used to study protein profiles based on cellular location where their molecular function is known to take place (i.e. myofibrillar, ribosomal, nuclear, enzyme etc. proteins). A study design including resistance training (RT), detraining (DT), and retraining (reRT) (2) enables investigating short- and long-term effects of RT and a potential "proteomic memory" of RT. Therefore, the present study aims to investigate the effects of RT, DT, and reRT on different protein profiles based on their cellular location.

METHODS: Thirty untrained participants were divided into training-detraining-retraining (TDR, n = 17) and control (n = 13) groups. TDR underwent 10 weeks of RT, 10 weeks of DT, and 10 weeks of reRT, while the control group remained non-trained for 10 weeks. Biopsies were collected from vastus lateralis in weeks 0, 10, 20 and 30. High-end diaPASEF on the mass spectrometry of the timsTOF Pro 2 platform was used for proteomics analysis. In total, > 3000 unique proteins were quantified. Of these, 50 unique proteins were classified based on the literature as myofibrillar proteins (37 sarcomeric and 13 sarcomere-associated proteins). Other quantified protein profiles were classified using Panther and Gene Ontology Cellular Component databases: mitochondrial (714 proteins), ribosomal (120), and nuclear (992) proteins. Statistics were conducted using ANOVA and Tukey's post hoc test. Statistical significance was set at $p < 0.05$.

RESULTS: The relative abundance of sarcomeric and sarcomere-associated proteins displayed no significant changes between the timepoints, suggesting these protein profiles change at the same rate as muscle proteins on average during RT, DT, and ReRT. Instead, the relative abundance of ribosomal, mitochondrial, and enzyme protein profiles increased during 10 weeks of RT ($p < 0.05$) and compared to controls, and there was a trend for increases in nuclear proteins ($p = 0.06$). Enzymes and mitochondrial proteins returned to baseline after DT, whereas nuclear and ribosomal proteins remained elevated after DT ($p < 0.05$).

CONCLUSION: Herein we show different temporal changes in protein profiles after resistance training depending on their classified cellular location. Our results suggest relative and persisting expansion of nuclear and ribosomal protein profiles after resistance training and detraining. This may indicate proteomic memory of resistance training-induced hypertrophy.

NEW INSIGHTS INTO HUMAN CIRCULATING MIRNA PATH IN EXERCISE: ARTERIOVENOUS CIRCULATING MIRNA BALANCE IN RESPONSE TO MAXIMAL ACUTE EXERCISE

FERNÁNDEZ VIVERO, D., MENENDEZ-RODRIGUEZ, L., BURR, J., GARCIA-FERNANDEZ, L., THOMPSON, K., HALLEN, J., BOUSHEL, R., GARCIA-GONZALEZ, E., GARCIA-PEREZ, G., MARTIN-RINCON, M., GALVAN-ALVAREZ, V., MARTINEZ-CANTON, M., DE NIGRIS, E., FERNANDEZ-GARCIA, B., CALBET, J.A.L., IGLESIAS-GUTIERREZ, E., FERNANDEZ-SANJURJO, M.
UNIVERSIDAD DE OVIEDO, INSTITUTO DE INVESTIGACIÓN SANITARIA DEL PRINCIPADO DE ASTURIAS (ISPA) - FINBA

INTRODUCTION: Physical exercise can modify circulating microRNA (c-miRNA) profiles in vein and skeletal muscle in a stimulus-specific manner [1]. Along with the posttranscriptional regulation of miRNAs, this makes them potential functional biomarkers in sports [2]. However, the specific secretory and target tissues during exercise remain unclear. Therefore, the aim of this study was to assess the c-miRNA profile in femoral artery and vein influenced by exercise and its potential physiological and performance implications. This approach enables to isolate the specific influence of the muscle environment on the c-miRNA profile in vivo.

METHODS: Nine healthy trained men performed a maximal aerobic test where VO_{2max} and W_{peak} were measured. Blood samples were obtained from femoral artery and vein immediately before and after the test. Plasma obtention was followed by miRNA extraction and massive sequencing. Only those c-miRNAs with at least 30 RPM in 3 or more subjects and in one of the two time points or vessels were considered. Principal Component Analysis followed by Principal Component Regression was used to relate c-miRNAs with performance parameters. Functional analysis was performed by a multiscale in silico analysis of the most enriched protein-protein interaction networks.

RESULTS: In basal state, 56% (23 miRNAs) of the c-miRNAs were present in both vessels. Of them, 83% showed a trend to a lower expression level in vein. Consistently, a higher number of c-miRNAs were unique in artery vs vein (16 vs 2), highlighting a possible role of the muscle environment as a target. After the test, 69% (25 miRNAs) of the c-miRNAs were shared between vessels, with a tendency to higher levels in vein (63%). In this line, exclusive vein c-miRNAs were predominant vs artery (1 vs 10), showing a shift of the muscle environment towards increased secretion after exercise. A significant

increase in miR-26b-5p (p-value=0.018, FC=9.07) and miR-21-5p (p-value=0.044, FC=4.04) was found in vein before and after the test, supporting the secretion role. Arterial miR-22-3p, miR-20a-5p, miR-107, miR-106b-5p, miR-103a-3p and let-7g-5p were found to be predictors of VO2max, while post-test arterial levels of miR-486-5p, miR-451a, miR-93-5p, miR-20a-5p, miR-144-3p and miR-15a-5p were related to VO2max. Higher uptake of miR-106b-5p by the muscle environment was correlated with VO2max (p-value=0.021, $r=-0.767$), highlighting a potential implication of c-miRNA regulation on performance. In silico analysis showed that c-miRNAs correlated with VO2max have a high association at the protein level involved in phosphorylation-mediated processes.

CONCLUSION: The specific c-miRNA profiles described in vein and artery suggest a role of secretion and uptake from the muscle environment, influenced by exercise. The association with performance parameters and phosphorylation functions highlights the importance of c-miRNAs in regulating the response to exercise.

NON-INVASIVE MONITORING OF ATHLETES BLOOD BIOCHEMICAL INDICATORS USING URINARY METABOLOMICS: A MULTIVARIATE REGRESSION APPROACH

YANG, Z., WEI, Q.

CHINA INSTITUTION OF SPORT SCIENCE

INTRODUCTION: Precision training management requires continuous monitoring of athletes physiological states to optimize performance and prevent overtraining. Traditional blood tests are limited by their invasiveness and complexity. Urinary metabolomics has emerged as a non-invasive and information-rich alternative, offering significant potential in sports physiology. This study uses UHPLC-HRMS-based urinary metabolomics to develop multivariate regression models for predicting key biochemical markers, including hemoglobin (Hb), testosterone (T), cortisol (C), creatine kinase (CK), and blood urea nitrogen (BUN). These models provide a novel tool for non-invasive monitoring and personalized training strategies.

METHODS: Urine samples from 90 National Level athletes were analyzed using high-throughput targeted metabolomics, detecting 416 metabolites per sample. Stepwise Multiple Linear Regression (SMLR) was employed to construct predictive models for the five biochemical markers. The models were evaluated using Adjusted R^2 , Mean Absolute Error (MAE), and Mean Relative Error (MRE). Predictive performance was validated through cross-validation and independent validation set testing. Comparative analyses with machine learning methods, including Random Forest (RF) and Neural Networks (NN), confirmed the superior stability, accuracy, and interpretability of SMLR.

RESULTS: The models demonstrated high predictive accuracy, with Adjusted R^2 values of 0.855 (Hb), 0.974 (T), 0.915 (C), 0.896 (CK), and 0.970 (BUN). Cross-validation results showed mean relative errors (MRE) of 14.25% (Hb), 21.16% (T), 6.12% (C), 20.8% (CK), and 27.27% (BUN), indicating robust performance across diverse markers. For example, the hemoglobin prediction model is represented as:

$$\hat{Y}_{Hb} = 122.71 - 0.008 \times \text{Indole-3-methyl acetate} - 0.003 \times \text{Glycolithocholic acid 3-Sulfate} + 0.034 \times \text{Dethiobiotin} + 0.003 \times \text{Nicotinamide} - 0.002 \times \text{Riboflavin 5-monophosphate} + 0.001 \times \text{Arginine} - 0.004 \times \text{Octanoylcarnitine} + 0.001 \times \text{X4 Pyridoxic acid} - 0.052 \times \text{N-Acetylphenylalanine} - 0.001 \times \text{Stachyose} - 0.006 \times \text{Methylcysteine} + 0.000054 \times \text{Cystine} - 0.006 \times \text{Adenosine monophosphate AMP} - 0.001 \times \text{Phthalic-acid} - 0.005 \times \text{Sepiapterin} + 0.259 \times \text{Glycoursodeoxycholic acid GUDCA} + 0.00008 \times \text{Uracil} - 0.033 \times \text{Acetylcholine}$$

The models effectively captured metabolic patterns associated with athletes physiological states, offering a non-invasive approach to optimize training and recovery.

CONCLUSION: This study is the first to establish urinary metabolomics-based predictive models for multiple biochemical markers, providing a non-invasive and efficient tool for athlete monitoring. Despite a higher MRE for BUN, the model offers valuable insights for optimizing recovery strategies. Future research will expand the sample size and explore advanced machine learning techniques to enhance predictive accuracy and applicability.

LONGITUDINAL CHANGES IN METABOLIC PHENOTYPE RESPONSE TO A 7 X 200 M HIGH-INTENSITY SWIMMING SESSION IN HIGH-PERFORMANCE MALE AND FEMALE SWIMMERS

HEIDENREICH, L., MITCHELL, L., CATO, L., LAWLER, N., GOLDSMITH, C., KOZLOVSKAIA, M., PYNE, D., SUPPIAH, H., GOVUS, A.
LA TROBE UNIVERSITY

INTRODUCTION: Swimming training combines high-volume, low-intensity work with high-intensity intervals, eliciting diverse physiological responses. Most (70-85%) swimming training occurs below the second lactate threshold, with <15% above it (Hellard et al., 2019). However, excessive low-intensity work near high-intensity thresholds may hinder metabolic adaptations. While lap times, heart rate, and blood lactate monitor performance, they provide limited physiological insight. Metabolic profiling offers a deeper view of long-term adaptations, yet longitudinal studies in swimming are rare due to sampling challenges and limited access to elite athletes. Here we examined metabolic phenotype changes in high-performance swimmers undergoing an 8-week high-intensity training program.

METHODS: Fourteen elite swimmers (8 males, 6 females; mean age 20.6 ± 1.6 years) ranked in Australia's top 200 completed a biweekly, standardised 7 x 200 m high-intensity swimming trial for 8 weeks. They adhered to a dietitian-prescribed diet and tracked daily wellness. Capillary finger prick blood samples, collected pre- and post-trial, were ana-

lysed using ¹H NMR and targeted LC-MS to assess metabolic phenotypes. Temporal changes were investigated using multivariate (ANOVA simultaneous components analysis) and univariate (linear mixed model) analyses.

RESULTS: Preliminary findings revealed distinct metabolic profiles over time, with sex-specific and individual variations. Key metabolites differentiating males and females were linked to oxidative stress (phosphocholines) and lipid metabolism (lipoproteins, sphingomyelins, ceramides). Further analysis will explore metabolite variability temporal shifts in metabolic phenotype.

CONCLUSION: This study enhances the understanding of molecular responses to training, supporting individualised training, recovery, and nutrition strategies. Findings may inform sport-specific metabolite monitoring panels, aiding coaches and sport scientists to prescribe training that optimise swimmers' performance.

ASSOCIATION BETWEEN ACTN-3 C.1729C>T POLYMORPHISM AND SHORT LINEAR SPRINT PERFORMANCE IN YOUTH FEMALE VOLLEYBALL PLAYERS.

TOCCO, F., CALO, C.M., FLORE, L., MURA, S., FRAU, F., CIESZCZYK, P., MASSIDDA, M.
CAGLIARI UNIVERSITY

INTRODUCTION: Quick accelerations and vertical jumping are key components of volleyball game [1;2]. Due to its short dimensions, volleyball court involves relatively short-distance sprints as well as quick movements [3]. Consequently, the volleyball performance is directly affected by the capacity of producing power in sprinting actions [4, 5]. The ACTN-3 c.1729C>T polymorphism is one of the genetic marker most studied in the field of sport sciences and it has been associated with sprint performance [6]. It codes for the α -actinin-3 protein, which is a decisive factor in the ability to produce high-power, high-velocity muscular contractions required for sprinting performance [7]. This study examined the influence of a common genetic variant in the alpha actinin-3 gene (ACTN-3, c.1729C>T (rs1815739)) on short linear sprint performance in youth female volleyball players. We hypothesized that volleyball players harbouring the C allele would have a best sprint performance than those players with the TT genotype.

METHODS: This was a cross-sectional study, conducted in a single visit. A total of 57 female youth sub-elite volleyball players (15.1 ± 1.1 years) participated in the study. Anthropometric variables such as weight and stature were measured and 5 meters linear sprint was assessed using 2 pairs of timing gates (Witty Gate, Microgate USA). Genomic DNA was extracted using a buccal swab, and the ACTN-3 genotyping was performed using a RFLP PCR method.

RESULTS: No significant differences have been found in age, training volume, BMI and in the distribution of positional roles across ACTN-3 genotypes ($p > 0.05$). The main finding was that CC players performed significantly better linear running speed than TT players ($CC = 1.23 \pm 0.09$ sec vs $TT = 1.37 \pm 0.08$ sec, $p = 0.004$). Moreover, the players harbouring a copy of the C allele ($CC+CT$ genotypes) showed a better sprint time than players carriers of the TT genotype ($CC+CT = 1.26 \pm 0.09$ sec vs $TT = 1.37 \pm 0.08$ sec, $p = 0.009$). The shorter running time (1.08 sec) was registered for a player carrier of CC genotype, while the higher sprint time (1.49 sec) was obtained by a player carrier of TT genotype. Differences were also found in the sprint test among positions on the field, with liberos that were significantly fastest than setters ($p = 0.021$) and middle blockers ($p = 0.010$). None of libero was carrier of the TT genotype.

CONCLUSION: We found, for the first time, an association between the ACTN-3 polymorphism and linear running speed in youth female volleyball players. If our finding will be replicated in larger research, it could be used in future to adapt the training protocols to enhance volleyball performance.

OP-MH35 Ankle Injuries

CORTICAL CHANGES DURING SINGLE-LEG LATERAL LANDING IN INDIVIDUALS WITH CHRONIC ANKLE INSTABILITY

RUAN, B., YANG, Y., CAI, J., DUAN, C., LIU, R., GAO, Q.
SPORTS MEDICINE AND REHABILITATION CENTER

INTRODUCTION: Chronic ankle instability (CAI) is not only a peripheral musculoskeletal injury but also involves neurophysiological dysfunction. After an initial ankle sprain, 40% of individuals develop CAI, while others (referred to as "Copers") do not, potentially due to central nervous system alterations. Investigating cortical electrophysiological parameters to under-

stand functional changes in brain activity post-injury holds clinical significance, as it may influence rehabilitation strategies. This study aims to assess sensorimotor cortex activation characteristics during single-leg lateral landing in individuals who developed CAI versus Copers.

METHODS: Participants included 46 individuals with CAI (male=23, female=23) and 41 Copers (male=18, female=23). A 64-channel EEG system was used to record cortical activity during a single-leg lateral landing task from a 16 cm-high platform onto a force plate. The α -band power spectral differences in the sensorimotor cortex and time to stabilization (TTS) during landing were analyzed. Statistical analyses included repeated-measures ANOVA (for α -power comparisons within and between groups) and independent t-tests (for TTS).

RESULTS: Individuals with CAI exhibited significantly higher α -power at the C3 electrode (sensorimotor cortex) compared to Copers (CAI: 0.53 ± 0.22 vs. Coper: 0.19 ± 0.28 , $P < 0.001$), while showing significantly lower α -power at the C4 electrode compared to Copers (CAI: 0.42 ± 0.23 vs. Coper: 0.57 ± 0.29 , $P < 0.001$). Within-group comparisons revealed hemispheric asymmetry, with CAI showing higher α -power at C3 compared to C4 ($P < 0.001$), whereas Copers demonstrated the opposite pattern (C4 > C3, $P < 0.001$). Additionally, the time to stabilization (TTS) was significantly shorter in the CAI group compared to the Coper group (CAI: 1.10 ± 0.43 s vs. Coper: 1.98 ± 0.62 s, $P < 0.001$).

CONCLUSION: During single-leg lateral landing, individuals with CAI demonstrated asymmetric sensorimotor cortex activation, which may enhance postural control efficiency. These findings provide neurophysiological evidence for altered neural mechanisms underlying postural adjustments in CAI, highlighting the role of central adaptations in functional recovery.

ACUTE EFFECTS OF TRANSCRANIAL STATIC MAGNETIC STIMULATION OVER THE VISUAL CORTEX ON SENSORY REWEIGHTING IN RECURRENT LATERAL ANKLE SPRAINERS WITH RELYING ON VISUAL INFORMATION

NONOYAMA, S., SHIMOZAWA, Y., MIMA, T., ISAKA, T., TERADA, M.

RITSUMEIKAN UNIVERSITY

INTRODUCTION: Sensorimotor maladaptation may contribute to diminished static postural control in individuals with recurrent ankle sprains (RAS). Individuals with RAS heavily rely on visual cues for maintaining posture [1]. Visual reliance is linked to poor postural control, potentially associated with increased activation in the visual processing cortices. Transcranial static magnetic stimulation (tSMS) is a non-invasive brain stimulation that reduce neural activity at a specific area, including the visual cortex [2]. tSMS over the visual cortex may decrease visual reliance via tSMS-induced reduction of the visual cortex in individuals with RAS. However, no study has explored effectiveness of tSMS in restoring optimal sensory reweighting in those with visual reliance. Therefore, this study aimed to investigate the acute effects of tSMS on sensory reweighting in individuals with RAS relying on visual cues.

METHODS: This randomized, double-blinded placebo-controlled study enrolled 45 participants with RAS from a convenience sample. Participants performed a single-leg assessment of the Clinical Test for Sensory Integration in Balance (CTSIB). Participants relying visual cues were identified by a preference ratio greater than 100 % from the CTSIB. Twenty participants with visual reliance were included ($M=11$, $F=9$; Age= 21.5 ± 1.5 years; Height= 167.1 ± 9.2 cm; Mass= 60.6 ± 8.0 kg) and randomly assigned to a tSMS ($n=10$) or sham group ($n=10$). During intervention, participants sat in an armchair while either a neodymium magnet (tSMS group) or an identical non-magnetic stainless-steel cylinder (sham group) was placed on the scalp over their visual cortex for 30 minutes. Following the intervention, participants completed the CTSIB. The CTSIB variables included scores of somatosensory, visual, vestibular, and preference ratios. Independent t-tests were used to compare absolute change scores for each outcome measure between groups. Cohen's d effect sizes, along with 95% confidence intervals (CI), were calculated for each comparison. Significance was set a priori at $P < 0.05$.

RESULTS: The absolute change scores of the preference ratio showed a trend toward a between-group difference with a large effect size ($P=0.087$, $d=-0.81$, 95% CIs: -1.71, 0.12). No significant findings were observed in other outcome measures ($P > 0.05$).

CONCLUSION: tSMS over the visual cortex demonstrated a trend toward a acute reduction in preference ratio scores. These findings indicate that tSMS might acutely decrease visual reliance during static postural control via tSMS-induced reduction of cortical activity at the visual cortex. Further studies should explore effects of tSMS with somatosensory-targeted interventions for increasing somatosensory use in populations with RAS who exhibit visual dependence.

THE ASSOCIATION BETWEEN FUNCTIONAL ABILITIES AND ANKLE SPRAINS IN NEWLY RECRUITED INFANTRY COMBAT SOLDIERS

SHENHAR, M., DAR, G., FINESTONE, A., WITCHALLS, J., WADDINGTON, G., STEINBERG, N.

LEVINSKY-WINGATE ACADEMIC COLLEGE

INTRODUCTION: Ankle sprain is a common injury in soldiers and comprises approximately 10% of all musculoskeletal injuries in the military. An ankle sprain is a risk factor for recurrent sprains and may impair the soldier's functional abilities. The aim of the study was to examine the associations between ankle sprains and functional abilities such as balance, agility, strength and proprioception in newly recruited soldiers during infantry training.

METHODS: One hundred and seventy-nine soldiers, all males between the ages of 18-21, were assessed throughout their infantry training at baseline (Pre), after 12 weeks (Post), and after additional 10 weeks (Follow up). The assessments included dynamic balance (Y-Balance test YBT), agility (Hexagon hop test), muscle strength (heel raise test) proprioception (Active Movement Extent Discrimination Assessment AMEDA), and 3,000m run. In addition, the participants filled out the Cumberland Ankle Instability Tool (CAIT) for perceived ankle instability. Injury data were collected once every two weeks on personal encounters of the physiotherapist with the soldiers throughout the first 12 weeks of the training. A repeated measures 2-way ANOVA [time (Pre, Post, Follow up) and injury (yes/no sprain)] was performed.

RESULTS: Fifty-two soldiers (29%) were diagnosed with ankle sprains in the first 12 weeks of training.

Time effect was found for hexagon, heel raise and YBT ($p=0.005$, $p<0.001$, $p<0.001$ respectively), the uninjured soldiers improved their performance throughout the training and the injured did not. In the AMEDA the injured improved and the uninjured did not ($p<0.001$), and in 3,000m run both groups improved ($p<0.001$). In the CAIT, both groups worsened ($p<0.001$).

Injury effect was found for YBT, Hexagon, Heel raise ($p<0.001$, $p<0.001$, $p<0.001$ respectively) where the uninjured performed better than the injured; and for the CAIT, where the uninjured reported more ankle stability than the injured ($p<0.001$).

Time*injury interactions were found for Hexagon ($F_{1,143}=15.999$, $p<0.001$) and YBT ($F_{1,144}=10.324$, $p=0.<0.001$), in both measurements the uninjured improved from Pre to Follow up, and the injured did not improve; for AMEDA ($F_{1,137}=3.409$, $p=0.034$) in which the injured improved from Pre to Follow up and the uninjured did not improve; and for the CAIT ($F_{1,154}=13.547$, $p<0.01$) where both groups worsened from Pre to Follow up.

CONCLUSION: Soldiers who sprained their ankles during basic infantry training performed worse than their uninjured peers at Post and Follow up assessments. An ankle sprain affects the soldiers' balance, strength, agility and aerobic fitness. Surprisingly, the injured soldiers' proprioception ability improved throughout the training. The injured soldiers may have been more attentive to the ankle from fear of recurrent sprains and attrition. An intervention program for the prevention of ankle sprains in infantry training is recommended.

JAPANESE BASKETBALL COACHES PERCEPTIONS AND IMPLEMENTATION OF ANKLE SPRAIN PREVENTION

ZHOU, Z., SOMEYA, Y., IZAWA, H., KOMATSU, T., NAKATAKE, M., TAKAZAWA, Y.

JUNTENDO UNIVERSITY

INTRODUCTION: Basketball requires jumping, landing, and rapid changes of direction, all of which place stress on the lower extremities. Ankle sprains have the highest incidence among basketball players, and it has been reported that ankle sprains in adolescence can lead to subsequent chronic ankle instability. Therefore, the prevention of ankle sprains is important, especially with proper coaching on prevention measures. However, coaches' perceptions and implementation of injury prevention are not clear. This study aims to investigate the perceptions and implementation of ankle sprains prevention measures among basketball coaches.

METHODS: A web-based survey was administered to 104 basketball coaches in Japan holding an E-level or higher coaching license, certified by the Japan Basketball Association. "Perception" was assessed through coaches' views on the importance of ankle sprain prevention; "Implementation" was analyzed according to the presence of ankle sprain prevention measures; and "Knowledge" was evaluated based on their awareness that ankle sprains are the most common injuries among basketball players.

RESULTS: After screening, 45 coaches with coaching experience (Age: 38.36 ± 12.14 years, Male: 40 [88.89%], Female: 5 [11.11%]) were analyzed. All respondents ($n=45$) perceived the importance of ankle sprain prevention. On the other hand, the actual implementation of ankle sprain prevention measures was 57.78%. Most coaches (86.67%) understood that ankle sprains are the most common injury in basketball players. However, 13 of 19 coaches (68.42%) who did not implement preventive measures cited a lack of resources for ankle sprain prevention as one of the main causes for non-implementation.

CONCLUSION: Coaches perceived the importance of ankle sprain prevention, but implementation was lacking. A lack of awareness of ankle sprain prevention was one of the reasons for poor implementation.

EFFECTS OF TISSUE FLOSSING ON ANKLE DORSIFLEXION, LOWER LIMB SKELETAL MUSCLE CONTRACTILE CHARACTERISTICS, AND TISSUE OXYGENATION: A RANDOMIZED CROSSOVER STUDY

TEO, J., MUKHERJEE, S.

NANYANG TECHNOLOGICAL UNIVERSITY

INTRODUCTION: Tissue Flossing (TF) as a self-myofascial release technique has gained attention as a pre-activity intervention to improve range-of-motion (ROM) and athletic performance [1]. However, the exact physiological mechanisms underlying these effects are poorly understood [2,3]. Initially involving both occlusion and movement under compression [4], recent studies have instead used floss bands to only induce occlusion on stationary participants [5]. This study investigated if movement is an essential component of TF and assessed whether TF leads to any neuromuscular or hemodynamic changes.

METHODS: Twenty-four high-intensity intermittent team sport athletes (age: 21-30years; height: 173.08 ± 5.68 cm; weight: 70.14 ± 13.06 kg) participated in a randomized crossover study. Participants underwent both movement TF (MTF) and sta-

tionary TF (STF) for quadriceps (RF, VL, VM) and calf (GL, GM) muscles. Three assessments were performed: the weight bearing lunge test (WBLT) for ankle dorsiflexion (DFROM), tensiomyography (TMG) for muscle contractile characteristics (Tc, Td, Tr, Ts, Dm), and near-infrared spectroscopy (NIRS) for tissue oxygenation (TSI%, O2Hb). Measurements were taken pre-intervention and post-intervention at 30-minute intervals (Pre, Post5, Post30, Post60). Repeated measures ANOVAs were used to detect changes across protocols and time points. Significance was set at $p < 0.05$.

RESULTS: Two-way ANOVAs for both WBLTs only revealed significant main effects of time [$F(3,69)=4.42$, $p=0.007$; $F(3,69)=7.39$, $p<0.001$]. Calf TMG analysis showed significant main effects of time for GMTc [$F(3,69)=3.07$, $p=0.034$], GMTd [$F(3,69)=6.63$, $p=0.001$], GLDm [$F(3,69)=8.16$, $p<0.001$]. Quadriceps TMG analysis showed significant main effects of time for RFTc [$F(3,69)=4.16$, $p=0.009$], VLTc [$F(3,69)=5.84$, $p=0.001$], VLTd [$F(3,69)=8.21$, $p<0.001$], VMTd [$F(3,69)=3.03$, $p=0.035$]. Additionally, a significant interaction was observed for VLTd [$F(3,69)=3.50$, $p=0.020$]. Calf NIRS analysis showed a significant main effect of time for TSI% [$F(4,184)=5.786$, $p<0.001$] and O2Hb [$F(4,184)=20.727$, $p<0.001$] along with a significant interaction effect [$F(4,184)=3.122$, $p=0.016$]. Quadriceps NIRS analysis showed significant main effects of time for TSI% [$F(4,180)=12.081$, $p<0.001$] and O2Hb [$F(4,184)=36.953$, $p<0.001$].

CONCLUSION: This study provides quantitative evidence on changes in WBLT, TMG, and NIRS measurements following an acute bout of either MTF or STF. While both produced significant time-dependent neuromuscular and hemodynamic changes, there were no substantial intervention-specific differences. Results suggest that occlusion is likely the primary driver of these changes, but it cannot conclusively rule out the importance of movement under compression.

FACTORS INFLUENCING BULLYING ATTITUDES IN TEACHER CANDIDATES: THE ROLE OF GENDER, TEACHING EXPERIENCE, PERSONAL AND SOCIAL RESPONSIBILITY

TEMİZ, C., GÁL, A., SOÓS, I.

HUNGARIAN UNIVERSITY OF SPORTS SCIENCE

INTRODUCTION: Attitudes towards bullying serve a precondition for effectively combating bullying shaping intervention preferences to prevention strategies. However, teachers' attitudes and their perceived responsibilities often follow a recurring pattern while some teachers feel responsible for intervening in cases of bullying, others tend to be reluctant and overlook the issue. Breaking this cycle requires raising awareness and providing comprehensive training for preservice teachers (PST). By examining the attitudes and perceived sense of responsibility of PST, this study offers insights into how teacher education can develop more effective anti-bullying strategies.

METHODS: The study sample consisted of 67 fifth-year physical education PST. Data were collected using modified Hungarian versions of Personal and Social Responsibility Scale and Attitudes Towards Bullying Scale. Additionally, participants reported gender and teaching experience. Data were analysed by using Jamovi Software employing descriptive, Mann-Whitney U test, correlation, regression, and mediation analyses.

RESULTS: PSTs had high levels of personal responsibility ($M=5.19$, $SD=0.70$) and social responsibility ($M=5.43$, $SD=0.72$) but their attitudes remained moderate ($M=3.50$, $SD=0.40$). Results indicated ($U=345$, $P=0.007$, $r=0.3839$) that female PSTs ($Mdn=3.76$, $IQR=0.56$) had higher attitudes than males ($Mdn=3.24$, $IQR=0.59$). PSTs with teaching/coaching experience had higher personal responsibility ($U=205$, $p=0.041$), social responsibility ($U=189$, $p=0.019$), but no significant difference was found in attitudes ($U=237$, $p=0.128$). A positive and significant relationship found between personal responsibility ($p=.361$, $p=.003$), social responsibility ($p=.444$, $p<.001$) and attitudes. Social responsibility was a statistically significant ($\beta=0.224$, $p=0.005$) and positive predictor of attitudes. It had a significant direct ($\beta=0.224$, $p=0.003$) and total ($\beta=0.269$, $p<.001$) effect on attitudes, while the indirect effect of personal responsibility was not significant ($\beta=0.045$, $p=0.317$).

Discussion: The findings indicate that while PST exhibit high level of personal and social responsibility their attitudes towards bullying remain moderate. This may stem from their sense of responsibility but lack of knowledge on how to intervene. The higher proactive attitude among female PST may be attributed to their greater empathy or sensitivity to bullying. Individuals, with teaching experience demonstrated a stronger responsibility in combating bullying, likely due to their exposure to more incidents in real educational settings. Another key finding is that social responsibility emerged as a key determinant in combatting bullying, whereas personal responsibility had no direct effect. This suggests that anti-bullying training should go beyond fostering personal awareness to cultivating a cooperative and supportive community. Consequently, PST may strive to transform not only their classrooms but the broader school culture.

INVESTIGATION INTO THE RELATIONSHIP BETWEEN PHYSICAL EDUCATION TEACHERS' EDUCATIONAL METHODS AND STUDENTS' MOTIVATION AND BEHAVIOUR, FROM THE PERSPECTIVE OF PERSONAL AND SOCIAL RESPONSIBILITY

SOOS, I., WHYTE, I., ASZALOS, I., DUNAI, P., VALERO-VALENZUELA, V., SZEKERES, D., HAMAR, P.

HUNGARIAN UNIVERSITY OF SPORTS SCIENCE

Teaching Hellisons model of personal and social responsibility is one of the most important roles of school education as it promotes better behaviour from students in their social environments and teaches them responsibility for themselves and others.

Personal and social responsibility (PSR) does this by developing skills, values, and virtues. such as respect for others, participation and effort in activities, self-direction towards positive values, caring for peers, transferring this knowledge to other areas of life, and supporting others to become more personally and socially responsible. As such, PSR prepares young people for life and helps to ensure successful transitions to adulthood.

Following University Ethics Committee approval (ethics ID number: 2913/2020) primary and secondary school physical education teachers from two settlements in Hungary were recruited for data collection (n=67; mean age of 49.1 years (s=11.4); teaching experience of 17.8 years (s=14.1); 48.6% were female). Participants voluntarily completed the Personal and Social Responsibility Questionnaire, the Behaviour Regulation Motivation Questionnaire, and the Black Pedagogy Scale. In addition, they also stated in writing whether they preferred to employ a traditional (disciplinary behaviour-type) or an autonomous (enjoyment-oriented) educational method during their work.

The results of descriptive statistical analysis showed that 2.9% of the respondents preferred to use traditional (disciplinary behaviour-type) educational methods during their work compared with 22.9% who preferred autonomous (enjoyment-oriented) methods. An amalgam of both educational methods were considered beneficial by 74.3% of the teachers, depending on the situation.

According to the results obtained by univariate analysis of variances (one-way ANOVA), no significant results were obtained. In summary, student motivation and student behaviour perceived by teachers were independent of teachers' educational methods. Since the number of respondents who preferred the method of education that required discipline was small, we deleted it from the database. We kept the autonomous and the combined methods of education on which a Kruskal-Wallis non-parametric test was performed to examine for differences. Confirming our previous results, no significant differences between the variables were found.

Our conclusion is that the joint use of both educational methods (traditional and enjoyment-oriented) is important during educational work as that was the most preferred way of optimising student motivation, developing personal and social responsibility, and shaping positive behaviour.

Further research is recommended to include a larger sample for greater representativeness and to involve students and parents to ensure that perceptions of other key stakeholders are considered.

PHYSICAL EDUCATION TEACHERS EXPERIENCE INFLUENCES THEIR EMOTIONAL REACTIONS AND DETERMINE THE APPROPRIATE USE OF SANCTIONS

HAMDI, F., ELLOUMI, A.

UNIVERSITY OF JENDOUBA

INTRODUCTION: The acceptance of deviant behaviours varies depending on the teacher, the activity, the class, and the school context (Richoz, 2010). The reaction to an emotional situation depends on our nature and past emotional experiences. The memory of our emotional experiences shapes how we emotionally engage in certain situations and our emotional states affect our behavioural response (Lazarus 2004). According to Maheu (2007). "Punishment serves to express the adults anger, often by reproducing what they have experienced. Punishment is a quick way to exert pressure without much thought." It has been hypothesized that novice physical education (PE) teachers experience stronger emotional intensities when facing conflicts with their students compared to experienced teachers. The aim of the current study was to investigate the PE teacher use of sanctions and their emotional experience.

METHODS: We interviewed 4 schools' categories of actors: 6 PE inspectors, 7 headmasters, 18 PE teachers (experienced and novices), and 6 students. Firstly, PE inspectors were interviewed, to identify students deviant behaviours and teachers reactions and to analyse the causal attributions of teacher-student conflicts (Goyette, et al., 2010). Next, we conducted an interview with headmasters. In the third phase, we interviewed PE teachers through a semi-structured interview. Finally, to identify and explain students deviant behaviours during PE lessons and the reactions of their teachers, we analysed 6 case study of students whose deviant behaviours ranged from verbal and physical aggression to absenteeism. Tropes (<https://www.tropes.fr>) software was used for semantic analysis.

RESULTS: The analysis showed that novices PE teachers were afraid of the consequences, or the "reaction", of the disruptive students and that they struggled to sanction their students in a determined, consistent, and deterrent manner. Novices PE teachers complained about the lack of academic training on how to manage conflictual situations with, or deviant behaviours of, their students. Moreover, they had trouble in managing their own emotions. They easily become angry in response to deviant behaviours of their students, which explained their excessive use of exclusion as a punishment. However, absenteeism and unpunctuality remained two deviant behaviours that are neglected by both novice and experienced PE teachers.

Discussion: Discipline is an educational need that help students to set boundaries and limits. It is important to explain them which behaviours are acceptable in the class and help them to be aware of the consequences of inappropriate behaviours. However, it is important to note that it is both possible and desirable to establish a hierarchy of sanctions that teacher administer depending on the severity of the transgression. Experienced teachers place more emphasis on discussions with students, which help them to understand why they were sanctioned.

ENHANCING FAIR PLAY, INCLUSION, AND PHYSICAL ACTIVITY IN PRIMARY EDUCATION: A MIXED-METHODS INTERVENTION STUDY

RUSSO, G., PAGANELLI, V., CECILIANI, A.

UNIVERSITY OF TUSCIA

INTRODUCTION: Fair play, respect, and inclusion are essential for children's psychosocial development and can be effectively promoted through physical education (PE). Research highlights that PE can foster moral decision-making and social integration (Opstoel et al., 2020); however, less is known about its impact in early childhood.

This study evaluates the impact of a structured PE intervention, grounded in social learning theory, on fair-play attitudes, moral decision-making, social behavior, and physical activity (PA) levels in primary school children.

METHODS: A seven-month intervention was conducted with 64 children (aged 9–10 years). The program integrated classroom-based lessons and structured PE activities emphasizing respect, fairness, and collaboration.

A mixed-methods approach was used, including validated questionnaires such as PAQ-C (PA levels), FPPEQ (fair play), AMDM-Q (moral decision-making), YSVQ-2 (sport values), RSEQ (self-esteem), and PSE (physical self-efficacy), and semi-structured interviews with teachers and students. Linear mixed-effects models were used to analyze quantitative data, while thematic analysis was applied to qualitative responses.

RESULTS: PA levels significantly increased over time, particularly among previously inactive children ($F(2, 10.63) = 10.63, p < .0001$). Self-esteem also improved ($F(2, 90.24) = 7.05, p = .002$). However, moral decision-making and fair-play attitudes showed limited changes. Team-sport participants exhibited higher acceptance of cheating ($F(2, 61.19) = 5.38, p = .007$) and gamesmanship ($F(2, 64.51) = 3.52, p = .035$) than individual-sport or inactive students.

Qualitative findings suggested improved emotional regulation, self-regulation, and peer respect. Teachers noted fewer conflicts and better classroom behavior, while students demonstrated increased awareness of inclusion, teamwork, and sportsmanship.

Discussion: This study supports the integration of fair-play education in PE to enhance children's social and emotional development. While quantitative findings showed limited change in moral attitudes, qualitative evidence suggested improved interpersonal behaviors, aligning with previous research on fair-play education (e.g., Domínguez et al., 2021). Additionally, the increase in PA among inactive children highlights the broader benefits of structured PE beyond social aspects, consistent with previous interventions promoting PA in school settings (Dobbins et al., 2013). However, future research should explore long-term effects and examine external reinforcements beyond the school setting.

PERFORMATIVE ACTIONS AT UNIVERSITY: AN OPPORTUNITY TO INCREASE EQUALITY IN SPORT

TORRENTS MARTÍN, C., CALVO-ESTELRICH, C., GARCÍAS DE VES, S.

INEFC UNIVERSITY OF LLEIDA

INTRODUCTION: This research examines how arts-based methodologies, particularly letter writing, Creative Dance, and Performance, can serve as powerful tools for raising awareness about gender inequality in sports within a university setting. Overcoming inequality in sports demands not only the efforts of athletes but also critical reflection on sports and transformative actions within educational institutions, especially those responsible for training future sports professionals. At INEFC, University of Lleida, a creative performance is held annually for International Women's Day, where women from the community share their experiences of discrimination in sports while students support them through movement, expression, and Creative Dance. This study assessed the impact of the creative intervention "The Equality Queens, the Reverse Parade," on student performers and the broader university community.

METHODS: 157 students enrolled in the Creative Dance course within the Physical Activity and Sports Sciences Degree participated as performers. Female participants and women in the community were invited to write letters to "Equality Queens" (inspired by Spain's Magical Kings tradition), outlining their desired changes to eliminate gender-based discrimination in sports. A total of 107 letters were collected. Meanwhile, students created choreographies to traverse the university campus, distributing these letters to the audience in a parade-like performance, emulating the traditional parade of the Magical Kings where children give letters with their wishes to the Kings.

A thematic analysis was performed on the collected letters to identify key themes and issues raised by the participants. Additionally, a post-performance questionnaire was created and given to 64 student performers to assess the intervention's impact on their perspectives and the university community.

RESULTS: Thematic analysis revealed recurring issues faced by women in sports, including systemic discrimination, underrepresentation in media, unequal access to opportunities, and the challenge of balancing professional and personal roles. Participants reported that Creative Dance was key in fostering empathy, enhancing expressive abilities, and sparking a meaningful dialogue about gender inequality.

Discussion: Innovative, embodied, and creative interventions are crucial to addressing gender inequality in sports. This study demonstrates that, despite progress in increasing women's participation in sports, gender inequalities remain a significant structural barrier. The analyzed proposal, aligned with the principles of arts-based knowledge translation, emerges as an effective educational tool for promoting social change. Creative methodologies can foster critical reflection, empathy, and empowerment among participants, offering a pathway to inspire social change through educational practices.

OP-PN15 Endurance Physiology II

PROFILE OF ULTRA-ENDURANCE RUNNERS: PHYSIOLOGICAL DIFFERENCES FROM LONG-DISTANCE RUNNERS

VENCKUNAS, T., SILINSKAS, V., MINDERIS, P., SALATKAITE-URBONE, S., CESANELLI, L., SNIECKUS, A., MACONYTE, V., STASIULIS, A.

LITHUANIAN SPORTS UNIVERSITY

INTRODUCTION: While ultra-endurance sports are growing in popularity, the prerequisites for successful participation and adaptation to such training remain vague. The aim of the study was to compare physiological profile between ultra-distance runners and long-distance runners.

METHODS: Road runners competing in 24-h races (ULTRAs, n=13) or distances 10 km to marathon (LDRs, n=12) arrived to the laboratory in an overnight fasted condition and performed resting metabolic rate measurement followed by oral glucose tolerance test. Anthropometric, muscle and tendon ultrasonography as well as muscle force and power tests were then conducted, after which athletes performed a progressive 4-min step treadmill test to exhaustion to assess the lactate curve, heart rate response, running economy, and fat oxidation, as well as to determine maximal oxygen uptake ($\text{VO}_{2\text{max}}$). Additionally, blood volume, plasma volume and total hemoglobin (Hb) mass were measured using the CO rebreathing.

RESULTS: Despite being of similar competitive level (personal bests for IAAF scores), age, training experience and body weight ($p > 0.05$ for all), ULTRAs had more body fat (mainly due to larger upper body skinfold thickness, $p < 0.001$), even if they had been training by substantially larger volume in terms of distance run and hours spent training ($p < 0.01$ for both).

Both absolute and relative to body weight plasma volume ($p < 0.01$) and blood volume ($p < 0.05$) were larger in LDRs, while Hb concentration, total Hb mass and Hb mass per body weight did not differ between the groups ($p > 0.05$ for all). Resting metabolic rate was similar and relative fat oxidation identical between the groups. There were no obvious differences in glucose handling and associated lactate disposal rate between the groups during oral glucose tolerance test.

Heart rate and lactate response to exercise were the same for the two groups, while maximal oxygen uptake was larger in LDRs (66.7 (5.1) vs. 59.1 (6.4) ml/kg/min, $p = 0.004$). In our conditions, neither maximal fat oxidation rate, nor the associated running speed differ between ULTRAs and LDRs. Running economy was comparable between the groups (206 (19) and 214 (22) ml/kg/km in ULTRAs and LDRs, respectively, $p = 0.347$).

Contractile properties of knee extensors and muscle power measured as different vertical jump parameters did not differ between the groups. Achilles tendon and calf muscle structural properties as well as passive stiffness of plantar flexors were also similar between the groups.

CONCLUSION: Ultra-distance runners exhibit largely similar physiological profile as long-distance runners, but do not have that large maximal oxygen uptake, at least to some extent due lower total blood volume and higher percentage of upper body fat.

IMPACT OF A NON-STOP 230 KM ULTRAMARATHON ON MARKERS OF BLOOD RHEOLOGY, NITRIC OXIDE PRODUCTION AND OXIDATIVE STRESS

GRAU, M., BRUNS, J., STÜCHER, M., MUNK, M., JOHN, L., SCHULZ, S., BIZJAK, R., WITZEL, J., SIEBERS, M., SIEBERS, C., BIZJAK, D.

GERMAN SPORT UNIVERSITY COLOGNE

INTRODUCTION: Ultramarathon events represent an extreme challenge for the human body and its physiological systems. Their impact on the red blood cell (RBC) system is underexplored and in particular changes in RBC deformability and aggregation, both critical for blood flow in the microcirculation, remain poorly understood. Additionally, the role of modifiers

such as nitric oxide (NO) metabolism in these processes has not been fully elucidated. This study aimed to investigate changes in hematological and hemorheological parameters, as well as markers of the NO pathway, during a 230 km non-stop ultramarathon.

METHODS: Twelve participants (3f/8m; 48±8 years, 71±14 kg, 176.7±8.1 cm) finished the ultramarathon race. Blood samples were taken before and 5 minutes after the race and parameters were either analyzed immediately or processed and frozen at the appropriate temperature until measurement. Data were tested for normal distribution using the Shapiro-Wilk test and pre-post differences were calculated using either the paired t-test or the Wilcoxon matched-pairs signed rank test.

RESULTS: Results revealed significant changes in RBC properties post-race. The osmoscan curve, representing deformability under an osmotic gradient, showed a distinct left-shift ($p<0.001$) and the mean cellular volume ($p<0.001$) and intracellular water content ($p=0.08$) both decreased, while the mean cellular hemoglobin concentration increased ($p<0.01$). These findings might be related to dehydration which causes cell shrinkage, mimicking increased fragility. However, haptoglobin levels and RBC count were not significantly altered which might indicate that cell lysis might not acutely be relevant in this setting. RBC deformability, measured using ektacytometry, increased ($p<0.05$) and correlated moderately with elevated RBC nitrite levels ($r=0.41$, $p<0.001$), suggesting a shear stress-dependent activation of NO production and its positive influence on deformation. RBC aggregation, obtained from a syllectogram, increased ($p<0.001$), and the time to half-maximal aggregation was reduced ($p<0.001$). These changes were independent of hemoconcentration, as hematocrit remained unaltered post race. Levels of free reactive oxygen and nitrogen species (ROS/RNS) and S-nitrosylation of RBC cytoskeletal spectrins decreased significantly ($p<0.05$), raising questions about the interplay between oxidative stress and NO metabolism. Remaining hematological variables remained unaltered.

CONCLUSION: In summary, the data indicate that ultramarathon participation exerts profound effects on RBC properties and its potential effect on microcirculatory blood flow. This study thus contributes to understanding the hemorheological adaptations to extreme endurance challenges and underscores the need for longitudinal studies to evaluate their long-term impact on RBC properties.

LONGITUDINAL ANALYSIS OF PERCEIVED MUSCLE FATIGUE AND SORENESS IN MARATHON RUNNERS: COMPARING MUSCLE FATIGUE RESPONDERS AND NON-RESPONDERS

FERRO, M., RAIMO, M., BERTOLLO, M., PAPINI, G.B., SARTOR, F.

UNIVERSITY OF STUDIES DANNUNZIO CHIETI-PESCARA

INTRODUCTION: The relation between muscle fatigue and marathon running is well established [1], but not all individuals respond to it in the same way. Overall fatigue, muscle fatigue, and muscle soreness are commonly experienced by marathoners. This analysis aimed to observe whether perceived overall muscle fatigue and soreness ratings over 8 weeks would differ in marathoners responding or not to a muscle fatigue protocol.

METHODS: Data from 17 habitual marathoners (15 males, aged: 38±12 y, height: 1.81±0.09 m, weight: 70±9 kg, VO₂max: 64±12 ml/kg/min) were analyzed. Training workload was measured using a chest strap. HR was used to compute total TRIMP (tTRIMP), composed of anaerobic TRIMP (anTRIMP) and aerobic TRIMP (aTRIMP), where (aTRIMP = z1+z2; anTRIMP = z3+z4+ z5). Runners kept a diary where they self-reported on a 0 to 10 scale overall fatigue, muscle fatigue and soreness every morning, evening, and before and after each training. Prior to the 8-week observation period (W38-45), they visited our laboratory twice for VO₂max and muscle fatiguability tests. The fatiguability tests consisted of a 10-minute baseline submax run and baseline maximal voluntary contractions (MVCs), then 100 drop jumps from a 40 cm height step with a 20-second rest between each jump, followed by an isometric contraction to muscle failure at 30% MVC output. This fatigue protocol was immediately followed by post-MVCs and a 10-minute run at the same speed as baseline.

RESULTS: Runners were divided into responders (R) who showed an MVC drop ≥20% and non-responders (NR) who did not. Pre- and post-fatigue MVCs, as well as pre- post-fatigue submax run HR, differ between R and NR (ΔMVC for R was -38%, and for NR=-2%, ΔHR for R was 10 bpm and for NR 4 bpm). During the 8 weeks a difference was found between the R and NR groups in overall fatigue ratings (F(1,382)=10.34, $p<0.001$); once followed-up it revealed differences at: W40 F(1,53)=4.88 $p<0.05$; W42 F(1,53)=4.27 $p<0.05$; W43 F(1,51)=7.01 $p<0.01$. Muscle soreness ratings showed a significant effect of group R vs. NR (F(1,382)=9.89 $p=0.002$); when followed up, there were not significant effects. Muscle fatigue ratings showed a significant difference between R and NR (F(1,382) =20.43 $p<0.05$), and follow-up showed differences at W38, W40, and W43 (F(1,41)=7.29 $p=0.01$; F(1,53)=9.91 $p=0.003$; F(1,51)=4.57 $p<0.05$). Overall ($r=0.40$, $r=0.26$, $p<0.001$), muscle fatigue ($r=0.40$, $r=0.37$, $p<0.001$), and muscle soreness ratings ($r=0.40$, $r=0.24$, $p<0.001$) significantly (within-subject) correlated with tTRIMP and anTRIMP, but not with aTRIMP.

CONCLUSION: This study confirms that not all athletes respond to muscle fatigue equally. Interestingly, those who did not respond in the lab had higher overall fatigue and muscle fatigue ratings in training, while muscle soreness did not differ from responders. Future studies should investigate the reasons behind these differences and whether they differ in competition results.

COMPARISON OF METABOLIC AND STRESS RESPONSES OF RUNNERS PARTICIPATING IN MARATHON AND ULTRAMARATHON RACES

BIZIAK, D., MUNK, M., JOHN, L., SCHULZ, S.V.W., BIZIAK, R., WIESING, A., LÜDERS, N., WITZEL, J., GRAF, J., KIRSTEN, J., SIEBERS, M., GRAU, M.

UNIVERSITY HOSPITAL ULM

INTRODUCTION: Marathon as the longest Olympian running distance is considered the ultimate frontier for the majority of recreational athletes, where musculoskeletal, cardiovascular and nutritional adaptation are required for reaching the finish line. Ultramarathon (all distances above 42.195 km) imposes even more stress on the athlete's body systems, but the respective stress extent compared to marathons are still insufficiently examined.

METHODS: Female and male participants of an ultramarathon (UM 100/160.9/230 km) and a marathon competition (MA) were examined regarding personal characteristics, nutritional strategies, race nutrition composition, energy expenditure/intake, motor skills, energy and cell metabolism as well as objective and subjective stress response. Pre and Post race, questionnaires, blood/saliva sampling, as well as body composition analysis were applied. The relative difference for the aforementioned parameters was calculated and compared between MA and UM.

RESULTS: 60 marathon (23% female) and 43 ultramarathon (37% female) runners finished the race. MA were younger, had lower body fat mass and less running training years compared to UM. Energy deficit after the race ranged from 2385 (MA) to 5221-8562 kcal (UM), while energy fueling during MA were provided by 90% carbohydrates, 5% fat and 5% protein, and during UM by 82% carbohydrates, 10% fat and 8% protein, respectively. Despite higher creatine kinase values in UM, other damage markers increased similar between running distances. Stress biomarkers increased more in MA, while inflammation was more pronounced and hunger/satiety hormones were more disturbed in UM. Both conditions showed a high immune system activation (e.g. leucocytes), while subjective exhaustion was higher in ultramarathon participants.

CONCLUSION: Running velocities and distances can be extremely different between recreational athletes participating in MA and UM events, resulting in distinct metabolic and cellular stress responses. Nevertheless, discrepancies between fueling strategies with less available recommendations during UM competition, which still mostly relies on individual experience, might contribute to the observed cellular damage and subjective fatigue. Optimizing energy intake by e.g. increased fluid protein intake might be a useful in-race and regeneration strategy as well as differential intervention/regeneration approaches for the different running distances that still has to be determined in more controlled settings.

THE INFLUENCE OF SOLAR RADIATION ON SELF-PACED CYCLING TIME-TRIAL PERFORMANCE

CLARK, B., BRIGHT, F.M.2, BROWN, H.A.1, JAY, O.2, PÉRIARD, J.D.1

1. UNIVERSITY OF CANBERRA

INTRODUCTION: Solar radiation plays a crucial role in human heat balance with black-globe temperature, an indication of how hot it feels in direct sunlight, often 10-15°C higher than dry-bulb (i.e. ambient) temperature. During outdoor sporting competitions, athletes are exposed to varying solar loads, often for extended periods of time. Despite this, there is minimal research on the influence of solar radiation on self-paced exercise performance. The aim of this study was to systematically investigate the impact of radiant heat load on thermal and cardiovascular strain, and time-trial performance, in well-trained male cyclists.

METHODS: Ten endurance trained male cyclists and triathletes participated in this study (mean $\pm$ SD: age = 40 $\pm$ 11 yr, height = 1.81 $\pm$ 0.04 m, body mass = 78.1 $\pm$ 7.6 kg, VO₂PEAK = 4.7 $\pm$ 0.5 L·min⁻¹). Participants completed four experimental 700-kJ time-trials in a counterbalanced order in an environmental chamber set to 35°C and 40% relative humidity with 3.5 m·s⁻¹ facing airflow. Each trial was completed with six radiant heat lamps placed behind the participant producing either 0 W·m⁻² (CON), 234 W·m⁻² (LOW), 434 W·m⁻² (MOD), or 760 W·m⁻² (HIGH). Data were analysed using linear mixed effects models with results presented as means with [95% confidence intervals].

RESULTS: Mean power output in CON (251 W [225, 276]) was higher than in LOW (5 W [1, 9], $P=0.013$), MOD (7 W [3, 10], $P<0.001$), and HIGH (8 W [5, 12], $P<0.001$). There were no other significant differences in power output between all other radiant heat load conditions. Mean rectal temperature (Tre) was 38.4°C [38.2, 38.5] in MOD, which was significantly higher than in CON (0.20°C [0.13, 0.27], $P<0.001$), LOW (0.07°C [0.00, 0.14], $P=0.039$), and HIGH (0.08°C [0.01, 0.15], $P=0.020$). Mean Tre in LOW (38.3°C [38.2, 38.5]) and HIGH (38.3°C [38.2, 38.4]) were significantly higher than CON (38.2°C [38.0, 38.3], $P\leq 0.001$). Final Tre was 39.3°C [39.1, 39.5] in MOD, which was significantly higher than in CON (0.29°C [0.06, 0.52], $P=0.016$) but not LOW (0.22°C [-0.02, 0.45], $P=0.069$) or HIGH (0.22°C [-0.02, 0.45], $P=0.072$). Mean heart rate in MOD (158 beats·min⁻¹ [146, 170]) was significantly higher than CON (3 beats·min⁻¹ [1, 4], $P<0.001$) and HIGH (2 beats·min⁻¹ [0, 3], $P=0.019$) but not LOW (1 beat·min⁻¹ [-1, 2], $P=0.278$). Whole-body sweat rate (2.2 $\pm$ 0.6 L·h⁻¹, all $P\geq 0.712$) and percent body mass loss (1.1 $\pm$ 0.7%, all $P\geq 0.324$) did not differ between trials.

CONCLUSION: In hot ambient conditions, low to high radiant heat loads lead to modest changes in performance relative to conditions without radiant heat. The changes in performance were accompanied by small increases in thermal and cardiovascular strain. Future studies are required to better understand how more extreme radiant heat loads, akin to those faced by athletes in certain geographical locations, influence physiological strain and self-paced exercise performance.

OP-PN27 Muscle Damage and Repair

EFFECT OF DECELERATION INTENSITY DURING REPEATED SPRINTS ON MUSCLE STIFFNESS AND DAMAGE KINETICS

GARCIA, J., SLAWINSKI, J., PRÉCART, C., DORO, V., YAMASHITA, D., BROCHERIE, F.

FRENCH INSTITUTE OF SPORT

INTRODUCTION: In team sports, horizontal deceleration (DEC) is a critical locomotor skill underlying sudden changes of velocity [1]. However, the effects of DEC during a repeated-sprint ability (RSA) test on muscle damage and underlying recovery kinetics are underexplored, despite the potentially damaging nature of recurrent DEC [2] due to the predominant eccentric muscle contractions [3]. This study therefore aimed to investigate the effects of different DEC intensities during an overground RSA test on subsequent kinetics of rectus femoris (RF) stiffness and serum creatine kinase levels ([CK]) to assess muscle damage.

METHODS: Twelve participants (25 ± 3.5 yrs) randomly performed a running RSA test [3 sets of 8×20 m; 20-s passive recovery between sprints, 5-min rest between sets] i) without DEC constraint after 20-m sprint (DECfree), ii) with enforced DEC of moderate intensity (DEC10; 10-m braking distance), and iii) with enforced DEC of intense intensity (DEC5; 5-m braking distance). Sprint time and DEC performances were assessed using timing gates and radar gun, respectively. RF stiffness and [CK] were assessed at rest before RSA test (baseline) and post 24 h, 48 h and 72 h using ultrasound elastography and dry-chemical colorimetry, respectively.

RESULTS: There was no significant effect of condition ($p=0.463$) for the best sprint time in each set, but a significant effect of time ($p=0.004$). Mean DEC was significantly lower in DEC5 (-3.57 ± 0.32 m/s²) than DEC10 (-2.52 ± 0.37 m/s², $p<0.001$) and DECfree (-1.82 ± 0.30 m/s², $p<0.001$), and lower in DEC10 than DECfree ($p<0.001$). There were significant effects of condition, time and interaction (all $p<0.001$) for relative stiffness vs. baseline. Relative stiffness were significantly higher in DEC5 than DEC10 and DECfree post 24 h ($+16.4 \pm 3.2$ vs. $+9.8 \pm 4.2$ and $+4.5 \pm 5.7$ %, respectively, $p=0.007$ and $p<0.001$), 48 h ($+15.9 \pm 4.7$ vs. $+6.5 \pm 5.1$ and $+3.3 \pm 4.8$ %, respectively, both $p<0.001$) and 72 h ($+10.8 \pm 4.9$ vs. $+3.6 \pm 5.4$ and $+0.2 \pm 3.8$ %, respectively, both $p<0.001$). There were significant effects of condition ($p=0.012$) and time ($p<0.001$) for relative [CK] vs. baseline. Pooled relative [CK] for all time points were significantly higher in DEC5 than DECfree ($+141 \pm 180$ vs. $+66 \pm 98$ %, $p=0.019$), while DEC10 (121 ± 144 %) was not significantly different from either DEC5 ($p=1.00$) or DECfree ($p=0.053$). Pooled relative [CK] for all three conditions significantly increased at post 24 h ($+171 \pm 151$ %, $p<0.001$), 48 h ($+111 \pm 175$ %, $p<0.001$) and 72 h ($+51 \pm 80$ %, $p=0.002$).

CONCLUSION: Repeated intense decelerations during repeated sprints induced an exacerbation of relative stiffness and creatine kinase levels over several days, peaking after 24 h and remaining elevated above baseline after 72 h. These findings indicate that the intensity of deceleration should be considered in order to adequately prepare the musculoskeletal system and mitigate the damaging effects.

RUNNING SHOES WITH ADVANCED FOOTWEAR TECHNOLOGY MITIGATES EXERCISE-INDUCED MUSCLE DAMAGE AND HEMOLYSIS

SUMI, D., NAKAYAMA, K., TAKII, Y., SAKAGUCHI, M.

ASICS CORPORATION

INTRODUCTION: During running, a greater mechanical stress (i.e., vertical load) is applied to the lower extremity at each ground contact, which promotes exercise-induced muscle damage and hemolysis. It has been shown that Advanced Footwear Technology (AFT) improve running performance by reducing the metabolic demand of running [1]. These shoes are designed with a combination of several components, including a compliant and resilient midsole foam. Thus, AFT shoes have a high cushioning function compared to traditional racing flats. Considering that the softer surface during running reduces the mechanical stress on the musculoskeletal system and the sole [2], the AFT shoes may attenuate exercise-induced muscle damage and hemolysis compared to traditional racing flats. Therefore, the purpose of present study was to determine the effect of AFT shoes on exercise-induced muscle damage and hemolysis after 2-h running.

METHODS: Nine endurance athletes performed a 2-h treadmill running at 70% of maximal oxygen uptake (VO_{2max}) wearing AFT shoes (METASPEED SKY PARIS, ASICS) (AFT trial) or conventional running shoes (HYPER SPEED 2, ASICS) (CON trial) on different days (Days 1 and 2). We measured blood samples and the drop jump (DJ) index before and after running to evaluate exercise-induced muscle damage and hemolysis. In addition, all subjects performed 15-30 straight running trials on a 50-m over-ground at 70% of VO_{2max} on Day 3 (on different day than Days 1 and 2). Kinetic and kinematic data were collected simultaneously using a 24-camera motion capture system and three force plates during over-ground running. We also calculated vertical loading rate and negative muscle mechanical work (an indication of eccentric muscle contraction) by using the musculoskeletal simulation (OpenSim).

RESULTS: Blood myoglobin (Mb) levels (an indication of muscle damage) significantly increased after 2-h running in both trials. However, blood Mb elevations following running tended to be lower in the AFT trial than in the CON trial ($P = 0.07$). Moreover, reduction in DJ index after 2-h running was significantly greater in the CON trial than in the AFT trial ($P = 0.03$). Blood haptoglobin (Hap) levels significantly decrease (an indication of hemolysis) after 2-h running in both trials. However, the CON trial showed a greater reduction in blood Hap levels compared to AFT trial ($P = 0.02$). Loading rate ($P = 0.001$) and negative muscle mechanical work in gastrocnemius ($P = 0.006$) and soleus ($P = 0.02$) during over-ground running were significantly lower in the AFT trial than in the CON trial.

CONCLUSION: The AFT shoe attenuated exercise-induced muscle damage and hemolysis after 2 hours of running compared to the traditional racing flats.

THE EFFECT OF ECCENTRIC EXERCISE-INDUCED MUSCLE DAMAGE ON CRITICAL POWER & FINITE WORK CAPACITY

PEARMAN, W., HORNER, D., DODD, E., BROWNSTEIN, C.

NEWCASTLE UNIVERSITY

INTRODUCTION: It is well established that severe intensity exercise performance is impaired following eccentric exercise-induced muscle damage (EIMD) [1, 2]. Given that performance during exercise within the severe intensity domain can be robustly predicted based on the hyperbolic power-duration relationship and its two parameters, critical power (CP) and the finite work capacity above CP (W'), it is likely that one or both of these variables are impaired with EIMD. However, no study has tested this hypothesis. This study assessed the effect of EIMD on CP and W' measured during a 3-minute all-out test (3MT).

METHODS: 15 recreationally active participants (age = 25 ± 4 years, 3 females, $VO_{2peak} = 46.8 \pm 8.7$ ml·kg⁻¹·min⁻¹) completed two, 3-minute all-out tests (3MT), one under control conditions (Control) and one 24 h following a bout of damaging eccentric exercise (Damage). CP, W' , peak power output (PPO), cardiopulmonary and electromyographic (EMG) data were collected during each 3MT. Potentiated twitch response ($Q_{tw,pot}$) and maximal voluntary contractions (MVC) of the knee extensor muscles were used to assess the degree of damage incurred.

RESULTS: EIMD reduced MVC and $Q_{tw,pot}$ by 32 and 30%, respectively ($p < 0.001$, $d \geq 1.14$). Paired t-test results showed that EIMD resulted in a reduction in CP from 241 ± 72 W to 231 ± 66 W ($p = 0.037$, $d = 0.15$), W' from 16.57 ± 4.5 kJ to 14.76 ± 3.9 kJ ($p = 0.008$, $d = 0.45$) and PPO by 776 ± 180 W to 696 ± 152 W ($p = 0.023$, $d = 0.48$). There was no difference in EMG during cycling between damage and control ($p = 0.766$). However, VO_2 , VCO_2 and VE were lower for damage than control ($p \leq 0.02$).

CONCLUSION: These results demonstrate that EIMD reduces CP, W' and PPO. Possible determinants of reduced CP with EIMD include a reduction in gross efficiency [3] and/or an impairment in muscle oxidative capacity [4]. Reductions in W' might be attributable to reduced glycogen stores and/or a more rapid rate of accumulation of intramuscular metabolites [4, 5], while the reduced MVC and $Q_{tw,pot}$ 24hrs post damage suggest that impaired contractile function is at least partially responsible for these reductions in PPO. The results shown in this study add new insight into the determinants of reduced severe intensity exercise performance with EIMD.

EXPLORING THE EFFICACY OF PALMITOYLETHANOLAMIDE (PEA) VERSUS NSAIDS IN ALLEVIATING SYMPTOMS ASSOCIATED WITH EXERCISE-INDUCED MUSCLE DAMAGE

COLE, P., BURNISTON, J., CLOSE, G., ERSKINE, R., OWENS, D.

LIVERPOOL JOHN MOORES

INTRODUCTION: Ultra-endurance running (>42.195km), often involves extensive downhill running (DR), leading to exercise-induced muscle damage (EIMD), of which pain and loss of function are key markers. Consequently, anti-inflammatory and pain medication use is common in athletes during competition and training. NSAID use in athletes is controversial, may not have ergogenic benefits and may be associated with adverse effects, including gastrointestinal and renal dysfunction. Palmitoylethanolamide (PEA), an endogenous fatty acid with anti-inflammatory and analgesic properties, offers a potentially safer alternative with no known side effects. This study investigates the efficacy of PEA and the NSAID, Ibuprofen (IBU) compared to Placebo (PLA), in alleviating symptoms of EIMD induced by laboratory DR protocol.

METHODS: Twelve healthy individuals were acclimated to DR during a 4-week training programme, consisting of 10 (15-30min) sessions on a motorised treadmill at different negative gradients (-5/-10/-15%) and a running speed equivalent to 60-65% VO_{2max} . After session 9, participants were randomised in a double-blind manner to receive: PLA (maltodextrin), PEA (600mg/day), or IBU (800mg/day) along with 4% deuterium oxide (D_2O) for 10 days for muscle protein synthesis measurement. At day 3 of supplementation, participants performed a 50-minute DR (-15-17%) to induce muscle damage. Blood for the analysis of kidney function and maximal isometric voluntary torque (MIVT) and voluntary activation (VA) was measured pre- and immediately post-DR and at 24h, 48h, 5d and 7d post-exercise. A Visual Analog Scale (VAS) was used daily during the 7d recovery to assess pain. A two-way mixed ANOVA was used to detect changes between time and condition, with significance set at $p \leq 0.05$. All data are expressed as mean $\pm$.

RESULTS: There was a significant effect of time on MIVT (Nm/Kg) ($p < 0.001$), but no significant effect of condition ($p = 0.40$) or interaction ($p = 0.91$). MIVT decreased with a loss of approximately 19% from PRE (3.1 ± 0.1) to POST (2.5 ± 0.2 , $p = 0.003$), and further reductions observed at 24h (2.4 ± 0.2 , $p = 0.006$), and 48h (2.5 ± 0.2 , $p = 0.005$). Similarly, there was a significant effect of time on VA (%) ($p < 0.001$), but no significant effect of condition ($p = 0.34$) or interaction ($p = 0.07$). VA decreased from PRE (87.7 ± 0.9) to POST (71.4 ± 2.3 , $p < 0.001$), 24h (78.9 ± 1.7 , $p = 0.002$), and 48h (79.8 ± 1.3 , $p < 0.001$). There was a significant effect of time on pain scores ($p < 0.001$), but no significant effect of condition ($p = 0.96$) or interaction ($p = 0.49$). Peak pain scores did not differ between conditions ($p = 0.32$); however, only the PLA group reported pain until day 7, while PEA and IBU reported pain until day 5.

CONCLUSION: Neither PEA nor IBU compared to PLA, significantly improved muscular function or peak pain scores, suggesting the modulation of inflammation through these interventions does not substantially influence neuromuscular recovery from a bout of downhill running inducing EIMD.

THE DOSE-RESPONSE EFFECTS OF HYDROLYSED CURCUMIN ON RECOVERY, INFLAMMATION AND OXIDATIVE STRESS FOLLOWING EXERCISE-INDUCED MUSCLE DAMAGE IN MALES.

HELDER, T., CONDON, S., GRANT, I., LEWIS, N., HILL, J., PEDLAR, C., HUGHES, L.

ST MARYS UNIVERSITY

INTRODUCTION: Polyphenols, specifically curcumin, are used in the aid of recovery post muscle damage. One method to improve curcumin bioavailability that is yet to be investigated with recovery is curcumin in a hydrolysed (liposomal) form. The aim of this study was to investigate the effect of two different dosages (750mg and 1500mg) of a novel hydrolysed curcumin supplement on physiological recovery following a bout of exercise induced muscle damage (EIMD).

METHODS: Using a randomised, placebo controlled, double-blind design, 34 recreationally active male participants (age: 27 ± 6 years; height: 180 ± 7.3 cm; body mass: 82 ± 11.3 kg) completed a supplementation trial over 7 days. Participants were randomly assigned to one of three groups; PLA: 2 x 750 mg/day placebo (identical supplement formulation without curcumin), LOW: 1 x 750 mg curcumin and 1 x 750 mg placebo; HIGH: 2 x 750 mg/day curcumin. Participants started supplementation 48h before exercise induced muscle damage continuing throughout the study. EIMD protocol consisted of 8 x 10 repetitions incorporating a 5s eccentric phase on the leg press machine. FORD, FORT, CK, IL-1B, IL-4, IL-6, IL-10, TNF- α and IL-1RA, PPT, VAS, BORG, thigh girth, and vastus lateralis diameter (ultrasound), isokinetic peak power and muscle endurance levels (50% peak power held until exhaustion) were collected Pre, Post, 24h, 48h, and 72h after EIMD. A two-way mixed measures ANOVA was used to investigate possible differences in absolute and relative changes (%) in biomarkers and performance indicators between the groups (PLA, LOW, and HIGH) and within groups across time points (Pre-EIMD, Post-EIMD, 24, 48, and 72 hours post muscle damage).

RESULTS: The HIGH group demonstrated superior effects in significantly reducing subjective pain, CK, FORT, and IL-6 levels during recovery days ($P < 0.05$). Notably, a significant difference ($P < 0.05$) was observed between the LOW and HIGH groups in the muscle endurance test at 24h post-exercise, with the HIGH group exhibiting a slower recovery. No other differences in performance measures were seen.

CONCLUSION: This study suggests there may be a dose-response relationship between curcumin dosage and recovery markers, proposing that higher doses (1500 mg/day) appear to reduce soreness, oxidative stress, and inflammation to a greater extent than lower doses (750mg/day). Furthermore, these findings support previous clinical research indicating that curcumin may exert a protective effect at the cellular level by significantly attenuating CK release post-exercise, thereby mitigating muscle damage. However, the data also suggest the potential for a non-linear, "inverse U-shaped" relationship between curcumin dosage and muscle performance during recovery.

Invited Symposium

RESEARCH AND REALITY: FEMALE HEALTH MONITORING IN DIVERSE ENVIRONMENTS

MIKKONEN, R.

UNIVERSITY OF JYVÄSKYLÄ

Intentional monitoring of female health alongside performance has gained popularity in the lab as an opportunity to: i) examine the potential influence of menstrual (or hormonal contraceptive) phase on acute responses to exercise and performance; ii) establish menstrual status as part of, or prior to inclusion in research. In field settings monitoring female health alongside performance also provides information that may help to: i) identify recurring patterns of negative and positive symptoms that may influence performance or subjective feelings of performance; ii) detect early warning signs of low energy availability and/or low carbohydrate availability as well as overtraining/accumulated physical/social/psychological stress; and iii) to promote health literacy and empower female athletes. Monitoring female health alongside performance is an essential tool for bridging the gap between research and practice to better understand the relationships between female athlete health and performance. When carefully planned and implemented, monitoring may, on both case and population levels, serve academics and researchers as well as those working within sport i.e. athletes, coaches, and multidisciplinary teams including physicians, physical therapists, and psychologists. As a compo-

nent of female health and performance monitoring, several approaches to menstrual cycle tracking are available. Where methodological recommendations for research regarding the menstrual cycle have been published^{2,3,4,5}, a "gold standard" protocol for tracking menstrual cycles in field settings has yet to be developed/identified. Furthermore, tracking hormonal contraceptive cycles and menstrual disturbances/dysfunction has received significantly less attention where methodological considerations may require further development. Nevertheless, tracking cycle characteristics and symptoms of athletes with menstrual disturbances/dysfunction or using hormonal contraceptives may also provide meaningful and valuable information for athletes, coaches and multidisciplinary teams. The purpose of this presentation is to discuss the suggested approaches and rationale for tracking menstrual and hormonal contraceptive cycles (incl. menstrual disturbances/dysfunction) in female athletes "in the field" including how this data can potentially contextualise other health and performance data in a way that is meaningful for athletes. The feasibility and potential limitations of different analysis methods from traditional paper and pencil records to more sophisticated digital applications and biochemical measures for use in the field will be addressed. THE EFFECT OF THE MENSTRUAL CYCLE ON PERFORMANCE; METHODOLOGICAL CHALLENGES AND THE IMPORTANCE OF DURABILITY

LAMBERTS, R.

STELLENBOSCH UNIVERSITY

Research on the effect of the menstrual cycle on performance has gained much interest over the last five years. Although this is encouraging, most studies do not find differences in performance outcomes (1), while self-reported effects of the menstrual cycle on training habits and performance by athletes clearly do (2,3). This discrepancy may be explained by the variation in individual responses to the menstrual cycle and the effect it has on performance. This variation can lead to not finding significant differences at group level, while at an individual level, clinically meaningful changes might be observed in certain athletes. Another possible contributing factor might be that most performance tests in these studies are conducted in a rested (fresh) state rather than a fatigued state. Recently, Erp et al. (4) showed that performance characteristics in highly versus less successful male professional cyclists were similar in a fresh state but differed significantly in a fatigued state. In line with this, van Erp and Lamberts (5) showed similar outcomes in female professional cyclists in the top-5 versus not top-5 finishers. These findings highlight the importance of durability when monitoring and predicting performance. In addition, it also raises the question of whether the menstrual cycle impacts performance more clearly and with less variation between individuals in a fatigued state. This presentation will discuss the challenges and limitations of conducting group analysis within menstrual cycle research and how to overcome these, while also discussing the importance of durability testing female cyclists. As part of this, we will present some new and novel data from a study in which female-trained cyclists (23 ± 5 years; 4.4 ± 0.6 W·kg⁻¹) performed a standardised submaximal warm-up test and a 20-min time trial test before (fresh) and after (fatigued) a 60km submaximal ride during which they burned an average of 22 kJ·kg⁻¹. Besides providing new and novel insights into improving menstrual cycle research, practical insight will also be provided on how to monitor the menstrual cycle and the impact on performance in the field on an individual level. TRANSLATION TO THE REAL WORLD; THE COLD, HARD REALITY OF NEEDING TO PERFORM ON ANY DAY

BRUINVERLS, G.

UNIVERSITY COLLEGE LONDON

As female athletes keep pushing the barriers of human performance, focus is increasingly being placed on data collection and analysis to facilitate more informed decision making. A key part of this involves the monitoring of female health markers alongside wellness and performance measures. Integrating these data streams aids with contextualisation and helps to identify times where an athlete may show altered physiological, physical or psychological readiness. The acceleration in female athlete research over the past decade has clearly demonstrated the significant inter- and intra- individual variation in response to changes in endogenous and exogenous hormones through a menstrual cycle and/or in response to use of hormonal contraception (1,2). For some, this may manifest in adverse symptoms at particular times, that have the potential to negatively impact exercise participation and performance, alternatively many feel times where they get a boost or feel a positive response (3). The increase in data collection has facilitated a means for better identifying and understanding these responses. With the ongoing emergence of scientific rationale for the aetiology of menstrual cycle-related symptoms alongside an increased understanding of the natural physiological response to hormonal changes, it makes prudent sense to look at means for both reducing symptoms and optimising support around overt changes in markers of readiness (3,4). This is of particular relevance in elite sport, where margins are fine, ensuring an athlete is able to perform at their best on any day is fundamental. This presentation will provide several case reports from team and individual elite athletes, outlining how strategies have been implemented to optimise readiness and wellness based on the longitudinal monitoring of multiple data streams. 1. Invited Symposium

IS-BM07 The aging brain in motor control and balance learning: from molecules to neurons and networks

REBALANCE THE BRAIN: THE EFFECT OF AGING AND PHYSICAL ACTIVITY ON CORTICAL INHIBITION AND EXCITATION

LAUBER, B.

UNIVERSITY OF FRIBOURG

Aging is a natural physiological process that leads to changes in function, which can result in reduced motor performance, cognitive decline, and impaired motor learning and consolidation. However, contrary to mid-20th-century beliefs, healthy aging is not associated with the same widespread neural loss seen in neurodegenerative diseases. As a result, there is growing interest in understanding how aging affects specific neural subpopulations and their synaptic connections. In particular, research on age-related changes in inhibitory neurons, which represent the most complex and diverse group of brain cells playing a critical role in modulating the activity of entire neural circuits, is considered crucial. Gamma-aminobutyric acid (GABA), one, if not the main inhibitory neurotransmitter in the central nervous system, is used by approximately one-third of neurons as their main form of communication. It appears that aging is associated with a decline in global GABA levels across in various brain regions and this decline in GABAergic function results in an imbalance between inhibitory and excitatory activity, disrupting multiple brain circuits. As a consequence, it impairs not only motor and cognitive behaviors but also neural plasticity. It is important to note that not only GABA concentration plays an important role but also the ability to task-specifically up- or downregulate intracortical inhibition is important. It was for example shown that skilled experts (e.g. piano and badminton players) were able to modulate intracortical inhibition in a task-specific fashion whereas novices showed much less modulation indicating that with motor learning, inhibitory processes can be modulated. With respect to aging, recent evidence suggest that longer training periods can also cause changes in the modulatory capacity of the brain and that these in intracortical inhibition are associated with improvements in performance. In this talk, I will address the importance of the cortical inhibitory network for motor control and motor learning and how aging and certain pathologies affect these inhibitory networks causing an imbalance between cortical excitation and inhibition. Furthermore, I will address how motor learning (e.g. balance learning, strength training) in general and particularly in the elderly will affect cortical inhibition and how the changes in the cortical inhibitory network might be related to other outcome measure such as sleep quality.

POSTURAL CONTROL, BALANCE TRAINING AND THE (MICRO-)STRUCTURE OF THE AGING BRAIN: THE CASE FOR QUANTITATIVE MRI

LEHMANN, N.

OTTO VON GUERICKE UNIVERSITY MAGDEBURG

Age-related deterioration in postural control is an important factor decreasing quality of life. A healthy brain, characterized by intact gray (GM) and white matter (WM), is vital for the efficient functioning of neural networks during daily life tasks, thus playing a critical role in maintaining and restoring mobility and balance in aging. Atrophy, which is usually measured based on structural magnetic resonance imaging (MRI), is one of the most important changes in healthy and especially in pathological aging of the brain. Consequently, most MRI studies investigating age-related changes in balance performance (including falls) and balance training-induced neuroplasticity focused on meso- and macroscopic shape of the brain as assessed with T1-weighted imaging (morphometric analysis). Usually, the volumes of the cortex and/or subcortical gray matter are measured and correlated with balance performance, or tracked longitudinally. When reviewing the results from these studies, it becomes clear that a comprehensive understanding of postural control and balance can only be achieved by studying distributed cortical and subcortical brain areas and their interconnecting fibre tracts, whereby the latter in particular have been largely neglected to date. A further problem is that the conventional analysis approach is relatively unspecific with regard to neurobiological tissue properties, since morphometric results also depend on cortical thickness, surface area and tissue density. Last but not least, since microstructural changes in the brains of older people, specifically pertaining to synapses, typically precede meso- and macroscopic atrophy, it is likely that the morphometric analysis approach has also limited sensitivity to detect training-induced changes and brain-behavior correlations. As a possible way forward, I will discuss how quantitative multicontrast MRI weighted towards diffusion, relaxation times and magnetisation transfer can be used in combination with advanced biophysical modelling to address these problems. The unprecedented insights into the relationship between GM/ WM microstructure and balance offered by such a novel approach are demonstrated based on unpublished data from two randomised controlled trials of balance training in older adults in which our laboratory was involved. I will draw attention to how multivariate combinations of MRI-derived metrics can uncover microstructural information that is typically concealed when focusing on single metrics, and I will discuss neuroplasticity and brain-behavior correlations against the background of previous studies. It is hoped that these novel multicontrast estimates of brain anatomy ("in-vivo histology") will be increasingly used in the field of movement neuroscience, with potential applications in early diagnosis, guiding treatment and assessing individual response to training and therapy.

METABOLIC CHANGES IN AGING: CURRENT EVIDENCE AND THE IMPACT OF PHYSICAL ACTIVITIES

KAISER, A.

EPFL

Aging affects brain structure, function, and metabolism, often leading to declines in cognition and motor performance. Proton magnetic resonance spectroscopy (^1H MRS) is a valuable non-invasive tool for studying age-related brain metabolic changes. Current studies focus on key metabolites such as N-acetylaspartate (NAA), linked to neuronal health; choline-containing compounds (Cho), involved in cell membrane and myelin metabolism; myo-inositol (ml), a glial marker and osmolyte; glutamate and GABA, the major excitatory and inhibitory neurotransmitters, and creatine (Cr), an energy metabolite. Decreases in NAA and increases in ml have been consistently observed with age, suggesting possible neural loss in grey matter, axonal damage in white matter, demyelination, inflammation, or glial activation. As the brain consumes high levels of energy, it is sensitive to ATP (adenosine triphosphate) fluctuations. ATP production and energy transport are essential for supporting neural function. Mitochondrial ATP is mainly synthesized through ATP synthase, using adenosine diphosphate (ADP) and inorganic phosphate (Pi). Phosphorus magnetic resonance spectroscopy (^3P MRS) measures phospho-metabolites involved in energy and membrane phospholipid metabolism, supporting the study of neuroenergetics and brain health. Our previous study revealed a metabolic network linking NAD metabolism with phospholipid turnover, energy production, and aging. Comparing younger and older subjects, we observed distinct metabolic profiles, including increased PCr, glycerophosphocholine (GPC), and glycerophosphoethanolamine (GPE) levels, alongside a rise in ATP synthase activity and declines in ATP and phosphoethanolamine (PE) levels. These findings highlight ^3P MRS as a powerful tool to uncover metabolic changes, supporting new therapeutic approaches targeting energy pathways in aging. Moreover, MRS can monitor energy metabolism and biochemical changes during cognitive or motor tasks, enabling analysis of activity-induced metabolic shifts. So far, a key question to address in aging-related brain research is whether motor learning can counteract brain changes associated with aging. Balance learning, a promising intervention, has been shown to enhance postural stability, structural and functional connectivity adaptations. However, most studies focus on young adults, it remains unclear if similar plasticity effects occur in older adults and what is underlying molecular mechanism. In this talk, I will first give an overview about age-related metabolic changes, focusing on neurotransmitters and energy metabolites, and then explore how advanced MRS techniques can map regional and functional brain changes. Finally, I will share findings from our recent study on long-term balance and strength training in older adults, examining how physical training may enhance brain metabolism and counteract aging-related decline in motor performance.

Invited Symposium

IS-PN03 From Sea to Space - Human Physiology and Performance in the Extreme Environments Underwater, High-Altitude, and Weightlessness.

ARTERIAL PARTIAL PRESSURE OF OXYGEN VARIATIONS IN BREATH-HOLD AND SCUBA DIVING: STATE-OF-THE-ART

BOSCO, G.

UNIVERSITY OF PADOVA

According to Boyle's law and current diving physiology, divers' arterial blood gas (ABG) levels vary proportionally to environmental pressure underwater. As experimentally demonstrated in hyperbaric chambers, the arterial partial pressures of O_2 (PaO_2) in SCUBA divers increase during the descent and progressively normalize when resurfacing. In breath-hold divers (BHDs) instead, PaO_2 rises during the descent - as lungs compress - but progressively falls when resurfacing due to metabolic consumption and redistribution in re-expanding lungs. This work summarizes the PaO_2 from ABGs obtained in the last 4 experimental campaigns on BHDs and SCUBA divers in the real underwater environment. All the experiments were approved by the institution's ethics committee and included healthy, expert SCUBA divers or BHDs. After inclusion, an arterial cannula was inserted into the radial artery of the non-dominant hand. The ABGs were drawn in different conditions: resting at the surface after cannulation; immediately before diving, after controlled ventilation, in water, face submerged; at depth (-15 mfw or -42 mfw), with BHDs using a sled or fins, and SCUBA divers before and after pedaling on a bike; at surface (after -15 mfw or -42 mfw dives). A scatter plot was used to describe PaO_2 distribution in different protocols. Lung ecography have been performed at depth. 34 subjects were included in the study (8 for SCUBA diving), and 150 samples were obtained. Different protocols were applied during these experiments, explaining the variability among the PaO_2 results. When at rest, out of the water, all the subjects showed to mirror physiological data. After the pre-dive controlled ventilation, a slight increase can be noted, probably due to water compressing the chest and the lungs of BHDs. Five BHDs out of 14 at -15mfw and 6 out of 20 at -42 mfw did not develop the predicted hyperoxemia at depth, potentially due to lung atelectasis or interstitial edema as reported by lung ecography. At the surface, PaO_2 values diminished, with the lowest measured on BHDs using fins to dive. SCUBA divers developed the predicted hyperoxemia at depth without variations after pedaling on the submerged bikes and returned to normal values at the surface. PaO_2 in SCUBA divers seems to follow diving physiology predictions; instead, BHDs show higher variability, probably due to environmental stress exerted on the lungs, resulting in lung edema or atelectasis, which affects gas exchange.

DOES MAXIMAL EXERCISE AT HIGH-ALTITUDE EXACERBATE THE BRAIN'S INFLAMMATORY RESPONSE?

CALDWELL, H.

UNIVERSITY OF COPENHAGEN

The interplay between hypoxia and exercise on the immune response is complex [1,2]. For example, the anti-inflammatory and immunosuppressive effects of strenuous exercise [3] may play a role in immune system sensitization and prevalence of infection at high-altitude [4,5]. Further, pro-inflammatory stress at high-altitude is implicated in the etiology of high-altitude illnesses [6,7]; however, it is controversial whether/how exercise alters pro-inflammatory mediators and therefore the implications of exercise on high-altitude illnesses. How acclimatization to high-altitude affects immune sensitization/suppression and hypersensitivity of inflammatory responses in the brain has not been investigated, particularly following maximal exercise. This talk will discuss the brain's inflammatory response to both 'practical' cycling exercise at a low intensity and in response to acute exhaustive cycling at sea level and following 6-8 days at 3,800 m. Healthy adults (n=12, 6/6 females/males) received radial arterial and internal jugular venous catheterizations to assess trans-cerebral exchange of inflammatory cytokines. Data were obtained prior to and following 60 minutes of steady-state semi-recumbent cycling at an altitude-specific intensity to elicit maximal fat oxidation, and at 5 minutes post- an incremental maximal exercise test. These results indicate that high-altitude per se reduces systemic pro-inflammatory cytokines at rest. Further, 6-8 days of acclimatization at 3,800 m does not provoke immune suppression or mediate elevations in systemic pro-inflammation in response to maximal exercise. Although acute maximal exercise per se does not provoke inflammatory stress in the brain, it appears that the additive duration/intensity effect of prolonged low-intensity exercise followed by acute maximal exercise – irrespective of altitude – provokes a shift toward trans-cerebral net release of pro-inflammatory cytokines. Exposure to high-altitude does not exacerbate pro-inflammatory stress in the brain in response to maximal exercise. Although not directly tested, the current exercise intervention did not initiate any symptoms of altitude illness or headache. As pro-inflammatory stress is implicated in the pathophysiology of altitude illness [6,7], these data support that, in the context of the current experimental study following acclimatization to 3,800 m, this duration and intensity of exercise is not a trigger for altitude illness via pro-inflammatory stress. These data provide insights into the tolerability of acute maximal exercise at high-altitude. [1] Vats et al. (2006). DOI: 10.1016/j.cmet.2006.05.011. [2] Weinberg et al. (2015). DOI: 10.1016/j.immuni.2015.02.002. [3] Shaw et al. (2018). DOI: 10.1016/j.cyto.2017.10.001. [4] Facco et al. (2005). DOI: 10.1249/01.mss.0000162688.54089.ce. [5] Feueracker et al. (2019). SPACEFLIGHT PHYSIOLOGY: THE ROLE OF COUNTERMEASURES FOR HEALTH AND PERFORMANCE IN WEIGHTLESSNESS

MÖLLER, F.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY

Prerequisites for human performance during spaceflight are survival in the extreme space environment and solutions to maintain health in weightlessness. Habitat and life-support solutions keep astronauts alive against the imminent threats of vacuum, temperature, and carbon dioxide accumulation, and countermeasures are implemented to maintain health and attenuate cardiovascular and musculoskeletal deconditioning. Specific risks associated with weightlessness, such as hypoxia, hypercapnia, and changes in pressure, are similar to those encountered in underwater and high-altitude environments. This talk discusses the physiological adaptations in weightlessness and the role of countermeasures and gravitational stress in maintaining health and performance during spaceflight. Current plans of national space agencies and commercial providers will increase the number of people in space, and tasks like extra-vehicular activities, the return to a gravitational field, and future planetary explorations demand intact high performance to ensure safety and mission success. Current countermeasures include engineering, medical, and exercise interventions, but astronauts continue to return with impaired vision and losses in bone mineral density, muscle mass, and strength [1–3]. Determining the necessary amount of gravity to maintain astronaut health remains a critical challenge. While 1G on Earth appears optimal, it is unclear how much gravitational stress is needed in space to achieve similar health outcomes. Weightlessness induces a cranial fluid shift with central hypervolemia, increased intracranial and intraocular pressures, and reduced venous return [4], suspected to cause the observed ocular morphology and vision changes during and following long-duration spaceflight [5,6]. Furthermore, the lack of gravitational stress deconditions the cardiovascular and musculoskeletal systems, reducing aerobic capacity and increasing the risk of bone fracture during planetary landings and orthostatic intolerance after returning to a gravitational field. While the International Space Station offers various countermeasures, medical support, and evacuation strategies, future long-duration spaceflight will amplify current risks while posing severe volume and weight limitations, demanding novel and comprehensive countermeasure solutions. OP-AP13 Training and Testing III - Interval / Sprint Training

ADAPTATIONS TO HIGH-INTENSITY INTERVAL TRAINING AND SPRINT INTERVAL TRAINING ARE INFLUENCED BY AN ATHLETE'S LOCOMOTOR PROFILE

THRON, M., SONDERMANN, Y., RUF, L., VAN HOOREN, B., DÜKING, P., WEHDEMEIER, L., BUDAY, L., WOLL, A., ALTMANN, S.
KARLSRUHE INSTITUTE OF TECHNOLOGY

INTRODUCTION: High-intensity interval training (HIIT) is frequently used to improve maximal physiological (e.g., VO_2max) or locomotor variables (e.g., maximal aerobic speed (MAS), maximal sprinting speed (MSS)) (Rosenblat et al., 2020). HIIT involves repeated bouts at intensities between the second lactate threshold and MAS, or sprints above MAS, i.e., sprint interval training (SIT). Previous literature does not favor one format over the other for physiological and locomotor adaptations (De Oliveira-Nunes et al., 2021). However, no study has analyzed the influence of an athlete's locomotor profile on adaptations to HIIT and SIT. Therefore, we aimed to 1) evaluate differences in physiological and locomotor adaptations to HIIT vs. SIT and 2) analyze the influence of the locomotor profile on those adaptations.

METHODS: Twenty-seven trained, male and female runners (27.67 ± 7.45 years; $n=12$ women) completed pre- and post-testing comprising a 40-m sprint test to assess sprint performance (t40) and MSS and an incremental treadmill test to determine VO_2max , MAS, velocity at lactate threshold 1 and 2 (vLT1 and vLT2), peak treadmill speed (vpeak), and running economy (RE). Anaerobic speed reserve (ASR) was calculated by subtracting MAS from MSS and speed reserve ratio (SRR) as a ratio of MSS and MAS. The latter served to categorize participants as endurance, hybrid, or speed types. Further, they were stratified and assigned to six weeks training of two sessions HIIT (4-6x 4min/2min @90-95% MAS) or SIT (6-10x 20s/3min all-out sprinting) per week. Linear mixed models (Outcome=Time x Group + (1 | ID)) and linear models (%change=Group x Type) were calculated.

RESULTS: Both groups showed significant improvements in MAS and vpeak ($p \leq 0.03$; $d \geq 0.87$), while MSS and t40 only improved in the SIT group ($p \leq 0.04$; $d \geq 0.84$). ASR declined and vLT2 inclined in the HIIT group only ($p=0.01$; $d=0.41$). VO_2max , vLT1, and RE did not change significantly ($p \geq 0.08$; $d \leq 0.71$). Independent of the group, MAS incline ($p \leq 0.02$; $d \geq 2.25$) and ASR decline ($p \leq 0.02$; $d \geq 1.70$) was higher for the speed compared to hybrid or endurance types. Endurance types improved t40 more in the SIT than HIIT group ($p=0.003$; $d=-2.03$) and more than hybrid types ($p=0.03$; $d=2.03$). VO_2max of speed types decreased in SIT but not in HIIT ($p=0.04$; $d=-1.81$).

CONCLUSION: In conclusion, both HIIT and SIT improved endurance performance in trained runners, with SIT showing additional benefits for sprinting and HIIT for endurance (vLT2). Locomotor profiles influenced adaptations, with speed types showing greater MAS improvements and ASR declines, while endurance types benefited more from SIT in terms of t40. These results suggest that both training methods are effective and the specific benefits can vary based on the prescribed form of high-intensity exercise as well as the athletes locomotor profile. This highlights the potential of considering individual locomotor profiles when designing high-intensity training programs to optimize desired adaptations.

HOW THE APPLIED LOAD DURING THE PREPARATORY PERIOD AFFECTS CHANGES ON THE ANAEROBIC AND PSYCHOMOTOR FATIGUE THRESHOLD

CHMURA, P., OLIVA-LOZANO, J.M., WEI, X., KRUSTRUP, P.
WROCLAW UNIVERSITY OF HEALTH AND SPORT SCIENCES

INTRODUCTION: The preparation period is a key time when players returning from a rest break are expected to improve their physical performance quickly and substantially in order to compete in a league lasting many weeks (Csala et al. 2021). The aim of this study was to investigate how the anaerobic threshold (ANT) and psychomotor fatigue threshold (PFT) change with the insertion of the 30-min block of high intensity interval training (HIIT) and normal training implemented during the preparatory period.

METHODS: Twenty selected U-19 players playing daily in a professional football team were studied. The team was randomly divided by a group of players. The first group realized two times per week a 30-min block of HIIT exercises (HIIT), and the second group realized normal training (CON). The research was carried out in the Exercise Research Laboratory. The players performed an incremental progressive all-out test at the beginning of the round and after the preparatory period lasting 4 weeks. The measurement of lactate (LA) determined anaerobic threshold (ANT), whereas the choice reaction time (CRT) indicated psychomotor fatigue threshold (PFT) among other selected physiological parameters. The repeated-measure analysis of variance (ANOVA) compared mean values for the examined variables using the Fisher post hoc test.

RESULTS: One of our main results is that the applied loads in the HIIT group significantly raised the anaerobic threshold at the velocity running from 13.20 to 14.49 km/h ($p \leq 0.000$). In contrast, the CON group did not show any significant change, remaining at 13.26 km/h before and 13.20 km/h after the 4-week preparation period. Regarding the psychomotor fatigue threshold, the HIIT group initially reached 14.00 km/h, and after the preparation period, it significantly increased to 15.44 km/h ($p \leq 0.000$). While the CON group also showed an increase, it was not statistically significant (from 13.75 to 14.12 km/h).

CONCLUSION: One advantage of HIIT is its ability to improve physiological parameters and performance in a short amount of time (Buchheit and Laursen 2019). Finally, it was shown that the group performing an additional 30-minute block of interval training tested thresholds shifted towards higher loads - higher running speed. In addition, no significant changes were observed in the control group. This indicates that coaches should incorporate HIIT exercises in the preparatory period.

THE FREQUENCY OF REPEATED-SPRINT TRAINING IN HYPOXIA DOES NOT IMPACT OVERALL PHYSIOLOGICAL AND PERFORMANCE ADAPTATIONS IN MALE UNIVERSITY BASKETBALL PLAYERS

YAMAGISHI, T., HAGIWARA, M., ANDO, R., SHIRAKI, S., HENDERSON, F., YAMASHITA, D.

JAPAN INSTITUTE OF SPORTS SCIENCES

INTRODUCTION: Repeated-sprint training in hypoxia (RSH) provides greater training adaptations than a similar training performed in normoxia (RSN) in competitive athletes [1, 2]. RSH is recommended to be performed 2 to 3 sessions per week over several weeks at a simulated altitude of around 3000 m [1, 2]. However, implementation can be challenging due to limited access to a hypoxia environment, e.g., few infrastructures, congested schedules (e.g., work, school). Thus, it is important for athletes and coaches seeking to optimise training implementation to understand the minimal dose (e.g., frequency) of RSH required for desired training benefits. In particular, adhering to the recommended frequency (i.e., 2 to 3 sessions per week), can similar adaptations be attained by replacing some RSH sessions with RSN? This study aimed to determine effects of frequency of RSH on physiological and performance adaptations in male university basketball players.

METHODS: Nineteen male university basketball players competing at a national level (20 ± 1 yrs, 181 ± 9 cm, 78 ± 12 kg, maximal oxygen uptake [$\text{VO}_{2\text{max}}$]: 55.6 ± 5.7 ml·kg⁻¹·min⁻¹) completed 6 training sessions consisting of 2 to 3 sets of 5 to 6 repetitions of 6-s all-out cycle sprints (inter-sprint rest: 30 s; inter-set rest: 300 s) over 2 to 3 weeks. While 9 of them performed all 6 sessions in normobaric hypoxia at a simulated altitude of 3000 m (HYPO), the remaining 10 players performed RSH and RSN alternately (i.e., 3 sessions each, MIX). Before and after the intervention, average power (AP) during a 6-s all-out cycle test, and maximal incremental power (MIP) and $\text{VO}_{2\text{max}}$ achieved in an incremental cycle test were determined.

RESULTS: A two-way (time and group) analysis of variance showed a significant main effect of time in all parameters (AP, MIP and $\text{VO}_{2\text{max}}$, $p < .05$), whereas a significant time-by-group interaction effect was not observed in any of those parameters. Consequently, the magnitude of improvements was similar between the groups (HYPO vs. MIX: AP, 7.2 ± 7.7 vs. $9.8 \pm 13.9\%$; MIP, 3.0 ± 3.5 vs. $3.5 \pm 3.2\%$; $\text{VO}_{2\text{max}}$, 2.9 ± 4.6 vs. $4.0 \pm 7.7\%$).

CONCLUSION: The frequency of RSH over a short period of time does not seem to impact physiological and performance adaptations in young male basketball players. Although RSH has been shown to be more effective than RSN in inducing adaptations [1, 2], combined effects of RSH and RSN remained unknown. The findings of this study indicate that 50% of RSH sessions can be replaced by RSN without diminishing the degree of adaptations, thus offering flexible options for athletes and coaches, especially when facing congested schedules and limited access to a hypoxic environment.

MEDIAL GASTROCNEMIUS STIFFNESS IS NOT CORRELATED WITH SPATIOTEMPORAL VARIABLES DURING 100-M SPRINT RUNNING IN COLLEGE SPRINTERS

FUJII, N., TAKAHASHI, K., KAWAMA, R., WAKAHARA, T.

DOSHISHA UNIVERSITY

INTRODUCTION: Passive muscle stiffness affects the power output of the muscle-tendon unit [1]. It has been shown that the stiffness of the medial gastrocnemius (MG) was negatively correlated with 100-m race time in well-trained sprinters [2]. This finding implies that MG stiffness is related to determinants of sprint running performance (i.e., spatiotemporal variables, such as step frequency, step length, flight time, stance time, flight distance, and stance distance [3]). However, this possible relationship has not been explored yet. Meanwhile, a previous study [4] reported that the stiffness of MG was correlated to drop jump height, suggesting that the stiffness may also be correlated with the flight distance during sprint running through rapid explosive force production. This study aimed to elucidate the relationships between MG stiffness and spatiotemporal variables during 100-m sprint running.

METHODS: Participants were twenty-one male college sprint runners (100-m best record: 11.03 ± 0.29 s). The shear wave velocity of MG was measured using an ultrasound scanner as an index of muscle stiffness at passive and active (during isometric plantarflexions at 20% and 50% of maximal voluntary contractions [MVC]) states. Participants performed 100-m maximal sprint runs, while their running times were measured using timing gates. Their sprint motions were recorded

with a high-speed camera (250 fps) to determine spatiotemporal variables at 50-60 m interval. Pearson's correlation analysis was used to investigate the relationships between two measured variables.

RESULTS: The shear wave velocity of MG at passive and active states was not significantly correlated with any spatiotemporal variables at 50-60 m interval ($p = 0.057$ to 0.937), even when considering the effect of body height. In addition, the shear wave velocity of MG at passive and active states was not significantly correlated with 100-m sprint running time ($p = 0.143$ to 0.659).

CONCLUSION: The present findings imply that the stiffness of MG has no significant effect on the spatiotemporal variables of the sprinters with 100-m sprint running time of around 11 s. A possible explanation for the lack of correlation between the shear wave velocity of MG and flight distance is the small contribution of MG to horizontal ground reaction force during sprint running (5). In addition, the MG stiffness was not significantly correlated with 100-m race time, unlike the previous study (2). This inconsistency may be associated with differences such as the best race time of 100-m (11.03 ± 0.29 s vs 10.88 ± 0.33 s). Our results suggest that athletes and coaches may not need to emphasize MG stiffness when planning training programs.

THE IMPACT OF UPPER BODY STRENGTH AND BODY COMPOSITION ON 500-METER FLAT-WATER SPRINT KAYAK PERFORMANCE

KRISTIANSEN, M., JENSEN, K., LUNDBYE-JENSEN, J., DE ZEE, M., KLITGAARD, K.
AALBORG UNIVERSITY

INTRODUCTION: Strength training plays a crucial role in enhancing performance in flat-water sprint kayaking. However, the specific physical attributes that should be prioritized in strength training remain unclear due to limited research in sprint kayaking. This study aims to elucidate the relationship between upper body strength, anaerobic power, body composition, and performance in the 500-meter flat-water sprint kayak event.

METHODS: 32 competitive kayak athletes (22 international-level, 23 men, 9 women) participated in two official 500 m on-water sprint kayak events in which their performance was recorded (114.0 ± 6.6 s). Within one week of the event, maximal dynamic strength, maximal isometric strength, maximal power output, and strength-endurance was assessed in the bench press and bench pull exercises. Body composition was assessed using dual-energy x-ray absorptiometry (DEXA) and anaerobic peak power (Ppeak) was assessed in a 5-s all-out ergometer sprint test. A partial least squares (PLS) regression analysis was conducted to evaluate the relationship between the dependent variable and the independent variables.

RESULTS: The age, height, body mass, lean body mass, and body fat percentage of the kayak athletes were 20.0 ± 3.3 years, 180.0 ± 7.9 cm, 77.9 ± 10.2 kg, 62.6 ± 9.7 kg, and $17.6 \pm 5.3\%$, respectively. The PLS regression analysis revealed that the independent variables explained 51.5% (adjusted R^2) of the variance in the 500m race performance using one latent factor in the model. The most important independent variables were lean mass of the torso (Variable importance in the projection (VIF) = 1.146), maximal dynamic strength in bench press (VIF = 1.129), lean mass of the arms (VIF = 1.079), and maximal dynamic strength in bench pull (VIF = 1.036).

CONCLUSION: Performance in the 500-meter flat-water sprint kayak event is influenced by lean body mass, particularly in the upper body, and maximal dynamic strength in the bench press and bench pull exercises. While this study does not establish a causal relationship, it suggests that strength training for kayak athletes should prioritize increasing upper body lean mass and enhancing maximal dynamic strength in the bench press and bench pull exercises.

COMPREHENSIVE ANALYSIS OF THE NEURAL, MUSCULAR AND MECHANICAL DETERMINANTS OF THE RATE OF FORCE DEVELOPMENT

SALVAGGIO, F., BIZET, B., TRINCHI, M., BERBENNI, T., D'EMANUELE, S., RAINOLDI, A., SCHENA, F., TAPERI, C., MONTE, A., BOCCIA, G.
UNIVERSITY OF TURIN

INTRODUCTION: The neuromechanical determinants of the rate of force development (RFD) have been widely investigated, each time within a different framework, often analyzing only a subset of the relevant neuromechanical variables. Studies

have examined central and peripheral factors such as neural drive estimates, motor unit recruitment, muscle contractility and excitability, fascicle behaviour, muscle-belly gearing, and tendon stiffness. However, these factors have rarely been assessed in combination, limiting the ability to understand the factors influencing rapid force capacity comprehensively. In the present study, we aim to provide a wider perspective on the determinants of isometric RFD.

METHODS: Right limb knee extensors of 32 healthy young adults (15 F) were tested in isometric conditions. The procedure included: evoked contractions (single and octets stimuli); 5s maximal isometric voluntary contractions to measure maximal voluntary force (MVF); 15 isometric burst-like contractions. HD-EMG from vastus lateralis, vastus medialis and rectus femoris were recorded throughout the session, while B-mode ultrasound data of the patellar tendon and vastus lateralis fascicle were recorded only during voluntary contractions. The root mean square (RMS) of HD-EMG of burst-like contractions was normalized to the peak-to-peak amplitude of the M-wave and then averaged. The patellar tendon stiffness was computed from 0-50% of MVF and 50-100% of MVF. Fascicle and belly shortening velocity and architectural gear ratio were derived from fascicle and belly length changes. Correlation and stepwise multiple linear regressions were run between each time-locked RFD metric and the other neuromuscular variables.

RESULTS: RFD at 25 and 50 ms are mainly explained by mean normalized RMS (R^2 0.68 and 0.83, respectively). RFD at 75 ms is explained by mean normalized RMS, tendon stiffness up to 50% of MVF and octet's RFD at 50 ms (R^2 =0.81). RFD at 100 ms is explained by octet's RFD at 50 ms, tendon stiffness in the first 50% of MVF and inversely by muscle velocity (R^2 =0.88). RFD at 125 and 150 ms are explained by octets RFD at 50 ms (R^2 =0.78 and R^2 =0.82, respectively).

CONCLUSION: Overall, early RFD is primarily influenced by early muscle activation, whereas late RFD underscores the importance of peripheral force-generating mechanisms, i.e. muscle contractility. Interestingly, mid-phase RFD (RFD at 75 and 100 ms) appears to be shaped by a combination of muscle-tendon properties, muscle activation, and peripheral contractile characteristics.

QUADRICEPS FORCE LOSS IS NOT DIFFERENT BETWEEN INDIVIDUALIZED AND STANDARDIZED FREQUENCIES OF NEUROMUSCULAR ELECTRICAL STIMULATION

PAISH, A., DALTON, B., EVES, N., MCNEIL, C.

UNIVERSITY OF BRITISH COLUMBIA

INTRODUCTION: Neuromuscular electrical stimulation (NMES) over a nerve or muscle belly can evoke involuntary contractions which allow for the assessment of intrinsic contractile properties. Repeated activation of the muscle via intermittent trains of stimuli can assess fatigability (i.e., force loss), the magnitude of which is influenced by NMES parameters such as stimulation frequency. For example, we determined recently that NMES at the frequency equivalent to the mean motor unit discharge rate (MUDR) expected during a voluntary contraction at 25% of maximal knee extensor force (10Hz) induces less force loss than frequencies that exceed the mean MUDR (i.e. 15 and 30Hz). Despite innate MUDR variability between people, it is currently unknown if a stimulation frequency equal to an individual's mean MUDR, which should optimally match NMES to intrinsic contractile properties, will mitigate fatigability to a greater degree than utilizing a standardized value based on population data (i.e., 10Hz). Thus, the aim of this study was to compare force loss during NMES at 10Hz vs. the frequency tailored to each participant's mean MUDR.

METHODS: Nine healthy, young adults (26+/-3y; 6 females) completed two testing sessions separated by at least 72h, identical in procedure except for stimulation frequency applied to the muscle bellies of the quadriceps. To assess strength and voluntary activation (VA), participants performed brief isometric maximal voluntary contractions (MVCs) of the knee extensors, with a single supramaximal stimulus delivered during and after each MVC. Individual MUDRs were collected using two concentric needle electrodes inserted into the rectus femoris, vastus lateralis, or vastus medialis during repeated 15-s contractions at 25% MVC force, separated by ≥ 90 s. For each participant, all MUDRs (≥ 24 per muscle) were averaged to determine the individualized NMES frequency. For the 3-min fatiguing NMES protocols, current was set to initially evoke 25% MVC force. The protocols consisted of 144 contractions, each separated by 1.25s (~0.6s on and 0.65s off), with the order of frequencies counterbalanced across participants.

RESULTS: Baseline MVC force (538.6+/-189.3N) and VA (95.9+/-1.9%) were not different between sessions ($p=0.231$). The mean MUDR at 25% MVC force was 11.6 $\pm$ 2.2Hz (ranging from 8.5-14.5Hz). At the end of the 3-min protocols, force loss was not different between 10Hz (26.6+/-20.6%) and individualized NMES frequencies (29.8+/-19.0%; $p=0.479$).

CONCLUSION: Despite matching participant knee extensor mean MUDR, NMES at a tailored frequency did not mitigate force loss compared to the standardized 10-Hz session. As the acquisition of MUDRs requires additional equipment, expertise, and time, and there was no functional benefit to a tailored NMES frequency, a standardized NMES frequency of 10Hz appears most appropriate for future studies involving intermittent stimulation of the quadriceps of young, healthy adults.

ELECTRICALLY INDUCED TORQUE LOSS REDUCES MAXIMAL HUMAN MOTOR UNIT FIRING RATES

ZERO, A., FANOUS, J., RICE, C.

THE UNIVERSITY OF WESTERN ONTARIO

INTRODUCTION: During a sustained (e.g., 60s) isometric maximal voluntary contraction (MVC), both torque and human motor unit (MU) firing rates decline by ~50% (1,2). The mechanism(s) for these rate adaptations during muscle fatigue (i.e., torque loss) are unclear, however, modified afferent feedback and alterations in descending drive have been implicated (1,3).

The purpose was to assess whether voluntary descending drive is obligatory to reduce maximal MU firing rates with fatigue. To test this, we compared maximal MU firing rates following a sustained 60s MVC and separately following 60s of tetanic peripheral nerve stimulation at similar high torque levels. If changes in descending drive contribute to reductions in maximal firing rates with similar torque losses in both conditions then with electrically induced contractile failure maximal firing rates should not be affected, or to a much lesser degree.

METHODS: Participants (7 males and 3 females, 23.7 ± 3 years) were seated upright on a chair with their left leg placed in a custom-made dynamometer to record isometric dorsiflexor torque. A bar electrode was placed over the common fibular nerve and a supramaximal current was used to induce electrically evoked contractions.

To record single motor unit (MU) activity two tungsten microelectrodes were inserted into the tibialis anterior by two independent operators. For baseline measures, three 5s dorsiflexion MVCs, separated by 5-min rest, were performed.

On separate days, participants completed a 60s sustained MVC or 60s peripheral nerve stimulation. To mimic the firing rate decline observed during MVCs, stimulation frequency was reduced from 40Hz to 20Hz over the 60s (2). Immediately (~2s), 1.5, 3, 5 and 10min post-task, a 5s MVC was performed, and MU activity was recorded. The protocols were repeated twice on separate days to increase MU yield. Two-way repeated measures ANOVAs and mixed linear models were performed.

RESULTS: Baseline MVC torque was 40.1 ± 10.8 Nm and tetanic nerve stimulation induced ~80% MVC.

Immediately (~2s) after both tasks MVC was similarly reduced (~30%) relative to baseline ($P=0.2$). Remaining post-task MVCs recovered similarly and by 10min returned to baseline ($P=0.3$, ~96%).

A total of 1531 MUs were analyzed. Baseline maximal MU firing rates of the tibialis anterior were 40.1 ± 11.5 Hz. Firing rates immediately declined by ~30% post-tasks ($P<0.001$) but recovered similarly (~95%) by 10min with no task differences at any time point ($P>0.1$).

CONCLUSION: The similar reductions and recovery in firing rates in both fatiguing tasks indicate that during a high-intensity 60s task voluntary drive is not a contributor to reductions in firing rates. These findings provide enhanced evidence that peripheral factors likely originating from the fatigued muscle are responsible for firing rate reductions during voluntary efforts.

MOTOR UNIT BEHAVIOUR DURING ISOMETRIC CONTRACTIONS IN MASTER POWER ATHLETES

CONNELLY, C., THOMASON, H., VALENCIC, T., OHANLON, M., JENZ, S., PEARCEY, G., PIASECKI, J., PIASECKI, M., FOLLAND, J., ŠKARABOT, J.

LOUGHBOROUGH UNIVERSITY

INTRODUCTION: Motor unit (MU) discharge rate and its modulation are key factors implicated in the loss of force-generating capacity and physical function with older age. However, there is limited knowledge of MU discharge rate modulation at higher forces or rates of force development (RFD) and whether the age-related neuromuscular alterations can be offset with higher physical activity levels. Therefore, we compared tibialis anterior (TA) MU discharge properties in older master athletes to older and young controls.

METHODS: Twenty-two power master athletes (MA; 74 ± 6 yrs, 6 females; competing in throwing, jumping or sprint events), 22 older (OC; 76 ± 4 yrs, 6 females) and 22 young controls (YC; 24 ± 4 yrs, 6 females) performed two unilateral maximum voluntary isometric contractions to assess maximal voluntary force (MVF), followed by five rapid contractions (~80% MVF) to assess RFD (maximal slope of the force-time curve from onset), and submaximal, triangular ramp contractions (30, 50 and 70% MVF). Electromyographic (EMG) signals were recorded from TA using a 64-channel electrode.

EMG signals were decomposed into individual MU spike trains using a Convolution Kernel Compensation algorithm. For rapid contractions, initial (first 5 spikes) and steady (20 spikes on the contraction plateau) discharge rate and MU recruitment speed were calculated. During triangular contractions, we calculated the peak discharge rate, and discharge rate hysteresis (ΔF) as an estimate of the contribution of persistent inward currents to the MU discharge rate.

RESULTS: The groups differed in dorsiflexion MVF (main effect: $p=0.0496$), however, post hoc testing did not suggest any specific between-group differences (MA: 344 [305, 383] N, OC: 288 [255, 322] N, YC: 348 [310, 385] N; $p=0.0496$). The groups also differed in the ability to express the available force rapidly ($p=0.0018$), with greater RFD noted for YC (432 [405, 459] %MVF/s) compared to MA (372 [345, 399] %MVF/s, $p=0.0074$) and OC (346 [318, 373] %MVF/s, $p=0.0001$). Nevertheless, this was not accompanied by between-group differences in MU recruitment speed ($p=0.3407$), or the initial ($p=0.1223$) or steady MU discharge rate ($p=0.2286$) during rapid contractions.

Regardless of contraction intensity, MU discharge rate and ΔF during submaximal contractions were greater in YC (26.4 [25.0, 27.9] pps, 5.6 [5.0, 6.1] pps) compared to both OC (21.1 [19.6, 22.5] pps, 3.8 [3.2, 4.3] pps; $p<0.0001$) and MA (21.6 [20.1, 23.0] pps, 3.8 [3.3, 4.3] pps; $p<0.0001$).

CONCLUSION: Both older groups exhibited smaller RFD compared to young adults, which was not accompanied by differences in MU discharge rate during rapid contractions. During submaximal contractions, younger individuals compared to

both older groups exhibited greater discharge rate, possibly due to the greater contribution of persistent inward currents. These results suggest that the age-related neuromuscular alterations are evident even in highly active individuals.

ACUTE EFFECTS OF ECCENTRIC AND CONCENTRIC MUSCLE FATIGUE ON NEUROMUSCULAR PERFORMANCE AND SINGLE-LEG JUMPS: A RANDOMIZED CONTROLLED CROSSOVER STUDY

BAUMGART, C., ZEMKE, J., HEINKE, L., RAPPELT, L., LEGERLOTZ, K.

UNIVERSITY OF WUPPERTAL

INTRODUCTION: Both concentric (CON) and eccentric (ECC) muscle actions regularly occur in everyday life. However, the underlying mechanistic explanations of ECC are poorly understood (1). Moreover, short-term effects of ECC training remain inconsistent (2). Therefore, this study aimed to investigate the acute effects of CON and ECC muscle fatiguing exercises on neuromuscular performance and single-leg jumps.

METHODS: At two sessions 36 sports students randomized performed five sets of 15 maximal isokinetic knee extensor contractions (ROM: 5-95°, 40°/s), either CON or ECC. Before and after all sets, isokinetic strength of the muscle action, not performed in the exercises, was also assessed. Surface electromyography (sEMG) of the vast. lat., vast. med., and rect. fem. as well as torque were measured. Before and after the strength tests, five single-leg counter-movement jumps were performed on a force plate wearing an inertial sensor system.

The effects of fatiguing muscle exercise type (CON and ECC) and time (PRE and POST) on measures of maximum strength (CON, ECC), sEMG (sum of signals relative to torque), and jump data (height, knee flexion) were analysed by traditional parametric tests and Statistical Parametric Mapping (SPM).

RESULTS: After ECC a significant reduction in the maximum CON strength by $10 \pm 12\%$ ($p < .001$) was observed, while the maximum ECC strength remained unchanged. In contrast, after CON significant reductions were found in maximum CON ($22 \pm 14\%$, $p < .001$) and ECC ($10 \pm 11\%$, $p < .001$) strength. No significant changes in jump height were observed after ECC, while it decreased after CON ($17 \pm 7\%$, $p < .001$). Knee flexion during the jump was reduced after CON ($11.4 \pm 8.3\%$, $p < .001$) and ECC ($10.5 \pm 18.7\%$, $p = .029$).

The angle-specific SPM showed no relevant interaction effects (exercise type x time) for CON and for ECC strength, but significant time effects almost over the entire ROM in both exercise types. In CON strength a main effect for exercise type was found with higher values for the ECC. For sEMG the SPM revealed comparable results (significant interaction and main effects) in CON and ECC strength with higher sEMG increases after CON compared to ECC exercise. The anterior-posterior and vertical force differed between PRE and POST in CON predominately during the mid and late jumping phase, while in ECC no substantial effects were found.

CONCLUSION: Maximum ECC strength remains almost unaffected by ECC exercises, whereas CON strength decreases following both muscle action exercises. The strength losses after CON exercises are more pronounced and affect both muscle actions. Additionally, maintaining post-fatigue torque levels requires increased neuromuscular activation, especially after CON.

The lower acute effects in eccentric fatiguing exercises may have implications for training strategies in rehabilitation and athletic performance optimization.

GPS-DERIVED METRICS AND MACHINE LEARNING MODELS FOR INJURY PREDICTION IN PROFESSIONAL RUGBY UNION PLAYERS

REN, X., BOISBLUCHE, S., PHILIPPE, K., DEMY, M., ÄYRÄMÖ, S., RAUTIAINEN, I., DING, S., PRIoux, J.

ÉCOLE NORMALE SUPÉRIEURE DE RENNES

INTRODUCTION: In sports, injury prevention is a key factor for success. Although injuries are challenging to predict, new technologies and the application of data science can provide valuable insights [1]. This study aimed to predict injury risk among professional rugby union players using machine learning (ML) models and optimized injury prevention strategies by pinpointing effective models and position-specific risk factors.

METHODS: Data from sixty-three professional rugby union players during three seasons were analyzed, categorizing into forwards and backs, further classified into five specific positions (tight five, back row, scrum-half, inside backs, outside backs). The dataset included GPS data and derived metrics such as total workload in the 1, 2, and 3 weeks prior to injury, acute-to-chronic workload ratio (ACWR) over different time windows, monotony, and strain. Five ML classification models—Logistic Regression, Naïve Bayes (NB), Support Vector Machine, Random Forest (RF), and eXtreme gradient boosting (XGBoost)—were applied separately for different player positions to assess injury prediction.

RESULTS: For forwards and backs, NB excelled in recall and balanced accuracy, while RF and XGBoost led in F1 score and AUC. Position-specific analysis showed RF achieving the highest balanced accuracy (0.81) and F1 score (0.68) for tight five players, whereas XGBoost dominated AUC (0.85). Scrum-half positions yielded poor model performance across all metrics. Inside and outside backs saw competitive results from NB and XGBoost, with NB leading in recall (0.69) and balanced accuracy (0.78) for outside backs. Additionally, feature importance analysis highlighted position-specific risk factors: forwards prioritized sprint running (SR, >25 km-h⁻¹) monotony and high-speed running (HSR, 18-21 km-h⁻¹) strain, while backs emphasized low-intensity accelerations and total distance. Tight five players were most influenced by SR monotony and exponentially weighted moving average ACWR 3:14, whereas inside backs relied on very high-speed running (VHSR, 21-25 km-h⁻¹) and accelerations >3 m-s⁻².

CONCLUSION: In conclusion, our ML-based approach can effectively predict injuries, particularly when applying a combination of GPS-derived metrics. Additionally, key characteristics indicative of injury risk for players in various positions have been successfully identified. These findings underscored the potential of ML to enhance injury prediction and inform tailored training strategies for athletes.

A COMPARATIVE ANALYSIS OF NETWORK METRICS IN MEN'S AND WOMEN'S FIFA WORLD CUPS: EVALUATION OF CONTEXTUAL INFLUENCES ON PERFORMANCE

LI, X., CAI, X., HAN, B.

BEIJING SPORT UNIVERSITY

INTRODUCTION: Despite the significant developments in women's football, there remains an excessive parametrization based on men's football, hereby creating a dearth of attention on women players performance and even more so on the disparities in performance between genders. In this study, we compared the women's and men's network metrics at both team and player levels according to contextual factors, aiming to determine how the women's passing performance differs from the men's.

METHODS: We analyzed the 128 matches (2816 observations of players) from the 2023 Women's World Cup and 2022 Men's World Cup. A total of 11 network metrics from both the team's and player's level and five contextual factors were considered. Linear mixed models were used to identify the differences between the men's and women's passing performance. For the team and player level analysis, using Team ranking, Quality of opposition, and Match stage as independent variables, and network metrics as dependent variables, the team as a random effect. For the positional and formation analysis, Gender as the independent variable, network metrics were the dependent variable and team as the random effect.

RESULTS: For the team-level analysis, according to the Team strength, Average Degree, Average Weighted Degree, and Density of the top 16 teams were significantly higher than the bottom 16 teams in both world cups ($p < 0.001$). For the Quality of the opposition, only the women's World Cup showed significant differences when facing the top 16 teams ($p < 0.001$). According to formation analysis, all the variables showed a significant gender difference ($p < 0.05$).

For the player-level analysis, for Team strength, all variables exhibited statistical differences ($p < 0.001$). For the analysis of position level, gender differences emerged in most of the variables except for women's Centre Forward ($p < 0.05$).

CONCLUSION: The top 16 teams in both cups exhibited better team cooperation, suggesting the possession-based play style (Average Weighted Degree, Average Degree, DENSITY, Closeness Centrality, and Eigenvector Centrality increased). Women's teams' performance is less stable than men's when facing the top 16 teams (Relative to the men's data, the gap between the women's bottom 16 teams and top 16 teams is larger and statistically significant). Better team cooperation and coordination can emerge in men's 1-4-4-2 and women's 1-3-5-2 because the Average Degree, DENSITY, and Average Clustering Coefficient reached the highest level among all formations. Except for CF, most of the positions in the men's World Cup had better passing performance than the women's cup, CB showed a central role in team cooperation in both cups because Weighted-Out Degree, Weighted-In Degree, Weighted Degree, and Out Degree reached the highest level among all positions. This study provides a base for the specific analysis of performance indicators, informing coaches about specific demands of the women's game with consequences for practice design.

PREDICTION OF NEXT-DAY SUBJECTIVE FATIGUE IN PROFESSIONAL SOCCER PLAYERS: A MACHINE LEARNING APPROACH

SIMONELLI, C., ROSSI, A.

UNIVERSITÀ DELL'INSUBRIA

INTRODUCTION: Predicting the state of fatigue in soccer players is useful to design training and optimize performance. Therefore, the aim of this study was to explore, using a framework of big data analytics, the most important predictors of daily fatigue in a group of professional soccer players using inexpensive and practical data monitoring tools.

METHODS: Six Italian third division (Serie C) professional soccer teams took part in this study, which included a total of 171 players for a total of more than 34,000 data collected. Every morning, the players rated fatigue, sleep quality, muscle soreness, stress and mood. After each training session or match, the session Rating of Perceived Exertion (sRPE) was obtained and multiplied by duration to calculate the Training Load (TL). Finally, some contextual factors, (i.e. distance to previous and next match) were also recorded. Four machine learning models were trained and tested to predict players'

subjective next day fatigue: i) Decision Tree classifier (DTC); ii) XGBoost classifier (XGB); iii) Random Forest Classifier (RFC); iv) Logistic regression (LR), in order to assess their ability to predict the players' daily fatigue.

RESULTS: Machine learning models can accurately predict the players' subjective fatigue (accuracy 79-84%) using practical and inexpensive training monitoring tools. Specifically, in the prediction of next day subjective fatigue, the main influential factor was the fatigue rating of the previous day. The mediation analysis shows a statistically significant direct influence of TL on next day subjective fatigue. This relation is strongly mediated by muscle soreness, sleep quality and stress. The other perceived items do not mediate this relationship.

CONCLUSION: Sport scientists and coaches can use the framework of big data analytics proposed in this paper to predict their players' fatigue status, understanding the influence of other perceptions, judgements and TL characteristics in order to improve the decision-making process when designing a training plan.

In particular, field experts could maximize the training effect by controlling the fatigue status of the soccer players simulating the scheduled training program, in order to maximize players' readiness and reduce the potential drops in performance associated with daily fatigue in a real-world scenario. Finally, this approach can be very useful for practitioners of amateur and grassroots with a limited budget. Both status and internal load measures' data collection, as shown above, is virtually free and it can be taken into account in assessing fatigue by our model.

ML-BASED SCENE CLASSIFICATION USING TRACKING DATA FOR PLAYER COORDINATION ANALYSIS IN TEAM SPORTS

TANAKA, T., MAGOME, T., GOUDA, N.

HITACHI, LTD.

INTRODUCTION: Popular professional sports teams such as soccer and basketball have introduced advanced measurement technology to strengthen their teams. In order to innovate team training, it is necessary to develop a tracking data analysis method that evaluates organizational ability rather than individual ability, and we have developed a method for evaluating cooperation between players using transfer entropy [1]. However, in order to evaluate the validity of the proposed method and make it easier to understand, it is necessary to compare it for each similar play scene such as attack and defense. In this study, we aim to build a system that can evaluate player-to-player coordination while simultaneously classifying scenes from the tracking data of player and ball movement trajectories using a deep learning model.

METHODS: First, we designed a deep learning network to classify scenes from the tracking data of player and ball movement trajectories, and evaluated its accuracy. Based on previous research [2], we applied a convolutional neural network (CNN) that takes the player and ball movement trajectories as input. In this evaluation, we considered using existing professional sports tracking data as training and verification data for building the deep learning model, and applied tracking data from the NBA professional basketball league and the J1 professional soccer league in Japan. In basketball, we classified whether or not a score was scored, and in soccer, we classified whether or not a player entered the area near the goal.

Next, we calculated the transfer entropy between players for each classified scene and evaluated whether the evaluation of cooperation between players in each scene showed the same trend as existing knowledge.

RESULTS: The accuracy of scene classification using tracking data was high, with an AUC of 0.92 for basketball and 0.87 for soccer. We calculated and compared the transfer entropy between players in scenes predicted to have a high probability of scoring opportunities and other scenes. As a result, we found that the transfer entropy of the attacking team of the opposing team was significantly higher in situations predicted to have a high probability of scoring opportunities than in other situations. These results were similar to those obtained in a previous study [1] that used a classification judged by a professional coach to be of high organizational performance.

CONCLUSION: From these results, we confirmed that a deep learning model trained from existing tracking data can accurately classify scenes such as scoring opportunities, making it easier to interpret the evaluation of cooperation between players using transfer entropy, and leading to the development of practical systems.

AN INNOVATIVE RPE-BASED APPROACH USING MACHINE LEARNING TO ANALYZE STARTERS AND SUBSTITUTES TRAINING LOAD IN SOCCER

LATERZA, F., CHAMARI, K., CAMINITI, G., ANNINO, G., BEATO, M., BOVENZI, A., DONOFRIO, R., MANZI, V.

PEGASO UNIVERSITY

INTRODUCTION: Current methods to distinguish starters from substituted are typically based on playing time. Not considering physical demands and internal load of different positions, can leading to inconsequential training and recovery protocols.

The aim of this study was to apply the k-means approach to effectively classify players based on their session-RPE and to provide specific session-RPE thresholds to discriminate starters and substitutes' match load.

METHODS: We analyzed 1,450 player-matches from four professional Italian Serie A teams, using video match analysis to measure total distance (TD) and high-intensity activities: metabolic power events (MPE), high-speed running (HSR), and

very high-speed running (VHSR). Players were divided based on the role as follows: forwards and wingers (FWs), midfielders (MFs), side-backs (SBs), and center-backs (CBs); Individualized sRPE zones (Very Low, Low, Medium, High, Very High) were identified with the K-means clustering approach discriminating starters from substituted.

RESULTS: FWs, MFs, and SBs were considered substituted, and compensatory training was recommended, when the sRPE was within the Medium sRPE zone. However, compensatory training focused on VHSR was recommended at sRPE $\leq$ low for FWs and MFs, and at sRPE = very low for SBs. CBs were defined as starters when reporting sRPE values $\geq$ Low sRPE, and VHSR training was always recommended.

CONCLUSION: Implementing this sRPE-based method offers a more accurate assessment of player workloads, enabling tailored compensatory training.

INTRA & INTER SESSION RELIABILITY OF A NOVEL ISOMETRIC BENCH PRESS ASSESSMENT IN ELITE PROFESSIONAL BOXING ATHLETES

LANGAN-EVANS, C., MOONEY, J.E., POMPHREY, C., MCQUILLIAM, S.J., HEENEY, C., ERSKINE, R.E.

LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: Professional boxing is a dynamic combat sport, whereby two competitors exchange punches. A boxing punch is a complex action involving biomechanical and neuromuscular elements, with end range impact resulting from enhanced peak force (PF), impulse, and rate of force development (RFD). Despite similar upper body movement patterns, traditional strength assessments such as the dynamic bench press one repetition maximum are not positively associated with punch impact outcomes, as this does not accurately reflect punching kinetics or kinematics, likely due to the 'sticking point' early in the concentric phase of the motion. To that end, isometric testing assessments potentially offer a more valuable insight into examining end range PF, impulse and RFD at various boxing punch specific joint angles. Therefore, this study aimed to evaluate the intra and inter session reliability of a novel isometric bench press (ISOBP) protocol on force-time characteristics in elite professional boxing athletes.

METHODS: Following a standardised warm-up, ten professional boxers completed the ISOBP three times within sessions, conducted across one familiarisation and two main trials each separated by a period of 48 hours. The ISOBP was conducted within an adjustable isometric rig, at 105° and 145° boxing punch specific joint angles, confirmed by a hand-held 360-degree goniometer. A padded bench was placed over two calibrated force plates to capture PF, impulse, and RFD variables. Multiple intraclass correlation coefficient (ICC) analyses utilising average measure two-way mixed and absolute agreement parameters, alongside typical error and coefficients of variation (CVs) to determine the magnitude of measurement error ($\leq 10\%$ classified as acceptable) were used to assess intra and inter session reliability.

RESULTS: Intra session reliability was good to excellent for PF, force at specific intervals, absolute impulse, and longer-epoch RFD measures (ICCs = 0.86-0.99; CVs = 2.0-9.3) at both angles. Inter session reliability was also good to excellent for PF and absolute impulse $<100\text{ms}$ at 105° (ICCs = 0.89-0.96; CVs = 3.6-4.3). However, reliability was poor for all RFD, most net force and impulse outcomes, and shorter-epoch measures.

CONCLUSION: The ISOBP demonstrated reliable intra session measurement of PF, interval-specific force, absolute impulse, and longer-epoch RFD, making it useful for evaluating strength training effectiveness and setting performance benchmarks. However, for longitudinal monitoring only inter session PF and impulse $<100\text{ms}$ in the 105° ISOBP were reliable, so other variables should be interpreted with caution. For outcome metrics with poor inter session reliability, standardisation of protocol conditions, testing frequency and incorporating additional measures of neuromuscular function are critical to provide a more global view of an athlete's capacity or progress. This approach, along with the use of typical error scores, ensures that observed changes reflect actual improvements alternate to natural variability in performance.

RELATIONSHIP BETWEEN A FORCE-VELOCITY-POWER PROFILE IN LANDMINE PUNCH EXERCISE AND BOXING PUNCHES FORCE AND VELOCITY.

SIMON, F., DUCHENE, Y., BANET, L., GAUCHARD, G.C.

UNIVERSITY OF LORRAINE

INTRODUCTION: In boxing, force and velocity of punches are discriminating performance parameters (Lenetsky et al., 2018; Loturco et al., 2016). A recent study has validated a force-velocity-power (FVP) profile for a landmine punch exercise (LPE), having technical similarities with a boxing punch which could be helpful for a simple training monitoring (Gusciglio & Morin, 2023). However, the FVP profiles parameters obtained (F0, V0 and Pmax) were not analyzed in relation to punches force and velocity, which was the objective of this study.

METHODS: 27 experimented boxers (23.9 ± 4.4 years old, $75.8 \pm 10.2\text{kg}$) performed LPE with a 10kg bar consisting in 2 sets of 4 repetitions with an additional load corresponding to 20% and 50% of their body mass (Gusciglio & Morin, 2023). An accelerometer (Delsys, USA, 500Hz) was fixed to the bar to record its acceleration and determine its linear velocity. Theoretical mechanical parameters of FVP were calculated using a custom-made spreadsheet (F0, V0, and Pmax). Participants

also performed 6 rear cross and hook punches with maximal intensity and their habitual technique on a 3D force plate (AMTI, USA, 2000Hz) fixed to a vertical support and covered by a body shield. A kinematic marker was placed on the rear arm glove at the 1st metacarpal level to registered punches 3D velocity (Qualysis, Sweden, 200Hz). Maximal punches velocity and force impulse were determined. Pearson's correlations were made to investigate the relationship between these variables and FVP theoretical parameters. Fisher's z was calculated to determine the effect size.

RESULTS: LPE F0 (10.6 ± 1.5 N/kg) was significantly correlated with cross (51.7 ± 10.9 N.s; $r^2=0.29$; $ES=0.61$; $p<0.01$) and hook force impulses (41.4 ± 14.8 N.s; $r^2=0.33$; $ES=0.65$; $p<0.01$). LPE V0 (3.2 ± 0.42 m/s) was significantly correlated with hook velocity (14.5 ± 1.3 m/s; $r^2=0.2$; $ES=0.48$; $p=0.02$) but not with cross velocity (9.9 ± 0.6 m/s; $r^2=0.15$; $p=0.051$). LPE Pmax (8.6 ± 1.6 W/kg) was also significantly correlated with cross ($r^2=0.22$; $ES=0.51$; $p=0.02$) and hook force impulse ($r^2=0.24$; $ES=0.53$; $p=0.01$) but only with cross velocity ($r^2=0.28$; $ES=0.60$; $p<0.01$).

CONCLUSION: F0 and Pmax of LPE are significantly correlated with the impulse of rear hook and cross punches but V0 was only significantly correlated to cross velocity. Thus, LPE seems to be an effective, fast and low-cost tool to help monitoring the force and power development of boxers. Nonetheless, the moderate correlation magnitudes should be considered and could be influenced by the movements' technical differences, where LPE requires a higher vertical component. It might be interesting to develop a FVP profile on a movement simulating a punch with different loads attached to a pulley and replicate this study.

RAPID WEIGHT LOSS, TECHNICAL PERFORMANCE, SCORING EFFICIENCY, AND COMPETITIVE SUCCESS IN ELITE JUDO ATHLETES

FRANCHINI, E., SANTOS, D.F.C.
UNIVERSITY OF SÃO PAULO

INTRODUCTION: Rapid weight loss (RWL) is a common strategy among combat sports athletes [1]. While previous studies have explored the impact of RWL on strength, endurance, and decision-making [2], its relationship with specific performance variables remains unclear. Therefore, this study investigated the correlation between RWL and key performance indicators in judo.

METHODS: Thirty-three judo athletes (age: 21.0 ± 2.2 years; judo grade: 1st dan) competing at national and international levels were monitored during an official competition. Body mass (BM) was recorded 10, 7, and 3 days before the weigh-in, on the day of the weigh-in, and competition day using a Tanita BC-558 scale with a precision of 0.1 kg. The BM reduction was calculated from seven days before the weigh-in to the official weigh-in. Performance metrics were assessed as follows: winning rate - the ratio of matches won to total matches competed; number of attacks per match - the total number of attacks divided by the total matches performed; technical variability - attack diversity, considering different attack sides and directions; and scoring index - the total points scored divided by the total number of attacks, reflecting scoring efficiency. Pearson correlation analyses were conducted to assess the relationship between the magnitude of RWL and performance variables, whereas logistic regression was used to analyze the association between BM reduction and medal success. A significance level of $p < 0.05$ was applied.

RESULTS: BM reduction over the seven days before weigh-in ($4.1 \pm 1.6\%$; 3.9 ± 1.5 kg) showed no significant correlation with winning rate ($r = 0.015$, 95%CI: -0.33, 0.36, $p = 0.935$), number of attacks per match ($r = 0.012$, 95%CI: -0.33, 0.35, $p = 0.947$), nor technical variability ($r = -0.077$, 95%CI: -0.41, 0.27, $p = 0.669$). However, a significant negative correlation was observed between BM reduction and the scoring index ($r = -0.392$, 95%CI: -0.65, -0.07, $p = 0.024$). Additionally, a greater BM reduction during the analyzed period increased the likelihood of winning a medal (OR = 1.63; 95%CI: 1.04, 2.56; $p = 0.033$).

CONCLUSION: Although BM reduction over the seven days before weigh-in did not significantly influence the winning rate, number of attacks, or technical variability, it was negatively associated with the scoring index. This finding suggests that greater BM reduction may impair scoring efficiency. Moreover, logistic regression indicated that greater BM reduction over ten days increased the odds of winning a medal.

OPTIMAL VS MEASURED FORCE-VELOCITY PROFILE AND CORRELATIONS OF ITS MECHANICAL OUTPUTS WITH GENERAL AND SPORT-SPECIFIC PERFORMANCE TESTS AMONG ADOLESCENT FENCERS

KONTOCHRISTOPOULOS, N., BOGDANIS, G.C., PARADISIS, G.P., TSOLAKIS, C.
NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS

INTRODUCTION: Rate of force development and power output are crucial in combat sports (Turner et al., 2020). Fencing actions are executed in <300 ms, confirming the importance of neural factors and intrinsic muscle properties during the initial phase of contraction. Force Velocity Profile (FVP) in adolescent fencers can therefore allow the exploration of their neuromuscular function limits, since adult fencers differed significantly from their optimal FVP (Giroux et al., 2016).

METHODS: Eighteen fencers (age: 14.6 ± 1.1 years, maturity offset (MO): 1.18 ± 1.38 years, training experience (TE): 7.5 ± 2.1 years) carried out, anthropometric, countermovement jump (CMJ), long jump (LJ), 5m sprint (S5) and change of direction fencing test (COD). Measured and optimal FVP were evaluated via unloaded and loaded squat jumps (SJ) of 20, 40 and 60% body weight. Best trial with each load was retained for the FVP assessment through a linear computation model (Samozino et al., 2008). Maximal theoretical measured and optimal force (F_0 & F_{0th}), velocity (V_0 & V_{0th}) and FVP slope (Sfv & Sfv_{opt}), maximal power output (P_{max}) and force-velocity imbalance (FVimb) were computed. Angle of optimal FVP slope was set at 30° , which corresponds to the push-off angle during lunge execution (Giroux et al., 2016). Depended variables T-test was used to investigate differences between FVP measured and optimal mechanical outputs. Pearson correlation (bivariate and partial controlling MO and TE) coefficients (r) was used to evaluate relationships of FVP mechanical outputs with anthropometric measurements and performance tests. Significance was set at $p < .05$.

RESULTS: Significant differences were revealed between measured and optimal force (28.36 ± 5.31 vs 41.4 ± 7.69 N/Kg, $t = -6.06$, $d = -1.97$, $p < .001$), velocity (4.41 ± 1.63 vs 2.87 ± 0.39 m/s, $t = 4.962$, $d = 1.3$, $p < .001$) and slope (-7.47 ± 3.39 vs -14.42 ± 24.44 N*s/m*kg, $t = 7.699$, $d = 2.57$, $p < .001$). Bivariate correlations showed significant relationship of TE with FVimb ($r = .479$, $p < .05$) and body fat with P_{max} , F_{0th} and V_{0th} ($r = -.520$ to $-.554$, $p < .05$). Performance tests except S5 were significantly correlated with V_{0th} ($r = -.567$ to $-.768$, $p < .02$) and P_{max} ($r = -.607$ to $-.608$, $p < .01$). F_{0th} was correlated only with SJ ($r = .511$, $p < .05$) and COD ($r = -.605$, $p < .01$). Partial correlations, enhanced the aforementioned correlations revealing a new one between LJ and F_{0th} ($r = .526$, $p < .05$).

CONCLUSION: Adolescent fencers' FVP differed significantly (force and velocity) from their optimal one. Performance correlations with P_{max} , highlights its crucial role in sports like fencing. Since most of the fencers had a high force deficit and their performance correlated only with F_{0th} and V_{0th} , training must enhance their force qualities in order to optimize their gains. Partial correlations revealed the crucial role of MO and TE on moderating fencers' neuromuscular performance during adolescence.

COMPARISON OF PHYSIOLOGICAL RESPONSES AND PERFORMANCE DECLINE BETWEEN A SIMULATED WRESTLING BOUT AND A NOVEL SPORT-SPECIFIC HIGH-INTENSITY TEST IN ELITE GRECO-ROMAN WRESTLERS

BOGDANIS, G., CHOIRAS, C.1, STAVRINOU, P.2, TSOUKOS, A.1

1. NATIONAL & KAPODISTRIAN UNIVERSITY OF ATHENS, GREECE; 2. UNIVERSITY OF NICOSIA, CYPRUS.

INTRODUCTION: Greco-Roman wrestling is a demanding sport requiring high levels of strength, power, anaerobic endurance and aerobic capacity to sustain high-intensity efforts with limited recovery during training and competition [1, 2]. This compared the physiological responses and performance decline between a simulated wrestling bout and a novel sport-specific high intensity laboratory test (HIT).

METHODS: Seven elite Greco-Roman wrestlers (age: 26.1 ± 8.8 yrs, BMI: 27.3 ± 3.8 kg/m²). completed two main tests: one in the laboratory where the HIT was conducted, and another on the wrestling mat, where a simulated wrestling bout (WRE) was performed. Both tests included 6 min of exercise time allocated in two 3 min rounds, with 1 min rest in between. In WRE each round included 2 x 1.5 min wrestling separated by 30 s or rest. In HIT each round consisted of 2 x [20s wrestling movement + 10s rest] followed by 30s of maximum isometric pull on a seated rowing machine. The wrestling movement included back and forth body motion between a baseline and three light sensors placed 1.8 m to the front, front-right and front-left of the wrestler (at 30° angles). The light sensors were touched as fast as possible in a random order determined by a computer. The number of successful touches and the force applied during the isometric pull were recorded. Counter-movement jump (CMJ) and handgrip strength (HaG) were evaluated before the first and after the second round. Blood lactate (BL) was measured at rest, between the two rounds, immediately after and 3 min after the second round. Heart rate (HR) was monitored continuously from the start until the first minute of recovery.

RESULTS: A two-way ANOVA showed a significant $14.5 \pm 4.5\%$ decrease in CMJ after HIT ($p < .003$), whereas a smaller, non-significant decrease was observed after WRE ($6.2 \pm 6.8\%$, $p = 0.103$). HaG declined similarly in both tests ($11.9 \pm 5.1\%$, $p = 0.01$). BL increased equally in HIT and WRE by the end of each test (17.1 ± 1.5 vs. 15.0 ± 2.6 mmol/L in HIT and WRE, respectively), but remained higher 3 min post HIT compared to WRE (15.8 ± 1.3 vs. 15.0 ± 2.9 mmol/L, $p = 0.04$). Average pull force decreased by $21 \pm 14\%$ only in the second round in HIT. Peak HR reached $96.1 \pm 0.4\%$ and $96.8 \pm 3.2\%$ of HR_{max} during HIT and WRE, with HR remaining above 90%HR_{max} for 5.3 ± 1.0 and 5.8 ± 2.6 min in each test, respectively.

CONCLUSION: The HIT closely replicated the physiological demands of a competitive 2x3 min Greco-Roman wrestling bout and may serve as a valid tool for assessing sport-specific fitness in wrestlers. The high physiological demands of Greco-Roman wrestling were evident in this study and may inform the design of effective sport-specific training programs.

EFFECTS OF SWIMMING PRACTICE AT NIGHT ON SLEEP IN MALE SWIMMERS

HIROKI, F., TOMOTAKA, N., TAKENOBU, C., CIHIRO, T., RIN, M., YURI, M., KAZUSHIGE, G.

RITSUMEIKAN UNIVERSITY

INTRODUCTION: For athletes, both intense exercise and adequate recovery are important to improve performance (Laursen, 2010; Bird, 2013). Inadequate quantities and quality of sleep following exercise can lead to impaired muscle functions and recovery of endurance performance (Fullagar et al., 2015). Previous studies have shown that high-intensity exercise at night reduces sleep quality (Oda and Shirakawa, 2014; Aloulou et al., 2019). However, these studies utilized land exercise (e.g., running, cycling), and the effects of swimming on sleep have not been elucidated. Therefore, the purpose of the present study was to clarify the effect of swimming exercise at night on subsequent sleep quality. We hypothesized that swimming exercise at night would disrupt sleep quality.

METHODS: Ten male swimmers (mean±SD; age: 19.9±1.3 yrs, height: 174.6±4.8 cm, weight: 69.0±5.1 kg) performed two trials on different days with a randomized, counterbalanced order. Between 6:30 p.m. 8:30 p.m., participants performed either (i) a 2h swimming practice session including high-intensity exercise (SWIM) or (ii) maintaining the rest without exercise (CON). Subsequently, participants in both trials took a shower and ate prescribed dinner at the same time, and then slept from 11 p.m. to 7 a.m. Blood lactate concentrations were measured before and immediately after exercise (or rest). Moreover, core body temperature was measured continuously using a pill thermometer from 30 min before exercise (or rest) until the next morning. Sleep quality was assessed using electroencephalograms (EEG).

RESULTS: Blood lactate concentrations markedly increased after exercise (pre: 1.9±0.6 mmol/l vs. after: 20.3±3.9 mmol/l, $p<0.001$). Mean core body temperature was significantly elevated during the swimming exercise compared to CON (SWIM: 37.8±0.4°C vs. CON: 37.1±0.2°C, $p<0.001$). However, no significant difference between conditions was found at bedtime (11 p.m.) and during sleep. Total REM sleep time was significantly decreased in SWIM compared with CON (SWIM: 82.4±27.1 min vs. CON: 107.6±39.5 min, $p=0.039$). However, other sleep variable (time of stage N1, 2, 3, total sleep time, sleep efficiency, sleep onset latency, REM sleep latency and wake after sleep onset) did not significantly differ between trials.

CONCLUSION: Strenuous swimming practice at night (6:30 p.m.-8:30 p.m.) increased core body temperature but it did not change markedly sleep quality in male swimmers.

EFFECT OF PRE-SLEEP ALPHA-LACTALBUMIN SUPPLEMENTATION ON THE HABITUAL SLEEP AND PERFORMANCE OF SPORTSPEOPLE WITH SLEEP DIFFICULTIES.

BARNARD, J., ROBERTS, S., LASTELLA, M., AISBETT, B., CONDO, D.

DEAKIN UNIVERSITY

INTRODUCTION: Up to 78% of athletes report poor quality sleep, with the average athlete obtaining less than seven hours per night (1). Acutely, insufficient sleep impairs technical and tactical performance, with the accumulation of sleep debt also seen to affect endurance (2, 3). As a result, poor-sleeping athletes are particularly vulnerable to performance decline. Prior research within poor-sleeping individuals suggests that the acute supplementation of a whey protein rich in the amino acid tryptophan (TRP), alpha-lactalbumin (ALAC), may be an effective strategy to improve sleep and physical performance (4, 5). Therefore, this study investigated whether sub-chronic supplementation of ALAC in the evening would improve the sleep and physical performance of a poor-sleeping athletic population.

METHODS: Twenty-four athletically trained participants (females, $n=7$) with sleep difficulties (Athlete Sleep Screening Questionnaire: 8.6 ± 2.2 , Pittsburgh Sleep Quality Index: 10.0 ± 3.0) completed this double-blinded, counterbalanced, randomised, cross-over trial. Participants were supplemented with 40 g of ALAC (1.9 g TRP) or an isocaloric placebo two hours prior to individualised bedtimes for seven consecutive nights within habitual settings. To minimise dietary influences on TRP levels, participants consumed standardised low-protein dinners (0.2 g/kg body weight) two hours prior to the supplement, with habitual diet replicated across trials. Sleep was assessed nightly using actigraphy, while subjective sleepiness, mood, and recovery questionnaires were completed every morning and evening. Following the seven-day supplementation period, physical performance testing was completed (i.e., 30-second countermovement jump test, Yo-Yo Intermittent Recovery Test Level 1, and reaction time) at Deakin University in a standardised sequence under controlled conditions.

RESULTS: Compared to control, objective number of awakenings were increased (CON: 10.25 ± 5.28 , ALAC: 11.01 ± 5.79 ; $p=0.031$), average jump height was reduced (CON: 28.58 ± 5.53 cm, ALAC: 27.68 ± 5.14 cm; $p=0.037$), subjective physical and mental performance capability were declined in the evening ($p<0.001$), and evening negative emotional states ($p=0.001$) were reduced during the ALAC condition. No other sleep, performance, or subjective outcomes were influenced following ALAC supplementation.

CONCLUSION: Seven days of ALAC supplementation may not improve the sleep and physical performance of an athletically trained population with mild-moderate sleep difficulties. Future research should recruit populations with more severe

sleep difficulties and measure sleep architecture over an extended period to fully ascertain the effects, and potential benefits, of ALAC supplementation for athletes.

RANGER SALIVARY HORMONE ASSESSMENT FOR DEPLOYED RESILIENCE AND PERFORMANCE PLUS EVALUATION OF NOCTURNAL ENDOCRINE RECOVERY (SHARP+ENER) STUDY

HUNT, A., KENDALL, J., WOODS, D.R., STACEY, M.J., GIFFORD, R.M.

RESEARCH AND CLINICAL INNOVATION, ROYAL CENTRE OF DEFENCE MEDICINE

INTRODUCTION: During military training, physical activity and psychological stress drive increased average cortisol levels and glucose mobilisation which, if sustained, may impair physical and mental health. An inverse relationship is commonly observed between cortisol and androgens which may impede physical and mental training outcomes. This study aimed to explore cortisol, androgen and glucose changes during the RANGER Assessment Cadre (RAC), a 10-day advanced selection course where candidates undergo intense exercise for selection into this elite regiment.

METHODS: Observational study of glucocorticoid and androgen profiles, overnight glucose, stress and sleep during the RAC. Saliva was sampled at 0530, 0700, 1500, 1800 and 2200 on days 1 and 10, continuous interstitial glucose (Dexcom G7) and physical activity and sleep (GENEActiv) were measured throughout. Perceived stress scale (PSS) and Connor-Davidson Resilience-10 (CDRISC-10) were measured on days 1 and 10. Salivary cortisol, cortisone, testosterone (T), androstenedione (A4) and dihydroepiandrosterone (DHEA) were measured via tandem mass spectrometry. Morning cortisol rise (0530 to 0700) and areas under the 5-point day curve (AUC) were calculated. Days 1 and 10 were compared using t-tests.

RESULTS: 17 men completed the study, aged 22 ± 8 years. From day 1 to 10, morning cortisol rise and area under the curve (AUC) cortisol decreased (d 1.81, d 0.67, both $p < 0.05$), and morning cortisol:cortisone ratio decreased (d 0.99, $p = 0.03$) but did not change at other times of day ($p > 0.3$). We found no change in morning androgens ($p > 0.7$) but a marked increase in evening T, A4 and especially DHEA (d 0.91, d 1.5, d 5.3, respectively, $p < 0.0001$; 13.3-fold rise in DHEA, 18.6-fold rise in DHEA:cortisol ratio). Mean overnight glucose increased (4.3 ± 1.0 mmol/L vs 5.2 ± 0.9 mmol/L, $p < 0.001$). Participants slept 6.2 ± 2.2 hours per night including 1.7 ± 1.3 hours on night 5. PSS and CDRISC-10 were 11 ± 5 and 34 ± 4 respectively on day 1 and did not change by day 10 ($p > 0.7$).

CONCLUSION: After an arduous 10-day cadre, morning cortisol and cortisol:cortisone decreased and evening cortisol was unchanged, yet overnight hyperglycaemia was demonstrated, suggesting metabolic dysregulation and increased average cortisol exposure. A dissociated cortisol-androgen response, with a pronounced rise in evening preandrogens, is a novel finding and may represent a buffering response to preserve the cognitive impact of sleep deprivation.

THE EFFECTS OF CONTACT FOOTBALL ON BLOOD BIOMARKERS OF BRAIN INJURY AND CEREBROVASCULAR FUNCTION

OSEI-BOATENG, C., ROSSI, G.1, MONTELEONE, J.2, ROY, M.A.3, BRASSARD, P.3, STUKAS, S.4, VIZCARDO-GALINDO, G.2, CARR, J.2, STEELE, A.2, GIBBONS, T.2, AINSLIE, P.A.2, GRIESDALE, D.E.4, SEKHON, M.4, TYMKO, M.M.1

1. UNIVERSITY OF GUELPH; 2. UNIVERSITY OF BRITISH COLUMBIA OKANAGAN; 3. UNIVERSITÉ LAVAL; 4. UNIVERSITY OF BRITISH COLUMBIA

INTRODUCTION: The association between increased brain blood biomarker concentration and concussion in collegiate contact sport athletes [1] supports the notion that repetitive trauma causes blood brain barrier disruption [2]. Blunted heart rate (HR) and blood pressure (BP) in concussed athletes during sympathetic nervous system (SNS) activation reveals that alterations in cardiovascular function occur following a mild brain injury [3]. Lower body negative pressure (LBNP) is a widely used approach to acutely increase SNS activity. Additionally, hypercapnia is used to assess vasomotor capacity of the brain. Thus, this study aimed to assess cardiovascular and cerebrovascular health in junior Canadian football athletes during a season, using blood biomarkers glial fibrillary acidic protein (GFAP) and neurofilament light polypeptide (Nf-L) as an index of injury, and to also evaluate cardiorespiratory and cerebrovascular function during LBNP and hypercapnia. We hypothesized that biomarkers would be elevated post-game compared to pre-game; and cardiorespiratory and cerebrovascular responses to LBNP and hypercapnia would be blunted post-season compared to pre-season, indicating a potential relationship between contact sport, cardiorespiratory and cerebrovascular function.

METHODS: 14 male junior football athletes had venous blood samples collected 24hrs pre- and 12hrs post-game, which were analyzed for GFAP and Nf-L. Cardiorespiratory and cerebrovascular responses to LBNP (-20, -40, and -60 mmHg) and 3-minute stages of hypercapnia (+5 and +10 mmHg; end tidal forcing system) were evaluated by measuring HR (electrocardiogram), BP (finger photoplethysmography) and blood velocity in the middle and posterior cerebral artery (MCA & PCA; transcranial doppler ultrasound).

RESULTS: GFAP concentration increased from 45.88 ± 16.70 pg/ml pre-game to 53.99 ± 32.89 pg/ml post-game ($P = 0.004$). Nf-L trended towards a decrease ($P = 0.06$). During LBNP, no changes in MCAv or PCAv were observed from baseline to -60 mmHg in both the pre- and post-season (both days; $P > 0.9$). Mean arterial pressure (MAP) remained stable, while HR increased with intensity ($P < 0.009$) and was elevated post-season compared to pre-season at -60 mmHg of LBNP ($P < 0.02$). The MCAv and PCAv response to hypercapnia did not change post-season compared to pre-season (MCAv, $P > 0.9$; PCAv, $P > 0.3$). Also, HR and MAP increased with hypercapnia, but there was no difference when comparing post-season to pre-season response. (HR, $P > 0.1$; MAP, $P > 0.2$).

CONCLUSION: This data demonstrates that GFAP acutely increases after a game of contact football, potentially indicating mild brain injury occurrence without a concussion diagnosis. Despite this rise in GFAP, only the HR response to LBNP was different post- compared to pre-season, as no differences in the cerebral blood flow response to LBNP and hypercapnia were observed. The clinical implications of these findings remain to be fully elucidated.

CATECHOLAMINE, STEROID, AND GROWTH HORMONE RESPONSES TO LOW-LOAD BLOOD FLOW RESTRICTION AND HIGH-LOAD RESISTANCE EXERCISE IN WELL-TRAINED MEN

ESERHAUT, D., DELEO, J., PROVOST, J., FRY, A.

THE UNIVERSITY OF KANSAS

INTRODUCTION: Low-load resistance exercise performed with blood flow restriction (LL-BFR) is often used as a substitute for traditional high-load resistance exercise (HL-RE) for stimulating muscular hypertrophy and strength adaptations, and can induce robust elevations in salivary endocrine markers (1,2). Whether LL-BFR induces greater blood-derived hormonal responses than HL-RE has yet to be investigated in individuals of a higher resistance training status and is of particular importance should LL-BFR be sought for use with healthy athletic populations. Therefore, the purpose of this study was to compare acute testosterone (T), cortisol (C), epinephrine (EPI), norepinephrine (NE) and 22kDa growth hormone (GH) responses to LL-BFR and an ecologically valid bout of HL-RE in well resistance-trained individuals.

METHODS: Twelve healthy resistance-trained men ($\bar{x} \pm SD$: age=24.1 $\pm$ 3.6yr; body mass=88.6 $\pm$ 13.8kg; back squat 1RM=162.5 $\pm$ 40.6kg) performed acute bouts of bilateral seated leg extensions consisting of 4 sets taken to momentary task failure with either low-load (30%1RM) and continuous BFR (LL-BFR) or high-load (70%1RM) and no BFR (HL-RE). A randomized crossover design with a 1-week rest period was used with time of day matched within-subjects. Upon arrival between 1200-1800, an antecubital vein was cannulated by certified phlebotomists and a 30min passive rest commenced where 24hr dietary recalls were performed by a registered dietician, followed by the pre-exercise blood draw. Blood was then sampled within 60sec (IP) and again at 5min post-exercise (+5min). Concentrations of T, C, EPI, NE, and GH were quantified via enzyme-linked immunoassays with intra- and inter-assay coefficients of variations for all analytes <5%, and <6%, respectively. Paired-samples t-tests compared total repetitions (REPS) completed and the volume-load lifted (V-L) between conditions, with 2x3 (Condition x Time) repeated measures analyses of variance performed for all analytes.

RESULTS: Greater REPS ($d=2.37$, $p<.001$) and less V-L ($d=2.86$, $p<.001$) was performed during LL-BFR. No significant Condition x Time interaction effects were found for any hormone measured ($p>.05$). Both LL-BFR and HL-RE elicited significant elevations in T, C, EPI, NE, and GH, evidenced by significant main effects for Time ($p<.05$).

CONCLUSION: LL-BFR and HL-RE both notably elevate the potent β_2 adrenergic receptor (β_2AR) agonist EPI (IP: 1.29 $\pm$ 0.44 and 1.35 $\pm$ 0.60nmol·L⁻¹, respectively), and the androgenic steroid T (+5min: 27.4 $\pm$ 12.9 and 29.0 $\pm$ 14.3 nmol·L⁻¹, respectively). Thus, skeletal muscle β_2AR mediated hypertrophic signaling cascades may be comparable following acute bouts of LL-BFR and HL-RE. When exposure to lower RE intensities and resultantly less V-L is desired, athletes may perform LL-BFR in place of HL-RE and experience no statistical difference in acute hormonal responses.

INTRODUCTION: Previous research has extensively examined the cognitive advantages at the individual level that athletes develop through their specific sport. However, these advantages at the group level remain underexplored. This study

investigates how sport type (team vs. individual) influences group decision-making and hypothesizes that team sport athletes will exhibit superior group decision-making abilities compared to individual sport athletes.

METHODS: 60 collegiate athletes participated, half from individual sports (track and field, swimming) and half from team sports (basketball, soccer, volleyball). Athletes were paired within the same sport type as a dyad and completed a visual search task both collaboratively and individually. We used AAND(t) from Systems Factorial Technology, a measure that compares group and individual performance while accounting for both information efficiency and accuracy, and vDiff from the Linear Ballistic Accumulator, which assesses the differences in information accumulation rate, a parametric measure of group decision making benefit, across the two sport types.

RESULTS: Although RT, accuracy, and vDiff showed no significant differences across group, the AAND(t) revealed that the benefits of group decision-making were greater for team sport athletes than for individual sport athletes in the earlier time intervals. This suggests that the group decision-making benefits of team sport athletes emerge primarily in the early processing stages.

Discussion: The results indicate that the dynamic and interactive nature of team sports may enhance athletes ability to navigate complex and fast-paced decision-making scenarios. These findings highlight the potential of sport-specific cognitive training in shaping decision-making skills, particularly within team sport environments.

COMPARING THREE NEAR-THE-END SESSION TIMEPOINTS ON SHORT TERM REMEMBERED AFFECT IN CONTINUOUS AEROBIC ACTIVITY

BASTOS, V., SANTOS, F., DAVIS, P.A., TEIXEIRA, D.S.

UNIVERSIDADE LUSÓFONA DE HUMANIDADES E TECNOLOGIAS

Affect-related cognitions such as remembered affect (i.e., how pleasant/unpleasant an exercise session is recalled) have been associated with future exercise behavior. However, memories of an episode steadily decrease in time after its termination, leaving it prone to heuristics and biases. The peak and end rule is a theoretical postulate proposing that the affective peaks and end encountered influence how an episode will be affectively remembered. Research in the exercise context has supported this influence but with considerable heterogeneity in what should be considered end affect and, therefore, what moment of the end of the session can better predict remembered affect. In light of this, the objective of the present study was to investigate the predictive power of three near-the-end session time points (during, immediately after, and one minute after completion) on remembered affect, in three continuous aerobic sessions performed with different intensities.

This experimental study involved 36 physically active males (Mage = 27.92; SD = 5.82 years) performing three 17-minute treadmill exercise sessions at different intensities (i.e., light, moderate, and vigorous) in a counterbalanced order. The affective response was measured seven times with the Feeling Scale but only the right before the end of the fundamental phase (FS5; 15'45"), immediately after the fundamental phase (FS6; 16'), and one minute after the fundamental phase (cool-down; FS7; 17') measures were used for this study. Remembered affect was measured two minutes after finishing the protocol with a Visual Analog Scale. Single linear regression analyses were applied across intensities with FS5, FS6, and FS7 as the dependent variables to test which near-the-end moment was the best predictor of remembered affect.

All three near-the-end time points significantly predicted remembered affect across the different exercise intensities. In the light-intensity session, FS5 was distinctively the best predictor (47%; 24% for FS6; 18% for FS7), also accounting for more variability (42%) than the other time points in the moderate-intensity session (35% for FS6; 20% for FS7). However, in the vigorous-intensity session, FS6 was the best predictor (59%), with the other moments also demonstrating considerable explanatory power (50% for FS5; 46% for FS7).

The affective response at the end of a continuous aerobic exercise session can predict how pleasant or unpleasant it will later be recalled. However, the last measurement during the fundamental phase was the best remembered affect predictor with light and moderate intensity, while for vigorous intensity, the measurement immediately after the fundamental phase presented the higher explanatory power. These nuances should be considered by practitioners when organizing an aerobic exercise session, particularly regarding the chosen intensity at the end of the fundamental phase and its potential consequences on how the session will be later recalled.

MAIN EFFORT MANAGEMENT STRATEGIES IN SHORT TRAIL RUNNING: QUALITATIVE ANALYSIS BY SELF-CONFRONTATION

DE COCK, F., FOSSION, G., ECCLI, C., PAQUOT, Q., JIDOVSTEFF, B.

UNIVERSITY OF LIÈGE

INTRODUCTION: Trail races are endurance running events characterized by many constraints (distance, positive altitude difference, obstacles, technicality, ...) that the runner must manage efficiently to perform well. To optimize effort management in this context, it is necessary to understand how trail runners' particular possibilities for feeling, thinking and acting which are embedded in the race topography, environment and circumstances. A qualitative approach using the self-confrontation method would appear to be a very appropriate way to investigate the main effort management strategies used by runners in the specific context of short trail running.

METHODS: 7 subjects participating in a short trail race (10 to 30km) were equipped with a GoPro, a Garmin watch and a Stryd accelerometer to record traces of their activity (video, GPS data, heart rate and stride frequency). In the 5 days following the race, each subject participated in a self-confrontation interview. They were asked to describe for each relevant

event what they feel, think and the decisions they make according to race chronology. Triangulation procedure and thematic analysis were used to determine main effort management strategies during short trail race. Analyses were performed using the Grand Unified Theory (GUT) model as a theoretical framework (Glazier, 2017).

RESULTS: Four major effort management strategies emerge from our results, three of which relate directly to the choices made by the runner (adaptation strategies; anticipation strategies; and automated behaviors or habits) and one of which concerns his/her level of vigilance (focused to unfocused). We also identified 10 critical elements that were directly concerned by the strategies: (a) running pace, (b) running pattern, (c) choice of trajectory and course, (d) positioning in relation to others, (e) equipment, (f) nutrition and hydration, (g) external interactions, (h) well-being and comfort, (i) preparation and training, and (j) goal and performance. All these various critical elements may be affected by one or more strategies at the same time. The analysis also identified the main key moments during the race and their chronology.

CONCLUSION: The results of this qualitative research were successful to identify main effort management strategies during short trail running. The data from this study provide a better understanding of how runners control themselves throughout the race, especially in delicate moments. Knowledge and proper use of these strategies could be used to optimize performance.

RESTING-STATE BRAIN FUNCTION IN COLLEGE STUDENTS ENGAGED IN COMBAT SPORTS: A CROSS-SECTIONAL STUDY

ZHANG, K., JIN, K., WANG, Y., ZHANG, X., ZHANG, D., CAO, C.
SOUTHEAST UNIVERSITY

INTRODUCTION: Long-term physical exercise is known to induce changes in brain plasticity. While extensive research has examined the effects of aerobic exercise, basketball, and badminton on brain plasticity in college students, the impact of combat sports on brain function remains underexplored. Combat sports, due to their high intensity and mental demands, may have unique effects on neuroplasticity. This study aims to investigate the influence of combat sports participation on brain function in university students, addressing a gap in the current literature.

METHODS: This study included three groups of participants. The experimental group consisted of 14 university students (8M6F, aged 20.9 ± 2.3 years) who practiced Combat Sports (Taekwondo, Judo, Brazilian Jiu-Jitsu, Chinese kickboxing, Muay Thai) for an average of 2.4 ± 0.9 years. The aerobic exercise group had 15 students (9M6F, aged 22.0 ± 2.3 years) with 2.2 ± 1.0 years of aerobic exercise experience. The sedentary control group included 17 participants (7M10F, aged 20.3 ± 1.2 years) who exercised less than 3 times per week. All participants provided informed consent and met the inclusion criteria for their respective groups. All participants were right-handed, free of major medical conditions, and had no contraindications for MRI scanning. Brain imaging data were acquired using a Philips 3T scanner with a 32-channel standard head coil. T1-weighted images (T1WI) were collected to capture structural brain signals. Additionally, echo-planar imaging (EPI) sequences were used to acquire resting-state blood-oxygen-level-dependent (BOLD) signals. During the scanning session, participants were instructed to "relax and not think about anything, keep their eyes closed and stay awake." The data were preprocessed using RestPlus12 software, followed by the calculation of fractional Amplitude of Low-Frequency Fluctuations (fALFF). Based on previous research, regions of interest (ROIs) were defined in the left premotor cortex (PMC), supplementary motor area (SMA), dorsal premotor cortex (dPMC), mid temporal gyrus (MTG), and bilateral hippocampus (Hipp). The fALFF signals from these ROIs were extracted for statistical analysis. A one-way ANOVA was first conducted to compare the three groups, followed by pairwise comparisons using t-tests.

RESULTS: The ANOVA revealed significant differences among three groups in PMC ($F = 13.509$, $p = 0.000$), dPMC ($F = 5.809$, $p = 0.006$), MTG ($F = 5.013$, $p = 0.011$), HippL ($F = 10.338$, $p = 0.000$). The Combat group exhibited significantly higher fALFF than the controls in the left PMC ($p < 0.001$), SMA ($p = 0.05$), dPMC ($p = 0.008$), and MTG ($p = 0.004$). Additionally, compared to the aerobic group, the Combat group demonstrated higher fALFF in the left dPMC ($p < 0.001$), while lower fALFF in the HippL ($p = 0.017$).

CONCLUSION: The current findings may suggest that long-term participation in Combat Sports leads to functional reorganization and optimization in brain regions related to mo

A RANDOMIZED, CONTROLLED TRIAL INVESTIGATING THE ACUTE NEUROCOGNITIVE EFFECTS OF AEROBIC EXERCISE ON HOT ASPECTS OF COGNITIVE CONTROL IN YOUNG ADULTS

UDYGA, S., SCHWARZ, A., LEUENBERGER, R., GERBER, M.
UNIVERSITY OF BASEL

Background: Evidence suggests that moderately-intense exercise elicits temporary improvements in cool aspects of cognitive control. In contrast, the sensitivity of its hot components, including risky decision making and regard processing, still remains unclear. These cognitive abilities have a unique predictive value for decision making in motivationally significant situations and for the avoidance of unhealthy behaviours among young adults in particular. We examined the effects of a single bout of aerobic exercise on risky decision making and underlying cognitive processes by combining behavioural and neurocognitive assessments. Additionally, we investigated exercise-induced effects on response inhibition to contrast benefits for cool and hot aspects of cognitive control.

Method: 60 participants (aged 24.0 ± 2.9 y) were randomly allocated to an intervention group, who performed 20 min moderately-intense running on a treadmill, and a control group, who watched a video. Computer-based and modified versions of the Go/NoGo task and Iowa Gambling task were administered before and after these sessions. The feedback-related negativity (FRN) and P300 components of event-related brain potentials elicited by wins and losses during the Iowa Gambling task were recorded with electroencephalography.

Results: We found no group differences in pre- to posttest changes in error rates on the Go/NoGo task and learning of long-term consequences on the Iowa Gambling task. However, there was a time by group interaction indicating a greater increase in the bias for infrequent losses in the intervention compared to the control group. With regard to event-related potentials, there was a time by group interaction supporting a greater increase of P300 amplitude and decrease of negativity of the FRN from pre- to posttest in the intervention compared to the control group. Following the intervention, a higher P300 amplitude was correlated with a higher bias for infrequent losses.

Conclusion: Acute aerobic exercise does not necessarily enhance performance on cool and hot aspects of cognitive control in young adults. However, an exercise session can alter the strategy in risky decision making by increasing the preference of less frequent, but larger losses over more frequent, smaller losses. On a neurocognitive level, this effect can partly be attributed to a better anticipation of outcomes of decisions and a higher maintenance of the feedback significance.

OP-AP43 Running II - Ultra and Long Distance

ANAEROBIC CAPACITY AND POWER IN ENDURANCE RUNNING – THERE IS MORE THAN LACTATE.

SONDERMANN, Y., THRON, M., SCHORB, K., WOLL, A., ALTMANN, S.

KARLSRUHE INSTITUTE OF TECHNOLOGY

INTRODUCTION: The anaerobic metabolism contributes 10 to 50% of total energy demand during endurance exercise of 8 to 2 min and is understood well on a cellular level.(1,2) Nonetheless, its role for endurance performance is a matter of debate. Uncertainty concerning valid measurement of anaerobic capacity and power (3,4) could be a confounding factor for addressing this debate. Hence, purpose of this study was to collect 13 different metrics of anaerobic capacity and power, test within-variable relationships and assess explained variance for 3- and 12-min running performance.

METHODS: 40 trained male and female runners completed three test days. The first two days incorporated a 3- and 12-min time trial (TT) to assess running performance, critical speed (CS) and finite distance capacity (D'). Additionally, participants completed a 100-m sprint (v100, MSS, clamax, ASR, SRR) and jump test (CMJ). The third day consisted of an incremental test to exhaustion and a 4-min TT one hour thereafter. Gas exchange was recorded to assess maximal aerobic speed (MAS), VO₂max, running economy, and maximal accumulated oxygen deficit (MAOD, %ANAER). Maximal post-test lactate concentration was measured for all exhaustive tests (LaRT, LaTT3, LaTT4, LaTT12). Interaction between anaerobic variables and explained variance of TT performance was tested through (multiple) regression analysis.

RESULTS: Metrics of anaerobic power (v100, MSS, CMJ, clamax) displayed high interrelationships ($r=0.76-0.98$, $p<0.001$). Anaerobic capacity metrics were interrelated to a moderate extent in the case of MAOD, %ANAER, D' and LaTT3 ($r=0.34-0.66$, $p<0.05$), but LaRT, LaTT4, LaTT12 showed weak or absent relationships with MAOD, %ANAER and D' ($r<0.47$). Anaerobic power explained 15- 51% of the variance for 3-min and up to 19% for 12-min TT performance. Capacity metrics (MAOD, %ANAER, D') 13- 36% and 1- 13% for 3- and 12-min TT, respectively. No variance in TT could be explained by post-exhaustive lactate measures. Multiple regression models increased explained variance to 86% and 89% for 3- and 12-min TT. VO₂max explained greatest variance for both TTs, and anaerobic metrics (MAOD, D') contributed to higher explained variance for 3-min TT but failed to do so for 12-min TT.

CONCLUSION: Amongst trained runners, both anaerobic power and capacity seem to be relevant for short but not longer duration endurance running. This is in line with previous work, which suggests high energy contribution from anaerobic pathways in short endurance exercise.(1) Absent relationships of post-exhaustion lactate and endurance performance may be attributed to the measurement of a net concentration, which can be influenced by various factors.(2) In accordance with previous articles,(3) we recommend caution with post-exhaustion lactate when testing trained runners. MSS, CMJ, MAOD and D' can be viable alternatives based on our results.

DURABILITY OF PARAMETERS ASSOCIATED WITH ENDURANCE PERFORMANCE IN MARATHON RUNNERS

HUNTER, B., MUNIZ-PUMARES, D.

LONDON METROPOLITAN UNIVERSITY

INTRODUCTION: Physiological models of marathon performance typically consider the maximal oxygen consumption (VO₂max), the fraction of VO₂max that can be sustained (VO₂ at lactate threshold [VO₂LT]), and running economy (RE) [1]. However, these parameters deteriorate during or after prolonged exercise [2]. The resilience to this deterioration has been termed 'durability' and exhibits considerable heterogeneity [3] but has not been studied extensively in running. Furthermore, it is unclear whether parameters that are typically measured in a rested state, when measured after a prolonged bout of running, can be used to predict marathon performance. The aims of this study were to examine: i) changes to physiological parameters associated with marathon performance following prolonged exercise, ii) the association of fresh and fatigued physiological parameters with marathon performance, and iii) whether marathon performance (i.e., average running speed during the marathon) could be better predicted using physiological parameters measured after prolonged exercise.

METHODS: Eighteen runners (11 males, age: 41±12 yrs, marathon finish time: 197.5±32.5 min) participating in the 2024 London Marathon underwent two incremental exercise tests to measure VO₂peak, VO₂LT, and RE. Tests were conducted in a fresh state (FRE), and in a fatigued state, after a 90-minute run at LT (FAT). Paired samples t-test was used to test for differences in VO₂LT, VO₂peak, and RE between FRE and FAT. To investigate the relationship between laboratory-derived measures in both FRE and FAT, as well as the percentage change from FRE to FAT, and marathon performance, Pearson product-moment correlation coefficient was used. Significance was set at P<0.05. A linear regression analysis assessed if VO₂LT and RE measured in FAT and FRE conditions could be used to predict marathon performance.

RESULTS: Reductions in VO₂peak (FRE: 56.7±7.2 ml·kg⁻¹·min⁻¹ vs. FAT: 53.4±6.3 ml·kg⁻¹·min⁻¹) and VO₂ at LT (RE: 43.4±6.0 ml·kg⁻¹·min⁻¹ vs. FAT: 40.7±6.5 ml·kg⁻¹·min⁻¹) were evident (both P<0.001), but RE remained unchanged (P=0.125). Marathon performance was strongly correlated with FRE VO₂peak (r=0.809), VO₂LT (r=0.693), and RE (r=-0.481), as well as FAT VO₂peak (r=0.812), VO₂LT (r=0.781), and RE (r=-0.628) (all P<0.01). The percentage change in VO₂LT between FRE and FAT was associated with marathon performance (r=0.543, P<0.05). Marathon performance was strongly predicted by combining VO₂LT and RE from both FRE (R²=0.883) and FAT (R² 0.933) conditions (both P< 0.001).

CONCLUSION: Prolonged running impairs key physiological parameters associated with endurance performance, and the degree of this deterioration, i.e., durability, is associated with, and helps explain marathon performance. Marathon runners and coaches should consider quantifying durability for accurate predictions of performance and talent identification.

PROJECT FURTHER: NEUROMUSCULAR RESPONSES TO A 6-DAY ULTRAMARATHON IN FEMALES

BRUCE, C., MCNEIL, C.

UNIVERSITY OF BRITISH COLUMBIA - OKANAGAN

INTRODUCTION: Participation in an ultra-endurance event is associated with the development of neuromuscular fatigue (i.e., force loss) due to suboptimal drive from the central nervous system as well as impaired muscle contractile function. This study aimed to quantify, in females, both central and peripheral mechanisms of fatigue in the muscles that lift the toes (i.e., the dorsiflexors) following a multi-stage ultramarathon.

METHODS: Ten females (26-47 years; 1.57-1.82 m; 49.3-132.6 kg), with diverse running experience and athletic backgrounds, participated in a 6-day ultramarathon staged around a 2.5-mile loop in La Quinta, California. Athletes completed neuromuscular testing 2-4 days prior to, and 24 hours following the event. A custom-built isometric ankle myograph was used to measure maximal voluntary as well as electrically-evoked torques of the dorsiflexors. Electrically-evoked responses were obtained by stimulating the common fibular nerve via a hand-held bar electrode. A single stimulus was delivered during the plateau phase of maximal voluntary contractions (MVCs) and ~1 second post-MVC in order to quantify levels of neural drive (i.e., voluntary activation; VA). To indirectly assess peripheral fatigue and temporary muscle damage, torque responses were recorded after a single pulse (i.e., the resting twitch; RT) as well as 1-second trains of low- and high-frequency stimulation (10 and 100 Hz, respectively).

RESULTS: By the end of the event, a range of 112.2-560.3 miles had been run by the athletes. Mean MVC torque as well as VA were not different between pre- and post-event measures (32.8±8.0 vs. 29.5±6.9 Nm and 99.8±0.5 vs 98.6±2.6%, respectively; P≥0.117). Peak torque and the peak rate of torque relaxation of the RT increased by ~14.5 and 14.8%, respectively from baseline following the event (P≤0.020). Peak torque of the 10-Hz tetanus increased by 19.1% (P=0.023), but the 100-Hz response was not different (P=0.540). The ratio of 10:100 Hz torque was also not different from baseline to 24 hours post-event (0.50±0.18 vs 0.53±0.11; P=0.340).

CONCLUSION: In conclusion, despite the long distances achieved among the athletes, there was no evidence of muscle damage or impairments to voluntary muscle strength and neural drive 24 hours following the 6-day ultramarathon. Our findings contribute to the growing narrative that females exhibit exceptional resistance to peripheral fatigue following ultra-endurance events.

ULTRAMARATHON RUNNERS SLEEP PATTERNS: PRIOR TO, DURING, AND FOLLOWING A 217KM BRAZILIAN ULTRAMARATHON

VILELA SILVA DANIEL, N., DA CUNHA, D., BELLI, T., MACULANO ESTEVES, A.
UNIVERSIDADE ESTADUAL DE CAMPINAS

INTRODUCTION: The interest in ultramarathons has increased in the last years, and sleep deprivation is one of the main physiological challenges faced by runners in this sport. Although research in the sleep-sports relationship is growing, there is a lack of objective data regarding ultramarathon runners sleep. Therefore, the aim of our study is to analyze athletes' sleep before, during, and after a race using actigraphy, and to evaluate their sleep behavior.

METHODS: We evaluated 15 male athletes, with a mean of 45.1 ± 10.5 years old, who participated in Brazil 135 Ultramarathon and covered 135km (n=4) or 217km (n=11). Wristwatch actigraphy (n=13) was used to measure sleep before (7 days), during, and after the race (7 days). Athletes also answered the Athlete Sleep Behavior Questionnaire (FACUNDO et al., 2021).

RESULTS: Athletes completed 135 km between 27:49-32:55 hours, while 217 km runners did between 36:24-51:49 hours. Most athletes (54%) did not define a sleep strategy for the race. The majority (53%) was classified with poor sleep behavior, and using "technology that emits light" before bed was the most frequent habit. Actigraphy also objectively indicated poor sleep, as only 15.39%, 61.54%, 30.77%, and 38.46% of the athletes slept for more than eight hours the week before (6 days), the day before, the day after, and the week (6 days) following the race, respectively. Although the average sleep latency in the 4 periods was adequate (<30 min), the Wake After Sleep Onset (WASO) was greater than the recommended (<20 min) for 83.33%, 83.33%, 69.23% and 84.62% of the athletes in the week before, the day before, the day after and in the week after the race, respectively. The average of total sleep time (TST) during the race was 67 ± 86 min, and there was a positive correlation between TST during the race and the TST ($p=0.05$ and $r=0.56$) and sleep efficiency ($p<0.01$ and $r=0.85$) on the night following the competition. When comparing sleep in the four evaluated periods, there was a significant difference between the TST ($p=0.05$). In the week before the race the athletes slept less than on the day before ($p=0.05$) and after the competition ($p<0.01$). It is also noted that the average TST during the following week was greater than the sleep time on the night immediately after the race ($p=0.05$).

CONCLUSION: Most ultramarathon runners had poor sleep quality and high WASO levels. Despite not having a set sleep plan for the race, it has been observed that many runners attempted to obtain more sleep than usual the night before. The increased TST the week after the ultramarathon suggests that there may be a sleep rebound taking place sooner rather than later.

ULTRARUNNING AND ITS EFFECTS ON MUSCLE, KIDNEY, CARDIAC, AND ENDOCRINE FUNCTION

ROELANDS, B., AMPE, T., GALLOO, X., DE PAUW, K.
VRIJE UNIVERSITEIT BRUSSEL

INTRODUCTION: Ultrarunning is gaining in popularity but the impact of extreme endurance events, such as the backyard ultrarunning (BYR) discipline, on medical parameters, is lacking in literature. BYR is an extremely demanding ultra-endurance event where athletes strive to complete a 6.7 km lap every hour and concludes when the second-to-last participant quits, leaving the final runner to complete the ultimate lap. The aim of this study is to determine the influence of a BYR event on organ function (kidneys, heart), hormones, inflammatory and muscle damage parameters.

METHODS: Eleven male ultrarunners (38 ± 8 yr, BMI: 23.1 ± 1.05 kg/m², VO₂max: 61.3 ± 4.4 ml/min/kg) were monitored during the "Backyard Ultra" event in Belgium (April 2023). Echocardiography was performed and blood was drawn at baseline (two weeks before the event), and (at around 24 hours) during the event. Among many other parameters, kidney parameters (creatinine, urea), inflammatory and muscle damage parameters (C-reactive protein, creatine kinase and aspartate aminotransferase), cardiac stress parameters (troponin, NT-proBNP), hormones (cortisol and testosterone) and echocardiographic parameters (left ventricular end-diastolic volume index, left ventricular global longitudinal strain, right ventricular end-diastolic area index RVEDAi, systolic pulmonary artery pressure) were measured.

RESULTS: Ultrarunning significantly increased creatinine and urea ($p \leq 0.002$), suggesting increased muscle breakdown and protein catabolism, respectively. Additionally, increased C-reactive protein, creatine kinase and aspartate aminotransferase ($p \leq 0.002$), referring to increased systematic inflammation and muscle damage, was observed. Cardiac stress markers increased ($p \leq 0.017$), cortisol showed a trend to increased levels ($p = 0.073$) and testosterone decreased ($p = 0.001$) during the event. No significant alterations were observed for echocardiographic parameters, with the exception that RVEDAi decreased ($p = 0.008$), reflecting decreased preload.

CONCLUSION: The BYR event induced significant physiological stress. The decreased testosterone and trend toward elevated cortisol suggest an endocrine response to prolonged endurance exertion. Unlike previous studies on marathon runners, which reported transient reductions in left ventricular strain, no such significant changes were found. RVEDAi (the right ventricular size in diastole) reduced which refers to reduced venous return to the right ventricle. Findings align with research on (ultra)marathon showing myocardial and muscular fatigue, and an association between endurance exercise and increased cardiac biomarkers.

Ultrarunning can be perceived as safe, but the observed physiological stress underscores the need for adequate training and recovery to mitigate potential risks. Future studies should examine the long-term effects of BYR on cardiovascular and renal function.

EXERCISE INTENSITY-DEPENDENT EFFECTS ON LACTATE, MATURE BDNF AND PROBDNF, AND THE INFLUENCE OF MUSCLE FIBER TYPE AND BDNF GENOTYPE

TARASSOVA, O.1,2, JIANG, Y.1, NILSSON, J.1, MOBERG, M.2, EKBLOM, M.1

THE SWEDISH SCHOOL OF SPORT AND HEALTH SCIENCES, STOCKHOLM, SWEDEN

INTRODUCTION: A single exercise bout can increase circulating levels of exerkines essential for neuroplasticity, such as mature BDNF (mBDNF), proBDNF and lactate (LAC) [1, 2]. Increases in these exerkines may furthermore be influenced by BDNF genotype [3] and muscle fiber type (FT) [2, 4]. This study investigated acute effects of exercise intensity on mBDNF, proBDNF and LAC, and how these effects are influenced by BDNF genotype and FT.

METHODS: Healthy, physically fit adults (n=16, 8 females, 31±6 yrs, body mass index 22.4±1.5, VO₂max 54.9±4.1 mL/kg/min) cycled for 20 min at 40% (I40), 60% (I60) and 80% (I80) of VO₂max, separated by 30-min rest. Forearm venous plasma LAC (mmol/L), serum mBDNF (pg/mL) and plasma proBDNF (pg/mL) were analysed in blood samples taken before and after cycling at each intensity. A muscle biopsy was used to identify participants with dominance of slow-twitch (%Type I >50, n=10) or fast-twitch (%Type I <50, n=6) muscle fibers. The BDNF rs6265 polymorphism was genotyped to identify Val66Met (G/A, n=5) or Val66Val (G/G, n=11) gene carriers. Linear mixed-effects models were used to assess the effects of time, intensity, as well as interactions with BDNF genotype and FT. Associations between exercise-induced changes (delta) in LAC, mBDNF and proBDNF were assessed with Spearman correlation. A significance level was set at p<0.05. All summary statistics are expressed as mean ± SEM.

RESULTS: LAC increased by 51% after exercise at I60 (1.3±0.1 vs 1.9±0.2, p<0.05) and by 495% at I80 (1.0±0.1 vs. 5.8±0.5, p<0.001). mBDNF increased by 16% after exercise at I40, by 30% at I60 and by 41% at I80 (10804.4±528.8 vs 12584.1±559.2, p<0.05; 10972.3±472.8 vs 14213.9±555.5, p<0.001 and 11279.3±643.0 vs 15900.0±985.9, p<0.001, respectively). proBDNF increased only after exercise at I80 (211.6±79.4 vs 317.9±109.2, p<0.001). The I80 effect on LAC was 65% larger in G/A versus G/G carriers (p<0.001). The I80 effect on mBDNF was 43% larger in participants with fast-twitch FT dominance (p<0.05). A non-significant trend of higher proBDNF levels in G/G carriers (p=0.06) was shown, irrespective of time and intensity. At I80, delta LAC was positively associated with delta mBDNF (r = 0.58, p=0.025), but not with delta proBDNF.

CONCLUSION: Exercise acutely induced intensity-dependent effects on LAC, mBDNF and proBDNF. Results furthermore suggest that these effects can indeed be influenced by BDNF genotype and FT. While an indication of higher proBDNF was shown in G/G carriers, delta LAC at I80 was higher in G/A carriers. However, in contrast to previous reports of G/As negative effect on aerobic training response [3], the acute mBDNF response was independent of BDNF genotype. Finally, higher neurotrophic response to aerobic exercise (higher delta mBDNF) was indicated in individuals with fast-twitch FT dominance.

THE ROLE OF SEX STEROID HORMONES IN SKELETAL MUSCLE MASS, FUNCTION AND GENE EXPRESSION ACROSS THE MALE LIFESPAN

WILLIAMS, R., CRITCHLOW, A., GATTO, B., ENGMAN, V., VAN BELLEGHEM, K., GARNHAM, A., HIAM, D., LAMON, S.

INSTITUTE FOR PHYSICAL ACTIVITY AND NUTRITION, DEAKIN UNIVERSITY

INTRODUCTION: The relationship between sex steroid hormones and skeletal muscle mass and function remains ambiguous in males, with much of our knowledge stemming from research relying on exogenous manipulation of testosterone. This study aimed to address the relationship between endogenous sex steroid hormones and muscle outcomes across the male lifespan.

METHODS: 82 biological males, aged 18-80 years and stratified by decade, participated in this study. Body composition was assessed via dual-energy X-ray absorptiometry (DXA) and peripheral quantitative computed topography (pQCT). Muscle strength was assessed using a leg press 5-repetition maximum (5RM) test. In a fasted state, a muscle biopsy was procured from the vastus lateralis and a venous blood sample taken. Testosterone and dihydrotestosterone were profiled using gas-chromatography mass-spectrometry, and sex-hormone-binding-globulin (SHBG) measured via immunoassay.

Free testosterone was estimated using the Vermeulen equation and the free androgen index (FAI). Transcriptomic analysis were performed using RNA-sequencing, and muscle samples were immunohistochemically stained to assess fibre morphology and type. All analyses were performed using RStudio (version 4.3.1).

RESULTS: Free testosterone ($\beta = -0.004$, $p < 0.001$) and FAI ($\beta = -0.669$, $p < 0.001$) decreased with age and were associated with measures of body composition and muscle strength. However, these relationships became non-significant following adjustment for age, physical activity and dietary protein ($p > 0.05$). Age was positively associated with bodyfat percentage ($\beta = 0.129$, $p = 0.02$) but not with intramuscular or subcutaneous fat mass ($p > 0.05$), and was negatively associated with thigh muscle cross-sectional area (CSA) ($\beta = -0.65$, $p < 0.001$), appendicular lean mass (ALM) ($\beta = -0.09$, $p < 0.001$), ALM index (ALM normalised to height) ($\beta = -0.018$, $p = 0.028$); relationships that remained significant following adjustment for physical activity, dietary protein, total testosterone, free testosterone, and FAI.

CONCLUSION: Our results suggest that age, not endogenous testosterone concentrations, is a primary determinant of muscle outcomes. Ongoing transcriptomic analysis aims to map muscle signalling pathways throughout the aging continuum and determine the influence, or lack thereof, of sex steroid hormones on skeletal muscle gene expression across the male lifespan.

ENDOCRINE ADAPTATION IN THE ANTARCTIC: GLUCOCORTICOID AND ANDROGEN CHANGES DURING A 1000KM SKI EXPEDITION

GIFFORD, R., TAYLOR, N., KENDALL, J., HATTERSLEY, J., HOMER, N., WOODS, D., IMRAY, C., WILSON, A.
ROYAL CENTRE OF DEFENCE MEDICINE

INTRODUCTION: Antarctic expeditions present extreme physiological challenges due to cold temperatures, high physical exertion, and 24-hour daylight. This observational study evaluated endocrine adaptation in nine participants (six men, three women) during a 47-day, 1,000 km unassisted ski expedition (Ex).

METHODS: Saliva was sampled at 5 times of day on 8 occasions: 30 d and 14 d before, 3 times during (1 d, 15 d, 30 d) and 3 times after the Ex (+1 d, +6 d, +30 d). Hair was sampled before, during after the expedition. Blood was sampled before and after. Cortisol, testosterone (T), and androstenedione (A4) were measured via tandem mass spectrometry, and thyroid hormones via immunoassay. Diurnal slope (DS) and Area under the curve (AUC) was calculated for saliva steroids. Body mass and body composition (skinfold thickness) was measured throughout the expedition. Body composition was measured before and after by DXA. The effect of time and sex X time were assessed with Aligned Rank Transform test.

RESULTS: Cortisol, A4 and T DS were preserved throughout the Ex. Average cortisol concentration increased during the Ex ($p < 0.05$) and reverted to baseline over the next 15d with no sex differences. Morning T and T:cortisol ratio decreased during the Ex with a greater effect seen among men. Post-ex recovery of T was demonstrated in men. A4:cortisol ratio decreased during the Ex and recovered afterwards with no sex differences. No significant changes were seen in blood or hair steroid hormones. Gonadotropins in women indicated central suppression pre-expedition, normalizing post-expedition. Thyroid-stimulating hormone levels increased post-expedition without significant changes in free T3 or T4, consistent with mild polar T3 syndrome. Weight decreased during the Ex (79.7 ± 20.6 vs 72.6 ± 8.6 kg) with near-linear decrease in FM for all participants, but a smaller rate of decrease for women than men ($p < 0.05$). FFM decreased overall but with substantial inter-individual variation, being relatively preserved among women. A sex-dimorphic clustering of body composition occurred after 30d. DEXA showed regional FM loss and FFM gain, especially in the trunk.

CONCLUSION: These findings highlight the adaptability of hypothalamic-pituitary function to combined stressors of exercise, energy deficit, and cold. Exercise demands overshadowed the effects of continuous daylight in controlling hypothalamic-pituitary-adrenal and gonadal axis function. This is the first study to capture in situ endocrine responses during an Antarctic traverse, advancing our understanding of human endocrine adaptation to exercise in extreme environments.

PERIPHERAL SKELETAL MUSCLE LAT1 CONTENT IS GREATER IN OLDER COMPARED WITH YOUNGER ADULTS AND IS NOT ALTERED DURING A 12-WEEK STRENGTH TRAINING INTERVENTION

LANDER, E., LEES, M.J.2, HAMARSLAND, H.3, MOORE, D.2, RAASTAD, T.1

1: NORWEGIAN SCHOOL OF SPORT SCIENCE. 2: UNIVERSITY OF TORONTO. 3: INLAND NORWAY UNIVERSITY OF APPLIED SCIENCES.

INTRODUCTION: Increases in postprandial amino acid availability in muscle fibers facilitate protein synthesis and is dependent on transmembrane-bound amino acid transporters (AAT) transporting amino acids from the blood into the cell. Dysfunctional AATs may be involved in the blunted protein synthetic response to protein intake, termed anabolic resistance, in older and sedentary adults. We have shown, using Western blot analyses, that untrained older had lower cytosolic protein expression of the L-type AAT 1 (LAT1) compared to younger adults ($p < 0.05$), where 12-weeks of strength training eliminated this difference. Resistance training can increase the uptake of amino acids into the cell and may normalize the anabolic resistance of aging. The purpose of this study was to investigate the localization of LAT1, which facilitates the uptake of essential amino acids, in type I and type II muscle fibers in young and older adults, before and after 12-weeks of strength training.

METHODS: Healthy young ($n=25$, 20-45 yrs) and older ($n=25$, 70-80 yrs) adults completed a 12-week whole-body strength training intervention (3 sessions/week). Before and after the intervention, we measured leg lean mass (LLM) by dual-energy X-ray absorptiometry and tested strength by leg press as one repetition maximum (1RM). Muscle biopsies were

obtained from m. vastus lateralis. Immunofluorescent analyses were performed to investigate LAT1 intensity in the membrane (M) and intracellular (IC) region and M/IC-ratio. Data were analyzed for LAT1 intensity in Type I, Type II and Type I+Type II combined (total LAT1) using two-way ANOVA for comparisons between time and age group, and t-test to compare the relative changes between young and old and between relative fiber-specific changes in each group.

RESULTS: Training increased LLM by ~1 kg in both groups ($p<0.001$). 1RM leg press increased more in the young than old (78 ± 32 kg vs. 50 ± 20 kg, $p<0.001$). Total LAT1 was 15% higher in M ($p<0.05$) and M/IC-ratio was 6% higher ($p<0.01$) in the old, compared with the young. For the young, total LAT1 decreased by $9\pm14\%$ IC ($p<0.05$) whereas the M/IC ratio increased $5\pm6\%$ ($p<0.01$). The old decreased the M/IC-ratio in Type I by $3\pm8\%$ ($p<0.05$). The young increased whereas the old decreased the M/IC-ratio in total and fiber-specific LAT1, causing a difference in the relative change between young and old adults in M/IC-ratio ($p<0.05$).

CONCLUSION: The strength training induced increases in muscle mass and strength, which were accompanied by decreased intracellular LAT1 for the young and increased M/IC-ratio for young and older adults. The greater total LAT1 protein at the periphery of skeletal muscle in older adults is consistent with our previous Western blot analysis and could be related to a compensatory mechanism for anabolic resistance. Future research should determine the biological impact of differential total and transmembrane-bound LAT1 on transport activity and anabolism in human skeletal muscle.

CYCLING USING ADAPTIVE FUNCTIONAL ELECTRICAL STIMULATION: A NEW APPROACH TO SIGNIFICANTLY ENHANCE PLASMA IRISIN CONCENTRATION

TOMMASINI, E.1, BOSIO, A.2, MISSAGLIA, S.1, RAMPININI, E.2,3, MORELLI, A.2, VAGO, P.1, PECCI, C.2, TAVIAN, D.1

<1> UNIVERSITÀ CATTOLICA DEL SACRO CUORE, MILAN, ITALY. <2> HUMAN PERFORMANCE LABORATORY, MAPEI SPORT RESEARCH CENTRE, ITALY. <3> HUMAN PERFORMANCE RESEARCH CENTRE, UNIVERSITY OF TECHNOLOGY SYDNEY.

INTRODUCTION: The effect of endurance training on irisin levels has been extensively studied over the past decade [1,2]. However, no research to date has explored how this myokine responds to endurance training combined with percutaneous Neuromuscular Electrical Stimulation in humans. This study compared the acute irisin response to cycling with and without a novel Adaptive Functional Electrical Stimulation Kinesitherapy (AFESK™) technology, delivered via the VIK8 device (VIKTOR S.r.l., Italy) at both the start and end of a 6-week training period (14 sessions), aiming to evaluate the added load imposed by AFESK.

METHODS: Sixteen active male participants (age, 39 ± 10 yrs; VO_{2peak} , 48.0 ± 4.8 ml·min·Kg⁻¹) were randomly allocated to two groups and matched for VO_{2peak} and age. The cycling (C) group performed 4x5min intervals at 60% peak power output (PPO) interspersed with 3min recovery at 40% PPO. The cycling group with AFESK (C+AFESK) followed the same training program, using the VIK8 device, which delivers electrical stimulation in synchrony with the voluntary contraction of the targeted lower limb skeletal muscles. Plasma irisin levels were evaluated before and after (15min, 24h, 48h) the first (S1) and the last training session (S14) and were detected by ELISA assay. Two-way repeated measures ANOVA (TimexGroup) and post-hoc Bonferroni were performed.

RESULTS: A significant TimexGroup interaction effect ($p=0.021$) was found. In the S1, training caused a significant increase in irisin levels from baseline (C: 7.3 ± 1.7 ng/ml; C+AFESK: 8.2 ± 1.5 ng/ml), peaking at 24h (C: 9.9 ± 1.3 ng/ml, $p<0.001$; C+AFESK: 11.8 ± 1.6 ng/ml, $p<0.001$) and returning to baseline after 48h (C: 7.2 ± 1.7 ng/ml, C+AFESK: 8.1 ± 1.5 ng/ml). Similarly, in the S14, irisin rose significantly from baseline (C: 7.3 ± 1.5 ng/ml; C+AFESK: 8.6 ± 1.5 ng/ml) to 24h (C: 10.0 ± 1.0 ng/ml, $p<0.001$; C+AFESK: 13.0 ± 1.6 ng/ml, $p<0.001$) and returned to baseline after 48h (C: 7.3 ± 1.4 ng/ml; C+AFESK: 8.7 ± 1.5 ng/ml). Before and after the training period, the increase in irisin levels from baseline to 24h post-exercise was greater in the C+AFESK group than C group (S1, $p=0.021$; S14, $p<0.001$). No significant changes in baseline concentrations were observed in either group. However, after 6 weeks, irisin levels measured 24h post-exercise were significantly higher in the C+AFESK group ($p<0.001$), while they remained unchanged in the C group.

CONCLUSION: AFESK during cycling led to a greater release of irisin one day after exercise compared to traditional cycling. The training period, with or without AFESK, does not appear to affect baseline irisin levels. The AFESK, by delivering a superimposed muscle contraction that increases muscle workload, may further enhance irisin release compared to normal cycling training, providing valuable insights into the mechanisms regulating irisin secretion.

EXPLORING MEDIA FRAMEWORK FOR SPORTS MEDICINE AND PHYSICAL THERAPY ON DOUYIN: REASONING DEVICES FOR SHARED DECISION-MAKING AND FRAMING DEVICES FOR EVIDENCE-BASED REPRESENTATION STRATEGIES

HUANG, L., BI, X., HONG, Y.

BEIJING SPORT UNIVERSITY

INTRODUCTION: Recently, short-video apps, such as TikTok, shows great potential in disseminating sports health information (Lopez & Bautista, 2022; Sidorenko, Casa & Cantero, 2020), especially in one of the most professional area, sport medicine and physical therapy. This information can be used(and produced) both by professionals and non-professionals(Eghtesadi & Florea, 2020). In such an environment, exploring the dissemination principles and strategies of these contents is necessary. This study starts from the Gain-Loss Framing of health communication (Yang, 2020), uses Gamson(1981)s Interpretative Package theory, and focuses on principles/consequences such as evidence-based practice(Sackett, 1996) and shared decision-making(Vogel, 2021) in the video contents produced by professional communicators, and explores the effective strategies of short video operation.

METHODS: Content analysis is adopted in this study. Through four sets of keywords, a pool of accounts of sports medicine and physical therapy professional communicators was first established from Douyin(Chinese TikTok). After comprehensively considering factors such as the number of fans and video interactions, sampling was carried out, and 2452 videos were finally coded.

RESULTS: The results are developed from two aspects: "reasoning devices" and "framing devices" based on Interpretative Package framework. Firstly, reasoning devices refer to the roots, consequences, and principle involved in valid health communication. Under the general logic of Gain-Loss Frame, there are three gain frames namely participatory science, economical and informed ideas, and three loss frames namely paternalistic culture, time cost and goal divergence. These six frames can be understood as established content frameworks based on the principle of shared decision-making. They are part of the evidence-based practice of sports related health issues and show the ability of short video platform to provide conditions for evidence-based practice. Secondly, "framing devices" refer to the communication strategies and approaches on short video platforms. Using Rodriguez and Dimitrovass (2011) comprehensive visual framework, the four-level analysis of denotative systems, stylistic-semiotic systems, connotative systems and ideological representations provides valid evidence for visual information and representations for shared decision-making.

DISCUSSION: Short video platforms fully demonstrate the advantages of the media with the help of technological affordance. The frameworks of the contents presented by professional communicators shows a consistent ideology, which is an acknowledgement and new implementation of evidence-based practices in the field of sport medicine and physical therapy. It also brings about a digital imagination of shared decision-making.

NORWEGIAN FOOTBALL CLUBS AND FANS HAVE DECLARED WAR ON VAR: "IT'S NOT HERE TO STAY"!

JOHANSEN, B.

UNIVERSITY OF AGDER

INTRODUCTION: Norwegian Premier League (NPL) have used the Video Assistant Referee (VAR) for the last two season increasing the correctness of referees' decisions from 87% to 97% (1). Still, VAR continues to spark substantial debate primarily among football supporters, players, and executives including concerns over match flow and delays (2). To improve stadium experience and time management, the Norwegian Football Federation (NFF) introduced in 2024 season the "goal button", quickly confirming goals, avoiding in secureness among supporters to whether VAR is investigating the goal or not. Furthermore, average match delay has been reduced from 81 to 41 seconds per match during this season. Nonetheless, many of the elite football clubs in Norway have decided to oppose VAR. The aim of this study is to explore the arguments for this statement considering VAR execution in NPL.

METHODS: This research utilizes official data from the NPL for seasons 2023 and 2024, focusing on VARs incidents in four key scenarios: goals, penalties, direct red cards, and cases of mistaken identity. This study analysed 480 matches, and time delay was noted from when the referee halted play for VAR checks. A qualitative document analyse (3) was conducted exploring official documents from board decisions in the 32 top clubs in football in Norway. The decision and recommendations for abandoning VAR from the Norwegian Top Football (NTF), representing elite football clubs in Norway, were also examined.

RESULTS: A total of 3695 incidents were reviewed by VAR, out of these, 2853 were quickly resolved, while 842 required further investigation. VAR upheld the initial decision in 725 cases but altered the outcome in 117 instances. Of these, 57 were factual checks (e.g., offside), with an average match delay of 44 seconds. The remaining 60 necessitated on-field reviews by the match official, with match delay averaging 1 minutes and 43 seconds. Subsequently, in January 2025 decided 19 of the 32 elite football club to vote for the removal VAR mainly rooted in concerns such as "ruining the moment", "killing the game", "incredibly sad and boring", and "lack of clarity for when VAR is used". The NFT board decision followed most of the clubs and recommend that VAR should be scrapped from NPL.

CONCLUSION: NTF representing the elite football clubs in Norway are putting pressure on NFF for abandoning VAR in 2025. If they succeed, Norway will be the first country in the world to abolish the controversial system. However, despite recommendations from NTF, representing the elite clubs and thereby also their football supporters, NFF and its executive board have decided a proposal to keep VAR in Norwegian football in the future. Accordingly, the destiny of VAR in Norwegian football is very much up in the air. Will VAR stay or not?

“IT WAS CLEAR FROM HIS CHILDHOOD HE WAS DESTINED TO BE A TOP STRIKER”: FOOTBALL ‘TALENT’ NARRATIVES IN THE ITALIAN SPORTING PRESS

MORGANTI, G., BLACKWOOD, T., LASCU, A., RUSCELLO, B., STRASSOLDI DI VILLANOVA, F., PADUA, E., KELLY, A.L.

SAN RAFFAELE OPEN UNIVERSITY OF ROME

INTRODUCTION: Research revealed variability in how talent is defined, identified, selected, and developed across contexts and cultures [1]. Studies investigating athlete development environments suggested media and press as sociocultural influences [2]. They frame and disseminate concepts and themes influencing collective understandings and ideals, indirectly shaping practitioners’ preferences and expectations and athletes’ behaviours and opportunities. Accordingly, this study aimed to explore football talent narratives in the Italian sporting press to understand macro-systemic influences on the construction of youth players in Italy.

METHODS: A Google News search using the keywords ‘football’ and ‘talent’ was used to collect articles. Only articles written in 2024 were considered. Supposing national sporting news outlets have a greater social impact than general and local ones, 25 articles from La Gazzetta dello Sport, the most read and downloaded Italian sporting newspaper, were included in the study. Qualitative and inductive content analysis was used to analyse articles.

RESULTS: Results revealed three dimensions of talent narrations interacting to shape perceptions of youth players’ pathways: (a) cultural, (b) social, and (c) temporal. The cultural dimension defined what talent looks like (‘he was deselected for disciplinary reasons, as he was considered lazy and overweight’), their preferred developmental corridors (‘he specialised in football at 5, and an Italian first division club selected him at 9’), and performance standards (‘he was the star of the local youth tournaments’). The social dimension presented youth players’ socioeconomic background (‘he comes from a poor community and played on the streets, there the only thing counting is dribbling opponents’) and interactions with family (‘his mother drove for 4 hours a day to take him to training’) and coach (‘after deselection, his former coach trusted in his abilities and took him with him’). The temporal dimension acknowledged talent as in-becoming (‘accumulating hours of training and playing to develop’). Each dimension is indirectly linked to the set of values promoted by Italian football (competition, youth performance, and work ethic).

Discussion: Findings presented three interacting dimensions contributing to the recognition phenomenon (youth players receiving the label of ‘talent’), which does not appear as an objective, linear, and unbiased process, being instead related to youth players’ conformity to the cultural values, dependent on the received developmental support, and influenced by the passage of time. This study highlighted the construction of football talent in the Italian press, contributing to understanding identification, selection, and development procedures, and presented the mechanisms behind talent recognition, describing what youth players should aim for to be considered talented in the eyes of journalism.

SPORTS PARTICIPATION AND ITS VALUES: A CASE STUDY OF AN UNIVERSITY IN THE NORTHWESTERN UNITED STATES

TANG CJ, KEH NC, LIN CP

NATIONAL TAIWAN NORMAL UNIVERSITY

Introduction: Taiwan has been gradually establishing a nationwide sports culture by introducing American physical education curricula, teaching models, and emerging sports concepts, although various differing views are still being debated. Rokeach (1973) classified values into terminal values, which pertain to the purposes of life and life goals, and instrumental values, which pertain to means and behaviors. Terminal values can be further divided into personal values that fulfill individual life and survival goals and social values that fulfill group development goals. Instrumental values can be divided into competence values that emphasize personal abilities to achieve self-goals and moral values that demonstrate appropriate interpersonal behavior. Whether sports are viewed as a terminal or instrumental value can influence individuals’ willingness to participate, and further affect school curriculum goals and content, and impact the development of various sports. Purpose: This study aimed to investigate the participation in sports and to understand the difference between the two areas. Methods: A qualitative interview approach was used to collect data. The participants were fifteen college students purposeful sampling from an university in the Northwestern United States. The participants included 7 females and 8 males, with an average age of 27. The interview consisted of 8 open-ended questions and 20 closed-ended questions. They were interviewed during the 2024 summer, individually for 20 to 30 minutes with answers directly recorded on a laptop respectively. The interview data were analyzed through content analysis for coding, classification, and interpreta-

tion. To ensure trustworthiness, triangulation method was used. The researchers analyzed some data individually and discussed to cross check some categories for consistency. Results: (1) All 15 participants had regular exercise habits, with a diverse range of activities. Outdoor aerobic exercises such as hiking, walking, and running were most common, followed by indoor activity such as weight training. (2) Most participants accumulated between 1 to 6 hours of exercise per week, followed by 13 to 19 hours. (3) The primary reasons for exercising were to achieve physical, mental and emotional health related goals, with many participants already experiencing these benefits but hoping to gain even more physical and mental health, and social interaction benefits. (4) The value of sports was predominantly related to physical and mental health. Participants believed that the value of exercise was primarily for "improving emotional health" and "maintaining health," rather than as a means for "losing weight" or "achieving academic and career goals." Conclusion: The personal goal values within terminal goal values of the participants in this study were the most prevalent. This findings have implications for Taiwan's physical education and sports development.

Invited Symposium

IS-AP01 Navigating the Perception of Time in Sport: Psychological and Physiological Insights

TIME PERCEPTION AND PRE-EVENT STRATEGIES

ELFERINK-GEMSER, M.

UNIVERSITY OF GRONINGEN, UMCG

An Olympic champion does not wake up one morning as a non-athlete, over breakfast deciding to become the best athlete at the world stage in a certain sport & winning the gold medal that very same evening. It's evident that a long process over the course of many years precedes being successful at the Olympics. Time perception plays a critical role in this developmental journey, influencing both athlete & coach in shaping effective long-term strategies. How well time is perceived & managed can affect not only training volume & intensity but also the timing of peaks & recovery periods. Athletes must manage not just the present moment, but their longitudinal careers. In this session, we will explore the importance of time perception for an athlete's development towards peak performance. This can relate to an Olympic champion but also extends to the broader population of recreational athletes who aim to improve themselves. When designing a training program a trainer needs to be aware of how many years, months, weeks & hours of training & recovery are needed for a certain athlete to meet the requirements of success during his or her sports career. Good time perception could be evident in structured long-term planning, such as periodization, managing avoiding injury and burn-out as well as pitfalls such as misjudging pace. Several models, such as the LTAD model (Balyi, 2002) give direction to choices regarding the content of training in different phases of development but research is limited in how well trainers perform in terms of time perception. For athletes, peaking at the right moment is key. To perform optimally at the most important competition of the season, it seems paramount that good time-perception about how many months, weeks, days, and hours are available for physiological and psychological preparation leading up to the event is essential. Pre-event strategies not only involve these long-term perceptions of time for training and recovery, but also involve knowledge of the duration of the event itself so that the race or match can be planned accordingly. Several studies underscore the positive relation between pre-event planning and performance. For example, international competing athletes outscore their national level counterparts on planning their course of action (e.g., Jonker et al., 2010). However, the specific role of time-perception herein is still under investigated. From practice there are clear indications for its importance. For example, world-class athletes have shown to be able to accurately state the time how long their race lasts while in rest, sitting on a chair. Prior experience and knowledge of the likely demands of the exercise (e.g., 'endtime') have been indicated to be important in managing physical resources to get the best possible outcome (Edwards & Polman, 2013). In this session we will explore how time perception influences the athlete's development journey from years out to the start of the race, drawing on research and examples of both good practice and common pitfalls to ensure success.

THE DYNAMIC PERCEPTION OF TIME DURING EXERCISE

MENTING, S.

ULSTER UNIVERSITY

Athletes often report contrasting perceptions of time during exercise: moments when time flies (the race has barely begun and energy feels limitless) and others where time drags (fatigue builds, and every second feels longer). Despite the commonality of this experience, scientific investigation into time perception during exercise has only recently gained momentum. This is surprising given that athletic competitions are frequently decided by marginal differences, where well-timed decisions can be the key to victory. We will explore the dynamic relationship between time perception and exercise intensity, drawing from recent research on how individuals perceive time at varying levels of physical exertion. Empirical studies comparing subjective time perception in both fixed-intensity exercises and self-paced time trials (with and without competitive contexts) have revealed fascinating insights. Initial findings suggest that during maximal effort, athletes expe-

rience a slowing of perceived time, likely due to a heightened focus on internal signals associated with fatigue (Edwards & McCormick, 2017). In contrast, during self-regulated efforts, athletes respond dynamically to both internal cues and the behaviour of competitors (Edwards et al 2024). Within this context, the competitive environment act as an external distraction, potentially counteracting the exercise-induced slowing of time. Physical discomfort during high-intensity efforts appears to narrow attentional focus, placing athletes "in the moment" and making time seem to drag. Conversely, competitive environments may shift attention outward, diverting focus from the present and seemingly overriding the sensation of time slowing down. To close out, we will survey the practical applications of these findings. By leveraging the effects of external stimuli on time perception, new strategies for enhancing performance can emerge. Cognitive distractions, such as the use of music, visualization, or social comparison in competitive environments, can counteract 'associative' sensations like pain feedback during exercise. For example, listening to fast-paced music during a workout has been shown to increase motivation and reduce the perception of effort, effectively altering the athletes experience of time and making intense intervals feel shorter. Virtual reality has the potential to immerse athletes in environments where time might be artificially sped up or slowed down, allowing for unique training experiences. Other techniques, such as visual pacing systems like LED lights on athletic tracks, have also helped athletes break long-standing world records by altering perceptions of time and effort. This exploration of time perception offers a fresh perspective on performance optimization, with broad implications for training, competition strategies, and athlete development.

POST-EXERCISE TIME PERCEPTION AND ITS IMPACT ON REFLECTION, ENJOYMENT AND TRAINING ADHERENCE

EDWARDS, A.

CANTERBURY CHRIST CHURCH UNIVERSITY

Time perception extends beyond the immediate experience of exercise, influencing how athletes reflect on their sessions, how much they enjoy the activity, and their future training adherence. The perception of time during exercise can distort the athlete's memory of the session, particularly if viewed as overtly painful or unenjoyable. This is critical because post-exercise reflections can shape motivation. Using latest time perception data from populations such as professional soccer (Edwards et al. 2024), this presentation will extend findings to other sports and physical activity contexts, offering practical applications for optimising training design, session structure, and motivation strategies. Research shows that athletes' enjoyment and perception of time during exercise vary greatly, usually driven by personal motivations. This perception of time not only affects athletes' in-the-moment experience, but also their reflection on the session afterwards, influencing their overall attitude towards future training. This concept has wide-reaching implications into all sports, physical activity, and public health. In endurance sports such as running and cycling, athletes often report that high-intensity intervals feel much longer due to perceived exertion, potentially making these sessions less appealing despite their physical benefits. This presentation will suggest strategies to manipulate time perception to enhance motivation and potentially reduce the feeling of time dragging, increasing perceived enjoyment, which is critical for long-term exercise adherence. In recreational physical activity settings, such as group exercise classes or public health programmes aimed at encouraging people to be more active, organising sessions to enhance enjoyment and reduce the "dragging" perception of time could have a substantial impact on retention and motivation. For example, research has shown that structured, engaging activities like dance-based fitness classes or sports-specific drills tend to increase enjoyment and make time feel as though it passes quickly. Conversely, less interactive and monotonous workouts, like steady-state cardio without engaging stimuli, often feel longer and lead to boredom, decreasing the likelihood that participants will adhere in the long-term. This session will highlight practical ways to restructure training to take advantage of time perception dynamics. For instance, incorporating enjoyable activities—such as sport-specific activities to create a dissociative effect, where athletes become less aware of physical discomfort, making the session feel shorter and more engaging. Integrating subjective time perception into more robust training load (TL) assessments could refine how coaches balance objective and subjective measures. Adjusting models like session-RPE to account for how long athletes feel they have worked—rather than just how hard—could provide a more comprehensive understanding of their mental and physical states, leading to better-managed workloads and recovery protocols.

Oral Presentations

MATCHED FOR PHYSICAL ACTIVITY THERE ARE SEX DIFFERENCES IN THE HYPOTENSIVE EFFECTS OF ACUTE DIETARY CAPSAICIN

IVES, S., GYAMPO, A.O., MATHIAS, M.N., ZALESKI, K.S., LORA, B.1, TOMASI, T., LYNCH, M., GIURIATO, G., BASSO, E., FINEGAN, E., SCHICKLER, J., FIORASO, E., VENTURELLI, M.

SKIDMORE COLLEGE

INTRODUCTION: Cardiovascular disease (CVD) is the leading cause of death worldwide, although there are known sex-based differences until the age of menopause in women. Interestingly, the consumption of spicy peppers and their active ingredient, capsaicin, has been suggested to reduce CVD-related mortality, but whether this effect may be due to reductions in blood pressure (BP) and the underlying mechanisms remains unknown. Thus, the study of sex differences in not only peripheral BP, but Central BP and vascular stiffness which are relatively novel independent risk factors for CVD, and

the acute effect of dietary capsaicin is warranted. As physical activity (PA) is recognized to reduce BP, it is imperative to match for this when making comparisons. Thus, we aimed to determine sex differences in the central and peripheral BP and vascular stiffness response to acute dietary capsaicin and potential differences in vasoactive biomarkers endothelin-1 (ET-1) and nitric oxide (NO) metabolites nitrite/nitrate (NOx), key regulators of vasomotor tone, vascular resistance, and thus BP.

METHODS: In a randomized placebo-controlled crossover design, 40 young males ($n=22$, 21 ± 2 yrs.) and females ($n=18$, 19 ± 1 yrs.) were assessed for peripheral systolic (SBP) and diastolic (DBP) BP, central systolic (cSys), diastolic (cDia) BP, augmentation index normalized to 75 beats/min (Alx@75), and pulse wave velocity (PWV), in duplicate, using an automated oscillometric sphygmomanometer under placebo and capsaicin conditions. PA was self-reported and allowed for matching of men and women to control for the influence of PA on BP. Urine samples were obtained and analyzed for ET-1 and NOx using enzyme-linked immunosorbent or Griess reagent assays, respectively. Data were analyzed using two-way ANOVA.

RESULTS: For peripheral BP, there was an interaction of sex*condition for SBP ($p=0.028$, $\eta^2p=0.201$), where capsaicin lowered SBP in women but not men. Though directionally similar, no significant effects were noted in DBP (sex*condition, $p=0.437$, $\eta^2p=0.028$). In central BP, no interaction effects were noted in central systolic (cSys, sex*condition, $p=0.126$, $\eta^2p=0.103$) and diastolic BP (cDia, sex*condition, $p=0.185$, $\eta^2p=0.078$), but again trended along the effects noted in SBP. Alx@75 was also similar (sex*condition, $p=0.135$, $\eta^2p=0.099$), but not PWV (sex*condition, $p=0.399$, $\eta^2p=0.033$). ET-1 was lower in women and tended to fall more so in women (sex*condition, $p=0.187$, $\eta^2p=0.045$), though the opposite seemed true in NOx (sex*condition, $p=0.099$, $\eta^2p=0.070$) and the ET-1:NOx ratio (sex*condition, $p=0.245$, $\eta^2p=0.035$).

CONCLUSION: Capsaicin lowered brachial SBP, where women responded favorably, with similar tendencies in cSys. While capsaicin tended to lower ET-1 in women, but not PA-matched men, and that NOx and the ET-1:NOx ratio do not exhibit this trend, suggests other mechanisms may be responsible, and warrants further study.

A CHAMBER OF SECRETS: SEX-SPECIFIC ADAPTATION TO EXERCISE IN THE LEFT ATRIUM

CRIDDLE, J., COLLIS, J., MARSH, C., THOMAS, H., GEORGE, K., NAYLOR, L., GREEN, D.

UNIVERSITY OF WESTERN AUSTRALIA

INTRODUCTION: The left atrium (LA) is responsible for modulating venous return and ventricular filling. Both pathological stimuli (e.g., hypertension, obesity, valvular disease) and endurance training (END) can influence LA structure and function. Clinically, an enlarged LA is associated with an increased risk of atrial fibrillation, including atrial dysrhythmias in some ultra-endurance athletes. Conversely, LA size is linked to higher cardiorespiratory fitness. Longitudinal studies of exercise-induced LA adaptations are limited, with existing research focused solely on END, demonstrating LA enlargement but sparse data on LA function. No studies have assessed LA adaptations to resistance training (RES) or utilized speckle-tracking echocardiography to evaluate mechanical function. Additionally, sex-specific changes to distinct exercise modalities have not been reported.

METHODS: Sixty-four participants (26 male, 38 female) were randomized in a crossover designed study involving 12-weeks of END or RES, separated by a 12-week washout. LA structure and function were assessed using 2D and speckle tracking echocardiography.

RESULTS: LAmx volume significantly increased following END (Delta 3.94 ± 1.53 mL, $P=0.01$) but not RES (Delta 2.68 ± 1.54 mL, $P=0.07$). The increase in LAmx volume following END was primarily due to a significant increase observed in males (Delta 6.19 ± 2.27 mL, $P=0.007$), not females (Delta 1.7 ± 2.05 , $P=0.41$). There was no significant change in LAmin volumes in response to training (END; Delta 1.03 ± 0.85 , $P=0.23$; RES; Delta -0.93 ± 0.89 , $P=0.30$), and no sex-dependent differences (all $P>0.05$). LA emptying fraction (LAEF) did not significantly change following END (Delta $-1.21\pm1.54\%$, $P=0.43$), but significantly increased after RES (Delta $3.66\pm1.6\%$, $P=0.03$), although no significant sex-dependent differences were apparent (all $P>0.05$). There were no significant training effects for either training type on LA reservoir, conduit, or contractile strain, nor sex-specific differences in these variables (all $P>0.05$).

CONCLUSION: END significantly increased LAmx volume, primarily driven by adaptations in males, whereas RES had no significant effect. Conversely, RES improved LAEF, with no sex-specific differences. Neither training type altered indices of LA strain. These findings suggest that END induces structural LA remodelling, particularly in males, while RES enhances LA emptying. Given the higher prevalence of atrial fibrillation and the larger a priori LA structure apparent in men, the END related LA enlargement we observed in males may have implications for long-term management of cardiac arrhythmias, particularly in ultra-endurance athletes.

SEX DIFFERENCES IN CYCLING EFFICIENCY, AEROBIC ENZYMES, AND GLYCOGEN STORES FOLLOWING A STRENUOUS MILITARY FIELD EXERCISE

VIKMOEN, O., TEIEN, H.K.2, TANSØ, R.2, AANDSTAD, A.3, LANDER, E.1, CUMMING, K.T.1, HELKALA, K.4, RAASTAD, T.1

1: NORWEGIAN SCHOOL OF SPORTS SCIENCES, 2: NORWEGIAN DEFENCE RESEARCH ESTABLISHMENT, 3: NORWEGIAN DEFENCE UNIVERSITY COLLEGE, 4: THE NORWEGIAN DEFENSE UNIVERSITY COLLEGE

INTRODUCTION: Strenuous military field exercises (MFE) causes muscle mass loss and long-lasting physical performance impairments. However, their effect on muscle efficiency during submaximal work and associated cellular muscle changes are poorly understood. Furthermore, the effects of MFE in women are not well documented. This study aimed to investi-

gate the impact of strenuous MFE on efficiency during submaximal work, muscle aerobic enzyme content, muscle glycogen content, and to identify potential sex differences in these aspects.

METHODS: Efficiency was tested on a cycle ergometer (200 W for men and 150 W for women) and CMJ on a force plate in 10 men and in 8 women before (T0), and 1 (T1), 7 (T7), and 14 (T14) days after a 10-days MFE consisting of rigorous physical activity with food and sleep restriction. Muscle biopsies from m. vastus lateralis were collected at T0, T1, and T7.

RESULTS: Countermovement jump height was decreased with $6.7 \pm 6.2\%$ ($p \leq 0.001$) at T1 and was still decreased at T14 with $4.1 \pm 4.7\%$ ($p = 0.003$) for the sexes combined. There were no sex differences in the changes from T0.

The men improved gross efficiency (GE) at T1 (0.7 ± 0.7 pp, $p = 0.019$), whereas it decreased in women (-0.9 ± 1.0 pp, $p = 0.042$). The change was different between sexes ($p = 0.002$), and these group differences persisted at T7 ($p = 0.022$). At T14, GE returned to pre-values in women, while it remained improved in men (0.4 ± 0.6 pp, $p = 0.038$), with no sex differences in the changes from T0.

Heart rate (HR) decreased at T1 in both men ($-12.9 \pm 3.4\%$, $p \leq 0.001$) and women ($-4.6 \pm 4.7\%$, $p = 0.030$), with a larger reduction in men ($p \leq 0.001$). HR remained reduced in men throughout recovery but returned to pre-values at T7 in women. Blood lactate concentration did not change significantly in either sex, though women showed a larger ($p = 0.037$) non-significant increase at T1 ($29 \pm 44\%$, $p = 0.198$) compared to a non-significant decrease in men ($-11 \pm 31\%$, $p = 0.109$). There were no sex differences in changes in respiratory exchange ratio or perceived exertion during submaximal cycling.

At T7, the sexes combined reduced the content of citrate synthase ($-23 \pm 28\%$, $p = 0.005$) and tended to reduce to content of COX4 ($-18 \pm 43\%$, $p = 0.056$), with no sex differences.

The changes in muscle glycogen content were similar in Type I and II fibers for both sexes. At T1, glycogen content in the muscle fibers combined was reduced in both men and women with $8 \pm 10\%$ ($p = 0.033$) and $8 \pm 8\%$ ($p = 0.02$), respectively. At T7, the percentage change from T0 was different between sexes ($p = 0.009$), where the men had increased glycogen content with $10 \pm 6\%$ ($p \leq 0.001$), while the women returned to T0 values.

CONCLUSION: A demanding MFE resulted in improved cycling efficiency in men but impaired efficiency in women. The reasons for this sex difference remain unclear, though it is likely unrelated to changes in aerobic enzyme levels or glycogen stores, which were similar between men and women.

EFFECT OF THE MENSTRUAL CYCLE ON FAT OXIDATION DURING A ONE-HOUR AEROBIC EXERCISE AT FATMAX

GARCÍA ORTIZ, C., FERNÁNDEZ-SÁNCHEZ, J., GARCÍA-ALBÍN, D., RANIERI, L.E., TRUJILLO-COLMENA, D., SOLANO, V., RODRÍGUEZ-CASTAÑO, A., COLLADO-MATEO, D., CASADO, A., DEL COSO, J.
REY JUAN CARLOS UNIVERSITY

INTRODUCTION: The potential influence of the menstrual cycle on the relative contribution of fat and carbohydrates to energy metabolism during moderate-intensity aerobic exercise remains uncertain, as previous studies have reported inconsistent findings. Overall, previous studies relied on laboratory-based exercise testing that did not reflect the training routines typically followed by women, limiting their applicability to real-world exercise conditions. To address this gap, the primary objective of this study was to examine the effect of the menstrual cycle on fat and carbohydrate oxidation rates during a one-hour cycling session at Fatmax.

METHODS: Fourteen physically active naturally menstruating women participated in a randomised crossover experimental trial consisting of one hour of cycling at their Fatmax performed in three phases of the menstrual cycle: (a) early follicular, (b) peri-ovulatory and (c) mid-luteal. These menstrual cycle phases were individually determined using a combination of methods, including a mobile application that tracked menstruation onset for four months prior, detection of luteinizing hormone surges in urine samples and monitoring of body temperature and body weight throughout an entire menstrual cycle. At each experimental session, respiratory variables were recorded with a gas analyser to calculate fat and carbohydrate oxidation rates through stoichiometry equations. Heart rate and the rating of perceived exertion were also measured at each session. Variables were analysed with one-way repeated measures ANOVA and post-hoc analysis was applied in the case of a main effect.

RESULTS: There was no main effect of menstrual cycle phase on total fat oxidised ($F = 0.764$, $p = 0.476$), total carbohydrate oxidised ($F = 1.047$, $p = 0.365$) or total energy consumed ($F = 0.123$, $p = 0.885$) during exercise. However, a significant main effect in heart rate was found ($F = 4.014$, $p = 0.010$) with higher values in the peri-ovulatory compared to the early follicular phase ($p = 0.021$). Last, menstrual cycle had a main effect on perceived exertion ($F = 5.460$, $p = 0.010$). Post-hocs revealed higher perceived exertion in mid-luteal compared to the early follicular ($p = 0.018$) and peri-ovulatory phases ($p = 0.022$).

CONCLUSION: Menstrual cycle did not affect the contribution of fat and carbohydrate as fuel nor total energy expenditure during a one-hour aerobic cycle-ergometer exercise at Fatmax. However, other variables such as heart rate and perceived exertion were affected by menstrual cycle, as heart rate was higher in peri-ovulatory vs. early follicular and rate of perceived exertion was higher in mid-luteal compared to early follicular and peri-ovulatory phases.

SEX DIFFERENCE IN THE COMBINED EFFECTS OF MODERATE-INTENSITY AEROBIC EXERCISE AND MEDIUM-CHAIN TRIGLYCERIDES ON WORKING MEMORY

YUUKI, I., DORA, K.1,2, MATSUMURA, T.1, FUKUZAWA, K.1, MURAKAMI, Y.1, HASHIMOTO, K.1, HASHIMOTO, T.1,4, TSUKAMOTO, H.3,4

RITSUMEIKAN UNIVERSITY. 1>, TOYO UNIVERSITY. 2>, WASEDA UNIVERSITY. 3>, RITSUMEIKAN UNIVERSITY. 4>

INTRODUCTION: Working memory (WM) is a core component of executive function (EF) and our previous study showed that compared to long-chain triglycerides (LCT) intake, a four-week medium-chain triglycerides (MCT) intake improved WM in young males (1). In addition to this observation, combining MCT with a four-week aerobic exercise (AE) intervention provided similar benefits to MCT alone in young males (1). Although females show better responses in EF improvement to regular AE (2), it remains unclear whether a combination of regular AE and MCT improves WM in females, as compared to MCT alone. Here, we aimed to investigate the combined effects of four-week MCT intake and AE training on WM in males and females and examined potential sex differences in response to the intervention.

METHODS: Thirty-six healthy young adults (21 ± 1 years) were randomly assigned to the MCT group ($n = 18$, 10 males, 8 females) or the MCT-AE group ($n = 18$, 10 males, 8 females). Participants consumed 16.3 ml of oil daily, which contained 12 g of MCT, for four-week in a single-blind manner (1,3). The MCT-AE group additionally performed moderate-intensity cycling AE (30 min/session, 3 sessions/week) at 50~70% heart rate reserve (HRR). For female participants, baseline measurements were conducted during the mid-follicular phase. Given the four-week intervention period, post-intervention measurements were scheduled to ensure they were also conducted during the mid-follicular phase. WM was assessed using the face n-back task, measuring reaction time (RT) and the number of errors (ERR) pre- and post-four-week intervention. A two-way analysis of variance (group [MCT, MCT-AE] $\times$ sex [male, female]) was conducted to analyze changes in RT and ERR from pre- to post-four-week intervention.

RESULTS: No significant main effects for the group and sex were found in either RT (group $P = 0.900$, $\eta^2 < 0.001$; sex $P = 0.885$, $\eta^2 < 0.001$) or ERR (group $P = 0.639$, $\eta^2 = 0.007$; sex $P = 0.749$, $\eta^2 = 0.003$). The group $\times$ sex interaction was also non-significant for RT ($P = 0.322$, $\eta^2 = 0.031$) and ERR ($P = 0.639$, $\eta^2 = 0.007$).

CONCLUSION: The combination of MCT and AE did not improve WM compared to MCT alone, and no sex differences in this effect were observed. These findings suggest that the four-week AE may not further enhance the cognitive benefits of MCT in both young males and females.

IMPACT OF WHOLE-BODY HOT WATER IMMERSION ON CEREBRAL HAEMODYNAMICS AND CEREBROVASCULAR REACTIVITY TO CARBON DIOXIDE

LEANEY, S., TOMMASINI, E., HUGHES, G., SHEPHERD, A., KINGDON, N., LAWLEY, J., COOMBS, G., MOORE, J., OLIVER, S.
BANGOR UNIVERSITY

INTRODUCTION: Passive heating may be an alternative or adjunct to exercise to maintain cardiovascular and cerebral function and health. Hot water immersion (HWI) improves peripheral vascular function via shear-mediated mechanisms; however, it remains unclear if acute HWI can improve cerebrovascular function. This study determined the influence of HWI on cerebral haemodynamics and subsequent cerebrovascular reactivity to carbon dioxide (CVRco₂) within the internal carotid artery (ICA), an index of cerebrovascular function.

METHODS: Fifteen healthy adults (six female, mean age 28 ± 8 years) completed two experimental trials separated by at least 48 hours. Females were tested in the same menstrual cycle phase for both trials. In the HWI trial, participants were immersed in 39°C water to the sternum for 60 min whilst in the CON trial they rested in 21°C air in the same semi-recumbent posture and duration as in the HWI trial. Thermal and haemodynamic variables were assessed throughout trials. CVRco₂ was determined before and 45 min after the 60 min HWI and CON interventions by participants breathing four minutes of a hypercapnic gas (6% CO₂, 21% O₂, N₂ balance) whilst ICA blood velocity and diameter were measured by duplex ultrasound.

RESULTS: At 60 min of the interventions core body temperature and heart rate were higher on HWI than CON (CON, $36.9 \pm 0.3^\circ\text{C}$; HWI, $38.1 \pm 0.3^\circ\text{C}$, $P < 0.001$. CON, 60 ± 10 bpm; HWI, 96 ± 13 bpm, $P < 0.001$). No differences were observed between the HWI and CON interventions for ICA diameter ($P = 0.34$), ICA blood velocity ($P = 0.97$), ICA shear rate ($P = 0.75$) and ICA blood flow (CON, 311 ± 80 ml·min⁻¹; HWI, 338 ± 92 ml·min⁻¹, $P = 0.39$). Compared to CON, HWI intervention reduced mean arterial blood pressure (CON, 82 ± 7 mmHg; HWI, 67 ± 8 mmHg, $P < 0.001$), and increased ICA conductance (CON, 3.9 ± 1.3 ml·min⁻¹·mmHg⁻¹; HWI, 5.2 ± 2.0 ml·min⁻¹·mmHg⁻¹, $P = 0.03$). A 45 min after the interventions no differ-

ence was detected for CVRco₂ between the trials (CON, pre: 13.9 ± 9.2 to post: 11.3 ± 6.1 ml·min⁻¹·mmHg⁻¹; HWI, pre: 14.6 ± 7.9 to post: 10.9 ± 5.4 ml·min⁻¹·mmHg⁻¹; Interaction P = 0.65).

CONCLUSION: HWI reduced blood pressure and increased ICA conductance (i.e. autoregulation) to maintain blood flow to the brain. Nevertheless, despite differences in cerebral vascular tone between interventions, HWI did not influence subsequent cerebrovascular function, as assessed by cerebrovascular reactivity to carbon dioxide. These findings support hot water immersion as an intervention to reduce blood pressure, which if repeated regularly may help to maintain cardiovascular and cerebral health.

GUT MICROBIOTA, PHYSICAL ACTIVITY, AND PHYSICAL FITNESS: EXPLORING RELATIONSHIPS IN CHILDREN AND IMPLICATIONS FOR EXERCISE NUTRITION

XIANG, P., ZHANG, Y., SUZUKI, K., GAO, Y.

1. CHINA INSTITUTE OF SPORT SCIENCE; 2. JUNTENDO UNIVERSITY

INTRODUCTION: This study aims to investigate the association between the gut microbiota and physical activity (PA) and physical fitness (PF) in children by comparing extreme levels of PA and PF, in order to provide a basis for the development of individualized exercise nutrition intervention strategies in early childhood.

METHODS: PF and PA were assessed in 6,074 children aged 6-9 years using the National Standards for Students Physical Health (2014 Revision) and the International Physical Activity Questionnaire Short Form, respectively. Children in the top 25th percentile (high) and bottom 25th percentile (low) for both PF and PA were selected and categorized into four groups: low PA-low PF, high PA-low PF, low PA-high PF, and high PA-high PF. Thirty participants were randomly selected from each group (total n = 120), and fecal samples were collected for 16S rRNA V3-V4 region gene sequencing. Gut microbiota composition and α and β diversity were analyzed for each group. Between-group differences in α diversity were assessed using the Wilcoxon rank-sum test; for β diversity, PERMANOVA was used to test the significance of between-group differences, and Principal Co-ordinates Analysis and Non-metric Multidimensional Scaling (NMDS) were used for visualization. Linear discriminant analysis effect size analysis was used to identify differentially abundant taxa. Pearson correlation and Mantel tests were used to analyze the correlation between the relative abundance of gut microbiota and exercise performance indicators.

RESULTS: At equivalent PA levels, children with high PF showed significantly greater gut microbiota richness and diversity (Chao1, Shannon indices; $p < 0.01$). The low PA-low PF group was enriched in Gammaproteobacteria (*Escherichia coli*), linked to dysbiosis and inflammation. The high PA-low PF group was enriched in SCFAs-producing Akkermansia and Bacteroides coprocola. The low PA-high PF group was enriched in fiber-fermenting Clostridia and Faecalibacterium. Community structure differed significantly between the low PA-low PF group and others ($p < 0.05$). Firmicutes correlated positively with weight, BMI, and sit-ups; Bacteroidetes negatively with BMI; and Proteobacteria positively with vital capacity and long jump, implicating these phyla in energy metabolism, body composition, and athletic performance.

CONCLUSION: children's gut microbiota composition varies significantly based on the combined levels of PA and PF. Children with high PF show greater microbial diversity within similar PA levels, particularly under high PA conditions. PERMANOVA-assessed group differences (weighted vs. unweighted UniFrac NMDS) suggest the low PA-low PF group harbors unique species, potentially linked to its distinct microbial enrichment. PA and PF are associated with gut microbiota composition and potential nutrient metabolism in children. Higher PF correlates with greater gut microbiota diversity and may reflect more efficient nutrient utilization.

PHOTOBIO-MODULATION DOES NOT INCREASE MITOCHONDRIAL RESPIRATION IN SKELETAL MUSCLE OR SKIN TISSUE IN VIVO IN HUMANS

AUSSIEKER, T., PETRICK, H.1, KUIN, L.1, KAISER, J.1, FUCHS, C.J.1, LAMMERS, S.2, PRAET, S.3, SNIJDERS, T.1, VAN LOON, L.J.C.1

1 MAASTRICHT UNIVERSITY, MAASTRICHT, THE NETHERLANDS; 2 REVICURA, GASTEL, THE NETHERLANDS; 3 UNIVERSITY OF CANBERRA, BRUCE, AUSTRALIA

INTRODUCTION: Laser therapy, now more referred to as photobiomodulation (PBM), is gaining interest as a non-invasive treatment for various conditions and as a potential means to enhance health and performance. While in vitro and in vivo animal studies provide promising evidence, surprisingly little research has been conducted on the proposed capacity for PBM treatment to activate metabolism in skin and skeletal muscle tissue in vivo in humans.

METHODS: In a within-participant study design, 12 healthy, young men and women (6/6 m/f; age: 25±6 y; BMI: 23.3±2.2 kg/m²) received PBM on a randomly chosen leg, while the other leg received sham-treatment (no light emitted, CON). Three cycles of PBM were performed for 5 min 16 sec each, separated by 5 min of rest. During the rest periods the other leg received the sham treatment. In total 16.8 kJ in form of light energy was applied (3 x 5.6 kJ) in PBM using wavelengths of 660, 800, 905 and 970 nm in intermittent Continuous Wave (CW), Pulsed Wave (PW), SuperPulse (SP), and IntenseSuperPulse (ISP) mode. Skin temperature was measured before and after treatment. After the treatment, skin and muscle tissue biopsy samples were collected from both legs at the location where the PBM and sham treatments were applied. Permeabilized muscle fiber bundles were prepared from skeletal muscle tissue to measure mitochondrial respiration in an Oroboros Oxygraph-O2k. Skin tissue was minced, and respiration was analyzed in an Oroboros Oxygraph-O2k. Mitochondrial respiration data were compared between treatments (PBM vs CON) using paired samples t-tests. Skin tempera-

ture data were analyzed by a repeated measures ANOVA with time (pre/post) and treatment (PBM/CON) as a within-participants factors. Statistical significance was set at $P < 0.05$. All data in text and figures are expressed as mean $\pm$ SD.

RESULTS: PBM increased skin temperature by 8.0 ± 1.4 °C ($P < 0.05$), with no changes in the control leg ($P > 0.05$). In permeabilized muscle fibers, leak mitochondrial respiration (pyruvate, malate) was not altered by PBM (25.7 ± 6.9 vs 24.2 ± 5.6 pmol/sec/mg dry weight in PBM vs CON, respectively; $P = 0.37$). Furthermore, maximal complex I+II-linked respiration (pyruvate, malate, ADP, glutamate, succinate) did not differ between legs (474 ± 114 vs 467 ± 81 pmol/sec/mg dry weight, respectively; $P = 0.71$). Furthermore, no differences were observed in mitochondrial sensitivity to submaximal ADP levels (apparent ADP half-time: 1310 ± 180 vs 1229 ± 240 μ M ADP, respectively; $P = 0.14$). In skin tissue, maximal complex I+II-linked respiration did not differ between legs (2.7 ± 0.8 vs 2.6 ± 0.7 pmol/sec/mg wet weight, respectively; $P = 0.66$).

CONCLUSION: A single session of photobiomodulation does not increase mitochondrial respiration in skin or underlying muscle tissue in vivo in humans. The proposed benefits of photobiomodulation via high intensity laser therapy are not attributed to the direct activation of tissue metabolism.

INFLUENCE OF CARBOHYDRATE OR NIACIN INGESTION ON POST-EXERCISE PLASMA BCAA AND KETONE BODY CONCENTRATIONS

BRADSHAW, L., MORENO CABAÑAS, A., SPELLANZON, B., HUTCHINS, K., NARANG, B., KOUMANOV, F., BETTS, J.A., GONZALEZ, J.T.

UNIVERSITY OF BATH

INTRODUCTION: Skeletal muscle metabolic adaptations to endurance exercise may be enhanced by training in a fasted state, which may be partly due to differences in the circulating metabolic and hormonal environment from differences in carbohydrate and/or fat availability (1). However, it is currently unknown how much of the circulating metabolic milieu is influenced by specifically carbohydrate or fatty acid availability. The aim of the study was to assess the effect of carbohydrate or niacin ingestion during exercise on plasma metabolite concentrations to isolate the role of suppressed NEFA availability from increased insulin and carbohydrate availability.

METHODS: Fifteen active males ($n=10$) and females ($n=5$) cycled on three occasions for 1 hour at 95% of lactate threshold 1 with ingestion of either carbohydrate (CARB), niacin (NIACIN), or placebo (FAST) in a crossover design. After baseline breath and blood samples were collected, participants consumed a drink (1.6g/kg maltodextrin or placebo) and tablets (10mg/kg niacin or lactose). Following 1 hour of rest participants cycled with further carbohydrate (0.8g/kg/hr maltodextrin), niacin (10mg/kg/hr) or placebo with blood and expired breath samples collected every 15 minutes. A final blood sample was taken 2 hours after completion of exercise. Plasma was analysed for NEFA and insulin concentrations and targeted nuclear magnetic resonance spectroscopy was performed to determine plasma lipoprotein and metabolite profiles. Normality of data were checked by visual inspection of residuals. Differences between conditions were analysed by two-way ANOVA with multiple comparisons assessed by paired t-tests with Bonferroni correction.

RESULTS: Total fat oxidation during exercise was higher in FAST compared to CARB (mean difference $\pm$ 95% CI; 11 ± 4 g, $p < 0.001$) and NIACIN (9 ± 5 g, $p = 0.001$). During exercise, plasma NEFA concentrations were lower in CARB and NIACIN compared to FAST (time $\times$ condition $p < 0.001$, all $p < 0.05$) and plasma insulin concentrations were higher in CARB compared to FAST and NIACIN (time $\times$ condition $p < 0.001$, all $p < 0.05$). Time by condition interactions were seen for total plasma BCAA and total plasma ketone body concentrations (all $p < 0.0001$). Total ketone body concentrations were higher in FAST compared to both CARB and NIACIN at 120 and 240 minutes and higher concentrations in NIACIN compared to CARB at 240 minutes (all $p < 0.01$). In contrast, total BCAA concentrations were lower in CARB compared to FAST and NIACIN at 120 and 240 minutes (all $p < 0.001$).

CONCLUSION: These data suggest that post-exercise BCAA concentrations are suppressed by insulin and carbohydrate availability but not by reduced fatty acid availability per se, whereas ketone body concentrations are suppressed by reduced fatty acid availability independent from insulin.

POST-EXERCISE COOLING REDUCES SKELETAL MUSCLE TISSUE PERFUSION AND IMPAIRS POST-PRANDIAL AMINO ACID INCORPORATION INTO MUSCLE IN ACTIVE YOUNG ADULTS

BETZ, M., FUCHS, C., CHEDD, F., MONSEGUE, A., HENDRIKS, F., VAN KRANENBURG, J., GOESSENS, J., HOUBEN, A., VERDIJK, L., VAN LOON, L., SNIJDERS, T.

MAASTRICHT UNIVERSITY

INTRODUCTION: Cold-water immersion is commonly applied by athletes to facilitate post-exercise muscle recovery. However, post-exercise cold-water immersion blunts the increase in muscle protein synthesis rates following protein ingestion. Whether this effect can be attributed to cold-water immersion-induced reduction in muscle microvascular perfusion and a subsequent decline in post-prandial amino acid provision to the muscle remains unknown.

METHODS: Twelve, recreationally active, young males (24 ± 4 y) performed a single resistance exercise session followed by water immersion for 20 min with one leg immersed in cold water (8°C: COLD) and the contralateral leg in thermoneutral water (30°C: CON). After immersion, a beverage was ingested containing 20 g free amino acids, 0.25 g L-[ring-13C6]-phenylalanine, and 45 g carbohydrates. Femoral artery blood flow and microvascular perfusion of the vastus lateralis

muscle were assessed for both legs simultaneously at rest, immediately following exercise and water immersion, and at $t=60$ and $t=180$ min following amino acid ingestion using Doppler and contrast-enhanced ultrasound, respectively. A percutaneous biopsy sample from the vastus lateralis muscle was collected from both legs at $t=240$ min to determine amino acid tracer incorporation in muscle protein. To assess differences between the CON and COLD leg, data were analyzed by two-way repeated-measures ANOVA (time $\times$ treatment leg; with post-hoc testing in case of significant interaction) or paired-samples t -tests where appropriate. Pearson's r was calculated to determine associations. A statistical level of $P<0.05$ was accepted. All data are expressed as mean $\pm$ SD.

RESULTS: Immediately following water immersion, femoral artery blood flow and microvascular blood volume were significantly lower in the COLD vs CON leg (82 ± 39 vs 165 ± 67 mL/min, and 1.24 ± 0.82 vs 3.13 ± 1.64 video intensity, respectively, both $P<0.001$). Femoral artery blood flow remained lower in the COLD vs CON leg at $t=60$ min (80 ± 52 vs 126 ± 52 mL/min, $P=0.008$), while microvascular blood volume remained lower at both $t=60$ and $t=180$ min following beverage ingestion (0.90 ± 0.84 vs 1.53 ± 0.98 , and 2.10 ± 2.53 vs 2.77 ± 2.81 video intensity, respectively, both $P<0.05$). Exogenous amino acid incorporation into muscle protein was lower in the COLD vs CON leg (0.011 ± 0.004 vs 0.016 ± 0.005 mole percent excess, respectively, $P<0.001$). The relative difference in post-prandial amino acid incorporation into muscle protein between the COLD and CON leg was strongly associated with the relative difference in microvascular blood volume between the two legs during recovery ($r=0.65$, $P=0.022$).

CONCLUSION: Cold-water immersion during post-exercise recovery greatly reduces muscle microvascular perfusion and, consequently, lowers post-prandial amino acid incorporation into muscle. Cold-water immersion during recovery from exercise should be avoided when nutrient delivery to muscle tissue is considered a priority.

Invited Symposium

IS-BM04 Neural modules in the control of movement: assessing the utility of EMG recordings

HIGH-DENSITY INTRAMUSCULAR ELECTRODE ARRAYS

MUCELI, S.

CHALMERS UNIVERSITY OF TECHNOLOGY

Although the concurrent activity of multiple motor units can be recorded with grid electrodes attached to the skin over a selected muscle, these recordings are limited to superficial muscles and are easily contaminated by crosstalk. More selective recordings can be obtained with intramuscular electrodes that can be inserted into both superficial and deep muscles. Importantly, relatively recent advances in technology have included the development of intramuscular electrodes with multiple detection points, so-called high-density intramuscular electrodes. These electrodes allow the simultaneous and accurate detection of large populations of motor units providing insight into mechanisms of human movement. Remarkably, the availability of multiple intramuscular EMG channels enables highly accurate automatic decomposition into the trains of motor unit action potentials activating a muscle compared with the decomposition of single channel EMG that requires considerable interaction by the human operator. We have used this technology in multiple experiments in humans and different animal species to investigate neural connectivity among trains of motor unit action potentials, compartmentalized activation of muscles, force estimation, responses to postural changes, and changes in motor unit composition following transfer of motor axons. The talk will focus on applications in the field of motor control and touch upon technological developments.

NEUROMUSCULAR CHARACTERISTICS OF INDIVIDUAL HAMSTRING MUSCLES

SAHINIS, C.

ARISTOTLE UNIVERSITY OF THESSALONIKI

The anatomy, mechanical properties, and relative contributions to the net hip extensor and knee flexor torques differ across the four hamstring muscles (semitendinosus, semimembranosus, and the long and short heads of biceps femoris). Pennation angle, for example, is greatest in the long head of biceps femoris and least in semitendinosus, which maximizes force capacity and range of motion, respectively, in the two muscles. Moreover, the force produced by the long head of biceps femoris varies with changes in hip and knee angles, whereas the torque produced by semitendinosus does not. The anatomy of semitendinosus differs from the other hamstring muscles by the presence of a tendinous inscription in its middle to which the muscle fascicles in the proximal and distal compartments attach. Moreover, each compartment is innervated by a separate branch of the tibial nerve. As a result of this anatomy, the neural drive to the two compartments during submaximal isometric contractions is independent, as indicated the low correlations in the neural drive to the two compartments as measured with high-density surface EMG electrodes. Although the overall activation of biceps femoris and semitendinosus does not differ across exercises, some exercises preferentially engage one muscle over the other. For example, hip-dominant exercises primarily engage the semitendinosus. Recent advances in high-density surface EMG have been used to acquire a more detailed assessment of muscle activation patterns and neural drive to the hamstring muscles during different exercises. Integrating these advanced techniques can enhance our understanding of hamstring function, with significant implications for improving injury prevention strategies, optimizing rehabilitation protocols, and augmenting athletic performance.

NEURAL MODULES AT THE MOTOR UNIT LEVEL

ENOKA, R.

UNIVERSITY OF COLORADO, BOULDER

In the field of motor control, the term “synergy” is used to denote a motor module developed by the nervous system to manage the redundant degrees of freedom that are available to perform an intended action. Motor modules derived from covariation in the amplitudes of surface EMG recordings are known as “muscle synergies”. They are presumed to reflect the concurrent activation of several muscles by the same motor command. Neural modules can also be defined at the motor unit level by using factor analysis to identify motor units with correlated modulation of discharge rates. This approach requires the use of high-density EMG technology to record the activity of many motor units in several muscles. Motor units with correlated discharge rates are presumed to share a significant proportion of synaptic input. These neural modules are referred to as “motor unit modes”. In contrast to the extensive literature on muscle synergies, recent findings indicate that not all the motor units in a muscle belong to the same motor unit mode. This means that the shared synaptic input is distributed to sets of motor units within and across muscles. Moreover, the strength of the correlated discharge rate among the motor units within a mode can be changed by a brief bout of physical activity. These findings provide new opportunities to explore the plasticity of networks within the spinal cord of humans.

CAFFEINE SUPPLEMENTATION ATTENUATES SEVERAL NEGATIVE EFFECTS OF MENTAL FATIGUE DURING SIMULATED RUGBY LEAGUE MATCH-PLAY

MULLEN, T., TWIST, C.2, HIGHTON, J.3

1. MANCHESTER METROPOLITAN UNIVERSITY; 2. LIVERPOOL JOHN MOORES UNIVERSITY; 3. UNIVERSITY OF CHESTER.

INTRODUCTION: Mental fatigue is characterised by feelings of tiredness, decreased motivation and a lack of energy, which can have adverse effects on subsequent cognitive, skilled and physical performance. Caffeine intake, in doses between 1-6 mg.kg⁻¹, is widely known for its ergogenic properties and has been shown to enhance endurance and cognitive performance. While caffeine has been shown to enhance endurance performance under mental fatigue, its effects on rugby-specific performance remain unexplored. The purpose of the study was to describe the effects of mental fatigue on simulated rugby league performance and to determine the effects of caffeine supplementation in the presence of mental fatigue.

METHODS: Ten male university rugby players (age = 23 ± 4 y, body mass = 81.2 ± 6.8 kg, stature = 1.79 ± 0.06 m, predicted maximal oxygen uptake [VO₂max] = 51.1 ± 5.5 ml.kg⁻¹.min⁻¹) completed four trials of the rugby league movement simulation protocol for interchanged players (RLMSP-i) in a randomised, repeated measures, double-blind design. After baseline measurements, participants completed a control, mental fatigue, caffeine (5 mg.kg⁻¹) and a placebo trial of the RLMSP-i, with 5-8 days between trials. Mental fatigue was induced using a cognitively demanding task (30 min incongruent Stroop). Throughout all protocols, movement characteristics using a GPS device, heart rate and rating of perceived exertion were recorded. Before, at half time and immediately after the protocol, reaction time and passing accuracy were measured. Subjective task load (NASA-TLX) was reported on completion of each trial. Data are presented as means $\pm$ SD and effect sizes (ES) $\pm$ 90% confidence intervals (CI).

RESULTS: Completing a mentally demanding task increased participants' subjective rating of mental fatigue (pre = 29 ± 25 AU; post = 55 ± 20 AU) immediately before completing a simulation protocol. Impairments in sprint speed (ES = -0.18; ± 0.19), sprint to contact speed (ES = -0.20; ± 0.27), high-intensity running (ES = -0.30; ± 0.24), high metabolic power > 20 W.kg⁻¹ (ES = -0.50; ± 0.51) and time to complete a passing accuracy task (ES = 0.54; ± 0.63) were observed after mental fatigue. Caffeine supplementation (5 mg.kg⁻¹) attenuated several adverse effects of mental fatigue, with increased sprint speed (ES = 0.40; ± 0.18), high-intensity running (ES = 0.50; ± 0.53), high metabolic power > 20 W.kg⁻¹ (ES = 0.33; ± 0.38) and decreased time to complete a passing accuracy test (ES = -0.70; ± 0.45).

CONCLUSION: Mental fatigue affected the internal loads, external loads and skill performance during simulated rugby league match play that appear to be centrally regulated by a decreased motivation and increased perception of effort. However, a single dose of caffeine (5 mg.kg⁻¹) taken 60 min before performance can attenuate several of these adverse effects, supporting its role as an effective countermeasure for mental fatigue-induced declines in team sport performance.

EXPLORING THE VARIANCE IN SUBJECTIVE SYMPTOMS AND PERFORMANCE IN AUSTRALIAN FOOTBALLERS ACROSS MENSTRUAL CYCLE PHASES AND HORMONAL CONTRACEPTIVE USE

DOWER, H., MCKAY, A., ROBERTSON, S., SWEETING, A.

VICTORIA UNIVERSITY

INTRODUCTION: Minimal evidence supports the implementation of an individualised approach to menstrual cycle management in team sports, especially one that accounts for cycle variability. This study explored strength and power performance changes across the menstrual cycle and phases of hormonal contraceptive (HC) use over two cycles.

METHODS: Fourteen professional female Australian footballers participated in a 13-week pre-season study, reporting daily symptom severity. Naturally menstruating athletes (AthletesNMC, $n=7$) completed countermovement jump relative peak power (CMJ RPP) and isometric belt squat relative peak force (IBSQ RPF) tests during menstruation (days 2–6 after bleeding onset), ovulation (within 48 hours of a positive ovulation test), and the luteal phase (7–9 days post-ovulation). Athletes using HC (AthletesHC, $n=7$) were tested during bleeding and across three arbitrary phases. Results are reported as 95% CI [upper limit, lower limit]

RESULTS: Two athletes (IUD users) did not experience regular bleeding. Ovulation was confirmed in at least one cycle for all (14 ± 1.73 days) and across two cycles for three athletes. Two AthletesNMC were found to have progesterone levels ($<16\text{mmol/L}$) in the mid-luteal phase in one cycle but were ($>16\text{mmol/L}$) in the following cycle. Average bleed duration and cycle length were 4.5 ± 1.38 and 28.68 ± 5.06 days, respectively. Abdominal cramps were the most reported symptom (count=78). Daily symptom severity (SS) scores were significantly higher in HC users ($p=0.004$), with greater variability ($SD = 4.33$) compared to AthletesNMC ($SD = 3.10$). Peak SS occurred at different times (AthletesNMC: Day 2, 4.1 ± 8.4 AU; AthletesHC: Day 29, 3 ± 6 AU). Peak Power (CMJ RPP) (W/kg) results across the three phases in cycle 1 were 47.11 [45.16–49.07], 42.26 [38.75–45.76], and 44.79 [41.53–48.05], respectively. In cycle 2, these values were 43.50 [40.50–46.50], 41.34 [37.14–45.54], and 42.84 [40.14–45.54], respectively. A general decline in peak power is observed from cycle 1 to cycle 2 across phases, though the magnitude of change varies. Peak Force (IBSQ RPF) (N/kg) results in cycle 1 were 38.80 [33.60–43.99], 38.30 [32.61–43.98], and 36.18 [31.62–40.73], while in cycle 2, values were 39.29 [35.60–42.98], 44.70 [35.03–54.37], and 42.11 [36.40–47.82]. Peak force showed a more mixed trend, with values generally increasing in cycle 2, suggesting greater variability in force production across cycles.

CONCLUSION: This study demonstrates the variability in strength and power performance measures across menstrual cycle phases and hormonal contraceptive use in elite female athletes. Moreover, this study showed variance in performance between consecutive cycles and daily symptom severity between athletes naturally menstruating compared with those on hormonal contraception. Practitioners working with female athletes should consider individualised approaches when working with female athletes.

DOES APPROACH DISTANCE MATTER? EXAMINING ITS EFFECTS ON SINGLE LEG VERTICAL JUMP EFFICIENCY AND PERFORMANCE OUTCOMES

HSU, T., HUNG, M., YU, C., LIN, J.

NATIONAL TAIWAN UNIVERSITY OF SPORT

INTRODUCTION: Running vertical jump is a fundamental movement pattern in various sports, particularly those requiring explosive takeoff, such as basketball layups, handball shooting and high jumping [1]. The effectiveness of approach distance in optimizing takeoff performance is influenced by multiple biomechanical factors, including takeoff technique, lower limb power and the conversion of horizontal velocity into vertical impulse. Moreover, variations in jumping mechanics between elite and general athletes may lead to distinct neuromuscular strategies. Therefore, this study aims to investigate the influence of different approach distances on lower-limb explosive force production and muscle activation during single-leg vertical jump, providing insight into the optimal approach strategy for maximizing performance.

METHODS: This study recruited 24 healthy male athletes, divided into elite group and general group (12 participants each). Participants performed single-leg vertical jumps with approach distances of 1 m, 3 m, and 5 m. The study analyzed lower limb joint angles, muscle activation, initial eccentric rate of force development (IRFD), speed strength index (SSI), reactive strength index (RSI), and reactive strength ratio (RSR). Two-way ANOVA, mixed design was conducted to compare lower extremities parameters across distances and groups.

RESULTS: The results indicated no significant difference in jump height across different approach distances. However, RFD, SSI, RSI and RSR were significantly higher in the 3 m and 5 m approaches compared to the 1 m approach ($p = 0.00$). Additionally, in the 3 m and 5 m approaches, the elite group exhibited significantly greater quadriceps activation and shorter contact time compared to the general group. The elite group also demonstrated less hip flexion ($p = 0.00$) and ankle dorsiflexion during takeoff ($p = 0.00$).

CONCLUSION: The findings suggest that approach distance does not significantly affect jump height, but takeoff velocity varies with approach distance. Notably, the 3 m and 5 m approaches resulted in significantly shorter contact times compared to the 1 m approach, facilitating greater explosive force output and more efficient energy utilization. Furthermore, the elite group demonstrated quadriceps activation, which enhanced the stretch-shortening cycle (SSC) effect. In contrast, the general group compensated for technical deficiencies with greater hip flexion and ankle dorsiflexion, potentially reducing energy transfer efficiency and jump performance. These results suggest that elite athletes may generate higher horizontal velocity in longer approach distances, affecting vertical energy conversion. Ultimately, lower-limb strength and SSC optimization remain crucial determinants of jump performance across different approach distances.

OP-MH22 Resistance Training in Older Adults

NMES CONDITIONING CONTRACTIONS IN COMBINATION WITH RESISTANCE TRAINING TO PROMOTE NEUROMUSCULAR AND FUNCTIONAL IMPROVEMENTS IN OLDER ADULTS

STAFUZZA, J., GONNELLI, F., DALLEVA, M., MARI, L., ZACCARON, S., FLOREANI, M., FLOREANCIG, A., PADOVAN, D., URSEALLA, G., BRUGNOLA, G., REJC, E., LAZZER, S.

UNIVERSITY OF UDINE

INTRODUCTION: Older adults experience physiological modifications in various aspects such as body composition, levels of strength, muscle mass quantity and quality, and bone density¹. Taken together these factors may lead to physical limitations, decreased quality of life, increased risk of developing non-communicable diseases and potentially hospitalization². To counter these modifications resistance training (RT) has proven to be a feasible and effective intervention that can also benefit older adults³. In this regard, Neuromuscular Electrical Stimulation (NMES) can be used to promote muscular reconditioning⁴.

METHODS: This study investigated the effects of 18 sessions of two different training methods. The experimental group (EXP) of 10 older adults (>65y) performed isometric RT with an NMES conditioning stimulus on the dominant (D) knee extensors. The control group (CTRL) of 12 active older adults (>65y) performed dynamic body weight and free-weight RT. Maximum voluntary contraction (MVC), peak power (P) of lower limbs, and physical capacities assessed with 5 Sit to Stand (5STS), Time Up and Go (TUG) and 6 Minutes Walking Test (6MWT) were assessed.

RESULTS: At the end of the intervention, the EXP group improved in MVC and power output in both legs (MVCD +30.4%, MVCDnD +13.5%, $p < 0.05$; PD +8.1%, PnD +7.1%, $p < 0.05$). Also, both groups improved performance in 5STS, TUG, and 6MWT (5STS EXP: -15.8%, 5STS CTRL: -15.1%, $p < 0.001$; TUG EXP: -9.9%, TUG CTRL: -9.3%, $p < 0.001$; and 6MWT EXP: +9.5%, 6MWT CTRL: +5.9%, $p < 0.001$).

CONCLUSION: Isometric training with NMES conditioning can be a useful strategy to enhance physical and functional parameters in older adults. This approach could be useful in situations where traditional RT cannot be performed.

NON-TRADITIONAL METHODS OF SUPERVISING RESISTANCE TRAINING ARE AS EFFECTIVE AS TRADITIONAL SUPERVISION AT IMPROVING PHYSICAL PERFORMANCE IN OLDER ADULTS.

DOWLING, C., KING, L., FITZPATRICK, P., OHAGAN, C.

SOUTH EAST TECHNOLOGICAL UNIVERSITY CARLOW

INTRODUCTION: Resistance training (RT) for older adults traditionally involves face-to-face supervision, but lack of time and requirements to travel are prevalent barriers to accessing RT among older adults. Non-traditional methods of supervising RT may alleviate these barriers and facilitate older adults' access to RT.

The aim of this study was to investigate the effect of RT supervision method on physical performance in older adults.

METHODS: Sixty-four community-dwelling, healthy older adults (OA) (66.4 ± 4.5 years; 66% female) were randomly assigned to a non-exercise control group (CON), or to 1 of 3 RT groups: traditionally supervised (TRAD) – 2 weekly supervised RT sessions in a community-centre; semi-supervised (SEMI) – 1 weekly supervised RT session in a community-centre and 1 weekly unsupervised RT session at home; and video-call supervised (VID) – 2 weekly RT sessions at home, supervised via video-call. Each participant was given 4kg, 8kg, and 12kg kettlebells and trained for 12 weeks, with training volume and intensity matched across groups. Physical performance was assessed pre- and post-intervention via Timed Up-and-Go (TUG), 30s Chair Stand (30CS), and Isometric Midthigh Pull peak force (IMTPPF). A two-way repeated measures ANOVA was used to determine the effects of training and supervision method on physical performance.

RESULTS: TUG improved in all training groups with no between-training group difference (TRAD: 7.36 ± 1.31 s vs 6.58 ± 1.02 s, $p < 0.001$, partial-eta squared = 0.18); SEMI: 7.90 ± 1.04 s vs 6.70 ± 0.73 s, $p < 0.001$, partial-eta squared = 0.29; VID: 7.11 ± 1.05 s vs 6.69 ± 0.88 s, $p = 0.048$, partial-eta squared = 0.06); there was no change in CON ($p = 0.795$). Similarly, 30CS (number of stands) improved in all training groups with no between-training group differences (TRAD: 19.05 ± 3.30 vs 24.40 ± 4.07 , $p < 0.001$, partial-eta squared = 0.44; SEMI: 19.93 ± 3.63 vs 25.00 ± 3.95 , $p < 0.001$, partial-eta squared = 0.34; VID: 20.37 ± 5.60 vs 22.90 ± 4.33 ; $p = 0.002$, partial-eta squared = 0.14); there was a decrease in stands in CON

(20.33 ± 4.08 vs 18.27 ± 4.65 ; $p = 0.02$, partial-eta squared = 0.08). There was no change in IMTPPF in any group ($p = 0.076$, partial-eta squared = 0.05).

CONCLUSION: Twelve weeks of supervised RT induced improvements in physical function (TUG and 30CS) in OA which were independent of the method of supervision used. Strength (IMTPPF) did not improve, which may be a function of the relatively low intensity of the RT prescribed in this study. Non-traditional methods of supervising RT may reduce barriers to participation while retaining effectiveness of a training intervention.

INTRODUCTION: Although exercise interventions have shown benefits in the oldest-old population [1,2], their potential for improving frailty and muscle power, both predictors of healthy ageing, has not yet been explored in institutionalized centenarians. Hence, this study aimed to determine whether a resistance training intervention can improve frailty and muscle power in frail institutionalized centenarians.

METHODS: Twelve frail centenarians living in nursing homes (age 101.36 ± 2.09 years; 83.33% women) were randomly assigned to either an exercise (EX; $n = 6$) or a control (CT; $n = 6$) group. The EX group conducted supervised resistance training twice weekly for 12 weeks, while the CT group received usual care. Each resistance training session included 8 exercises with 1-3 sets of 8-10 repetitions, conducting the concentric phase as fast as possible at 50-70% of the estimated one-repetition maximum. The Frailty Trait Scale short form (FTS5), Fried's Frailty Phenotype (FP), and 30-s sit-to-stand (STS) muscle power test were assessed at baseline and after 12 weeks. Baseline values for both groups were compared using the Mann-Whitney test. Analysis of covariance (ANCOVA) with Bonferroni adjustment was used to determine within- and between-group differences in the effects of the intervention on the assessed outcomes. The significance level was set at $p < 0.05$. The effect size (ES) was calculated using Hedge's g , and the percentage of change (Δ) was calculated as $((\text{mean post} - \text{mean pre}) / \text{mean pre}) \times 100$.

RESULTS: No significant differences between groups were observed at baseline in FTS5, FP and relative and allometric STS muscle power ($p > 0.07$). After intervention, the EX group significantly improved FTS5 ($\Delta -9.8\%$; $p < 0.01$; $ES = 0.59$), FP ($\Delta -21.7\%$; $p < 0.01$; $ES = 1.11$) and relative ($\Delta +82.2\%$; $p < 0.01$; $ES = 0.79$) and allometric ($\Delta +79.9\%$; $p < 0.01$; $ES = 0.76$) STS muscle power. The CT group exhibited no significant changes in any outcome after 12 weeks ($p > 0.11$; $ES = 0.75$ to 0.13). ANCOVA revealed significant differences between the changes in the EX and CT groups, respectively, for allometric ($+14.51$ vs. -3.87 W·m⁻²; $p < 0.01$) and relative ($+0.68$ vs. -0.22 W·kg⁻¹; $p < 0.01$) STS muscle power, and FP (-0.83 vs. $+0.33$ points; $p < 0.01$); while a no significant between-group difference was found for FTS5 (-3.33 vs. $+0.33$ points; $p = 0.15$). No side effects were detected.

CONCLUSION: Supervised resistance training effectively and safely reduced frailty and improved muscle power among frail institutionalized centenarians. These results underscore that no one is too old or unfit to benefit from exercise-based interventions.

PROTEIN ENHANCES MUSCLE STRENGTH FOLLOWING PROGRESSIVE RESISTANCE TRAINING: A RANDOMIZED CONTROLLED TRIAL

BIERSTEKER, E., BENALI, M., VAN DEN HELDER, J., TIELAND, M., SCHOUFOUR, J., WEIJS, P.
AMSTERDAM UNIVERSITY OF APPLIED SCIENCES, AMSTERDAM, THE NETHERLANDS

INTRODUCTION: Progressive resistance training combined with adequate protein intake is recognized as a key strategy to combat the age-related decline in muscle strength in older adults. Despite substantial research in this area, the extent to which protein enhances strength gains from resistance exercise training remains unclear. This study aims to evaluate the additional effects of a protein intervention during progressive resistance training on skeletal muscle strength, and to determine whether this effect differs by habitual protein intake levels in frail community-dwelling older adults.

METHODS: This 12-week randomized controlled trial included 295 frail community-dwelling older adults (≥ 65 years) into 12 training intensity groups (25–80% of one-repetition maximum). Under one-to-one supervision, participants performed twice weekly full body resistance training until volitional muscular failure. In addition, participants were allocated to either a protein intervention or no protein intervention. The protein intervention comprised dietary counselling and free daily availability of 20g whey protein products to achieve a total daily protein intake of 1.2–1.5 g/kg bodyweight. The outcome was lower-extremity muscle strength leg press. Linear Mixed Models were performed using SPSS with time and time x intervention interaction.

RESULTS: Participants with a mean age of 74 (SD=6), 69% female and 64% overweight or obese had a baseline protein intake of 1.1 ± 0.3 g/kg/day. The participants in the protein training group significantly increased their protein intake ($\beta \pm \text{SE}$) compared to the training only group with $+0.4 \pm 0.1$ g/kg/d ($p < 0.001$). For all participants, muscle strength significantly improved with $+25 \pm 1$ kg ($p < 0.001$) after 12 weeks. Muscle strength significantly increased more in the protein training group than in the training only group ($+5$ kg, $p = 0.032$). For participants with a baseline protein intake of < 0.8 , 0.8 – 1.0 , 1.0 – 1.2 , and > 1.2 g/kg/day, the protein training group demonstrated muscle strength improvements of $+14 \pm 5$ kg ($p = 0.014$), $+5 \pm 4$ kg ($p = 0.259$), $+7 \pm 5$ kg ($p = 0.134$) and -2 ± 4 kg ($p = 0.583$), respectively compared to the training only group.

CONCLUSION: A protein intervention combined with progressive resistance training is effective in enhancing muscle strength in frail community-dwelling older adults, particularly when habitual protein intake is low.

THE BENEFICIAL EFFECT OF 12 WEEKS OF RESISTANCE TRAINING ON BALANCE CONTROL OF MILD COGNITIVELY IMPAIRED OLDER ADULTS

CESNAITIENE, V., KUŠLEIKIENE, S., VINTS, W.A.J., MICKEVICIENE, L., MASIULIS, N., LEVIN, O.
LITHUANIAN SPORTS UNIVERSITY

INTRODUCTION: The interplay between motor functions and cognitive abilities is a critical focus in aging research. Studies consistently show a strong relationship between motor and cognitive functions, which becomes particularly important as individuals age. Deficits in one area can impact the other, underscoring the complex dynamics between motor and cognitive interactions. For instance, reduced balance and poor movement control have been linked to a higher risk Mild Cognitive Impairment (MCI) and Alzheimers disease. Our study is based on the hypothesis that strength training reduces the dual-task effect on both balance control and cognitive function.

METHODS: A total of 53 participants completed the intervention (mean age: 69 ± 6.2 years). Based on the MoCA test results, participants were divided into two groups: those with a high risk of MCI (hrMCI, MoCA score 25 or below) and those with low risk of MCI (lrMCI, MoCA score 26 or above). Static posturography was evaluated using a force plate (KISTLER, Slimline System 9286). Postural sway velocity of the center of pressure (Vcop) was assessed across two positions—Dual Stance (DS) and Tandem Romberg Stance (TR). Cognitive domains were tested with Automated Neuropsychological Assessment Metrics (ANAM) battery. Participants completed two-choice reaction time, mathematical processing, and memory search cognitive tests. Participants in the experimental group took part in a 12-week progressive resistance exercise (RT) program, while participants in the control group did not receive any treatment. Training sessions were held twice a week, each session lasting 1 hour. The effect of 12 weeks of resistance training on cognitive function and balance control was assessed using a three-factor ANOVA, where "Time" was a repeated measure, and "Group" and "MCI Risk" were between-group factors.

RESULTS: The 12-week RT intervention yielded some balance improvements in the experimental hrMCI group as observed by the marginal three factor interaction ($F = 3.151$, $p = 0.082$, $\eta^2 = 0.062$). Exploratory analysis of this interaction showed significant reduction of Vcop in hrMCI group while performing the ST-TR-EO condition in both the ML [Vcop pre $16.1(5.96)$ mm/s – Vcop post $12.34(4.98)$ mm/s ($p = 0.03$)] and AP [Vcop pre $16.44(6.69)$ mm/s – Vcop post $14.68(6.08)$ mm/s ($p = 0.023$)] directions. Regarding between-subject effects, no significant differences were found between the experimental and control groups for any of the cognitive tests ($p = 0.124$).

CONCLUSION: Our study partially supported the hypothesis that strength training can improve balance control. While balance control indicators significantly improved after the training, cognitive performance did not change, indicating that the RT induced more pronounced beneficial effects on balance control than on cognitive performance.

MUSCLE FORCE DYNAMICS ACROSS INCREASING SQUAT INTENSITY CONDITIONS IN ELITE POWERLIFTERS

PÜRZEL, A., KOLLER, W., KAUFMANN, P., PÖHLMANN, L., BACA, A., KAINZ, H.
UNIVERSITY OF VIENNA, DEPARTMENT OF SPORT AND HUMAN MOVEMENT SCIENCE

INTRODUCTION: Since the rise of powerlifting, consisting of the squat, bench press, and deadlift, calls for biomechanically informed coaching strategies have become increasingly important to maximise performance and enhance technique. Understanding the muscle forces at work can play a key part in this endeavour and musculoskeletal modelling provides a

non-invasive and valid means for estimating in-vivo muscle forces [1]. So far, only a small number of musculoskeletal modelling studies focussed on analysing muscle forces during squats in elite athletes [2]. The aim of this study was to investigate the effects of increasing intensity in the squat on muscle forces in elite powerlifters.

METHODS: 3D movement data and ground reaction forces were recorded from 29 top-ranked powerlifters (age: 26.1 ± 5.4 years; 1-repetition-maximum: $2.4 \pm 0.4 \times$ body mass) performing squats at 70%, 75%, 80%, 85% and 90% of their 1-repetition-maximum. Personalized musculoskeletal models based on the "Catelli"-model [3] were used to estimate muscle forces in OpenSim [1]. Maximum isometric muscle forces of the models were adjusted based on the muscle volumes obtained from magnetic resonance imaging of six athletes [4]. Statistical Parametric Mapping was used to compare muscle forces waveforms throughout the squat across various intensity conditions.

RESULTS: While muscle forces increased significantly at higher intensities, the extent of this increase varied between the muscles examined. The gluteus maximus showed the greatest increase in muscle forces (eccentric: $+25.1\% \pm 8.6$; concentric: $+24.6\% \pm 7.2$) and the vasti muscles exhibited the highest absolute muscle forces (eccentric: $13.2 \pm 2.4 \times$ body weight; concentric: $12.3 \pm 2.5 \times$ body weight) but did not show a significant increase in the deepest position of the squat with increasing intensities. Furthermore, the ratio between the muscle forces of single-joint and multi-joint hip extensors was inversely correlated with the performance level of the athletes.

CONCLUSION: According to our results the increase in muscle forces was not uniform between the muscles tested. Consequently, the gluteus maximus could be identified as the muscle increasingly involved at high intensities, while the vasti muscles contributed to the squat with the highest muscle forces. The higher the athletes performance level, the more likely they were to rely on multi-joint hip joint extensors. Athletes should therefore favour a hip dominant squatting style. By tailoring training programmes and fine-tuning squat techniques based on these biomechanical findings, lifters can maximise their performance.

EFFECTS OF RANGE OF MOTION VARIATIONS ON MUSCLE EXCITATION DURING TWO UPPER BODY RESISTANCE EXERCISES

FISCHER, J., BURGER, C., MANIEU SEGUEL, J., RODOPLU, C., PATERNOSTER, F., TILP, M., KONRAD, A.

UNIVERSITY OF GRAZ

INTRODUCTION: Recent research has highlighted partial range-of-motion (ROM) exercises as potentially equal or superior to full-ROM training for promoting hypertrophy and strength adaptations [1,2]. However, possible differences in muscle excitation between full and partial ROM—and thus potential mechanisms underlying these adaptations—remain largely unexplored, particularly for upper-body exercises. Therefore, this study investigated the effects of ROM variations during two resistance exercises, bench press (BP) and the prone barbell row (PBR), on muscle excitation.

METHODS: Nineteen resistance-trained male participants (24.3 ± 3.1 years) performed 10-repetition-maximum (10RM) sets of the BP and PBR in three ROM conditions: full ROM, upper-half ROM, and lower-half ROM. Surface electromyography (sEMG) was recorded from primary muscles (BP: pectoralis major [clavicular, sternocostal], triceps brachii [long, lateral], anterior deltoid; PBR: latissimus dorsi, trapezius transversus, rear deltoid, biceps brachii). BP repetitions were standardized by controlling movement velocity (2s up, 2s down for full ROM; 1s up, 1s down for partial ROMs), whereas the row was standardized by matching total time under tension (2s up, 2s down) across all ROMs. Mean and peak sEMG amplitudes were analyzed across repetitions. A repeated measures ANOVA (one factor, levels: full ROM, upper-half ROM, lower-half ROM) assessed possible differences in performance and muscle activity. Bonferroni post-hoc tests followed significant main effects. The alpha level was set to $p \leq 0.05$.

RESULTS: In the BP, significant differences ($p < 0.01$) in mean sEMG were found across all tested muscles for the three ROM conditions. The upper-half ROM showed the highest mean excitation in the triceps, while both partial-ROM conditions showed greater mean excitation in the pectoralis major and anterior deltoid compared to the full ROM. For the PBR exercise, the latissimus dorsi exhibited significantly greater mean excitation during the upper-half ROM compared to lower-half and full ROM ($p < 0.01$), whereas the trapezius transversus showed lower peak excitation in the upper-half ROM ($p < 0.05$).

CONCLUSION: In summary, these findings highlight that partial-ROM strategies can alter muscle excitation in both pushing and pulling exercises. Moreover, the method of standardization (i.e., movement velocity versus total time under tension) may influence the observed activation patterns. However, these results are based on the acute relationship between muscle excitation and ROM and do not provide direct insights into long-term adaptations [3,4]. Future research should investigate how these excitation patterns translate to changes in muscle hypertrophy and strength over time.

IS MUSCLE ACTIVATION REGULATED ACCORDING TO ITS MECHANICAL ACTION? THE OPTIMAL ACTIVATION ANGLE OF HIP MUSCLES IS NOT NECESSARILY ALIGNED WITH THE PROJECTED MOMENT ARM VECTORS IN THE TRANSVERSE PLANE

TOZAWA, H., KAWAMA, R., TAKAHASHI, K., NAKAMURA, Y., WAKAHARA, T.

DOSHISHIA UNIVERSITY

INTRODUCTION: The nervous system controls the activation of hip muscles according to the magnitude and direction of the muscle forces required during various movements (1). The mechanical action of each muscle is traditionally estimated as the projected moment arm vector (2). However, it remains unclear whether neuromuscular activation is appropriately regulated according to its mechanical action. To investigate this, we developed a novel method to quantify the direction in which a muscle exhibits the highest level of neuromuscular activation among multiple external force directions (the optimal activation angle). This study aimed to determine the optimal activation angles of hip muscles and evaluate their deviations from the projected moment arm vector in the transverse plane.

METHODS: Eight male participants performed maximum voluntary isometric contractions (MVICs) for 3 s in eight directions (hip adduction, flexion, abduction, extension, and in between them [every 45°]) at the hip flexed by 0° and the knee flexed by 90°. Surface electromyograms (EMG) were recorded from the major 14 hip muscles. A root mean square (RMS) of EMG during MVICs (1 s) and corresponding direction of external force were plotted in a polar coordinate system, with the RMS as the radius and direction of external force as the angle from the polar axis. For each muscle, the centroid of the eight MVICs was calculated in the polar coordinates. The optimal activation angle for each muscle was defined as the angle of the line connecting the centroid and the pole from the polar axis. The projected moment arm vector was calculated using the musculoskeletal simulation model (OpenSim) for each muscle. The Wilcoxon signed-rank test was used to compare the optimal activation angle with the projected moment arm vector.

RESULTS: The optimal activation angles deviated from the projected moment arm vector in the sartorius, adductor longus and magnus, gracilis, biceps femoris long head, upper and lower parts of gluteus maximus, and anterior part of gluteus medius (12.0-63.5° [all $p < 0.05$]). However, the optimal activation angles of the other six muscles did not deviate from the projected moment arm vector.

CONCLUSION: Our findings showed that the optimal activation angles of several hip muscles deviated from their projected moment arm vector, with the lower part of gluteus maximus exhibiting deviations over 60°. These results suggest that certain hip muscles prioritize other functions (e.g., joint stabilization) rather than their mechanical actions. Training exercises that considering the optimal activation angle of the target muscles may be more effective than traditional exercises based on their mechanical actions.

A WEIGHTLIFTING BELT INCREASES SQUAT PERFORMANCE AND SUBJECTIVELY PERCEIVED BUT NOT OBJECTIVELY MEASURED POSTURAL STABILITY

LEGERLOTZ, K., VETZKE, F., FANJI, Q., BEY, M.E.

BERGISCHE UNIVERSITÄT WUPPERTAL

INTRODUCTION: Weightlifting belts are subjectively perceived to enhance stability and improve athletic performance. However, the mechanisms behind performance enhancement are poorly researched. This study thus aims to determine whether athletic performance and postural stability are objectively increased by wearing a weightlifting belt and whether the effects are affected by sex or experience with belt application.

METHODS: Belt experienced ($n=15$) and unexperienced ($n=14$) men (height 182 ± 7 cm; weight 88 ± 10 kg), and experienced ($n=11$) and unexperienced ($n=9$) women (height 168 ± 6 cm; weight 66 ± 6 kg) participated in two measurement sessions one week apart. In each session, two sets of squats to exhaustion with the beltless 6-repetition maximum weight (6RM) were performed while standing on force plates, wearing (B) or not wearing (noB) the belt in a randomized order, which was reversed in the second measurement session. The number of repetitions, movement duration, postural sway and subjectively perceived stability were compared between conditions.

RESULTS: With belt application, the number of repetitions increased regardless of sex or belt experience (B 8.1 ± 1.7 ; noB 6.5 ± 1.3 , $p < 0.001$), while the duration of the concentric phase of squats decreased (B 1.99 ± 0.2 s; noB 2.09 ± 0.2 s, $p < 0.001$). Wearing the belt subjectively increased postural stability but did not do so objectively. The normalized path length, adjusted for movement duration, was significantly increased in experienced individuals, indicating reduced postural stability with belt application ($p < 0.05$).

CONCLUSION: As hypothesized, the belt application led to increased movement velocity, the completion of more repetitions, and increased subjectively perceived trunk stability and sense of security. These effects were observed regardless of sex. However, in contrast to our hypothesis, neither static nor dynamic postural stability improved by wearing the belt and experience with belt application was not necessary to benefit from its positive effect on performance.

Thus, if athletes or coaches aim to acutely improve performance e.g. at competition, it is advisable to wear a belt during squatting. However, in agreement with other publications, it may not be advisable to constantly wear a weightlifting belt during training, as this could result in negative and unwanted side effects, and affect muscular adaptation and injury risk. The higher movement velocity with belt-wearing observed by us and others, may increase the stress acting on joints. In

addition, the subjective perception of improved stability and sense of security, while objectively measured postural stability decreases at the same time, could potentially mislead the athlete to perform a less controlled movement, thereby increasing the risk of injury.

BIOMECHANICAL CORRELATION ANALYSIS USING INDEPENDENT WIRELESS SYSTEMS IN YOUTH FOOTBALL PLAYERS

DAVIDOVICA, A., SEMJONOVA, G., DAVIDOVICS, S., KATASEVS, A., OKSS, A., TOMSONE, S., LANCERE, L., ZOLOVS, M.
RIGA STRADINS UNIVERSITY

INTRODUCTION: Youth football is a globally popular sport but carries significant injury risks, particularly for younger athletes [1]. Injury prevention relies on monitoring movement patterns during functional tasks, traditionally achieved using lab-based motion capture systems [2]. However, these systems are resource-intensive and unsuitable for on-field use. Wireless sensor systems, such as the DAid® smart sock, provide portable and real-time solutions for measuring specific biomechanical variables [3]. Despite their potential, widespread adoption is hindered by challenges such as calibration, data synchronization, and compatibility between independent sensor systems [4]. Additionally, using multiple sensor systems to measure specific biomechanical variables is often complex and time-consuming [5]. Therefore, it is crucial to explore correlations between different systems to identify a unified and convenient solution that ensures reliable and practical data collection.

METHODS: Thirty-two youth football players (16 males, 16 females, aged 14–15) participated. Participants performed “Single Leg Squat” tests while data was collected using the DAid® smart textile socks (center of pressure (COP)), the NOTCH® inertial sensor system (thigh and lower leg angles), and the PLUX® Wireless Biosignals (muscleBAN kit) (muscle electrical activity). Correlations were calculated using Spearman’s rank correlation analysis.

RESULTS: Significant correlations demonstrated the utility of wireless systems. Hip adduction correlated with medial plantar pressure (COP1X: $r = 0.785$, $p < .001$), and hip internal rotation with anterior plantar pressure (COP1Y: $r = 0.585$, $p < .01$). Knee flexion correlated with GM muscle activity ($r = 0.66$, $p < .001$). Negative correlations included medial plantar pressure (COP2W) and GMx muscle activity ($r = -0.592$, $p < .001$). Gender-specific analysis showed males had stronger associations between hip adduction and COP1X, while females exhibited stronger relationships between knee flexion and plantar pressure parameters.

CONCLUSION: Wireless systems, such as the DAid® smart sock, show great potential for assessing lower limb biomechanics in youth football players by using one sensor system at the time, providing a portable on-field monitoring solution. Gender-specific differences underscore the need for individualized assessments, supporting injury prevention and performance optimization.

THE EFFECT OF HMB SUPPLEMENTATION AND HIGH-INTENSITY FUNCTIONAL TRAINING STIMULI ON RESTING AND POST-EXERCISE BLOOD HEMATOLOGICAL AND ACID-BASE BALANCE INDICES IN TRAINED AND UNTRAINED MALES

MARCHELEK-MYSLIWIEC, M., NOWACZYK, P.M., PODGÓRSKI, T., STEFFL, M., GLÓWKA, N., SZYMOCHA, M., ADAMCZEWSKI, J., PRZYBYLIK, B., DZIUBA-HUT, I., MURAWA, M., DURKALEC-MICHALSKI, K.

POMERANIAN MEDICAL UNIVERSITY, CLINIC OF NEPHROLOGY, TRANSPLANTOLOGY AND INTERNAL MEDICINE; POZNAN UNIVERSITY OF PHYSICAL EDUCATION, DEPARTMENT OF SPORTS DIETETICS

INTRODUCTION: The study aimed to verify the effect of HMB (90 mgHMB/kgFat-free mass[FFM]) supplementation alone (SUP) and in combination with high-intensity functional training (HIFT) on resting (REST) and post-exercise (POST-EX) blood hematological and acid-base balance indices in trained (TR) and untrained (UTR) adult males.

METHODS: The randomized double-blind placebo(PLA)-controlled parallel study was performed in 30 TR (28.6±9.4 yrs) and 30 UTR (33.9±8.0 yrs) males. After the baseline (BAS) visit, participants were randomized into HMB (TR_HMB, $n = 15$; UTR_HMB, $n=15$) or PLA (TR_PLA, $n=15$; UTR_PLA, $n=15$) supplementation. There were two 3-week periods: 1) SUP – ingestion of either HMB or PLA and performing usual training cycle (TR) or no training (UTR), and 2) SUP+FGB – ingestion of either HMB or PLA and implementing the additional exercise stimuli (TR and UTR; two Fight Gone Bad workouts per week). Blood samples were taken at REST and POST-EX (3 min after the incremental cycling test to exhaustion [ICT]). Hematological evaluation was performed using the hematology analyzer Mythic®18 (Orphée, Switzerland) and gasometric/acid-base balance evaluation using a blood gas analyzer (ABL90 FLEX, Radiometer, Denmark). The data were analyzed using RM ANOVA with training status and type of supplement as qualitative factors.

RESULTS: There were no significant effects of training status x supplement type interactions across study visits for REST and POST-EX white blood cell and subset counts and percentage, red blood cell counts, concentration of hemoglobin, or other hematological indices. Similarly, no such effects were observed for blood pH, base excess [BE], anion gap [AG], or concentration of H^+ and bicarbonate (HCO_3^-). Still, regardless of the type of supplement (HMB/PLA) or training status (TR/UTR), POST-EX pH (7.161±0.064 vs 7.184±0.062; $p=0.005$) and HCO_3^- concentration (15.6±2.1 vs 16.3±2.1 mmol/L; $p=0.001$) were significantly lower at SUP+FGB compared to BAS; while POST-EX H^+ concentration (69.7±10.6 vs 66.1±9.5 mmol/L;

$p=0.006$), absolute BE (-9.6 ± 3.8 vs -8.5 ± 4.1 mmol/L; $p=0.015$) and AG (22.5 ± 3.5 vs 21.5 ± 3.1 ; $p=0.012$) were significantly higher at SUP+FGB compared to BAS. There were no significant effects of training status x supplement type interaction across study visits for REST and POST-EX concentrations of lactate, glucose, Na⁺, K⁺, Ca²⁺, and Cl⁻. There was a significant effect of training status x supplement type interaction for REST blood osmolality (OSM; $p=0.028$). Being TR and ingesting HMB was related to lower OSM.

CONCLUSION: No association was found between HMB supplementation alone and combined with HIFT stimulation on REST and POST-EX blood hematological and acid-base balance indices in trained and untrained males. Furthermore, the observed POST-EX changes in acid-base balance at SUP+FGB treatment may result from a higher intensity during ICT efforts rather than the implemented HIFT stimulation.

HABITUAL DIETARY COLLAGEN INTAKE IS LOWER IN WOMEN AND OLDER IRISH ADULTS COMPARED TO YOUNGER MEN

NULTY, C., WALTON, J., ERSKINE, R.M.

LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: There has been growing interest in the effects of dietary collagen intake, with and without exercise, on joint pain, exercise recovery, body composition, sleep quality, and muscle and tendon function (1,2). However, the quantity of collagen intake in the diet of European adults is unknown. The aim of this study was to investigate collagen intake in the habitual diets of Irish adults, and whether it differed by sex and/or age.

METHODS: We conducted secondary analysis of the Irish National Adult Nutrition Survey, which assessed typical dietary intake using a four-day semi-weighed food diary in 1,500 adults, aged 18-90 years. Participants were categorised into young (18-39 years, $n=630$), middle-aged (40-64 years, $n=644$), and older (≥ 65 years, $n=226$) adults. Collagen composition of food items was determined by applying a percentage collagen value from analytical sources, allowing computation of collagen mean daily intake (MDI), collagen MDI relative to body mass, and collagen/total protein MDI. Age and sex differences in intakes were analyzed using ANCOVA, with physical activity as a covariate due to its positive association with total protein intake in European adults (3).

RESULTS: Collagen MDI for the entire population was 3.2 ± 2.0 g·day⁻¹, representing just $3.6\pm1.9\%$ total protein intake. Men had higher absolute and relative collagen MDI than women, regardless of age (4.0 ± 2.1 g·day⁻¹ vs. 2.3 ± 1.4 g·day⁻¹, $p<0.001$), and the collagen MDI as a proportion of total protein MDI was also higher in men ($4.0\pm1.9\%$) than in women ($3.4\pm1.8\%$, $p<0.001$). Furthermore, older adults had lower absolute collagen MDI than middle-aged adults (2.9 ± 1.8 g·day⁻¹ vs. 3.3 ± 2.0 g·day⁻¹, $p=0.021$).

CONCLUSION: Collagen intake in the Irish adult population was low relative to total protein intake and considerably lower than the 15-30 g doses of collagen necessary to enhance collagen synthesis in intervention studies (4). Women and older adults had particularly low intakes, suggesting they may benefit most from dietary strategies or supplementation to optimise the health and performance of collagen-rich tissues, although achieving effective doses through food alone may be challenging.

NO DIFFERENCE IN EXERCISE-INDUCED MUSCLE DAMAGE AFTER CONSUMING COW'S MILK OR A SOYA DRINK: A RANDOMISED CONTROLLED TRIAL

HANSELL, E., REYNOLDS, K., THORLEY, J., ŠKARABOT, J., JAMES, L., CLIFFORD, T.

LOUGHBOROUGH UNIVERSITY

INTRODUCTION: Cow's milk is rich in protein and considered a cheap, accessible food-first option for augmenting skeletal muscle protein synthesis. Several studies have also suggested that consuming cow's milk after exercise can attenuate symptoms of exercise-induced muscle damage (EIMD), such as delayed-onset of muscle soreness (DOMS) and decrements in muscle function, likely due to the stimulatory effects of dietary protein on skeletal muscle remodelling. However, a growing number of individuals avoid consuming cow's milk for ethical, health, or sustainability reasons. Soya drinks have a comparable macronutrient composition and therefore may be a promising plant-based alternative to cow's milk. However, it remains unclear whether soya drinks have comparable effects on symptoms of EIMD to cow's milk. Thus, this study aimed to examine whether protein-equivalent doses of soya drink or cow's milk similarly affected EIMD symptoms after strenuous exercise.

METHODS: In a randomised, double-blind, parallel groups design, 23 strength-trained individuals (16 M, 7 F; age 24 ± 3 y; height 1.8 ± 0.1 m; mass 77.3 ± 13.3 kg) consumed cow's milk ($n=11$) or a soya drink ($n=12$) after 100 drop jumps from a 60 cm platform. Doses (0.25g/kg body mass of protein) were consumed immediately post-exercise and 30 mins prior to sleep on two consecutive days (4 total). Pre- (PRE), 24 h-post- (24H), and 48 h-post-exercise (48H), knee extensor maximum isometric voluntary force (MIVF), torque (MIVT), and rate of force development (RFD); countermovement jump height (CMJ); modified reactive strength index (RSIMOD); DOMS (0-200 mm VAS); and pressure pain threshold of the rectus femoris (PPTRF) and vastus lateralis (PPTVL) were measured. Mixed-model ANOVAs assessed group x time interactions (Bonferroni-adjusted for post-hoc tests). Data are presented as Δ percentage change from PRE, and mean $\pm$ SD.

RESULTS: MIVF, MIVT and RFD decreased post-exercise ($P < 0.001$) but were not different between SOY and MILK ($P \geq 0.193$), decreasing by $\leq 19\%$ and $\leq 25\%$ at 24H, and remaining $\leq 16\%$ and $\leq 15\%$ below baseline at 48H, respectively. MIVF was reduced from PRE (803 ± 226 N, 792 ± 209 N) at both 24H (665 ± 200 N, 793 ± 667 N) and 48H (724 ± 231 N, 678 ± 223 N), in SOY and MILK, respectively. Similarly, CMJ and RSIMOD decreased in both groups at both post-exercise time-points ($\geq 13\%$), but this was not different between groups ($P \geq 0.284$). DOMS, PPTVL, and PPTRF increased post-exercise, but this was not different between groups ($P \geq 0.185$). At 24H, DOMS increased from PRE (7 ± 9 mm, 9 ± 13 mm) by 158% and 163% (59 ± 42 mm, 88 ± 37 mm), and 150% and 159% at 48H (49 ± 47 , 78 ± 44 mm), in SOY and MILK, respectively.

CONCLUSION: Protein-matched doses of cow's milk and soya drink did not differentially modulate muscle function or DOMS after strenuous exercise, suggesting that soya drinks and cow's milk have comparable effects on symptoms of EIMD.

INGESTION OF 20 G WHEY OR CANOLA PROTEIN DOES NOT FURTHER INCREASE MUSCLE PROTEIN SYNTHESIS RATES DURING RECOVERY FROM RESISTANCE EXERCISE IN HEALTHY, YOUNG FEMALES

BOOT, N., HERMANS, W.J.H., KUIN, L.M.E., MALOWANY, J.M., HENDRIKS, F.K., SENDEN, J.M., OVERMAN, A., GOESSENS, J.P.B., VERDIJK, L.B., VAN LOON, L.J.C.

MAASTRICHT UNIVERSITY

INTRODUCTION: Protein ingestion during recovery from exercise can further increase muscle protein synthesis rates. The capacity of a protein source to stimulate muscle protein synthesis is largely determined by its digestion and amino acid absorption kinetics, and amino acid composition. Plant-derived proteins are generally believed to have lesser anabolic properties when compared to animal-derived proteins. Canola, a rapeseed-derived protein, has a well-balanced amino acid profile and may, therefore, be effective in stimulating muscle protein synthesis during recovery from exercise. Here, we assessed post-prandial plasma amino acid profiles and muscle protein synthesis rates following the ingestion of 20 g canola protein, 20 g whey protein, or a non-caloric placebo during recovery from a single bout of resistance exercise in healthy, young females. Given the paucity of data in women, we specifically included healthy, young females.

METHODS: In this randomized, parallel group, double-blind placebo-controlled design, 36 healthy young females (23 ± 4 y, BMI: 22.7 ± 2.2 kg/m²) performed 8 sets of lower-body resistance exercise at 80% of their predetermined 1-repetition maximum after which they ingested a 300 mL beverage providing either 20 g canola protein isolate, 20 g whey protein isolate, or a non-caloric placebo. Primed continuous L-¹⁵-ring-¹³C6]-phenylalanine infusions were applied with frequent sampling of blood and muscle tissue to assess post-prandial plasma amino acid profiles and both basal and 5-hour post-exercise muscle protein synthesis rates. Post-exercise muscle protein synthesis rates were compared between groups as primary outcome, using one-way ANOVA; time-dependent variables were analyzed using a repeated measures ANOVA with time as a within- and treatment (canola, whey, placebo) as between-subject factor. Data are presented as means $\pm$ SD.

RESULTS: Plasma essential amino acid concentrations strongly increased following ingestion of both canola and whey protein when compared with the placebo treatment (Peak: 1249 ± 173 , 2113 ± 354 , and 780 ± 60 $\mu\text{mol/L}$ respectively; $P < 0.001$) with greater post-prandial plasma essential amino acid availability following whey vs canola protein ingestion (158 ± 50 vs 90 ± 23 mmol/5 h/L; $P < 0.001$). Muscle protein synthesis rates significantly increased from 0.042 ± 0.016 to 0.067 ± 0.015 %/h during recovery from exercise across all treatment groups (Time: $P < 0.001$). No differences in post-exercise muscle protein synthesis rates (0.071 ± 0.015 , 0.069 ± 0.016 , 0.061 ± 0.013 %/h, $P = 0.200$) were observed following the ingestion of canola protein isolate, whey protein isolate, and placebo, respectively.

CONCLUSION: A single session of resistance exercise strongly increases muscle protein synthesis rates in young females. Ingestion of 20 g canola or whey protein does not further augment muscle protein synthesis rates during the early stages of post-exercise recovery in healthy, young females.

FOREARM FOUR-POOL MODELLING: A NOVEL APPROACH TO QUANTIFYING SKELETAL MUSCLE AMINO ACID FLUXES

DIRKS, M., JAMESON, T., ANDREWS, R., ABDELRAHMAN, D., MURTON, A., WALL, B., STEPHENS, F.

WAGENINGEN UNIVERSITY / UNIVERSITY OF EXETER

INTRODUCTION: Current methods to study the role of amino acid (AA) availability in the regulation of skeletal muscle mass are limited. Available methods often capture merely part of muscle AA metabolism, and tend to rely on assumptions e.g. that AA uptake (measured indirectly as plasma AA disappearance) equals muscle protein synthesis (MPS; measured via direct incorporation). Our aim was to establish an innovative model to comprehensively assess forearm muscle protein metabolism in a four-pool kinetics manner, by combining the arterialised venous-deep venous forearm model with stable isotope tracer infusion and m. brachioradialis biopsy sampling under rested and insulin-stimulated conditions.

METHODS: Nineteen healthy participants (4/15 F/M, 22 ± 1 yrs, BMI 23.1 ± 0.5 kg·m⁻²) took part in an experimental test day during which they were intravenously infused with L-[ring-2H5]phenylalanine. Repeated arterialized venous-deep venous forearm balance measurements and m. brachioradialis biopsies were collected in the fasted state and during a 2.5 h hyperinsulinaemic (50 mU·m⁻²·min⁻¹)-hyperaminoacidaemic (0.11 g·kg⁻¹·h⁻¹)-euglycaemic (5.0 mmol·L⁻¹) clamp. This enabled quantification of two-pool kinetics (i.e. AA net balance (NB), rate of disappearance (Rd, i.e. AA uptake) and appearance (Ra, i.e. AA efflux)), three-pool kinetics (i.e. two-pool expanded by intracellular fluxes to and from the intracellular AA pool), and four-pool kinetics (i.e. including mixed muscle fractional synthesis rate) of forearm muscle tissue.

RESULTS: The clamp increased arterIALIZED insulin (9 ± 1 vs 153 ± 8 mU·L⁻¹; fasted vs clamp), phenylalanine (39 ± 1 vs 68 ± 3 μmol·L⁻¹), and leucine (124 ± 5 vs 214 ± 7 μmol·L⁻¹) concentrations (all $P < 0.05$). As a result, two-pool kinetics revealed an increase in phenylalanine NB (i.e. -23 ± 3 vs 10 ± 3 nmol·min⁻¹·100 mL forearm volume⁻¹, fasted vs clamp, $P < 0.05$), which was driven by an increase in Rd (i.e. 18 ± 3 vs 46 ± 6 nmol·min⁻¹·100 mL forearm volume⁻¹, $P < 0.05$) whilst Ra was unaffected ($P > 0.05$). Intracellular pool phenylalanine concentrations increased from 0.251 ± 0.011 to 0.295 ± 0.012 nmoles·mg⁻¹ during the 2.5h clamp, while L-[ring-2H5]phenylalanine enrichment increased from 0.029 ± 0.001 to 0.044 ± 0.001 MPE. Three-pool AA fluxes were overall increased by the clamp, with increases in arterIALIZED AA supply, uptake, incorporation into protein, efflux and arteriovenous shunting all observed ($P < 0.05$), while AA appearance from breakdown was not affected ($P > 0.05$). Forearm mixed muscle FSR during the 2.5h clamp was $0.053 \pm 0.003\%$ ·h⁻¹, corroborating and extending on the three-pool kinetics demonstrating a shift towards forearm anabolism.

CONCLUSION: This newly established forearm model is suitable to measure four-pool AA kinetics under fasted and insulin- and amino acid-stimulated conditions, thereby enabling comprehensive quantification of arterIALIZED delivery, uptake, intramuscular utilization (i.e. protein synthesis and breakdown), and efflux of AAs.

CARDIOPULMONARY RESPONSES TO HIGH-INTENSITY ECCENTRIC CYCLING: COMPARISON WITH ISOENERGETIC CONCENTRIC CYCLING

VILLENEUVE, M., RICHARD, R., TREMBLAY, J.

UNIVERSITÉ DE MONTRÉAL

INTRODUCTION: Eccentric cycling allows for a greater mechanical power output at a lower oxygen consumption (VO₂) than concentric cycling. Prior research on low-intensity eccentric cycling (<300W) reported higher cardiac output (Q_c) and heart rate (HR) than concentric cycling at matched VO₂ (~150 mL or 6%). However, physiological responses to higher-power eccentric cycling remain underexplored. This study expands on previous findings by investigating cardiopulmonary responses to high-intensity eccentric cycling (up to ~1000W) compared to isoenergetic concentric exercise.

METHODS: Seven participants (2F, 5M; age: 31.4 ± 7.7 years; VO₂max: 56.8 ± 4.6 mL·min⁻¹·kg⁻¹), who completed a 12-week progressive eccentric training protocol (1 session/week) completed incremental cycling tests in both eccentric and concentric modes. Each test comprised four 5-minute stages, with eccentric power at 25%, 50%, 75%, and 100% of maximal power (P_{max}) attained at training's end. Concentric power was adjusted to match eccentric VO₂ assuming a net mechanical efficiency of 24%. When VO₂ equivalence was not achieved, a fifth concentric exercise stage was added. Q_c, HR (impedance cardiography) and VO₂ (metabolic cart) were continuously recorded and averaged over the last 60 seconds of each stage, while blood pressure (BP) was measured after each stage.

RESULTS: In the last stage, eccentric P_{max} was 4.2 times higher than its concentric counterpart (756 ± 110 vs. 181 ± 50.2 W) despite a similar VO₂ (2.38 ± 0.67 vs. 2.50 ± 0.65 L·min⁻¹; 56.8 ± 19.2 vs. $59.9 \pm 21.6\%$ of concentric VO₂max). Arteriovenous oxygen difference (a-VO₂) was lower in eccentric mode (124 ± 25.7 vs 159 ± 36.8 mL O₂·L⁻¹, $p < 0.05$), suggesting reduced peripheral oxygen uptake despite matched metabolic demand. Ventilatory responses also differed, with eccentric cycling eliciting higher breathing frequency (46.6 ± 6.95 vs 32.9 ± 5.18 cycles·min⁻¹, $p < 0.05$) and lower tidal volume (1.75 ± 0.57 vs 2.02 ± 0.48 L, $p < 0.05$). Eccentric cycling resulted in a significantly higher cardiac output (19.5 ± 5.9 vs 16.2 ± 5.21 L·min⁻¹, $p < 0.05$) and heart rate (173 ± 24.5 vs 148 ± 22 bpm, $p < 0.05$) despite lower systolic (142 ± 14.8 vs 166 ± 18.7 mmHg, $p < 0.05$) and diastolic (69.1 ± 4.49 vs 85.4 ± 7.30 mmHg, $p < 0.05$) blood pressures. Systemic vascular resistance decreased significantly during eccentric cycling (5.08 ± 1.12 vs. 7.35 ± 1.65 mmHg·L⁻¹·min⁻¹, $p < 0.05$), indicating peripheral circulatory adjustments despite greater mechanical load.

CONCLUSION: High-intensity eccentric cycling allows for >4x greater mechanical work at similar VO₂, eliciting distinct cardiopulmonary responses characterized by higher Q_c and HR, reduced peripheral oxygen uptake, and lower vascular resistance. These findings highlight its potential as a high-output yet metabolically efficient training modality, particularly for populations with reduced cardiovascular capacity.

CARDIORESPIRATORY RESPONSES AND TOLERANCE TO ECCENTRIC VERSUS CONCENTRIC CYCLING PERFORMED AT THE SAME RELATIVE INTENSITY

BARRETO, R., LIMA, L., DUFOUR, S., NADDAFHA, S., DENADAI, B., NOSAKA, K.
SAO PAULO STATE UNIVERSITY

INTRODUCTION: Eccentric cycling (ECC) results in lower cardiorespiratory responses with lower heart rate (HR) and oxygen uptake (VO₂) in comparison to conventional concentric cycling (CON) when they are performed at the same mechanical power output. However, higher HR has been documented in ECC vs CON when performed at the same VO₂ [1,2]. Therefore, it remains unclear whether any difference in cardiorespiratory responses exists between ECC and CON performed at the same mode-specific relative intensity. Thus, the present study compares cardiorespiratory responses and exercise tolerance between ECC and CON conducted at the same mode-specific relative intensity.

METHODS: Eleven healthy men (31 ± 7 yr, BMI 25.2 ± 3.2 kg/m²) participated in six sessions separated by at least 72 hours. The first two sessions were used to familiarize them with ECC. In the next two visits, the participants completed a CON and an ECC ramp incremental test until exhaustion (30W/min slope, starting from 100W at a pedal cadence of 50-60 rpm) to determine mode-specific maximal power output (P_{max}) in each cycling mode. The fifth and sixth sessions consisted of CON or ECC constant-load trials performed at 100% of the mode-specific P_{max}. The CON and ECC constant-load trials were performed until exhaustion and the total trial duration (i.e., tolerance) was recorded. Cardiorespiratory responses were continuously recorded during the trials by indirect calorimetry and telemetry, with mean values used for analysis. Paired Student's t-tests compared variables between cycling modes (mean $\pm$ SD, significance at $p < 0.05$).

RESULTS: Mean power output was higher ($p < 0.001$) during ECC (386 ± 55 W) than CON (287 ± 49 W) without difference ($p = 0.381$) in pedal cadence (56 ± 5 rpm). Tolerance was greater ($p < 0.01$) for ECC (7.9 ± 5.1 min) than CON (2.1 ± 0.5 min). Mean VO₂ (1.74 ± 0.31 vs 2.13 ± 0.39 L/min), pulmonary ventilation (42.22 ± 9.94 vs 53.14 ± 13.72 L/min) and tidal volume (1.67 ± 0.40 vs 2.23 ± 0.37 L) were lower ($p < 0.05$) during ECC than CON, but respiratory frequency was not different ($p = 0.071$) between ECC (31 ± 9 cycles/min) and CON (27 ± 7 cycles/min). However, no significant differences ($p = 0.290$) in mean HR were evident between ECC (139 ± 15 bpm) and CON (134 ± 16 bpm).

CONCLUSION: The results show unique characteristics of ECC enabling higher mechanical power output with lower pulmonary ventilation and VO₂ responses but similar HR to CON despite similar mode-specific relative intensity. Therefore, prescribing ECC at the same mode-specific relative intensity to CON increases mechanical load to lower limb muscles while reducing breathing load and metabolic demand, without imposing additional cardiac burden. This could be a useful strategy for exercise interventions to improve health and fitness.

THE EFFECT OF RAMP SLOPE ON THE PREDICTION OF W' FROM A SINGLE RAMP TEST

STUER, L., VAN RIE, K., BOONE, J., CAEN, K.
GHENT UNIVERSITY

INTRODUCTION: Ramp incremental (RI) exercise tests have been proposed to determine critical power (CP) and the work capacity above CP (W'), as a more feasible alternative to the traditional methodology, which requires multiple exhaustive constant work rate (CWR) tests. W' estimated from a RI test is defined as the total work done above CP during such test (WR). This study assessed the influence of ramp slope on the magnitude of the estimated W' , and the agreement between W' derived from the traditional method and WR.

METHODS: 13 healthy men (23 ± 3 yr, 56.2 ± 7.5 mL·min⁻¹·kg⁻¹) performed a maximal RI test with a standard slope (30 W·min⁻¹) on an electromagnetically braked cycle ergometer, followed by a series of CWR trials to determine CP and W' . Subsequently, they performed two maximal RI tests with slow and fast slopes (10 and 50 W·min⁻¹). Each RI test was immediately succeeded by a CWR bout above CP to compute the additional amount of work that could be delivered above CP (W'_{extra}). CP and W' were estimated using the two-parameter model equations, selecting the model with the lowest total error on an individual basis. Total work done above CP during the different RI tests (WR₁₀, WR₃₀ and WR₅₀) were compared with the conventionally determined W' . Pulmonary gas exchange was measured during all tests on a breath-by-breath basis to ensure the attainment of maximal oxygen consumption (VO_{2max}) at task failure. Differences in performance parameters and W' estimates across the different tests were assessed using Repeated Measures ANOVA with pairwise comparisons (LSD adjustment).

RESULTS: Time to exhaustion (TTE) became longer with decreasing ramp slope (1615 ± 262 s $>$ 661 ± 91 s $>$ 430 ± 26 s, $p < 0.001$). Conversely, PO_{peak} was the lowest in the slow and the highest in the fast protocol (319 ± 44 W $<$ 378 ± 48 W $<$ 405 ± 52 W, $p < 0.001$). VO_{2max} did not differ across the three RI tests ($p = 0.15$). CP and W' were respectively 251 ± 44 W and 19.1 ± 3.4 kJ. We found significantly lower values for WR₁₀ (14.4 ± 6.2 kJ, $\Delta = 4.7 \pm 5.1$ kJ, $p = 0.006$), WR₃₀ (16.4 ± 2.5 kJ, $\Delta = 2.7 \pm 3.6$ kJ, $p = 0.018$) and WR₅₀ (14.6 ± 3.5 kJ, $\Delta = 4.5 \pm 3.3$ kJ, $p < 0.001$) compared to the conventionally determined W' . W'_{extra} was the highest in the fast protocol (3.1 ± 1.5 kJ) compared to the normal (1.6 ± 1.5 kJ, $p = 0.013$) and slow protocol (1.7 ± 1.4 kJ, $p = 0.007$), whereas there was no difference between the normal and slow test in W'_{extra} ($p = 0.899$). For all three RI protocols, the sum of WR and W'_{extra} did not differ from each other, nor from W' ($p = 0.098$).

CONCLUSION: A standard ramp slope of 30 W·min⁻¹ showed the lowest underestimation of W' , indicating that a full depletion of W' is obstructed during particularly slow or fast ramp protocols. However, performing an additional work bout above CP, immediately after the RI test, led to higher estimates of W' that were closer to the conventionally determined W' .

THE EFFECT OF INTERMITTENT VS. CONSTANT HIGH INTENSITY AEROBIC EFFORTS WITH EQUAL TOTAL WORK ON VO₂ KINETICS, FATIGUE AND PERFORMANCE

ZUKERMAN RICHMAN, G., KODESH, E., IBRAHIM, R., JONES, A.M., WILKERSON, D.P., REUVENY, R., SEGEL, M.J.

TEL AVIV UNIVERSITY

INTRODUCTION: Exercise-induced fatigue (EIF), a reduction in muscle force or power output following prolonged or high-intensity exercise, is a key factor in endurance sports. Oxygen uptake (VO₂) kinetics reflect the metabolic response of working muscles, and are related to EIF, exercise tolerance and performance. To date, these relationships have been studied only regarding what the exercise bout itself provoked; the effect of different fatiguing efforts on VO₂ kinetics, EIF and performance in a consecutive effort, mimicking conditions in training and racing, has not been studied. We studied the effect of two fatiguing protocols on VO₂ kinetics and EIF during a subsequent severe-intensity effort.

METHODS: Twelve male endurance athletes participated in a random-order cross-over study, involving five visits (V1-V5). At V1, participants performed a graded cardiopulmonary exercise test to exhaustion, to assess the gas exchange threshold (GET), the respiratory compensation point (RCP) and VO₂max, so as to individualize workloads in subsequent tests; and familiarization with time to exhaustion (TTE) and sprint performance (ST) tests. During each of visits V2-V5, participants completed one of two equal work fatiguing protocols (FPs): heavy constant exercise (CONT) at an intensity corresponding to 90% of RCP; or severe intermittent exercise (INT) at 120% of RCP with recovery periods at 50% of RCP. Each FP was performed on two different consecutive visits, in random order. VO₂ kinetics were assessed pre- and post- FPs (i.e. fresh and fatigued, respectively).

RESULTS: No significant differences were found in VO₂ kinetics measured in a subsequent effort after CONT and INT (τ =35.3 $\pm$ 8 vs. 33.5 $\pm$ 5 sec, amplitude=2471 $\pm$ 697 vs. 2590 $\pm$ 546 mL/min). Additionally, TTE duration (413 $\pm$ 153 vs. 359 $\pm$ 124 sec) and ST peak power output (1106 $\pm$ 230 vs. 1091 $\pm$ 229 W) did not differ significantly. However, when comparing pre- to post- FP values, a significant increase in VO₂ amplitude was observed only post-INT (2404 $\pm$ 639 vs. 2590 $\pm$ 546 mL/min, p =0.012). During FPs - cumulative O₂ uptake was greater in CONT than INT (40.8 $\pm$ 7.7 vs. 39.2 $\pm$ 8.8 L, p =0.04), and excess post-exercise O₂ consumption was significantly greater after INT compared to CONT (2.39 $\pm$ 0.48 vs. 2.06 $\pm$ 0.27 L, p =0.04).

CONCLUSION: When total work is equal, different high-intensity aerobic fatiguing efforts (continuous vs. intermittent) have a similar effect on VO₂ kinetics, EIF, and performance during a subsequent effort.

CHARACTERISTICS AND ANALYSIS OF THE DURABILITY OF HIGH-LEVEL FEMALE ROWERS

HE, G., ZI, W.

CHINA INSTITUTE OF SPORT SCIENCE

INTRODUCTION: Besides VO₂max, threshold power or velocity, and exercise economy, durability has been considered the fourth dimension in evaluating endurance performance in sports such as road cycling and marathon running in recent years. However, there have been no reports or research on durability in rowing, which is also an endurance sport. Therefore, this research aims to explore the durability characteristics of high-performance Chinese female rowers during anaerobic threshold intensity continuous training.

METHODS: Thirteen female rowers (age = 26.3 $\pm$ 3.2 years, height = 182.6 $\pm$ 4.4 cm, weight = 77.8 $\pm$ 4.0 kg) from the Chinese National Rowing Team completed several 30-minute rowing ergometer training sessions (100% AT = anaerobic threshold), 2 km maximal tests on the rowing ergometer, and multi-step (3 $\times$ 8 min) tests on the rowing ergometer during winter training in 2024 (from October 2023 to March 2024). Real-time heart rate and power were recorded every 3 minutes during the 30-minute rowing ergometer training, along with average power (P30) and lactic acid (L30) afterward. The time (T2km) to finish the 2 km rowing test on the ergometer and anaerobic threshold power (P4) obtained from the multi-step test were also recorded. The interval between each training session and test should be more than 48 hours, and both training and tests should be completed within one week. According to this requirement, data from 23 instances per person were selected for this research. Based on their 2 km maximal test performance on the rowing ergometer, the data were divided into three groups: low performance (LP, n = 8, $t \geq 410$ s), medium performance (MP, n = 6, $405 \leq t < 410$ s), and high performance (HP, n = 9, $t < 405$ s). The time course of the ratio of interval vs. external (In/Ex) training load during the 30-minute rowing ergometer training was plotted, and the magnitude of In/Ex (denoted as Δ In/Ex) was determined by the difference between the 6th and 27th minutes.

RESULTS: T2km values were 414.8 $\pm$ 4.1s (LP), 407.1 $\pm$ 1.3s (MP), and 401.9 $\pm$ 2.1s (HP), with significant differences ($p < 0.01$) between each group. P4 values were 229.4 $\pm$ 18.2 W (LP), 248.3 $\pm$ 14.2 W (MP), and 252.1 $\pm$ 11.3 W (HP), with significant differences ($p < 0.01$) between HP, MP, and LP. Δ In/Ex values were 0.078 $\pm$ 0.022 (LP), 0.068 $\pm$ 0.021 (MP), and 0.054 $\pm$ 0.018 (HP), showing a gradual decrease in opposition to their performance levels, with significant differences between HP and LP ($p < 0.05$). There was a low correlation between P4 and Δ In/Ex (r = -0.205, $p > 0.05$) but moderate correlation between T2km and Δ In/Ex (r = 0.566, $p > 0.002$).

CONCLUSION: There was a decoupling in continuous training at anaerobic threshold intensity in high-performance elite rowers, which can be described as durability. This index is related to performance level but not to traditional physiological indicators such as anaerobic threshold power.

VALIDITY OF THE TYME WEAR STRAP MEASURING RESPIRATORY FREQUENCY DURING CYCLING EXERCISE

GRECO, G., INNOCENTI, L.1, ROMANO, C.2, MASSARONI, C.2, SACCHETTI, M.1, NICOLÒ, A.1

1 UNIVERSITY OF ROME FORO ITALICO; 2 UNIVERSITY OF CAMPUS BIO-MEDICO DI ROMA

INTRODUCTION: Respiratory frequency (fR) is an objective marker of physical effort and is very sensitive to changes in exercise tolerance, especially during high-intensity exercise (1). An abundance of technological solutions is currently available to meet the increasing demand for breathing monitoring during training and competitions, with strain sensors representing a promising solution to estimate fR via chest-wall movements (2). However, robust methodological approaches are required to validate commercial breathing sensors before encouraging their widespread use. Thus, the current study aims to validate a commercial breathing device with a thorough cycling protocol designed to describe its accuracy and precision during both progressive and abrupt changes in fR.

METHODS: Ten competitive cyclists (M/F: 8/2; stature: 173 ± 10 cm; body mass: 64 ± 8 kg) performed a single-visit validation protocol wearing the Tyme Wear (TW) strap (Tyme Wear Inc, Boston, MA, USA). The protocol was composed of: i) a 10-min warm-up (80 W M, 60 W F); ii) a ramp incremental test until exhaustion (25 W/min M, 20 W/min F); iii) a self-paced 8-min intermittent protocol (20:40 s); and iv) a 5-min time trial. The performance of the TW device was compared against that of a reference metabolic cart (Quark PFT, Cosmed, Rome, Italy). Both reference and TW breathing waveforms were recorded at 25 Hz and processed with custom-based algorithms to extract fR. Mean absolute error (MAE), mean absolute percentage error (MAPE), mean of difference (MOD), and limits of agreement (LoAs) were computed to verify the accuracy and precision of the TW strap during the cycling protocol. The validation analysis was conducted breath-by-breath and on 30-s windows.

RESULTS: The fR time course measured with the TW strap fairly resembled that measured with the reference system throughout the cycling protocol. The breath-by-breath comparison showed an average MAE value of 1.56 breaths·min⁻¹ and an average MAPE value of 3.76 %. The 30-s comparison showed average MAE e MAPE values of 0.60 breaths·min⁻¹ and 2.00 % respectively. In addition, a good agreement was found between the TW strap and the reference system for both breath-by-breath (MOD $\pm$ LoAs: -0.03 ± 5.71 breaths·min⁻¹) and 30-s (MOD $\pm$ LoAs: -0.13 ± 3.34 breaths·min⁻¹) values.

CONCLUSION: The present findings suggest that the TW strap is a suitable device to measure fR in cycling. The good performance and wearability of this commercial device may facilitate the daily measurement of fR in cycling and potentially in other endurance sports.

EXPLORING WEARABLE TECHNOLOGY IN SKIING: USER FEEDBACK ON THE CONNECTED BOOT'S USABILITY AND PERFORMANCE BENEFITS

KRANZINGER, S., KRANZINGER, C.1, HOLLAUF, E.1, STÖGGL, T.2

1 SALZBURG RESEARCH FORSCHUNGSGESELLSCHAFT MBH; 2 RED BULL ATHLETE PERFORMANCE CENTRE, AUSTRIA

INTRODUCTION: The integration of wearable technology in sports has advanced rapidly, enabling athletes and recreational users alike to gain personalized insights into their performance. In skiing, where skill development and technique are essential for safety and enjoyment, tools that provide real-time feedback have the potential to transform the user experience. The Connected Boot sensor system, which consists of two inertial measurement units (IMUs) mounted at the upper posterior cuff of the ski boot, offers an innovative approach to assessing skiing style by capturing objective sensor data through a calculated ski quality score [1]. This study aims to evaluate the usability, learning curve when using the app, and perceived effectiveness of the Connected Boot among recreational skiers. By analyzing user feedback and engagement, this research seeks to assess the devices potential as a tool for enhancing skiing style.

METHODS: Data were collected during the 2022/23 season from a sample of 89 recreational skiers (23 female 66 male; age: avg 46.3, sd = 14.8). Participants were equipped with IMUs to collect sensor data that was used to calculate turn size, turn speed, edge angle velocity, edging of the ski boot and other metrics. The participants installed a specially developed mobile application to process and visualize this objective sensor data and to calculate a ski quality score. In addition, the app was used to collect subjective questionnaire data at the beginning and end of the study to determine the acceptance of the Connected Boot sensor system.

RESULTS: Survey results indicate a generally positive reception of the Connected Boot across multiple dimensions. Most participants found it easy to use (71%) and beneficial for improving skiing style (81%). Statements regarding ease of learning received particularly strong support, e.g., over half of respondents strongly agreed that both familiarizing themselves with the Connected Boot (54%) and learning to use it (48%) were easy. The high level of agreement on usability (72%) highlights effective design and alignment with user needs. However, a small proportion of negative responses regarding usefulness of the provided information about the individual skiing style (18%), learning of how to use the Connected Boot

and ease of use (15% each) could indicate that some users find the Connected Boot less intuitive. Moreover, it suggests that individual differences, such as skill level or technological familiarity, may influence user experience.

CONCLUSION: The Connected Boot is promising when it comes to improving the skiing experience through feedback and ease of use, as shown by the high agreement in the areas of ease of use and perceived benefits. Nevertheless, to improve the product's appeal and satisfaction, further refinements might focus on increasing user enjoyment and addressing specific pain points highlighted by the minority of users who reported lower satisfaction.

VALIDATION OF SMART SWIM GOGGLES HEART RATE MEASUREMENT FOR SWIM TRAINING MONITORING

KITS, A., CHHATRE ELDER, N., EISENHARDT, D., DARYOUSH, Y., HOSKINSON, R., MADELEINE, P., SAMANI, A., KRISTIANSEN, M., CLARKE, D.C.

SIMON FRASER UNIVERSITY

INTRODUCTION: Accurately measuring training intensity in swimming is challenging due to a lack of validated measurement devices. Smart swim goggles (FORM goggles, Vancouver, Canada) that harbour a temple-mounted optical heart-rate (HR) sensor enable real-time feedback of HR during training. These HR data facilitate the calculation of HR-based training loads (TL) such as Banister training impulse (bTRIMP) and cumulative TRIMP (cTRIMP) [1]. However, the HR measurement from these goggles has yet to be validated. The purpose of this study was to assess the validity of the FORM goggles HR measurements for use in swim training monitoring.

METHODS: We applied a criterion validation approach in which the FORM goggles HR measurements were compared to those from a gold-standard electrocardiogram chest-strap (Garmin HRM-Swim). Twenty-five experienced recreational swimmers (proficient in freestyle, backstroke, and breaststroke) completed one of two workouts, with two participants completing both. The workouts differed in intensity and distance. Comparisons were made at four levels: individual heart-beat, interval, main-set, and workout. At each level, the average (HRmean), maximum (HRmax), and minimum (HRmin) HR were assessed using Lin's concordance correlation, Bland-Altman, and regression. The analysis of cTRIMP and bTRIMP was performed at the interval and workout levels, respectively. Statistics are presented as ranges across all levels.

RESULTS: HRmean from the FORM goggles and Garmin HRM-Swim were similar in both workouts, with respective mean $\pm$ SD values of 131.1 $\pm$ 16.4 bpm and 131.1 $\pm$ 17.3 bpm (Workout 1), and 142.3 $\pm$ 17.0 bpm and 141.8 $\pm$ 17.7 bpm (Workout 2). HRmean, HRmax, and HRmin correlation ranged from 0.90-1.0, 0.87-0.92, and 0.59-0.90, respectively, while the TRIMPs correlation was 1.0. The fixed bias (limits of agreement) ranged from -0.34 to 0.11 (3.6-9.5) bpm, -0.11 to 2.6 (8.9-12.0) bpm, and -0.6 to 1.2 (10.1-26.9) bpm for HRmean, HRmax, and HRmin, respectively, and from -0.38 to -0.20 (4.3-4.6) arbitrary units (a.u.) for the TRIMPs. Proportional bias was observed for HRmean (individual heartbeat, interval, and workout levels), and for HRmax (interval level). Regression intercepts from the differences between devices showed no statistically significant difference from zero: HRmean (-0.20 to -0.05 bpm), HRmax (-0.25 to 2.1 bpm), HRmin (-0.66 to 0.89 bpm), and TRIMPs (-0.43 to -0.29 a.u.).

CONCLUSION: This study revealed strong agreement between the FORM goggles and Garmin HRM-Swim for HR measurements, particularly for HRmean and TRIMP values. Given that HRmean serves as the primary input for HR-based TL metrics, the goggles provide valid data for monitoring swim training. Larger discrepancies between devices were noted for HRmin and HRmax. Further research should explore the impact of these observed discrepancies on adhering to HR intensity zones during training when utilizing real-time HR feedback.

SMART SWIM GOGGLES WITH REAL-TIME VISUAL FEEDBACK IMPROVE ADHERENCE TO TRAINING INSTRUCTIONS IN RECREATIONAL SWIMMERS: A RANDOMIZED CONTROLLED TRIAL

EISENHARDT, D., KITS, A., MADELEINE, P., SAMANI, A., CLARKE, D., KRISTIANSEN, M.

AALBORG UNIVERSITY

INTRODUCTION: Swimmers commonly face challenges in adhering to prescribed workout metrics, such as intensity and duration, which can hinder fitness and performance improvements. Wearable technology providing real-time feedback has the potential to enhance adherence by offering swimmers immediate performance insights. This study examined the effects of real-time feedback on compliance with prescribed training metrics in recreational swimmers during a 12-week unsupervised intervention.

METHODS: Fifty-seven recreational swimmers were randomly assigned to two groups: feedback (FB) and non-feedback (NFB). Both groups were prescribed 35 structured workouts over 12 weeks. The FB group used FORM Goggles, which provided real-time visual feedback on performance metrics, including swimming pace, heart rate, and time splits. The NFB group used printed workout instructions and relied on either a pool clock or waterproof sports watches to track time and splits. Key compliance metrics analyzed included workout length count, workout effort, incomplete workouts, interval effort, interval rest time, and interval stroke type. Statistical analyses were conducted to compare compliance between the FB and NFB groups. **RESULTS:** The FB group demonstrated significantly greater compliance with workout length counts compared to the NFB group ($p < 0.001$). Mean deviations from prescribed lengths were consistently lower in the FB group across various contexts (FB: 0.5–0.1 lengths vs. NFB: 3.5–2.4 lengths), showing large effect sizes (rate ratio > 3.00). No significant differences were observed between groups for other compliance metrics.

CONCLUSION: Real-time visual feedback significantly improved compliance with prescribed workout length counts. These findings suggest that wearable feedback technology can improve adherence to structured swim training, making it a valuable resource for recreational swimmers seeking to optimize their workouts.

VIRTUAL REALITY AS A TOOL FOR ASSESSING RESPONSE TIME IN ELITE VOLLEYBALL: GENDER AND LIMB DOMINANCE INSIGHTS

IMPERIALI, L., CODELLA, R., LA TORRE, A., PRANDONI, E., BIZZOZERO, S., BORGHI, S.

IRCCS ISTITUTO ORTOPEDICO GALEAZZI

INTRODUCTION: Virtual Reality (VR) technology has seen widespread adoption in recent years, with an increasing number of individuals integrating it into their daily routines. VR systems immerse users in a three-dimensional computer-generated environment, making assessments reproducible and simulating gestures very similar to those of real life. Research highlights the potential of VR in sports, indicating that these systems can improve perceptual-cognitive and motor skills. The aim of this study was to employ VR to assess response times (RT) to visual stimuli in elite male and female volleyball players, with the intent of identifying differences between sexes and potential asymmetries between dominant and non-dominant upper limbs.

METHODS: Forty elite volleyball players of the Lega Pallavolo Serie A (Age= 24.2±5.6 years; Male: n = 20; Female: n = 20) were recruited for the study. VR-CNS Sprint Software was used to assess RT in response to visual targets appearing randomly in the field of view. The assessments were always conducted using a standard panel with targets positioned within the visual field. The panel consisted of 16 targets arranged in 4 rows and 4 columns. Participants wore hand controllers and were instructed to touch the target that turned green in less time as possible (hit). An interval of rest was randomly repeated between hits, and the assessment included a total of 96 hits, with each target being activated six times (16 targets x 6 = 96 hits).

RESULTS: Results indicated that while males had slightly faster average RT ($M = 453.7 \pm 45.2$ ms) than females ($F = 481.8 \pm 59.3$ ms), the differences were not statistically significant ($p = 0.100$). Similarly, no significant differences in RT were observed between dominant (461.3 ± 54.1 ms) and non-dominant limbs (474.2 ± 55.2 ms, $p = 0.296$).

CONCLUSION: This study, utilizing VR technology as a standardized and individualized tool for assessing response time in elite volleyball players, suggests that gender differences could be mitigated at the highest levels of training and that limb dominance has no significant impact in a bilateral sport. Future research could explore the use of VR not only for evaluation but also as a training tool to enhance response time in athletes.

ASSOCIATION BETWEEN PHYSICAL EXERCISE AND PROSPECTIVE MEMORY IN SCHOOLCHILDREN: SINGLE SESSION EFFECTS AND CROSS-SECTIONAL RELATIONS

GLÄTTLI, A., GERBER, M., ANNEN, H., LUDYGA, S.

UNIVERSITY OF BASEL / MILITARY ACADEMY AT ETH ZÜRICH

Introduction

Prospective memory is a cognitive ability required to remember to perform an intended task without an explicit reminder. Research showed that this ability is linked to other higher-order cognitive functions, such as working memory or attentional processes (Ball et al., 2022). Physical exercise is known to be related to executive function and further, research found that a single session of endurance exercise can enhance performance in such abilities (Ludyga et al., 2016). Due to an overlap in underlying neural structures in executive function and prospective memory, it's likely that acute effects of exercise will also influence the latter (Loprinzi et al., 2018). This study aimed to investigate a possible link between prospective memory, executive function and physical activity and further, evaluate the potential of one single exercise session on prospective memory performance.

Methods

98 schoolchildren completed a prospective memory task embedded in a 1-Back and Flanker paradigm. The Flanker task served as a distractor after prospective cues were introduced and participants had to remember that prospective trials embedded in a subsequent 1-Back task required a different response. Participants were then randomly assigned to either an experimental group (25-minute endurance exercise) or a control group (25-min stretching). After the intervention, the cognitive assessment was repeated. Physical activity was recorded over seven consecutive days using accelerometers and the 7-day physical activity recall questionnaire.

Results

With regard to the chronic exercise paradigm, partial correlations that controlled for age and sex showed that higher MVPA was associated with higher accuracy on the prospective memory task. VPA was positively associated with executive function performance. In contrast, linear mixed models showed no effect of a single exercise session on prospective memory and executive function.

Discussion

The association of physical exercise and prospective memory differed based on the exercise paradigm. Children with higher physical activity levels showed better prospective memory performance. However, engagement in a single exercise session does not necessarily lead to an improvement in prospective memory. This provides an indication that prospective memory seems to be more sensitive to long-term changes in regular physical activity and exercise levels.

SINGLE AND COMBINED EFFECTS OF ACTIVE BREAKS AND STANDING DESK: COMPARISON OF STATISTICAL ANALYSIS METHODS FOR RANDOMIZED TRIAL PRE-POST DESIGNS

PRIVITERA, M., TORRIANI, C., DELLANNA, S., VILLANI, S., MONTOMOLI, C., BUZZACHERA, C.F.

UNIVERSITY OF PAVIA

INTRODUCTION: Active breaks and standing desks are innovative strategies to promote physical activity in schools setting. The Yes, We Can! study assessed the effectiveness of these interventions, both individually and combined, on physical health and cognitive performance in secondary school students (aged 15–17). A cluster-randomized controlled trial with pre- and post-intervention assessments over 12 weeks was conducted. However, this study design poses analytical challenges: while ANCOVA and repeated measures ANOVA are commonly used to compare effects between groups over time, there is ongoing debate regarding the most appropriate methodology. This study aims to identify the most effective statistical model for accurately estimating the impact of active breaks and standing desks on health and cognitive abilities, providing evidence to support future school-based physical activity interventions.

METHODS: In Italy, 86% of boys and 92% of girls aged 11 to 17 fail to meet recommended physical activity levels. Therefore, our study involved students from second-year classes of linguistic and human sciences high schools.

Four classes (n=100) were randomly assigned to one of four groups: control (CT, n=20), active breaks (ACT, n=26), standing desks (STD, n=26), and a combination of both interventions (ACT+STD, n=28). Health-related fitness parameters—including muscular strength, endurance, flexibility, aerobic fitness, and blood pressure—were assessed, along with cognitive performance measures such as short-term memory, working memory, visual attention, and processing speed.

For statistical analysis, we compared repeated measures ANOVA (RM ANOVA), which accounts for repeated measurements over time, with ANCOVA, which controls for baseline covariates.

RESULTS: We analyzed three key variables: Systolic Blood Pressure (SBP), the Six-Minute Walking Test (6MWT), and the Digit Span Test (DS), representing physiological parameters, physical abilities, and cognitive performance, respectively.

The comparison between ANCOVA and RM ANOVA revealed differences in estimated coefficients and information criteria, Akaike Information Criterion (AIC) and Bayesian Information Criterion (BIC). ANCOVA showed lower AIC and BIC values across all cases, indicating a higher model precision. RM ANOVA estimated a greater number of parameters but with lower statistical efficiency.

The results indicate significant improvements in several analyzed parameters, primarily in the ACT group.

CONCLUSION: ANCOVA proved to be the most effective methodological choice for evaluating the effects of active breaks and standing desks, ensuring greater precision and statistical power. This study confirms the effectiveness of active breaks as a valuable intervention for improving students physical health and cognitive performance, supporting the integration of active strategies into school settings.

EFFECTS OF PHYSICAL ACTIVITY INTERVENTIONS ON PHYSICAL LITERACY OF PRESCHOOL CHILDREN AGED 3-6 YEARS: A SYSTEMATIC REVIEW WITH META-ANALYSIS

ZHENG, Y., CARL, J.2, LIU, F.3, CHOI, S.M.4, TANG, D.1, CHOW, J.Y.5, RUDD, J.R.6, LEUNG, K.Y.S.1, SIT, H.P.1, SUM, K.W.R.1
1 THE CHINESE UNIVERSITY OF HONG KONG; 2 DEAKIN UNIVERSITY; 3 BEIJING SPORT UNIVERSITY; 4 UNIVERSITY OF MACAU; 5 NANYANG TECHNOLOGICAL UNIVERSITY; 6 NORWEGIAN SCHOOL OF SPORT SCIENCES

INTRODUCTION: Physical literacy (PL) in early childhood is crucial for lifelong physical activity and health of individuals (Lugossy et al., 2021). Physical, cognitive, affective/psychological, and social aspects are considered the four main domains of PL (Keegan et al., 2019). However, previous systematic reviews have focused on the impact of physical activity-related interventions on health indicators, implying that little is known about the reasons for the heterogeneity in effectiveness given potential differences in intervention design. This systematic review with meta-analysis aims to describe and assess the impact of physical activity-related interventions on physical literacy among typically developing preschool children aged 3–6 years.

METHODS: 10 databases (e.g., Web of Science, Scopus) were systematically searched for peer-reviewed English-language intervention studies. Eligibility criteria aligned with PICOS principles. Two reviewers independently screened records, extracted data, and assessed risk of bias using the Effective Public Health Practice Project (EPHPP) tool. Meta-analysis was conducted using random-effects models to calculate standardized mean differences (SMD).

RESULTS: Out of 42,134 records, 205 studies (N=30,775 children) met inclusion criteria, with 160 being included in meta-analysis (Cohens Kappa: 0.69-0.89). Studies were mainly from North America and Europe (66.3%). Most studies used structured approaches (86.3%). Risk of bias assessment classified 35.6% of studies as having strong, 35.6% moderate, and 28.8% weak quality. Meta-analysis revealed small-to-moderate total effects across PL domains: physical (N=469, $d=0.50$), cognitive (N=152, $d=0.35$), affective (N=46, $d=0.33$), and social (N=34, $d=0.04$). Subgroup analysis showed that interventions facilitated by external teachers/coaches/researchers were more effective than those facilitated by preschool teachers in all four domains of PL. Combined interventions did not show better outcomes than single interventions.

CONCLUSION: Physical activity related interventions demonstrate positive effects on various PL domains in preschoolers, while affective and social domains remain understudied. This review provides evidence for the importance of PL-focused interventions in early childhood. Further evidence-based research is needed to optimize intervention design and implementation to maximize PL development across all domains.

EFFECTS OF DANCE ON FUNDAMENTAL MOVEMENT SKILLS IN YOUNG CHILDREN

SHU, H., AKIRA, M., NORIKAZU, H.
WASEDA UNIVERSITY

INTRODUCTION: Fundamental movement skills (FMS) are an important indicator of health and well-being in young children. Locomotor and object control skills play a crucial role in their future growth and well-being. It has been suggested that dance could improve young children's FMS, thereby promoting motor development. Therefore, this study aims to investigate the impact of dance practice on FMS in young children.

METHODS: The study involved 62 five-year-old Japanese children from a kindergarten without physical education classes. Participants were divided into two groups: the Dance Group (DG) and the Control Group (CG). For five months, the DG participated in dance-based physical education classes three times a week, while the CG did not receive any structured physical activity intervention. FMS was assessed before and after the intervention, measuring locomotor and object control skills, including the 25-meter run (m/s), standing long jump (cm), and softball throw (m).

RESULTS: Indicated a statistically significant interaction between "time" and "group" for the standing long jump [$F(2,405) = 19.43$, $p < 0.001$, $\eta^2 = 0.42$]. The post-hoc test revealed that the DG showed a significant improvement in its average score after the intervention, whereas the CG experienced a decline.

For the 25m run, the DG demonstrated a statistically significant improvement in the post-test compared to the pre-test ($Z = -4.422$, $p < .001$), whereas the CG showed no significant change ($Z = -0.009$, $p = 0.993$). Additionally, the DG group outperformed the CG in the post-test ($Z = -3.006$, $p = 0.003$), despite no initial differences between the two groups in the pre-test ($Z = -0.490$, $p = 0.634$). In the softball throw, both groups showed some improvement in the post-test compared to the pre-test; however, these improvements were not statistically significant for either group.

CONCLUSION: Overall, the findings suggest that dance training positively influenced FMS, particularly in sprinting and jumping ability, likely through improvements in lower-body strength and body coordination[1]. Dance requires precise control of posture, rhythm, and dynamic movements (lunges and strides, running and jumping movements), which could have enhanced body coordination, speed and explosive power. This increased efficiency in movement execution may have led to better sprinting mechanics and improved jumping ability, as seen in the significant improvements in the 25m run and standing long jump. Future research should incorporate exercises that specifically target upper-body strength could help maximize the benefits of dance training for overall physical development of young children.

This study suggests that dance intervention improved FMS in young children and have a positive impact on their development.

MORE MOVEMENT, BETTER SLEEP? THE EFFECTS OF TEN DAYS AT A DIABETES SUMMER CAMP ON ACTIVITY, SEDENTARY BEHAVIOR AND SLEEP PATTERNS

PRESTANTI, I.1, MONTENEGRO, S.1, SERAFINI, S.1, VAMVAKIS, A.2,3, SIROUKIDOU, K.2, TOULIA, I.2, IZZICUPO, P.1
UNIVERSITY OF GABRIELE DANNUNZIO OF CHIETI-PESCARA

INTRODUCTION: Managing type 1 diabetes in children and adolescents is challenging for both patients and families. Regular physical activity improves glycemic control and overall well-being, but maintaining adequate levels can be diffi-

cult. A structured environment, such as a summer camp, may help increase activity while also influencing sleep and sedentary behavior. This study aimed to assess physical activity, sleep, and sedentary behavior in children and adolescents with type 1 diabetes before and during a diabetes summer camp.

METHODS: This study investigated physical activity, including steps taken and time spent in light, moderate, and vigorous activity, sleep quality and quantity, and sedentary behavior in 23 children and adolescents (13.3 ± 2.1 years) before and during a diabetes summer camp. These variables were assessed using two types of Fitbit devices (Fitbit® Inc., San Francisco, California, USA), the Fitbit Inspire HR for adolescents and the Fitbit ACE for children. The devices were worn on the non-dominant wrist over two periods: 7-10 days prior to the camp and 10 days during the camp, monitoring continuously day and night both activity and sleep. The Student's t-test and Wilcoxon rank-sum test were conducted to assess differences between the two periods, based on the data distribution.

RESULTS: The results showed that the number of steps taken was significantly higher during the camp (18901.9 ± 3330.6) compared to the pre-camp period (8772.1 ± 2823.8 ; $p < .001$). Similarly, time spent in light physical activity increased from 258.3 ± 52.7 min/day before the camp to 436.3 ± 61.9 min/day during the camp ($p < .001$). Moderate physical activity also increased significantly, from 28.5 ± 16.4 min/day before the camp to 71.0 ± 43.7 min/day during the camp ($p < .001$). Vigorous physical activity showed a smaller but significant increase, from 24.7 ± 18.1 min/day pre-camp to 39.3 ± 36.2 min/day during the camp ($p = .016$). In contrast, sedentary time was significantly lower during the summer camp (505.5 ± 75.2 min/day) compared to the pre-camp period (717.0 ± 80.6 min/day; $p < .001$). Regarding sleep, the average duration of nighttime awakenings was significantly higher before the camp (46.1 ± 17.0 minutes) compared to the camp period (39.7 ± 13.6 minutes; $p = .005$), while total sleep duration decreased from 408.9 ± 61.3 min/day before the camp to 365.2 ± 49.8 min/day during the camp ($p < .001$).

CONCLUSION: A summer camp significantly increased physical activity and reduced sedentary time in children and adolescents with type 1 diabetes. Although total sleep duration decreased, fewer nighttime awakenings suggest improved sleep continuity. These findings highlight the positive impact of structured environments on both activity levels and sleep quality.

OP-SH21 Female Sport and Physical Activity

FEMALE ATHLETES' KNOWLEDGE OF BIOPSYCHOSOCIAL PUBERTY-RELATED TOPICS IN SPORTS DURING ADOLESCENCE: WHAT IS MISSING?

RADOVAN, F., ERLAND SOLSTAD, B., BAGGER KJÆR, J., MELIN, A., AUSLAND, Å., BJÄRSHOLM, D., IVARSSON, A., KLUNGLAND TORSTVEIT, M., LAXDAL, A., RYMAN AUGUSTSSON, S., LINNER, S.

LINNAEUS UNIVERSITY

Background: Puberty is a key factor in the decline of girls' sports participation during adolescence. Knowledge, preparation, and social support can make the biopsychosocial (BPS) puberty-related changes more manageable. Yet, research on knowledge about BPS puberty-related topics in the sport context of female athletes is limited.

Aim: Thus, the main aims of the study were to (a) examine female athletes' perceived knowledge and knowledge needs regarding BPS puberty-related topics in sports during adolescence and to (b) examine how perceived knowledge and knowledge needs, respectively, were interconnected across BPS domains. Additionally, as a secondary aim, the study sought to (c) explore potential differences between athletes participating in team versus individual sports regarding perceived knowledge, knowledge needs, and interconnections across BPS domains.

Method: Swedish and Norwegian female athletes from ten sport disciplines (football, horseback riding, handball, swimming, gymnastics, floorball, athletics, cycling, and cross-country and alpine skiing) were invited to fill out an anonymous online survey with questions focusing on perceived knowledge and knowledge needs regarding BPS puberty-related topics, such as individual differences and social comparisons, during adolescence. Both perceived knowledge and knowledge needs were measured using a 7-Point Likert Scale.

Results: A total of 1323 female athletes ($n=657$ (49.7%), athletes from team sports; $n=656$ (49.6%) from individual sports) responded to the online survey. Findings revealed low perceived knowledge as well as knowledge needs regarding BPS puberty-related topics among female athletes. The Mann-Whitney U test was used, revealing that athletes in team sports perceived their knowledge to be slightly higher regarding individual differences, social cohesion, social comparison, acceptance within the group, and recovery, compared to athletes in individual sports. Athletes in team sports reported higher knowledge needs regarding social comparisons, sports nutrition and recovery, while athletes in individual sports reported higher knowledge needs regarding changes in sex hormones, individual differences, and changes in body composition. A network analysis identified clusters of biological, psychosocial, and behavioral topics in both perceived knowledge and knowledge needs, indicating that knowledge regarding BPS puberty-related topics is concentrated within subdomains.

Conclusion: Our findings underscore the urgent need of and the considerable opportunity for a more holistic understanding of BPS puberty in the sport context of female athletes. Future educational programs should therefore be holistic and interdisciplinary in scope.

DEVELOPMENT OF THE FIDES ADP “GIRLS ARE NOT SMALL BOYS” DIGITAL EDUCATIONAL INTERVENTION

LINNÉR, S., RYMAN AUGUSTSSON, S., RADOVAN, F., AUSLAND, Å., BJÄRSHOLM, D., BAGGER KJÆR, J., LAXDAL, A., ERLEND SOLSTAD, B., KLUNGLAND TORSTVEIT, M., MELIN, A.

LINNAEUS UNIVERSITY

INTRODUCTION: Girls who participate in exercise and sports face unique challenges regarding acceptance of pubertal weight gain and hormonal fluctuations in a way that most boys and young men do not. Lack of female-specific knowledge within the sporting environment may be preventing girls from reaping the full benefits it has to offer. Therefore, the aim of this study was to develop a cost-effective, sustainable educational program for girls in organized sport, their parents and coaches.

METHODS: We developed the study methods and the digital educational program in different steps 1) Content validity of the female-specific topics of the intervention was established by a) literature reviews performed by the research group including specialists within subdisciplines ranging from pedagogy, psychology, sociology, and film science to physiology, and sport medicine; and b) an online survey examining female athletes' perceived knowledge needs regarding biopsychosocial puberty-related topics during adolescence including 1323 female athletes aged 16-24, from different sport disciplines; and c) the film scripts were read aloud in a pilot group of six 13-16-year-old girls who provided immediate feedback. 2) On-line surveys aimed to estimate changes in well-being, sporting experiences and parental, peers, and coaching support were constructed and pilot tested. 3) The construction, production, and delivery form of the intervention was developed in collaboration with a film crew and a technical specialist.

RESULTS: The intervention development resulted in 12 films à 5-7 minutes with a mix of experts and female athletes delivering the female-specific topics: 1) Misconceptions About Female Athletes, 2) Understanding Your Whole Self, 3) How Do We See Ourselves?, 4) and 5) Physical Development During Puberty Part 1 and Part 2, 6) Self-Image During Puberty, 7) You, Your Training Partners, and the Sense of Belonging, 8) Get to Know Your Menstrual Cycle, 9) Physical and Mental Recovery, 10) Nutrition for Health, Exercise, and Recovery, 11) The Relationship Between You, Your Coaches, and Parents, 12) Putting it all together. The protocol development resulted in a case-control design including a 6-week control period followed by a 6-week intervention period with assessment of main variables (well-being and sporting experiences) every second week, and selected variables (e.g., perceived social support) at baseline, pre-, and post-intervention. The delivery of the intervention and the distribution of surveys were most effectively administered using the m-Path app.

CONCLUSION: This paper describes the development of a cost-effective, sustainable digital educational intervention for girls in organized sport, their parents and coaches. The study suggests that a digital intervention is best co-developed in an interdisciplinary environment, at the interface between different areas including technical specialists and in collaboration with the intended population.

SUPPORTING FEMALE PARTICIPATION IN SPORT AND ACTIVE RECREATION DURING PERIODS

SNIPPE, R., BROWN, H., BRUCE, L., CARR, A., MAIN, L., LAMON, S.

DEAKIN UNIVERSITY SCHOOL OF EXERCISE AND NUTRITION SCIENCES

INTRODUCTION: Periods are a normal part of female reproductive function. However, there remains a lack of understanding and research on how periods influence participation in sport and active recreation, and what strategies can be used to support participation during periods.

METHODS: A mixed-method survey of 325 menstruating females was conducted to explore how periods influence participation in sport and active recreation. Descriptive analysis and relative risk (RR) were used to analyze quantitative data, and thematic analysis was used for qualitative data analysis. A working group of sport and recreation representatives (n=8) reviewed the survey data to inform evidence-based strategies to support participation during periods.

RESULTS: Over half reported having missed training for sport (57%) or active recreation (55%) due to their period but only 14% missed competitive sport events. The main reasons for missing sport/active recreation training were symptoms (96/91%), and concerns about leaking (35/49%) and reduced performance (16/15%). Period-related training modifications were more common in active recreation (74%) than in sport (40%). Females with menorrhagia (heavy menstrual bleeding) were more likely to have missed training for sport (74% vs 52%, RR 1.4), active recreation (71% vs 51%, RR 1.4) and sport events (26% vs 11%, RR 2.4); and perceived periods as a greater barrier to participation than females without menorrhagia (sport: 50% vs 29%, RR 1.7; active recreation: 58% vs 34%, RR 1.7). Adolescent females (15-18 years) perceived periods as a greater barrier to sport participation than older females (>18 years; 65% vs 30%, RR 2.2). Thematic analysis identified that the barriers to participation included physical (inadequate facilities, sport uniforms), social (stigma/embarrassment, unsupportive cultures, communication with coaches), policy (inadequate education and awareness, medical support), and individual psychological considerations (fear of underperformance, body image issues). The working group identified 15 potential strategies to support participation during periods, with a guide for sport and active recreation organisations to create supportive environments voted as the most feasible strategy for short-term implementation.

CONCLUSIONS:

Periods are often perceived as a barrier to sport and active recreation participation and can influence attendance and participation of females at training. Females with menorrhagia experience greater barriers and challenges to participation during periods. Understanding the attitudes and preferences of women and girls is essential for co-developing strategies that support participation. A guide for sport and active recreation organisations could address some of the identified barriers, but will require co-design, piloting, and evaluation to ensure effectiveness in supporting participation during periods.

HOW CAN WE CONTRIBUTE TO DESTIGMATIZE THE MENSTRUAL CYCLE IN SPORTS?

PFLEIDERER, L., RASCHNER, C., RAUSCH, L.

UNIVERSITY OF INNSBRUCK

INTRODUCTION: Training, sports performance and general well-being is perceived to be affected by the menstrual cycle (MC) among female elite athletes [1]. The often limited communication in the athlete-coach relationship, partly due to knowledge, interpersonal and structural barriers [2], poses a persistent difficulty in finding optimal strategies for dealing with sport and MC. The aim of this study was to identify taboo de-activators regarding the MC in the context of sports and to investigate whether and to what degree communication could contribute to de-stigmatization.

METHODS: 28 adult amateur athletes (15 males, 13 females; aged 20-35 years) took part in an interactive workshop, consisting of a lecture addressing the current scientific literature regarding the interaction between sport and the MC and small group discussions, according to the World Café method, a qualitative research technique distinguished by its innovative approach to participatory action research (PAR; [3]). Three rounds of conversations on three separate tables with up to 10 randomly assigned participants (organized in mixed-gender groups) addressed the following topics: Perception of MC as a taboo subject in sports; Importance & learnings of the workshop; Self-experienced effects of MC on performance. Table conversations were recorded and transcribed anonymously. A qualitative content analysis [4] was conducted with data being facilitated using MAXQDA 24 software.

RESULTS: The investigated male amateur athletes described an existing lack of knowledge and the fear of crossing their opposites' personal boundaries as hindering factors in initiating a conversation about the MC. Therefore, they phrased their communication role primarily as listeners. Several female participants expressed emotionality as correlated to the topic of the MC and referred to the positive aspect of talking to other women about the MC, as knowledge and empathy are assumed to be given, whereas in mixed-gender conversation the perception of a gap of neutral wording was mentioned. However, female amateur athletes described the degree of intimacy towards their contact person and not their gender as decisive. Respondents further reported that an enhanced number of female elite athletes to talk about the MC in public and corresponding media coverage could contribute to destigmatize the MC in sports.

Discussion: According to previous studies, knowledge and strong interpersonal relationships help to overcome the taboo in communication about the MC [1]. The results of the present study further suggest a potential in the de-emotionalization of communication, focusing on wording, in athletic communities.

THE ROLE OF CARDIORESPIRATORY FITNESS AND BRAIN HEALTH IN AGE-RELATED COGNITIVE DECLINE: INSIGHTS FROM TIP-OF-THE-TONGUE STATES

RAHMAN, F., TSVETANOV, K., FERON, J., JOYCE, K., GILANI, A., FERNANDES, E., WETTERLIN, A., WHEELDON, L., LUCAS, S., SEGAERT, K.

LOUGHBOROUGH UNIVERSITY

INTRODUCTION: As global populations live longer, understanding the factors that contribute to cognitive decline in healthy ageing is increasingly important. Even in the absence of neuropathology, ageing is associated with wide-ranging cognitive difficulties, yet the rate and severity of decline vary across individuals. This variability may be explained by an interplay between brain-based and lifestyle factors, such as cardiorespiratory fitness. While research has examined these factors in isolation, here, we integrate their joint contributions to neurocognitive ageing. We employed commonality analysis that combined multimodal neuroimaging and fitness-based measures to explain variability in tip-of-the-tongue states—a prototypical cognitive problem in ageing which involves a temporary failure in producing a known word.

METHODS: The study involved 78 neurologically healthy older adults (mean age = 65.53 [4.94], range 60–81, 39 female) who underwent structural, functional, and perfusion MRI alongside a maximal, treadmill-based cardiorespiratory fitness

test that was used to quantify VO2Peak. Structural (T1-weighted anatomical) and perfusion (pseudo-continuous arterial spin labelling) imaging were used to estimate global grey matter density and cerebral blood flow, respectively, while functional imaging captured blood-oxygen-level dependent (BOLD) signal during a cognitive task designed to elicit tip-of-the-tongue states.

RESULTS

Replicating prior work, we first confirmed that there was a positive association between age and tip-of-the-tongue rates ($r = .288$, $p = .014$). Examining the functional MRI in isolation, we found that tip-of-the-tongue states recruited a broad language network within the brain, namely precuneus, bilateral angular gyri, and superior and middle frontal gyri. Next, using commonality analysis—a statistical technique that partitions variance in an outcome variable to identify unique and shared contributions of multiple predictors—we examined how age-related tip-of-the-tongue states were jointly explained by cardiorespiratory fitness together with brain structure, function, and perfusion. We found that tip-of-the-tongue occurrences were best predicted by a shared effect of age, fitness, and the functional recruitment of language-related brain regions ($t = 1.842$, $p = .002$).

CONCLUSION

These findings suggest that brain health and fitness work together to shape individual differences in age-related cognitive decline. Our results align with classic models of neurocognitive ageing, such as compensation, maintenance, and reserve by demonstrating that brain function is modified by both age and fitness levels. This interdisciplinary evidence underscores the importance of lifestyle factors, particularly aerobic fitness, in mitigating cognitive decline. By integrating neuroscience and exercise physiology, we highlight the potential for targeted fitness interventions to promote cognitive resilience in ageing populations.

EXERCISE INTENSITY AGREEMENT, NEEDS FULLFILMENT, BEHAVIORAL REGULATION, AND EXERCISE-BEHAVIOR OUTCOMES: A DOUBLE SERIAL MEDIATION ANALYSIS

TEIXEIRA, D., MARQUES, P.J., RODRIGUES, F., MONTEIRO, D., BASTOS, V.

ULHT - UNIVERSIDADE LUSÓFONA DE HUMANIDADES E TECNOLOGIAS

Introduction: Vicennial efforts to promote physical activity have fallen short of their intention and societal needs. The contemporary lifestyle millions adopt daily is often detached from several health-prone practices, as is often the case of physical activity, resulting in increasingly dire consequences on Human health. Grounded on the emerging trend of exploring behavior and decision-making through dual process theories, investigating potential mechanisms that can articulate implicit and explicit variables relevant to exercise adherence seems paramount. As such, this study aimed to test a hypothesized model where the exercise intensity agreement to individual preference/tolerance is proposed to be a facilitator of exercise behavior and related variables (intention to continue exercising and exercise habit). This exploration sustains that this would occur indirectly, through the improvement of the bright and dark sides of motivation as proposed by Self-Determination Theory (SDT), and directly, as theoretically proposed by previous related studies.

Methods: A total of 369 participants (Mage = 43.6 years $\pm$ 12.96; 214 females) from 26 health clubs fulfilled a psychometric battery for psychological (preference/tolerance agreement, basic psychological needs satisfaction/frustration, and behavioral regulations) and behavior-related variables (intention to continue to be physically active, exercise habit, and exercise frequency by attendance). Descriptive and correlational analysis, followed by double serial mediation procedures using model 18 of the PROCESS macro v.4.2, were utilized to test the direct and indirect effects of the hypothesized models.

Results: The analyses showed positive associations between intensity preference and tolerance agreement with basic psychological needs satisfaction, behavioral autonomous regulations, intention to continue exercising, and exercise habit. Negative associations were found with basic psychological needs frustration, and behavioral controlled regulations. Mediation analyses revealed direct effects of both preference ($\beta = 0.49$ [0.36, 0.62]) and tolerance agreement ($\beta = 0.41$ [0.28, 0.55]) on the intention to continue exercising. Indirect effects emerged mainly from the path with both BPN satisfaction and behavior-autonomous regulations in all models.

Conclusion: The results suggest that aligning exercise programs with individual intensity preference and tolerance may facilitate intention. Moreover, it can act as a BPN satisfaction facilitator, which has been extensively reported as being positively associated with improved behavioral regulation, an increase in exercise habit, and higher exercise frequency. When articulating these results with current evidence, increasing support emerges for the need to understand the individual relation with exercise intensity and respective implications manifesting on implicit and explicit variables across Human behavioral theories.

INTERPERSONAL VIOLENCE IN MEXICAN ATHLETES

REYES-HERNÁNDEZ, O., LÓPEZ-WALLE, J., TRISTÁN, J., ORNELAS-CONTRERAS, M., MARTÍNEZ-ALVARADO, J.R., MEDINA VALENCIA, R.T., ESQUEDA VALERIO, E.I., LARIOS DELGADO, A., FERNÁNDEZ-BARRADAS, E.Y., FLORES GALAZ, M.M., MOSQUEDA, S., APPLETON, P.R.

UNIVERSIDAD AUTÓNOMA DE NUEVO LEÓN

This study examined differences in violence experienced by athletes from teammates and coaches. The sample consisted of 2,633 Mexican athletes ($M = 21.17$, $SD = 5.03$), with 53.4% men and 46.6% women, and an average of 7.80 years of experience in their discipline ($SD = 5.80$).

The instrument used was the Violence Towards Athletes Questionnaire (VTAQ; Parent et al., 2019). The overall results show significant differences in psychological violence ($M = -0.31$, $SD = .43$, $T = -3.72$, $p < .001$) and physical violence ($M = -0.16$, $SD = .37$, $T = -2.20$, $p < .05$). No significant differences were found in sexual violence scores ($M = 0.001$, $SD = .25$, $T = 0.24$, $p = .81$).

Regarding gender differences, women reported significantly higher levels of psychological violence from teammates than men ($T = -3.87$, $p < .001$), with women scoring higher ($M = 1.20$, $SD = .45$) than men ($M = 1.14$, $SD = .41$). Likewise, physical violence by the coach showed significant differences ($T = 2.88$, $p < .01$), being higher in men ($M = 1.11$, $SD = .42$) than in women ($M = 1.07$, $SD = .32$).

These results suggest that athletes are more frequently subjected to psychological violence (e.g., threats, ridicule) by teammates (mainly women) than by coaches. Additionally, they have also been victims of physical violence (e.g., hitting, pushing), predominantly by their coaches (mainly men), with the difference being minor in both cases.

These findings highlight the need for prevention and intervention strategies targeting both athletes and coaches.

A 1-YEAR OF LOW-INTENSITY EXERCISE TRAINING IN HYPOXIA ON MENTAL HEALTH IN THE ELDERLY

TANIGUCHI, S., KUZUHARA, Y., OTAKE, T., SHIRAI, Y., GOTO, K.

RITSUMEIKAN UNIVERSITY

INTRODUCTION: Exercise training in hypoxia has been shown to cause greater improvements of fat reduction (Wiesner et al. 2010), insulin sensitivity (Haufe et al. 2008) and muscle strength (Park et al. 2019) compared with the same training in normoxia. Although majority of previous studies utilized short- or middle- term (< 24 wk) of moderate-intensity exercise training, long-term effects (> 24 wk) of low-intensity exercise in hypoxia in the elderly remains unclear. Especially, how the long-term exercise training in hypoxia affects mental health has not been fully elucidated. The purpose of the present study was to determine the effect of 1 year of low-intensity exercise training in hypoxia on mental health, sleep quality and cognitive function in the elderly.

METHODS: Twenty-two elderly (mean $\pm$ SD; 72.8 ± 6.1 yrs) were recruited. They were divided into either "group with exercise training in hypoxia (HYP, $n=15$)" or "group without exercise training (CON, $n = 7$)". HYP performed low-intensity exercise session for 60 min under moderate hypoxia (FiO_2 : 16.4 %), while CON did not join the exercise training session and maintained normal lifestyle. The exercise training was conducted twice per week for 1 year. Before and after the intervention period, all subjects answered questionnaires to assess depression status (Geriatric depression scale-15 [GDS15], The depression anxiety stress scales [DASS21]), health related quality of life (SF8), cognitive function (Mini-mental state examination [MMSE]) and sleep quality (Pittsburgh sleep quality index [PSQI]). Physical fitness levels were also evaluated before and after the intervention period.

RESULTS: In HYP, average SpO_2 during training session was constant during the intervention period (1st month: $92.6 \pm 1.7\%$, 12th month: $94.6 \pm 2.2\%$). The pulse rate during training session was around 90 bpm (1st month: 88 ± 10 bpm, 12th month: 90 ± 10 bpm). The score of GDS15 presented significant interaction (group $\times$ period, $p = 0.035$), and it was significantly lowered after the intervention period only in the HYP ($p = 0.021$). The score of MMSE presented significant main effect of period ($p = 0.002$), but no significant interaction or main effect of group was found. The score of PSQI did not change significantly in both groups. In HYP, systolic blood pressure was decreased significantly after the intervention period (pre: 129 ± 17 mmHg, post: 120 ± 11 mmHg, $p = 0.015$). For physical fitness levels, number of sit-ups, (pre: 10.6 ± 6.5 , post: 12.9 ± 7.1 , $p=0.025$), and time for 10m obstacle walk (pre: 6.1 ± 1.2 s, post: 5.4 ± 1.5 s, $p=0.02$) were significantly improved.

CONCLUSION: A 1 year of low-intensity exercise training under moderate hypoxic environment decreased depression score with improved physical fitness levels and systolic blood pressure in the elderly.

FACTORS INFLUENCING PERFORMANCE IN SQUARE-STEPPING EXERCISE AMONG HEALTHY OLDER ADULTS

FU, H., HUANG, S.W., KAO, S.C., WANG, C.H.

UNIVERSITY OF OXFORD

INTRODUCTION: The Square-Stepping Exercise (SSE) is a structured program that integrates both physical and cognitive demands, designed to enhance balance, memory, and fall prevention, particularly among older adults. However, the extent to which SSE relies on physical and/or cognitive abilities remains unclear. This study aims to explore the relationship between these factors in a sample of healthy elderly adults.

Method: A total of 135 healthy older adults from the local community were recruited and completed a series of assessments, including questionnaires (Geriatric Depression Scale, Mini Mental State Examination, Montreal Cognitive Assessment), memory tests (Forward and Backward Digit Span), and fitness tests (30-Second Sit-to-Stand, Chair Sit-and-Reach, One-Leg Stand, 8-Foot Up-and-Go, Timed Up-and-Go, Functional Reach), along with the SSE. Stepwise ordinal logistic regression was conducted to examine the relationship between these variables and SSE performance, which was defined by the level participants could imitate following the instructors demonstration once or twice.

RESULTS: We developed three separate models focusing on demographic, mental state, and lower-limb fitness variables. The analysis showed that age, education level (demographic model), Backward Digit Span (mental state model), and performance on the TUG test (lower-limb fitness model) were significantly linked to SSE performance. After combining these factors into a final model, Backward Digit Span emerged as the only variable significantly associated with SSE performance.

Discussion

In conclusion, this study identified working memory as the strongest predictor of SSE performance among older adults, underscoring the key role that cognitive abilities play in SSE. We propose that, given the significant involvement of cognitive abilities over physical fitness components in SSE, incorporating this exercise into physical activity interventions has the potential to enhance both cognitive and physical abilities in older adults while promoting increased physical activity.

OP-MH41 Interventions I ---

TWO YEARS FOLLOW-UP OF THE REMOTE HIGH-INTENSITY AEROBIC INTERVAL TRAINING EFFECTS ON PHYSICAL FITNESS OF BREAST CANCER SURVIVORS

KLAVINA, A., LIEPINA, S., BERNANS, E., VISKINTE, M.

RIGA STRADINS UNIVERSITY

INTRODUCTION: Exercise interventions during neoadjuvant chemotherapy treatment (NACT) for patients with BC have been studied extensively during last decade demonstrating beneficial effects related to reducing treatment-associated side effects. High intensity interval training (HIIT) interventions have demonstrated clinically meaningful benefits for physical health and quality of life in BC patients in a relatively short time during therapy, while long-term effects remain unclear (Mijwel et al., 2019). This study aimed to investigate the effects of remote aerobic HIIT intervention during neoadjuvant chemotherapy treatment (NACT) on physical health outcomes 18-24 months following end of intervention in breast cancer (BC) survivors

METHODS: The HIIT intervention study was two arm randomized control trial (RCT) implementing remotely supervised 4x4 min HIIT at an intensity of 85-95% of peak heart rate for 6 months during NACT during 2022-2023 (Cancerbeat 1 study, Klavina et al., 2024). Incremental exercise test (VO₂peak) and physical performance (6MWT and sit-to-stand test including 5 sec (5xSTS) 30 sec (30STS) assessment) was measured pre-post NACT and at 18-24 months follow-up (2024, Cancerbeat 2 study). The data were analyzed for 24 participants (HIIT= 13, CG = 11) who agreed to participate in follow-up study.

RESULTS: HIIT demonstrated significant effects for 6MWT (ES = .27, p = .012), Sit-to-stand scores (5 x) sec (ES = .233, p = .023), VO₂peak outcomes (ES = .186, p = .045) and time to exhaustion (TTE) (ES = .25, p = .012) compared to CG. Both groups, HIIT and CG, significantly improved in 6MWT at 18-24 months follow-up compared to pre- and post-NACT (p < .05). Significant positive correlations were found between TTE scores and 6MWT (r = .564, p = .045) and minute ventilation (VE) outcomes (r = .645, p = .017) in HIIT group at follow-up. In CG the TTE was significantly correlated with VO₂peak (r = .966, p < .001).

CONCLUSION: Participants in the HIIT group 18-24 months after intervention were demonstrating significant differences in aerobic endurance and leg muscle strength outcomes compared to CG. The CG presented physical health outcomes close to the pre-treatment follow-up. The remote 4x4 min HIIT intervention during the 6 months of NACT may lead to long-term benefits of physical health related outcomes. Future studies should emphasize the benefits of physical activity in long-term health maintenance by exploring individualized exercise prescriptions that align with the specific needs and post-treatment goals of each BC survivor.

A CO-DESIGNED INTERVENTION (ACTIVE-FAB) TO REDUCE SEDENTARY BEHAVIOUR AND INCREASE PHYSICAL ACTIVITY IN ADULTS WITH FABRY DISEASE

BAILEY, D., GOSLING, S., HUGHES, D., KILBRIDE, C., MANSFIELD, L.

BRUNEL UNIVERSITY LONDON

INTRODUCTION: Fabry disease is a rare inherited metabolic disorder caused by a genetic fault in the alpha-galactosidase A enzyme. Breakdown of glycolipids in the lysosomes of cells is impaired, leading to excess storage of globotriaosylceramide that results in multi-organ disease (most notably affecting the brain, heart and kidneys). Mental health and quality of life is often severely impacted in Fabry disease, yet treatment is pharmacological and predominantly focuses on physical symptoms. Reducing sedentary behaviour and increasing physical activity are associated with improved mental health and quality of life in the general population. The aim of this study was to co-design a sedentary behaviour and physical activity intervention tailored for adults with Fabry disease.

METHODS: Barriers and facilitators linked to sedentary behaviour and physical activity were identified through focus groups with adults with Fabry disease (N=13), family members (N=8), and staff of the Society for Mucopolysaccharide Diseases (N=6). This was in addition to semi-structured interviews with 10 healthcare professionals (physicians, clinical nurse specialists, and a physiotherapist). Participatory workshops were then undertaken (N=12 adults with Fabry disease), informed by focus group and interview data, to test concepts and define the intervention content. The design process and intervention components were further refined through patient and public involvement. Data analysis used the Framework Method with inductive and deductive coding.

RESULTS: Barriers to reducing sedentary behaviour (e.g. habit, previous negative experiences, work environment) and increasing physical activity (e.g. comorbidities, perceived inability to be active, lack of understanding around Fabry disease in the community) were identified. Themes generated from the focus groups, interviews, and workshops led to a multi-component intervention, 'ACTIVE-FAB', that includes: (1) initial consultation with a physiotherapist to discuss sedentary behaviour, physical activity levels and set goals, (2) progress consultations with a physiotherapist focusing on intervention engagement and reviewing goals, (3) online education covering the importance of limiting sedentary behaviour and engaging in physical activity, and information to support engaging in adaptable physical activities, (4) a smartwatch that tracks sedentary behaviour and physical activity, and (5) online peer support.

CONCLUSION: This study has led to the co-design of a multi-component intervention to reduce sedentary behaviour and increase physical activity in adults with Fabry disease. The feasibility, acceptability and potential effectiveness of ACTIVE-FAB is being evaluated in a randomised controlled feasibility trial. This intervention could provide an effective adjunct to pharmacological treatment and improve management of Fabry disease in the future.

EFFECT OF TWO DIFFERENT DIETARY-NUTRITIONAL THERAPIES COMBINED WITH ADAPTED PHYSICAL ACTIVITY ON HEALTH-RELATED QUALITY OF LIFE IN CHRONIC KIDNEY DISEASE: A PILOT STUDY

MURRI, A., GRAZIOLI, E., CERULLI, C., DI MARCO, L., MARRONE, G., DI LAURO, M., CORNALI, K., MASCI, C., NOCE, A., PARISI, A.

UNIVERSITY OF ROME FORO ITALICO

INTRODUCTION: Chronic kidney disease (CKD) is associated with several comorbidities, including uremic sarcopenia (US), which negatively influences patients' health-related quality of life. Dietary-nutritional therapy (DNT) and adapted physical activity (APA) are effective nonpharmacological strategies to counteract the CKD progression and its complications. Among dietary approaches, low-protein diets (LPD) (0.6-0.8 g/kg body weight/day) with controlled intake of phosphorus, sodium, and potassium and adequate energy intake can help mitigate the metabolic imbalances that contribute to US. An alternative DNT, such as the plant-dominant LPD (PLADO), with $\geq 50\%$ plant-based protein intake, may further slow the CKD progression through modulation of the gut microbiota and reduction of uremic toxins. However, the combined effects of PLADO and APA on the prevention of US remain unclear. This pilot study analyses the impact of a 12-week online APA protocol combined with PLADO or LPD on muscle mass, physical capacity and quality of life in CKD patients.

METHODS: 15 CKD patients, aged 59.8 ± 9.8 years, were randomized into 2 groups: A) Online APA protocol (3 sessions per week, lasting 1 hour each) combined with PLADO; B) Online APA protocol combined with LPD. Physical capacity (6-minute walking test), muscle strength (Handgrip), body composition (bioelectric impedance analysis), quadriceps femoris muscle thickness, and laboratory parameters were evaluated at baseline (T0) and after 12 weeks (T1). SF-36 was administered to assess patients' general health.

RESULTS: At T1 Group A and Group B increased the distance in the 6-minute walking test ($p=.001$; $p=.034$). Handgrip strength significantly improved in Group A for the left limb ($p=.014$), showing a positive trend in the right limb as well. In addition, there was a significant reduction in body mass index (BMI) in Group A ($p=.022$). While quadriceps femoris muscle thickness increased significantly in Group B ($p=.050$). No significant differences in free oxygen radical defense (FORD) and free oxygen radicals test (FORT) values were observed in both groups. Positive trend was reported in general health perception in both groups, and the item health change increased significantly in Group A ($p=.050$).

CONCLUSION: Both PLADO and LPD, combined with APA, seems to positively affect muscle function and body composition of CKD patients. The results suggest that combining dietary interventions with structured exercise may improve health-related quality of life in CKD. Further investigations into long-term outcomes and larger sample are required.

12-WEEK EXERCISE INTERVENTION TO IMPROVE PHYSICAL AND MENTAL HEALTH IN POST-SURGERY COLORECTAL CANCER PATIENTS

MANDERS, R., FISH, Y., MCCLATCHIE, E., SILVERDALE, N., ROBERTS, H.
UNIVERSITY OF SURREY

INTRODUCTION: Colorectal cancer is the third most common cancer worldwide¹. Surgery is the main method of treatment in this tumour type, but many patients still experience surgery and cancer related complications such as fatigue, pain, bowel dysfunction and reduced quality of life². There is increasing evidence that shows that increased physical activity is beneficial to improve disease prognosis³ but there is still a need for more applied evidence assessing the effectiveness of exercise interventions in a referral setting.

METHODS: All patients undergoing curative colorectal resections without metastases were eligible to take part. 24 patients (14 male, 66.7±11.6y, BMI:27.06±4.1 kg/m² and 10 female, 60.3±11.5y, BMI:24.62±6.5 kg/m²) have currently finished the intervention. The intervention consisted of a 12-week individualised, progressive resistance training plan with one supervised and two self-managed sessions per week. At baseline and after 4, 8 and 12 week we assessed physiological and health parameter (e.g. W:H, blood pressure, grip strength), fitness outcomes (6min bike test (6mBD), strength assessments) and questionnaires to determine physical activity (DASI) and functional assessment (FACIT-G/F).

RESULTS: Adherence to the exercise sessions was good at 82% of all sessions completed. Comparing results pre and post intervention, 6mBD improved (2.5±0.5 vs 2.7±0.5 km, p=0.03), as did DASI predicated VO₂peak (25.18±6.63 vs 30.01±5.15 mL/kg/min, p=0.03) and physical activity levels (DASI 36.2±15.4 vs 47.5±12.0, p=0.03). Of the strength measures attained only left-hand grip strength changed over the 12-week intervention (27.2±9.5 vs 29.5±9.9 kg, p=0.003). Functional Assessment of Chronic Illness Therapy scores did not reveal any changes because of the intervention (FACIT-F: 37.3±5.5 vs 40.7±8.0, p=0.29 and FACIT-G: 87.8±9.8 vs 90.2±15.1, p=0.66).

CONCLUSION: Twelve weeks of individualised semi-supervised exercise was shown to be effective in improving overall physical activity and exercise capacity in a cohort of post-surgery colorectal cancer patients. Functional capacity remained unchanged following the intervention, which may, to some extent, be attributed to the patients overall good health. Ongoing analysis is required to further elucidate the specific responses to the exercise interventions based on gender, surgery type and cancer stage.

A MULTIDISCIPLINARY APPROACH TO IMPROVING FUNCTIONAL ABILITIES IN A CHILD WITH DCD: A CASE REPORT

AFRICA, E., RAINSFORD, I., VAN BAALEN, G., CLOTHIER, J.
STELLENBOSCH UNIVERSITY

INTRODUCTION: Developmental Coordination Disorder (DCD), diagnosed around 5-6 years of age, significantly impacts gross motor development, affecting 5-6% of school-aged children globally and up to 15% in some South African regions, with a higher prevalence in boys (2-3:1 ratio). Children with DCD struggle in daily activities and academics due to motor skill difficulties, influenced by factors like poor postural control and proprioception¹. While physical activity is crucial, their engagement is often lower than peers, necessitating tailored strategies, including impairment-oriented programmes, perceptual-motor therapy, and kinaesthetic training, to optimize outcomes in fundamental movement skills, muscle development, and overall quality of life. This report represents a 12-year-old girl diagnosed with DCD to showcase the positive effects of a multi-disciplinary intervention on her everyday motor abilities. To the authors' knowledge, this is the first case-report of this nature.

METHODS: An InBody evaluation was used to accurately measure the client's body composition, with emphasis on the segmental lean analysis results. The Quick Neurological Screening Test, 3rd Edition Revised (QNST-3R) was used by a Kinderkineticist (Paediatric Movement Therapist) to test for the client's fundamental and gross motor abilities. In addition, various functional assessments were performed by a Biokineticist (Clinical Exercise Therapist).

RESULTS: The pre-and-post-test results showed the lean analysis percentage of the right and left arm changed from 108 and 106,5 to 112,4 and 109,6 respectively. The total score of the QNST changed from 38 during the pre- to 21 during the post-test. In terms of functional assessments, the largest improvements were seen in seated hip flexion (left & right) (pre: 10.3° & 14.3°; post: 19.8° & 22.1°), and external rotation (left) (pre: 13°; post: 19.5°).

CONCLUSION: The InBody segmental lean analysis results showed an increase in both the client's arms and core, although a slight decrease was recorded in both legs. The positive change observed in QNST-3R scores is clinically relevant and positive results were recorded in all the functional assessments done. The results suggest that a close collaborative approach to movement interventions might have a larger beneficial effect of enhancing the motor abilities, daily functioning, and quality of life in children with DCD and that this approach is more beneficial than a single disciplinary treatment approach. This approach may reduce long-term societal burdens, such as academic struggles, limited physical activity,

and related health issues. Research in this area raises awareness and highlights the importance of early intervention for better outcomes.

CAN WE COMPARE JUMP HEIGHT MEASUREMENTS ACROSS DIFFERENT FORCE PLATFORM SYSTEMS?

EYTHORSDDOTTIR, I., GLØERSEN, Ø., WERKHAUSEN, A., RICE, H., ETTEMA, G., SOLBERG, P., SEYNNES, O., PAULSEN, G.

THE NORWEGIAN SCHOOL OF SPORT SCIENCES

INTRODUCTION: Maximal vertical jump height is a key performance metric in research and athlete testing. Force platforms are the most common measurement tool, but systems vary across and within laboratories and sports clubs. Different force platform systems give rise to hardware and calculation (software) differences, which may impact data comparability. While prior research has examined force platform differences for some hardware solutions, to our knowledge, no studies have quantified discrepancies across multiple hardware and software solutions for several jump modalities. This study aimed to compare jump height measurements across four portable force platform systems for countermovement jumps (CMJs), squat jumps (SJs), and drop jumps (DJs).

METHODS: Twenty-seven participants (26.2 ± 3.8 yrs, 1.76 ± 0.08 m, 73.2 ± 11.2 kg) were included in this study. Four portable force platform systems were tested: Kistler, ForceDecks, MuscleLab, and HurLabs. Each force platform was placed on top of an in-ground reference force platform (AMTI) to concurrently measure ground reaction forces (GRFs) during SJs ($n=678$), CMJs ($n=667$), and DJs ($n=998$). 3D motion capture was collected for 14 of the participants (1426 jumps) as a secondary reference. Jump height was estimated using two analytical approaches. In the Hardware analysis, GRF data from each force platform (reference and portable) were processed using the same standardized algorithm. In the Software analysis, jump height was computed from the portable system using each system's built-in (proprietary) software, comparing it to the standardized algorithm. System differences were assessed using Bland-Altman comparisons, and typical error of estimate was evaluated. A one-way ANOVA detected significant differences between force platform systems across all jump modalities for both analyses, followed by a Tukey-Kramer post hoc test.

RESULTS: Across all jump types, systematic differences in jump height between portable systems and the reference system ranged from -2.9% to 3.8% for the Hardware analysis, with a typical error of 1.1% to 5.0%. The Software analysis showed larger systematic differences (-11.6% to 11.1%) and greater typical error (3.2% to 22.3%). Similar trends appeared when using kinematics as reference. The Tukey-Kramer post hoc test found significant differences ($p < 0.05$) across all force platforms and jump modalities in both analyses.

CONCLUSION: Jump height measurements varied significantly across different force platform systems, even when using identical jump protocols and calculation methods. Different force platform systems should be used interchangeably in this way with caution. Proprietary software calculations should not be assumed valid, and different software cannot be used interchangeably for jump height measures if accuracy below 2 ± 2 cm is important. The results of this study are useful to understand and interpret jump height measured from different commercial force platform suppliers.

ESTIMATION OF ENERGY EXPENDITURE IN TEAM GAME SPORTS VIA LOCAL POSITION SYSTEMS AND METABOLIC POWER MODEL VERSUS INERTIA MEASUREMENT UNITS

HUANG, I., BONT, P., FIOLO, N., WAGNER, H., FUCHS, P.X.

NATIONAL TAIWAN NORMAL UNIVERSITY

INTRODUCTION: Monitoring loads and energy costs (EC) is important, but obtaining EC via spiroergometry (gold standard) during competitions is not feasible, especially not in contact game sports. A unique method (metabolic power model) addressed this problem by estimating EC based on players' acceleration derived from a local position system (LPS) [1]. Since the method's accuracy has been debated despite model updates [2], inertia measurement units (IMU; often incorporated in LPS) may be an alternative or addition to estimate EC more accurately. The study aimed to compare EC estimations derived from spiroergometry, LPS, and IMU during a validated game sports test.

METHODS: Eleven professional female handball players completed a validated, team handball game-based performance test [3]. Data were collected via a portable spiroergometry system (K5 Cosmed) and an LPS with integrated IMU (Catapult ClearSky T6). Indirect calorimetry derived ECSpiro from spiroergometry data, and the updated metabolic power model estimated ECLPS based on position data (10 Hz). IMU data (100 Hz) were used to calculate horizontal, vertical, and total PlayerLoad [4]. Differences between ECs were examined via repeated-measures ANOVA (p $\leq$ 0.05). Pearson correlation coefficients (r) expressed the relationship between time- and body mass-normalized spiroergometry, LPS, and PlayerLoad data. Stepwise regression analysis (R²) explored the predictability of ECSpiro via metabolic power model and PlayerLoad. Significance level was set at $p < 0.05$.

RESULTS: ECSpiro (727 ± 87 J/kg/min) differed from ECLPS (266 ± 28 J/kg/min) ($p = .98$, $p < .001$) and did not significantly correlate with ECLPS ($r = .56$, $p = .07$). ECSpiro correlated with horizontal ($r = .68$, $p < .05$) but not with vertical ($r = .47$, $p = .15$) and total ($r = .57$, $p = .07$) PlayerLoad. A final regression model included only horizontal PlayerLoad ($R^2 = .46$, $p < .05$).

CONCLUSION: The large difference and insufficient correlation between ECSpiro and ECLPS advised against using ECLPS as the only estimate. PlayerLoad metrics demonstrated stronger correlations, suggesting greater potential for EC estimations than the metabolic power model. Combining ECLPS with PlayerLoad did not improve regression predictions due to strong co-linearity.

Regression analysis was statistically underpowered due to the limited sample size including only elite athletes to capture realistic dynamics. Nevertheless, the findings highlighted the significant discrepancy between ECSpiro and ECLPS, suggesting ECLPS unsuitable as a direct proxy for EC but not undermining its value for intra- and inter-subject comparisons.

SLEEP ARCHITECTURE IS ALTERED WITH TRAVEL AND MATCHES IN PROFESSIONAL RUGBY UNION PLAYERS

UCHIYAMA, K., PEELING, P., HALSON, S., REID, M., WALLMAN, K., WALSH, J., THOMAS, S., GIRARD, O.

UNIVERSITY OF WESTERN AUSTRALIA

INTRODUCTION: Field-based research highlights the susceptibility of elite team-sport athletes to irregular sleep patterns, particularly during competition due to travel and matches. Currently, field-based data is derived from wrist-worn activity monitors (tracking sleep-wake patterns) and subjective assessments, however, they cannot measure sleep architecture (i.e., sleep-staging). While polysomnography is the gold standard for sleep assessment, its use in ecological settings remains impractical. Advancements in wireless home-based polysomnography and commercial sleep technology now enable the measurement of sleep architecture outside of laboratory environments. Given that each sleep stage plays a role on next-day function and performance, assessing sleep architecture could offer valuable insights into the consequences of travel and matches during competition. Therefore, the aim of this study was to examine the effects of travel and matches by comparing the sleep quantity, quality, and architecture of professional male rugby players during a home and away match fixture.

METHODS: Twenty-six players, contracted for the Super Rugby season, were recruited for a prospective observational study. The experiment was conducted during the first two rounds of the competition to compare sleep (quantity, quality and architecture) across two conditions: a home (no travel; HOME) and an away (eastbound travel across three time zones; AWAY) match fixture, separated by eight days. Sleep data was collected using home-based polysomnography over three nights per condition: two nights preceding the match (MD-2), match night (MD), and the following night (MD+1). Sleep quantity (sleep duration), quality (sleep efficiency), and architecture (sleep onset/offset, latency, wake after sleep onset, awakenings, and sleep stages) were monitored. Sleep stages (light, deep and rapid eye movement [REM] sleep) were evaluated as proportion (%) and duration (min).

RESULTS: Twenty athletes participated in the study (age: 27.5 ± 4.1 years; height: 185.4 ± 7.1 cm; body weight: 99.6 ± 12.3 kg; positions: 9 forwards and 11 backs), with sleep data collected from 69 out of the 120 nights. Compared to HOME, AWAY increased sleep onset latency ($+12 \pm 23$ min; $p < 0.01$) and altered sleep architecture (light: $-6.2 \pm 7.1\%$; $p < 0.01$). Regardless of condition, MD incurred delayed bedtime ($+71 \pm 135$ min; $p < 0.001$), reduced sleep duration (-94 ± 120 min; $p < 0.05$) and altered sleep architecture (deep: $+9.8 \pm 10.0\%$; REM: $-6.9 \pm 8.3\%$; both $p < 0.05$) compared to MD-2. On MD+1, sleep duration ($+96 \pm 147$ min; $p < 0.01$), and time in light and REM sleep all rebounded (light: $+52 \pm 44$ min; REM: $+39 \pm 52$ min; both $p < 0.05$) in both conditions.

CONCLUSION: Professional male rugby union players experience alterations in sleep quantity, quality, and architecture on nights surrounding both home and away matches, with variability among players. Teams should arrange in-season training and flight schedules to ensure adequate sleep opportunity to optimise recovery.

LOAD-VELOCITY PROFILING AS A PREDICTOR OF 50 M SPRINT PERFORMANCE IN 11-YEAR-OLD SWIMMERS: INSIGHTS ACROSS ALL FOUR STROKES

LJØDAL, I., REICHMANN, F.3, GONJO, T.1,4, OLSTAD, B.H.1

AFFILIATIONS: 1NORWEGIAN SCHOOL OF SPORT SCIENCES, OSLO, NORWAY. 2UNIVERSITÉ DE ROUEN, NORMANDIE, FRANCE. 3ZURICH UNIVERSITY OF APPLIED SCIENCES WINTERTHUR, SWITZERLAND. 4HERIOT-WATT UNIVERSITY, EDINB

INTRODUCTION: Load-velocity profiling has been shown to predict sprint performance in elite swimmers [1], yet its potential in adolescent swimmers remains unexplored. Identifying performance-related characteristics at an early stage could provide valuable insights for talent identification and training optimisation. This study examines the relationships between load-velocity profiles and 50 m sprint performance in 11-year-old swimmers across all four swimming strokes.

METHODS: A repeated cross-sectional design was employed with 147 11-year-old swimmers (44 boys, age 11.2 ± 0.5 y, height 152.4 ± 6.9 cm, weight 43.6 ± 7.6 kg, and 103 girls, age 11.2 ± 0.5 y, height 153.1 ± 7.0 cm, weight 42.2 ± 6.8 kg). Sprint performance was recorded with an automated race analysis system (AIMsys, Lund, Sweden), to obtain 50 m velocity (V50)

and time (T50) in a 25 m pool. Load-velocity data was collected using a robotic resistance device (1080 Motion, Lidingö, Sweden), where swimmers performed three maximal semi-tethered 25 m sprints with increasing resistance (~1, 2, 3 kg). A 5 m segment (10-15 m) was analysed for mean velocity, and load-velocity profiles were modelled using linear regression to determine theoretical maximum velocity (V0), theoretical maximum load (L0), and relative L0 (rL0, normalized to body mass). Pearson's (parametric) and Spearman's (non-parametric) correlation coefficients examined relationships between V0, L0, rL0 and T50, V50.

RESULTS: V0 showed very large correlations with both T50 and V50 across all strokes. In front crawl, correlations were -0.796, $p < 0.001$ for T50 and 0.819, $p < 0.001$ for V50. In backstroke, correlations were -0.724, $p < 0.001$ for T50 and 0.784, $p < 0.001$ for V50. Breaststroke showed correlations of -0.629, $p < 0.001$ for T50 and 0.772, $p < 0.001$ for V50. In butterfly, correlations were -0.758, $p < 0.001$ for T50 and 0.795, $p < 0.001$ for V50. Large correlations were found for L0 and rL0 with both T50 and V50 in front crawl and backstroke: T50 (front crawl L0 -0.556, $p < 0.001$ and rL0 -0.503, $p < 0.001$, backstroke L0 -0.534, $p < 0.001$ and rL0 -0.524, $p < 0.001$). V50 (front crawl L0 0.564, $p < 0.001$ and rL0 0.537, $p < 0.001$, backstroke L0 0.613, $p < 0.001$ and rL0 0.619, $p < 0.001$). Breaststroke showed small correlations between L0 and both T50 (-0.171, $p < 0.05$) and V50 (0.204, $p < 0.05$). Butterfly L0 showed moderate correlations with both T50 (-0.318, $p < 0.001$) and V50 (0.314, $p < 0.001$).

CONCLUSION: V0 strongly predicts 50 m sprint performance across all strokes in 11-year-old swimmers. L0 and rL0 are strong performance indicators in front crawl and backstroke, but less relevant in breaststroke and butterfly. Thus, load-velocity profiling is a valuable tool for assessing sprint performance in 11-year-old swimmers, particularly in front crawl and backstroke. Future research should investigate training interventions targeting load-velocity parameters to optimise adolescent sprint performance.

SEX DIFFERENCES IN THE SLEEP DEPRIVATION EFFECT ON MUSCULAR STRENGTH, POWER AND ENDURANCE PERFORMANCE IN RESISTANCE-TRAINED PARTICIPANTS

DEL VAL MANZANO, M., MONTALVO-ALONSO, J.J., GONZALO-ENCABO, P., VALADÉS, D., FERRAGUT, C., PÉREZ-LÓPEZ, A.
UNIVERSIDAD DE ALCALÁ

INTRODUCTION: Nightly rest is essential for preserving both physical and mental health. Despite its importance, nearly 45% of adults in Western countries do not achieve the recommended 7 to 9 hours of sleep per night. This is of special interest in athletes who have a higher predisposition to experiment with poor sleep or sleep deprivation, which cause a reduction in exercise performance. However, the effect of sleep deprivation on exercise performance is mainly obtained from evidence in men. Thus, this study aimed to examine sex differences in the impact of total and partial sleep deprivation on muscular strength, power, and endurance performance in resistance-trained participants.

METHODS: Twenty-four resistance-trained participants (age: 22.1 ± 3.3 years; sex (F/M): 12/12; training experience: 3.4 ± 2.4 years) took part in a randomized, cross-over and counterbalanced trial with four sleep conditions: 8h normal sleep at home (SH) and the remaining three at the laboratory: normal sleep 8h (SL), early sleep deprivation 4h (pSD) and sleep deprivation 0h (SD). After each experimental condition, participants performed a muscular strength and power, and muscular endurance tests in the bench press and back squat exercises using a linear transducer. The muscular strength and power test was performed at 25%, 50%, 75%, 90% and 100% of 1RM loads, while the muscular endurance test was assessed for both exercises at 65% 1RM, performing one set until task failure. Velocity and power production were obtained in all tests. Dietary and physical activity habits were replicated 24 hours before the trials.

RESULTS: In the muscular strength and power test at 50%1RM, a condition effect was found in both bench press and back squat exercises for Vmean, Vpeak and Time to Vpeak ($P < 0.048$, $\eta^2 > 0.10$). These effects were only found in male participants when comparing in both exercises SH and SL to pSD in Vmean (11-12%, $P < 0.048$), Vpeak (7-10%, $P < 0.049$) and time to reach Vpeak (-7-15%, $P < 0.049$), and SL to SD in back squat exercise for Vmean (10%, $P = 0.048$), Vpeak (7%, $P = 0.008$) and time to reach Vpeak (-11%, $P = 0.050$). In muscular endurance test, condition effect was found in the back squat exercise for Vmean, Vmax, Time to Vpeak, Wmean, Wpeak, and time to Wpeak ($P < 0.01$, $\eta^2 < 1.61$), differences that were only found in female participants when comparing SH and SL to pSD and SD in Vmean (10-12%, $P < 0.025$), Vpeak (9-12%, $P < 0.02$), Time to Vpeak (-13-15%, $P < 0.05$), Wmean (10-11%, $P < 0.05$), Wpeak (11-14%, $P < 0.04$) and time to Wpeak (-14-16%, $P < 0.05$).

CONCLUSION: In conclusion, performance reduction in muscular strength, power and endurance performance caused by total and partial sleep deprivation occur differently according to sex. While male participants experienced a reduction in muscular strength and power performance, particularly at moderate loads (50%1RM), in females the reduction in performance occurred in muscular endurance test.

THE REMOTE EFFECTS OF FOAM ROLLING: EVIDENCE OF MYOFASCIAL CHAINS?

PINTO, G., DI BARTOLO, L., SCARDINA, A., NAKAMURA, M., WARNEKE, K., PATTI, A., BELLAFFIORE, M., BIANCO, A., THOMAS, E.

UNIVERSITY OF PALERMO

INTRODUCTION: Foam rolling (FR) is widely used to enhance joint range of motion (ROM). However, limited evidence is available regarding the remote effects of FR. Thus, this study aims to examine the acute local and remote effects of FR,

with this being performed on the right knee flexors (RKF) and relevant outcomes being also measured in the cervical spine.

METHODS: Eighteen participants (26.3 ± 4.87 years, 169 ± 9.63 cm, 66.4 ± 14.5 kg) were recruited. Each participant underwent two conditions in a randomized order: a control (CC) and a FR intervention. In the FR session, participants performed 4 sets of 30 rolls (15 in each direction) with a 30 seconds rest between sets in the RKF using a GRID surface roller. Outcome measures were skin temperature (TsK), tissue hardness (TH) and ROM. Data were assessed upon arrival (T0) and immediately after the sessions (T1). The environmental temperature was standardized at 24° C. Before starting the first session, anthropometric measures were taken. Participants then underwent a 15-minute acclimatization period lying on a medical bed in a prone position. Afterward, TsK and TH were measured in the RKF (both the biceps femoris (BF) and semitendinosus (ST)) and the cervical region (to the right and left of C7) using an infrared thermal camera and a portable TH meter, respectively. Then, active hip flexion and cervical (flexion, extension, rotation and inclination movements) ROM were measured using a Gyko inertial sensor system. In the CC session no intervention was applied, and participants were asked to lie on a medical bed in a prone position for 4 minutes. Immediately after each session, all measurements were re-evaluated (T1) and compared to the T0.

RESULTS: Our results showed that hip flexion ($p < 0.001$), cervical flexion and extension ($p < 0.001$), right and left rotation ($p < 0.001$), as well as right ($p < 0.001$) and left ($p = 0.003$) inclination ROM, significantly increased only for the FR intervention. Conversely, TH significantly decreased in BF, ST ($p < 0.001$) and right cervical region ($p = 0.030$) but not in left cervical region ($p = 0.287$) for FR. Lastly, RKF TsK significantly decreased ($p = 0.019$) for CC, while no effect was observed ($p = 0.242$) for FR, with no changes in cervical TsK.

CONCLUSION: The FR intervention acutely improved local (right hip flexion) and remote (cervical) ROM. A reduction of tissue hardness was associated with the ROM increase both locally and in a remote region, with no variations in skin temperature. Our results suggest that the remote ROM improvement may be attributed to strain transfer along a myofascial meridian rather than a warm-up effect.

EFFECT OF HAMSTRING ECCENTRIC PRECONDITIONING ON MUSCLE DAMAGE INDUCED BY A STRENUOUS REPEATED-SPRINT TASK IN MALES AND FEMALES

DEMEUSOY, P., BONTEMPS, B., ERSKINE, R.M., NICOL, C., PIPONNIER, E.

AIX-MARSEILLE UNIVERSITÉ

INTRODUCTION: Repeated sprints are crucial regarding physical performance in many sports but result in reversible hamstring muscle damage (HsMD) (1). In females, the hamstring-to-quadriceps ratio decreases at high knee angular velocities (2), which could lead to greater HsMD following sprinting. Eccentric preconditioning is reported to reduce muscle damage in response to subsequent exercise - a phenomenon known as the repeated bout effect. Thus, this study aimed to investigate whether performing a hamstring-specific eccentric exercise a few days before a repeated-sprint task could attenuate HsMD to a greater extent for females than males.

METHODS: Participants were randomly assigned to either a preconditioning (PC; $n=21$; 11 females; age= 20.1 ± 2.1) or a control group (CT; $n=22$; 11 females; age= 20.6 ± 3.1) and underwent 3 visits scheduled according to the menstrual cycle. The first visit included a familiarisation with the procedures but only the PC group performed a preconditioning exercise (4x10 eccentric hamstring contractions). Fourteen days later, participants performed a repeated sprint task (3 sets of 5x30m) (1). To assess the acute and delayed effects of HsMD, participants were tested before (PRE), immediately after (POST) and two days (2D) after the strenuous sprinting task. Indirect markers of HsMD included muscle soreness (MS; assessed via visual analogue scale), muscle swelling (decreased echo-intensity; EI), maximal voluntary isometric torque (MVT) and low-frequency fatigue (myostimulation trains: 10-50Hz; T10 to T50). Linear mixed models were performed fitted with time, group and sex as independent factors and participant as random intercept.

RESULTS: No significant differences were found between PC and CT groups over time for any of the measures. Regardless of group, MVT decreased by $-13.4 \pm 8.9\%$ ($p < 0.001$) at POST and $-4.4 \pm 9.1\%$ ($p < 0.01$) at 2D, respectively. Evoked responses to T10, T20 and T30 decreased at POST ($-9.6 \pm 23.6\%$, $-15.0 \pm 19.6\%$, $-7.6 \pm 12.8\%$; $p < 0.05$) but returned to baseline at 2D, in all groups. A time x sex interaction effect was found for EI and MS. Only females showed significant loss of EI (i.e. increased muscle swelling) at 2D ($-5.8 \pm 5.0\%$; $p < 0.001$). Moreover, females showed increased MS at POST and 2D ($+2.9 \pm 2.4$ and $+3.6 \pm 2.8$, respectively; $p < 0.05$), whereas MS increased only at 2D for males ($+2.2 \pm 1.5$; $p < 0.05$).

CONCLUSION: Our results do not support a repeated bout effect from hamstring-specific eccentric preconditioning against future HsMD induced by repeated sprinting. Nevertheless, only females showed indirect signs of hamstring swelling at 2D (associated with increased MS), which reinforces their higher sensitivity to HsMD (3). These findings highlight the necessity for sex-specific strategies to prevent HsMD. For females, longitudinal eccentric training may serve as an effective approach to mitigate HsMD following running-based activities.

STRENGTH VARIABILITY AND UPPER BODY COMPOSITION: A COMPARATIVE ANALYSIS ACROSS EXERCISES

BURGER, C., FISCHER, J., MANIEU SEGUEL, J., RODOPLU, C., KONRAD, A.

INSTITUTE OF HUMAN MOVEMENT SCIENCE, SPORT AND HEALTH

INTRODUCTION: Assessing body composition, particularly muscle morphology, can help coaches predict strength outcomes in athletes and evaluate their training status [1]. The relationship between muscle strength and muscle morphology is less studied in the upper body. Thus, the purpose of this study was to measure the 10-repetition maximum (10RM) strength performance during the bench press (BP) and the horizontal row (HR), and determine a correlation between muscle mass, muscle stiffness and anthropometrics.

METHODS: Twenty-one resistance-trained males visited the laboratory for three sessions, during which the cross-sectional area (CSA) of the pectoralis major and triceps brachii, as well as muscle thickness (MT) of the biceps brachii and trapezius transversus, were assessed using 2D ultrasound imaging. Muscle stiffness was evaluated using shear wave elastography (SWE) at multiple sites. Upper-body anthropometrics, including biacromial distance, chest girth, upper arm length, and arm span width, were measured at key anatomical landmarks. Participants further performed the 10RM tests for the BP and HR. Data normality was tested with the Shapiro-Wilk test, using Pearson's correlation for normal and Spearman's correlation for non-normal distributed data.

RESULTS: Strong correlations were observed between pectoralis major CSA (i.e., medial and lateral point) and BP 10RM strength ($r = 0.80 - 0.82$, $p < 0.001$), while proximal triceps CSA showed a moderate correlation ($p = 0.49$, $p = 0.027$), with no significant relationship for distal CSA. For HR 10RM strength, no correlations were found with trapezius MT (i.e., area, medial and thickest point), but moderate to strong correlations were identified with biceps brachii MT at the proximal ($r = 0.61$, $p = 0.006$) and distal ($r = 0.56$, $p = 0.013$) sites. BP 10RM correlated significantly with chest girth ($r = 0.57$, $p = 0.007$) and biacromial distance ($r = 0.59$, $p = 0.005$), while HR 10RM correlated with chest girth ($r = 0.61$, $p = 0.006$), upper arm length ($r = 0.52$, $p = 0.022$), and span width ($r = 0.51$, $p = 0.025$). Regarding stiffness, strength and morphology, no correlation was found for any of these outcomes.

CONCLUSION: These findings emphasize pectoral muscle mass as a key contributor to BP strength [2] and biceps brachii to HR strength. SWE muscle stiffness in the upper body at rest showed no link to strength performance, suggesting stiffness may not be critical for strength adaptations. This was also confirmed in interventional studies, whereas resistance training did not consistently result in stiffness increases in the muscle [3]. Upper-body width may predict BP strength, while arm length and chest girth may serve as HR strength indicators.

ARE BODY COMPOSITION ESTIMATES AFFECTED BY THE MENSTRUAL CYCLE IN FEMALES WITH OR WITHOUT HORMONAL CONTRACEPTION? - A CASE-CONTROL STUDY

SCHULTZ, L., STEIN-BRÜGGEMANN, D., FÜRST, J., KIEFER, K.M., SCHRÖDER, J.

MEDICAL SCHOOL HAMBURG

INTRODUCTION: The menstrual cycle (MC) is characterized by rapid changes in female sexual hormone concentrations, resulting in subsequent water retention alterations, which may affect the estimates of body composition (BC) parameters [1]. Thus, MC phase-dependent variations in BC measurements might be expected in females for bioelectrical impedance analysis (BIA) or air-displacement plethysmography (ADP), but not for skin-fold calipometry (CAL).

This study aimed to evaluate the accuracy of BC estimates during a regular MC by means of BIA, ADP, and CAL in females with or without hormonal contraception, with males serving as a control group [2], and to examine the impact of hormone-induced water retention on these measurements.

METHODS: In a case-control design, BC was determined using BIA, ADP and CAL in 54 participants (age 18-33; BMI 17.0-27.8) divided into females using hormonal contraceptives (HC) ($n=19$), eumenorrheic females using non-hormonal contraceptives (no-HC) ($n=17$) and males ($n=18$). In a repeated measure design with four cycle-related time points (t1-t4) a complete MC was covered (t1: start of menstruation, t2: late follicular, t3: ovulation, t4: mid-luteal).

Fat mass (FM), fat-free mass (FFM) and bodyfat (BF%), as well as total body water and extracellular water served as BIA outcomes for statistical analyses. Body weight, body volume, BF%, FM and FFM served as dependent ADP parameters and BF% served as the CAL dependent variable for latter statistical analyses.

RESULTS: There were only small intraindividual BC variations during the MC (CV% 0.5-5.2) and neither significant time effects within any group ($p=0.065-0.939$) nor significant time*group interactions ($p=0.151-0.956$) for all measuring devices in any BC parameter.

CONCLUSION: Hormone-induced water retention during the MC did not affect BC estimates of ADP, BIA and CAL or were too small to influence the estimates of the devices neither in females with HC nor in females with no-HC. Thus, female athletes do not have to consider their menstrual phase when assessing their BC in their athlete monitoring.

PERFORMANCE INDICATORS OF BALL HANDLER'S DECISION-MAKING IN BASKETBALL

CHEN, C., LIU, Y.T.

NATIONAL TAIWAN NORMAL UNIVERSITY

INTRODUCTION: In the team sport of basketball, passing decisions significantly influence cumulative scoring and achieving victory. Ball handlers determine their following action based on the positions of teammates and defenders. The outcomes of these decisions are often reflected in the defenders performance. Performance indicators in the notational analysis of sports usually refer to successful actions or outcomes. This study aims to investigate ball handlers decision-making performance indicators through notational analysis.

METHODS: Six group-stage matches from the FIBA 3x3 U23 World Cup womens division, featuring the top six and bottom six teams, were analyzed. The Simi Scout notational analysis software was used to record the outcomes of defensive actions following ball handlers decision-making (steals, effective defensive positioning, or defensive failure). Intra-observer reliability was tested using Cohen's Kappa. Statistical analyses were performed using Jamovi 2.3.28.0. One-tailed independent samples t-tests were conducted to compare the quantity and proportion of defensive outcomes between the top and bottom six teams.

RESULTS: Intra-observer reliability was found to range from 0.798 to 0.978. Regarding the number of defensive outcomes, the top six teams demonstrated a significantly higher number of defensive failures by opponents than the bottom six teams ($p = 0.028$). However, no significant differences were observed in the other two defensive outcomes. Regarding proportions, the top six teams exhibited a significantly higher proportion of defensive failures by opponents ($p = 0.043$) and a significantly lower proportion of steals by opponents ($p = 0.026$) compared to the bottom six teams.

CONCLUSION: Using basketball's defensive outcomes as performance indicators of ball handlers decision-making, it was found that ball handlers from top-performing teams generated more open opportunities due to defensive failures and experienced fewer turnovers from steals. Opponents defensive actions can also be used as performance indicators of ball handlers decision-making. Beyond team-based comparisons, this method could also assess changes in athletes decision-making abilities before and after training.

THE REINVENTION OF BEACH VOLLEYBALL - PREVALENCE AND EFFECTIVITY OF THE SWEDISH JUMPSET

LINK, D.

TECHNICAL UNIVERSITY MUNICH

INTRODUCTION: In the last years, the Swedish world class Team Ahmann / Hellvig (AH) reinvented beach volleyball by introducing the so-called "Swedish Jumpset". On the second ball contact, they create two Second Ball Options (SBO) either a) by attacking the second ball or b) by faking an attack on the second ball and playing a fast jumpset to the teammate. This style causes massive temporal pressure on the opponent block player in moving to the correct blocking position. This study focusses on seven research questions including i) how of-ten and in which situations do AH create SBO, ii) which factors influence the decision second ball attack vs. jumpset, iii) is setting quality reduced in SBO?, iv) is block quality reduced in SBO, v) how do AH attack in SBO, vi) how effective is attack in SBO, vii) are opponents able to adapt to this playing style?

METHODS: In order to answer these research question, we analyzed 34 matches on world tour 2021-2023 (19 won, 15 lost). The sample includes pairs of matches against the same team (ear-ly match, second match around one year later). Notational analysis based on video re-cordings uses a compressive observational system including performance variables as-sociated with SBO, such as position of contacts, quality of reception, setting, block and at-tack as well as direction of the attack and temporal variables.

RESULTS: Results show a surprisingly high ratio of situations with SBO (50,5%). Against power serve on Ahman, SBO rate is decreased (50.7% vs. 59.3%) Both players chose the attack-ing option on contact 2 more often (66%) than playing a jump set (34%). There are nor hints towards setting problems when using jump set. Block quality against attack on con-tact 2 is quite low (only 35% in time). On optimal receptions, kill rate ion SBO is increased by ~12% compared to non SBO situations. Opponents were less successful in blocking against AH in the second match.

CONCLUSION: AH used the "Swedish Jumpset" very often. By doing this, they reduced back quality without introducing inaccurate setting. This leads to an increased attacking success compared to non SBO situations. Most opponents were not able to create countermeasures in the second match. Attacking success suggests that AH were only able to establish themselves under the world top teams, because of the use of this tactical-technical mean.

ANALYSIS OF PHYSICAL AND PERFORMANCE METRICS IN CZECH WOMENS LACROSSE TEAMS IN PREPARATION FOR THE 2028 OLYMPICS

CASRI, T., NOVAKOVA, M., PEKNY, M., CUNAT, M.

CASRI

INTRODUCTION: With lacrosse returning to the Olympics in 2028, this study aims to examine the physical and performance characteristics of elite Czech women's lacrosse players and compare them with previously published results for their NCAA Division I and III counterparts in the US. The goal is to identify areas for improvement and align with the performance standards set by advanced lacrosse programs such as those in the United States.

METHODS: The study included Czech national team players (N=24) and club players (N=41), measuring metrics such as body weight, height, skeletal muscle percentage, body fat percentage, and performance tests including shooting speed. Performance evaluations also involved countermovement jumps without added weight and with 20 kg and 40 kg weights, as well as static jumps with a 40 kg load. Our findings were compared with existing NCAA data to identify training gaps and standardize training practices.

RESULTS: There were significant physical and performance disparities between Czech players and their NCAA counterparts. Specifically, the shooting speed for Czech national players was recorded at 87.84 km/h (± 12.63 km/h), considerably lower than the 129.02 km/h (± 16.42 km/h) observed for NCAA Division I athletes. Additionally, the countermovement jump for Czech players was 29.1 cm (± 4.2 cm) compared to 44 cm (± 6.2 cm) for NCAA Division I. Somatic differences were also notable with Czech players averaging a height of 169.3 cm (± 6.2 cm), weight of 67.42 kg (± 11.1 kg), and body fat percentage of 23.2% ($\pm 5.3\%$), which contrasts with their NCAA Division I and III counterparts. These findings underscore the need for targeted training improvements to reach competitive standards set by top-tier U.S. programs.

CONCLUSION: The findings indicate significant disparities in physical characteristics and performance outputs between Czech women's lacrosse players and their NCAA counterparts. This knowledge is crucial for optimizing the preparation of Czech players for the 2028 Olympics.

THE ROLE OF EXTERNAL POWER IN ASSESSING NEUROMUSCULAR LOAD IN PROFESSIONAL RUGBY MATCHES

BOTTER, A., MANIERA, M., OSGNACH, C., DI PRAMPERO, P.E., MORIN, J.B., PAVEI, G.

BENNETTON RUGBY TREVISO

INTRODUCTION: The precise measurement of mechanical load in rugby is crucial for optimising player performance, controlling fatigue, and minimising the risk of injury. Conventional metrics that assess acceleration and velocity independently do not adequately consider their combined impact on high-intensity movements during gameplay. This study introduces the external power approach [1], based on individual acceleration-speed profiles (ASP) to provide a more thorough analysis of player workloads [2].

METHODS: Data were gathered from 51 professional rugby official matches across two seasons using a GPS system (gpxe Pro², 18.18 Hz). Acceleration events (accs) and distances (D-acc) exceeding 2.5 m/s² were evaluated alongside the external power parameters, which combine acceleration and velocity, for a more effective assessment of mechanical load; based on the individual ASP, bursts and external mechanical work surpassing 80 % of the maximum power output across the entire speed spectrum were calculated.

RESULTS: Regardless of playing time, the number of accs and the corresponding D-acc per unit of time were 0.47 events/min and 0.82 m/min, respectively. In contrast, the external power approach provided a more precise and tailored assessment of neuromuscular load. Indeed, the number of bursts was 0.21 events/min, corresponding to a mechanical energy output, above the 80 % power threshold, of 205.8 J/kg for an overall playing time of about 89 minutes.

CONCLUSION: Traditional acceleration metrics frequently misrepresent and overestimate player demands by disregarding the influence of initial velocity, leading to an erroneous classification of high-intensity efforts [1].

A comparison of match workload patterns between rugby and soccer players [2] further clarifies this situation. Due to the lower starting speed of plays in rugby, the number of accelerations is generally greater than that in soccer for the same number of bursts. This implies that certain runs exceeding 2.5 m/s² in rugby do not necessarily require a substantial amount of effort since the low initial velocity facilitates surpassing the acceleration threshold. Indeed, the average ratio accs/bursts for rugby and soccer players is 2.06 and 0.58, respectively. This indicates that, relying solely on the acceleration number, the most demanding actions experienced by the players are overestimated in rugby and underestimated in soccer.

By addressing the limitations of traditional metrics, the external power approach presents a more accurate method for assessing mechanical load in rugby. This model supports improved monitoring, targeted training strategies, and performance optimisation while mitigating injury risk.

SPORT-SPECIFIC AND INDIVIDUAL DETERMINANTS OF THE ENERGY COST OF CONSTANT SPEED RUNNING IN TEAM SPORTS

VENZKE, J., SCHÄFER, R., PLATEN, P.

RUHR-UNIVERSITY BOCHUM

INTRODUCTION: Metabolic Power has emerged as a valuable metric for assessing the physical demands of team sports, considering both speed and acceleration to provide a comprehensive view of energy expenditure. However, accurately determining the energy cost of constant speed running (EC₀) remains crucial for refining these estimations and improving player load management. The energy cost of constant speed running, a key component of this approach, is influenced by factors such as running velocity and VO₂max. While traditionally determined from steady-state oxygen consumption, EC₀ may differ between athlete groups due to specific training adaptations. A more precise estimation of energy expenditure based on positional data will enhance player monitoring, training recovery, and load management in team sports.

METHODS: An experimental cohort study was conducted, with data collected from 368 incremental treadmill tests across different team sport athletes to determine the energy cost of constant speed running. 15 sport students, 12 elite male handball players, 24 elite male field hockey players, 197 elite female field hockey players and 121 elite male soccer players. Athletes performed a treadmill protocol to exhaustion while oxygen uptake, CO₂ output, respiratory exchange ratio and ventilation was measured breath-by-breath. Data processing included verifying steady-state conditions, net EC₀ was calculated from the energy expenditure above resting divided by the speed. Type of sports, velocity, and VO₂max were defined as fixed effect variables.

RESULTS: Our random intercept and slope model with all predictors performed best. Sport students had the highest EC₀ (estimated total mean, in J/kg/m) with 4.12 CI95% 3.91, 4.18 followed by handball players (4.05 CI95% 3.97, 4.28), field hockey players (3.98 CI95% 3.99, 4.03) and soccer players (3.60 CI95% 3.51, 3.69). However, the increase seems to be rather curvilinear with a decrease in EC₀ starting at a velocity of 3.5 m/s (see Figure 2). If the sample is split into smaller groups and only athletes who complete the same steps are compared, the EC₀ stays constant over different velocities. Athletes with a higher VO₂max exhibit lower RER values at the various speed levels compared to athletes with a lower VO₂max.

CONCLUSION: The original approach established an EC₀ value of 3.6 J/kg/m based on mountain endurance runners, which was later refined to 4 J/kg/m. Our data suggest that multiple predictors must be considered to determine an appropriate EC₀ for each individual athlete. Although EC₀ remains relatively constant across different velocities for a given athlete, it varies significantly across sports and VO₂max levels, highlighting the need for individualized assessments. Ideally, EC₀ should be calculated for each athlete to ensure accuracy in energy cost estimations. These findings may enhance the accuracy of the Metabolic Power approach and enable a more precise analysis of metabolic data based solely on positional tracking.

KEY PERFORMANCE INDICATORS IN ELITE BLIND AND PARTIALLY SIGHTED FOOTBALL.

LEIVERS, H.1, TIMMIS, M.1, ALLEN, P.1, RUNSWICK, O.2

1. ANGLIA RUSKIN UNIVERSITY 2. KINGS COLLEGE LONDON

INTRODUCTION: Athletes with vision impairment compete within three adapted forms of futsal: (1) male blind football, where players, at best, can perceive light; (2) partially sighted football, where individuals use their remaining sight; and (3) female blind football, where athletes compete together. Key performance indicators (KPIs) for scoring and winning in these forms of the sport are currently unknown. The study aimed to identify KPIs in elite blind and partially sighted football.

METHODS: Notational match analysis of 39 male blind, 18 female blind and 15 partially sighted world championship matches were conducted. Team win ratio was calculated by dividing the number of games won by the number of games played. The impact of team strategy was assessed by hybrid KPIs such as total ball possession index (TBPI), defensive ball possession index (DBPI) and offensive ball possession index (OBPI). Separately, hybrid and notational data were used within linear mixed models to identify significant predictors of a team's win ratio.

RESULTS: Male blind football: possession (%), attacking third entries and open play passing success (%) were significantly predictive of win ratio. Open-play passing success (%) had the most significant impact on a team's win ratio. Female Blind football: win ratio was significantly predicted by open play passing success, possession, attacking third entries, players used, and total shots. Attacking third entries had the greatest impact on a team's win ratio. Partially sighted: the number of VI players who competed within a game per team significantly predicted win ratio; open-play passing success was trending towards significance but did not reach this threshold. TBPI, OBPI and DBPI were significant predictors of win ratio for blind (male and female) and partially sighted football. In each version of the sport, OBPI had the greatest impact.

CONCLUSION: In male-blind football, teams with greater passing success are likely to make it more difficult for opposing players to orient the balls location and attempt to regain possession whilst impacting the oppositions defensive positioning, which could lead to a team's improved chance creation and therefore correspond to improved offensive performance. Female blind football teams that employ an offensive game strategy will likely be more successful. This supported by attacking third entries being strongly predictive of win ratio and suggesting regular pressure on opposing teams contributes to greater success. The physical demands of futsal may explain why squad rotation was such a key performance

metric, as the world championships were a knockout competition, and players competed frequently over a short period, possibly contributing to physical fatigue. Therefore, teams that could rotate their squads could maintain these effects more regularly on their physical performance.

RUNNING ECONOMY OF ELITE DISTANCE RUNNERS DURING PROLONGED RUNNING IN ADVANCED FOOTWEAR TECHNOLOGIES

SCHWALM, L., FOHRMANN, D., SCHAFFARCZYK, M., GRONWALD, T., HOLLANDER, K.
MSH MEDICAL SCHOOL HAMBURG

INTRODUCTION: Since the introduction of advanced footwear technologies (AFTs) in 2016, all world records from 5km to the marathon have been broken (1). This is due to an improved running economy (RE) with AFTs (2). To this date, these improvements have been investigated only during short running bouts, while there are indications that performance effects may be greater over longer distances (3). The aim of this study was to compare RE during a 90min run in AFTs compared to lightweight trainers (non-AFTs) in elite distance runners.

METHODS: Nine elite distance runners visited our laboratory on two separate sessions within 14 days. In each session, they performed a submaximal threshold assessment treadmill test, followed by a 90min run below the first lactate threshold. Blood lactate concentration (BLa) as well as ratings of perceived exertion (RPE) were assessed every 15min. Mean $\dot{V}O_2$ determined during the last 3min of each 15min period was expressed as RE. We used linear mixed effects models (with random intercepts for participants) to examine the effects of time, shoe condition, and their interaction on energetic and oxygen cost of transport (ECOT and OCOT). Post hoc pairwise comparisons of estimated marginal means were performed using Tukey's correction.

RESULTS: The nine participants (55.6% females, age: 32.4 ± 8.4 y, body mass index: 20.8 ± 1.2 kg/m²) had a highest achieved world athletics score of 929.9 ± 83.8 points which corresponds to 10km times of 30:17 and 36:09min for males and females, respectively. ECOT and OCOT were lower in AFTs (ECOT: $2.8 \pm 0.7\%$, $p < 0.001$, $\beta = 0.56$ [0.41 to 0.71]; OCOT: $1.9 \pm 0.9\%$, $p < 0.001$, $\beta = 0.40$ [0.26 to 0.55]). ECOT and OCOT increased over time (ECOT: $p < 0.001$, $\beta = 0.40$ [0.30 to 0.51]; OCOT: $p < 0.001$, $\beta = 0.33$ [0.23 to 0.44]) from minute 15 to 90 (ECOT: $6.1 \pm 3.7\%$; OCOT: $5.3 \pm 3.7\%$) but these changes did not differ between shoes (time x shoe interaction: ECOT: $p = 0.809$; OCOT: $p = 0.649$). RPE was lower in AFTs up to 60min ($p = 0.007$, $\beta = 0.40$ [0.16 to 0.64]), while BLa did not differ between shoe conditions at any time point ($p = 0.908$).

CONCLUSION: Although the change of RE during the 90min run did not reveal statistical differences between shoe conditions, AFTs maintained their beneficial properties over time. The duration and intensity of the exercise may have been too small to reveal differences in RE deterioration between shoe conditions over time. Therefore, AFTs are probably a good choice for long distances, but future studies should investigate the effects of AFTs during more intense and even longer running.

INVESTIGATION OF THE EFFECT OF CYBERDYNE HAL LUMBAR AND TECNOBODY D-WALL COMBINED EXERCISES ON EXPLOSIVE POWER IN HEALTHY INDIVIDUALS

AÇAR, G., SEYHAN, S., UZUMCU, B., BIYIKLI, T.
MANISA CELAL BAYAR UNIVERSITY

INTRODUCTION: Jump, a significant component in the assessment of explosive power, constitutes a fundamental element of sporting performance. The squat jump (SJ) is a prevalent evaluation method employed to ascertain lower extremity strength, explosive power and balance. In recent years, there has been a notable advancement in the integration of advanced technologies into exercise and rehabilitation processes. In this context, a study was conducted to analyze the effects of the Cyberdyne Lumbar HAL and TecnoBody D-Wall systems on jump performance. The Cyberdyne HAL system employs hybrid support technology to optimize muscle activation, while the TecnoBody D-Wall system utilizes digital analysis of movement in three dimensions. The present study aims to evaluate the effects of both systems on jump height, force production and acceleration parameters in healthy subjects.

METHODS: Thirty healthy volunteers, aged between 20 and 40 years, participated in this study. The participants performed four different exercise protocols using the Cyberdyne HAL Lumbar device, and their jump performance was evaluated with the TecnoBody D-Wall. Total work (Joule), jump height (cm), maximum acceleration (m/s²) and peak force (Newton) were measured as part of the SJ tests. The exercise program consisted of 60-minute sessions performed three times a week for eight weeks, performed using the Cyberdyne HAL Lumbar devices Cybernetic Voluntary Control (CVC) mode. Data were

analyzed with IBM SPSS 26.0; continuous variables were presented as mean $\pm$ standard deviation, and categorical variables were presented as percentage (%). The normality of distribution was analyzed using the Shapiro-Wilk test, and a Paired t-test was used for intergroup comparisons. A significance level of $p \leq 0.05$ was accepted.

RESULTS: A total of 30 healthy individuals, 13 males (43.3%) and 17 females (56.7%), participated in this study. The mean age of the participants was 28.7 years (± 4.79 years), height 169.83 cm (± 8.76 cm), body weight 65.56 kg (± 10.09 kg) and BMI (body mass index) 22.71 kg/m² (± 2.97 kg/m²). The present study investigates the effects of the combined use of Cyberdyne HAL Lumbar and TecnoBody D-Wall systems on jumping performance in healthy individuals. According to the data obtained after the applied exercise protocol, a statistically significant increase was observed in Joule and cm values ($p < 0.05$). However, no significant change was found in m/s² and Newton values ($p > 0.05$).

CONCLUSION: The findings of this study indicate that the incorporation of Cyberdyne HAL Lumbar into an exercise program results in a favorable impact on lower extremity endurance and energy production. However, it does not yield a substantial enhancement in terms of maximum force production and acceleration. Consequently, further comprehensive studies are advised to ascertain the long-term implications of combined exercise protocols on neuromuscular adaptation and motor performance.

A COMPARISON OF MATCH DEMANDS USING BALL-IN-PLAY VS WHOLE-MATCH DATA IN SUPER RUGBY AMÉRICAS FROM THE 2023 CHAMPION TEAM

CONSONNI, L., POLLARD, B., IZETA, F., TURNER, A.

LONDON SPORTS INSTITUTE, MIDDLESEX UNIVERSITY LONDON, UK

INTRODUCTION: Rugby union is an intermittent, high-intensity sport requiring players to perform various physical activities with distinct positional demands (1, 2). Previous research assessing match demands using whole-match (WM) GPS data may underestimate peak physical outputs (1, 2). This study aimed to compare match demands in Super Rugby Américas using ball-in-play (BiP) vs. WM data.

METHODS: GPS data from 35 elite players of the 2023 Super Rugby Américas champion team was collected across 14 matches. Metrics analyzed included total distance (TD), high-speed running (HSR), accelerations (ACC), and high metabolic-load distance (HMLD). Data were reported in absolute terms and relative to playing time (per minute). Linear mixed models assessed differences between BiP and WM data, considering positional variations between forwards and backs.

RESULTS: BiP phases exhibited significantly higher physical demands than WM periods. Absolute match demands were generally lower in BiP than in WM, except for HSR, which showed no significant difference. TD per minute was ~2.5 times greater in BiP (114.9 ± 7.7 m/min) than WM (45.5 ± 3.2 m/min; $p < 0.001$). Similar trends were observed for ACC per min (0.8 ± 0.1 vs. 0.2 ± 0.03 , $p < 0.001$), HSR per min (15.4 ± 2.6 vs. 3.4 ± 0.4 , $p < 0.001$), and HMLD per min (27.9 ± 3.7 vs. 6.6 ± 0.7 , $p < 0.001$). Positional differences were evident, with backs covering greater TD ($p < 0.001$) and engaging in more HSR than forwards ($p < 0.001$) (1, 2).

CONCLUSION: BiP analysis provides a more accurate representation of peak match demands than WM data, highlighting the need for training programs tailored to BiP-specific intensities (1, 2). Given the significantly higher relative demands observed in BiP, training should emphasize high-intensity efforts rather than relying solely on WM averages, which underestimate match intensity. These insights may contribute to more effective game strategies and physical conditioning programs. Additionally, positional differences reinforce the need for individualized training interventions to optimize performance. Future research should explore tactical variations influencing BiP demands, as well as how different styles of play impact the physical demands experienced during elite-level competition.

EFFECTS OF THERMAL ALUMINUM SHEET ON THE PHYSIOLOGICAL STRESS EXPERIENCED WHILE STAYING IN A SNOW CAVE: COMPARISON OF THE INNER/OUTER AND OUTER COVER CONDITIONS

ONODERA, S., ISHIDA, Y.2, TAMARI, Y.3, HAYASHI, S.4, TAKAHARA, T.5, NISHIMURA, K.3, ARATANI, Y.6, NOSE, Y.7, FURUMOTO, K.2, MATSUO, K.1, YOSHIDA, N.9, FUJISAWA, T.1, WADA, T.10, ISHIMOTO, Y.1, YOSHIOKA, A.11, YAMAGUCHI, H.5, TANAKA, K.12, HARA, H.13, YUI, N.14

1KAWASAKI UNIV OF MED WELFARE; 2OKAYAMA UNIV OF SCI; 3HIROSHIMA INST OF TEC; 4FUKUYAMA CITY UNIV; 5KIBI INT UNIV; 6CHUGOKU JR COL; 7YASUDA WOMENS COL;

INTRODUCTION: This is a field study on using snow caves to prevent hypothermia while participating in mountain activities. Thermal aluminum sheets are effective at preventing hypothermia in snow caves [1-8]. A previous study found that using the inner cover condition of thermal aluminum sheets accurately reflects heat emitted by the body [9]. We hypothesized that the thermal aluminum sheets' inner and outer covers would work together to provide even greater benefits. The efficacy of the double-cover thermal aluminum sheets was compared to that of the outer cover using physiological and psychological indices.

METHODS: Eight healthy Japanese male volunteers (35 ± 6 yrs old, 171 ± 5 cm tall, 68 ± 6 kg) were randomly divided into two groups of four. The control group consisted of only one cover (outer cover). The experimental group used the double-

cover (inner and outer covers) configuration. All subjects wore identical outfits, including hats, gloves, and footwear. Heart rate, rectal temperature, blood pressure, perceived cold temperature sensation, and urinary catecholamine levels were all measured. The subjects stayed in a tunnel-style snow cave for an hour in pairs, with one subject under the double-cover thermal sheets. The weather was cloudy, with a temperature of 4°C outside and 1°C inside. This study was authorized by the Research Ethics Committee.

RESULTS: The decrease in rectal temperature in the experimental group (0.2°C) was significantly less than in the control group (0.4°C). The control group's heart rate (80bpm $\pm$ 6) was 8 bpm higher than the experimental group's (72bpm $\pm$ 12), but the difference was not significant. The systolic blood pressure in the control group (120 $\pm$ 6 mmHg) was nearly identical to that in the experimental group (124 $\pm$ 6 mmHg). The control group had higher diastolic blood pressure (80mmHg $\pm$ 4) compared to the experimental group (70mmHg $\pm$ 8). The control group (3; Median) reported a higher subjective cold temperature sensation than the experimental group (2). However, these differences were not statistically significant.

CONCLUSION: The study's novelty is that it clarified that using both inner and outer aluminum sheet coverings increases heat retention. Cold stimulation increases the heart rate. Cold stimulation causes an increase in diastolic blood pressure. Cold stimulation increases the subjective sensation of cold temperature. Our hypothesis is supported by the improved heat retention of the double-cover thermal aluminum sheets. Aluminum sheets are likely useful because they reflect far infrared rays (wavelength 10 μ m) emitted by the human body, reflected by the aluminum sheet as radiant heat, resulting in an increased heat retention effect. The logic behind double covering is that the gaps between layers of clothing provide the most insulation. The heat retention effect of the double-cover condition is significantly greater than the single cover condition.

EFFECTS OF VIRTUAL REALITY VIDEO USING A HEAD-MOUNTED DISPLAY ON AUTONOMIC NERVOUS SYSTEM AND STANDING CENTER OF GRAVITY SWAY

KOIBUCHI, K., MURAYAMA, T.

NIIGATA UNIVERSITY GRADUATE SCHOOL

INTRODUCTION: The number of Virtual reality launches is rising every year. As the number of users increases, health risks have also been pointed out. Health risks can be broadly classified into two types: "light stimulus load type" and "spatial information confusion type". The most serious health problem of the spatial information disruption type is called VR sickness. It is said that peripheral vision stimulation and visually-induced self-motional sensation are likely to be induced by Virtual Reality images, and more effective and practical training would be possible if clinical application becomes possible.

METHODS: Ten young adult students (10 males: 23.3 $\pm$ 0.9 years old) with no subjective abnormalities in vision, balance, or hearing were selected. The students were presented with two conditions: a stimulus image using a virtual reality head-mounted display and a static standing posture, and their center of gravity sway was measured using a center of gravity sway meter.

RESULTS: The results showed that the total trajectory length increased more in the VR standing condition than in the static standing condition in all segments, suggesting that visual stimulation in VR has a greater influence on the standing center of gravity sway than in the static standing posture.

CONCLUSION: We examined the effects of visual stimulation on total locus length and autonomic balance in 10 young adult students. The results showed that the total trajectory length increased more in the VR standing condition than in the static standing condition in all segments, suggesting that visual stimulation in VR has a greater influence on the standing center of gravity sway than in the static standing posture. The fact that there was a significant difference in the total trajectory length in the VR standing condition compared to the static standing condition is discussed. This may be due to the visual change caused by VR. Previous studies have also shown that visual changes affect the center-of-gravity sway. In the VR standing condition, the visual information changes in accordance with the head movement, and it is considered that the sensation of visually induced self-motion sensation is more easily generated.

INSTRUMENTED CLIMBING HOLD FOR FORCE MEASUREMENT IN SPEED CLIMBING

SHINTANI, T., KAWAMURA, A., AIHARA, S., KURAZUME, R.

KYUSHU UNIVERSITY

INTRODUCTION: Speed climbing is the discipline of climbing a standardized route on a 15-meter wall as fast as possible. This discipline was held as a stand-alone event at the 2024 Paris Olympics and is attracting worldwide attention. Competitors in speed climbing have been checking and improving their performance daily. Currently, performance evaluations generally rely only on geometric motion information from video or motion capture systems. Although information on forces applied to the limbs is important in motion analysis, it is not widely used since it is difficult to obtain the force information. To detect force information, several force measurement systems have been proposed in speed climbing [1][2]. These systems require specially constructed walls, which have high installation costs and make it challenging to install them in competition venues and climbing gyms. Therefore, an instrumented climbing hold to sense the force applied to

the hand hold in speed climbing is proposed in this paper. This system can be installed on existing speed climbing walls at low costs.

METHODS: The proposed instrumented climbing hold measures 3-axis force and 3-axis moment by embedding a 6-axis force sensor into the hand hold in speed climbing. It can transmit force data via wireless communication and is battery powered. Thereby, cables and other wiring do not interfere with competitors movements.

The devices such as a force sensor, microcomputer, battery, and wireless communication module are embedded inside the hold. Therefore, there is no major change in appearance. Battery power can be supplied from a connector located on the side of the hold, allowing power to be supplied without removing the proposed system. Furthermore, assuming that a point of effort exists on the hold surface, the point of effort is calculated from 6-axis force. This information is useful to the competitors in indicating where the force is being applied to the hold.

RESULTS: An experiment to verify the usefulness of the instrumented climbing hold was conducted. It was installed on a starting position hand hold in speed climbing and measured the forces and moments applied to the hold by a professional climber. The climber applied a large force at the moment of start. The force was equivalent to 145% of body weight. Also, the point of effort estimated from the measured data was nearly matched to the position where the professional climber gripped the hold.

CONCLUSION: We proposed an instrumented climbing hold for force measurement that can be installed on existing speed climbing walls at low costs and does not interfere with climbing movements. The experiment shows that the instrumented climbing hold works properly in actual environments, and the point of effort can be estimated from the measured data.

WHY TRAINING THE IRON CROSS WITH HERDOS DEVICES AND EXTERNAL LOAD ADDED TO BODY WEIGHT IS BENEFICIAL FOR YOUNG GYMNASTS

MARINA, M., TORRADO, P., FERRER-URIS, B., BUSQUETS, A.
INEFC BARCELONA

INTRODUCTION: The iron cross on the rings (IC) demands holding ones body weight with fully extended arms, exerting adduction effort at a 90° angle in the frontal plane. This position places significant stress on the upper body [1,2]. To minimize injury risk, it is essential to develop training methods supported by research that examines muscle interactions in different training conditions. Intermuscular coordination is crucial for stabilizing the shoulder complex [3] and the elbow joint, which serves as a connection between the shoulder and hand, acting as a fulcrum for the forearm lever [4]. We investigated whether training IC with assistive devices (herdos; HIC) and added external load (LHIC) while matching the force moments on the rings could serve as an intermediate step between the unloaded herdos condition (HIC) and the standard IC on the rings.

METHODS: EMG activity was normalized relative to a standing IC before comparing gymnasts capable of performing the IC on the rings (achievers) and those who were not (non-achievers) under HIC and LHIC conditions. Seven muscles were analyzed using EMG: Pectoralis Major (PM), Latissimus Dorsi, Teres Major (TM), Lower Trapezius, Serratus Anterior, Biceps Brachii (BB), and Triceps Brachii (TB). Additionally, three indices were calculated to assess coactivation levels: Elbowidx, Scapulaidx, and Shoulderidx.

RESULTS: The greatest variations in EMG activity across conditions were observed in the PM and BB ($F \geq 30.7$; $P < 0.001$). When comparing overall muscle activity, as well as PM, TM, BB, and TB activation between groups, non-achievers exhibited higher activation levels than achievers, regardless of the herdos condition ($P \leq 0.046$). Among the calculated indices, only the Elbowidx of achievers was significantly higher ($P \leq 0.005$) during IC compared to LHIC and HIC.

CONCLUSION: The fact that non-achievers could sustain the IC in the LHIC condition without being able to do so on the rings suggests two key factors: 1) the reduced number of upper limb joints involved in LHIC decreases the need for overall tension, which non-achievers struggle to generate; 2) herdos devices significantly reduce torque at the elbow, preventing excessive hyperextension and safeguarding joint integrity. PM and BB EMG activity showed particular sensitivity to changes in training conditions, regardless of achievement level. We recommend incorporating external load in herdos training to enhance muscle activation to levels closer to ring performance while mitigating injury risks.

USING WEARABLE TECHNOLOGIES TO INVESTIGATE THE PHYSIOLOGICAL DEMANDS OF AN ULTRA-DISTANCE OBSTACLE COURSE RACE IN THE DESERT: A CASE STUDY

NEAL, R., MILLER, M.2, PEÑA IGLESIAS, D.2, VERDOUKAS, P.2, MUNIZ-PARDOS, B.3, JAMES, C.4, PITSILADIS, Y.2,4

[1] BOURNEMOUTH UNIVERSITY; [2] TELEMETRICS LTD; [3] UNIVERSITY OF ZARAGOZA; [4] HONG KONG BAPTIST UNIVERSITY

INTRODUCTION: Obstacle sports will appear in the Modern Pentathlon at the 2028 Summer Olympic Games. Obstacle course races (OCR) range from 60 meters to ultra-distance and have occurred in indoor, desert, and mountain environments. However, the physiological demands of OCR have yet to be determined. This study investigated the physiological demands of extreme competitive OCR using wearable technologies.

METHODS: The Tough Mudder Infinity event is a competitive time-constrained OCR where participants complete maximal distance (repeated 10 km laps with 20 obstacles) within 9 hours, and in February 2024 occurred in the desert in AlUla, Saudi Arabia. This event provided a complex demand for endurance, strength, and thermoregulation within moderate heat stress (ambient temperature: $20.3 \pm 3.5^\circ\text{C}$; relative humidity: 30%; wind speed: 19.0 ± 1.9 km·h⁻¹; WBGT: 13.8°C). A case study observational and descriptive approach was used to study one female athlete (age: 32 years) who completed 70km and 120 obstacles in 8h and 43mins on sand, in daylight. Wearable sensors monitored physiological and biomechanical variables synchronously and in real-time using the methods previously described (Muniz-Pardos et al., 2021b). The primary outcome measure was the core temperature (T_{core}) achieved by swallowing a temperature pill (12h and 3h prior to the start). Additional measures included heart rate (telemetric chest strap and wrist-worn), GPS, and running biomechanics via a foot-worn inertial sensor. Real-time monitoring was achieved by a 'gateway', connected to a bespoke app within a smartwatch with e-SIM, and transmitted to the research team's remote applications.

RESULTS: This is the first-time physiological data from a competitive OCR has been presented. In addition to the variable ambient conditions (16–25°C, wind gusts up to 49.4km·h⁻¹ and direct sun exposure), the nature of the obstacles presented an additional challenge to both the athlete and technology battery life, including repeated sudden immersion to ice water. The athlete's T_{core} increased by 1.24°C to a peak of 39.07°C during the 8:43:13 race, heart rate peaked at 153 b·min⁻¹. Biomechanical data was affected by the water immersion on some laps, but smartwatch battery life was maintained throughout (min 11%).

CONCLUSION: The participant reported to the investigators that the wearable technology did not interfere with performance or comfort during the race. The race organisers agreed that the technology inclusion was not intrusive and were satisfied with the style of information. This novel technique utilising wearable technology enabled the athlete to be monitored in real time from a remote location and offers the opportunity to protect the health of athletes during extreme competition. Considerations should be made for optimising measurement accuracy and data privacy. The rise of biometrics has relevance for broadcasting, as well as public health and sports performance.

EVALUATION OF A HELMET-INTEGRATED PPG SENSOR FOR REAL-TIME HEART RATE MONITORING IN DIVERSE PHYSICAL ACTIVITY CONDITIONS

CHEN, J., TAI, J.X., YANG, C.H., CHEN, Y.R., HUANG, T.H.1

NATIONAL CHENG KUNG UNIVERSITY

INTRODUCTION: Photoplethysmography (PPG) sensing module has been adopted as a heart rate (HR) sensor for the last decades. Base on detecting volume changing of blood vessels caused by heartbeat, PPG sensors can be located in various regions of human skin. Although wrist PPG sensing is widely used for different wearable devices, errors due to blood redistribution especially caused by different exercise modes lead to inaccuracy of HR measurement. Due to head blood supply is vitally essential for physiological status maintaining, a relatively stable blood supply going through facial skin would be expectable. In the current study, a PPG HR sensor was integrated into a cycling helmet to determine its feasibility for HR measurement on facial skin during various conditions.

METHODS: Ten amateur cyclists were recruited for the current study. All participants completed a time serial test with resting, warm-up and exercise phases. During the test, all participants wore a HR chest strap and two PPG sensors located on the skins of wrist and temple, respectively. Data acquired from three sensors were compared using repeated measure one-way ANOVA. Pearson's correlation was used to analyze relationship among data of various sensors.

RESULTS: Along the time serial, HR data were divided and averaged for every 10-second period. During the initial 60 seconds of the rest phase, HR values showed no significant differences and consistently high correlation co-efficient ($r > 0.95$, $p < 0.001$) among the three sensors. In the subsequent 6-minute warm-up phase, a significant lower HR was observed from the wrist-worn PPG as compared electrocardiography (ECG) chest strap heart during the 0~10th second ($p = 0.012$) and 11th~20th second period ($p = 0.022$). In the same time periods, relatively lower correlation co-efficient ($r = 0.599$, $p = 0.088$ and $r = 0.742$, $p = 0.022$, respectively) were shown between wrist-worn PPG HR and ECG HR. On the other hand, no significant difference and high correlation were revealed between the HR data of helmet-integrated PPG and ECG chest strap throughout the warm-up phase. In the following 6-minute exercise stage, no significant differences and high correlation were shown among data of three sensors.

CONCLUSION: In general, PPG HR values demonstrated highly consistency and correlation to ECG HR sensors during rest and exercise. By using ECG HR data as a standard, PPG HR data from a sensor located on facial skin showed higher accuracy, which might be due to a high physiological priority of blood supply redistributions.

Conventional Print Poster Presentations

VIENNA TEST SYSTEM: A WIDELY USED METHOD FOR ASSESSING COGNITIVE FUNCTION IN THE ATHLETIC POPULATION: A SCOPING REVIEW

NÉGYESI, J.

HUNGARIAN UNIVERSITY OF SPORTS SCIENCE

INTRODUCTION: In psychology, questionnaires are often used to permit valuable insights into an individual's cognitive functions, however, supplementary objective alternative measures are needed to collect a more diverse range of information about such outcomes. The Vienna Test System (VTS) is one of the most widely used computerized tools for assessing psychology-related constructs in the athletic population. In the present scoping review, we aimed to draw attention to the challenges in the practical application of the VTS for assessing cognitive functions.

METHODS: A systematic literature search was conducted across four databases (PubMed, Web of Science, ELSEVIER Scopus, and EBSCOhost). Besides the participants' characteristics and key findings, the highest Scimago Journal Ranking (SJR) of each paper in the year of the publication was also considered.

RESULTS: Our literature search identified 41 relevant articles, including 2 of our previous papers (Horvath et al 2022, Horvath et al 2023). The total number of participants was 1789 (n = 256 females and n = 1316 males, seven studies did not provide information on gender) with a mean age of 21.2 years (range between 10-64 years). The participants' field of sport ranged from yoga-practicing older females to professional athletes (e.g., racing drivers, soccer players, wrestlers and taekwondo competitors, Polish amateur boxers, and rhythmic gymnasts). Of the 41 articles, 10 were published in Q1 journals, 7 in Q2, 6 in Q3, and 2 in Q4. Notably, 16 (39% of the studies) were published in journals that do not appear in SJR.

CONCLUSION: The wide spectrum of cognitive tests of the VTS has the potential to assess e.g., sustained attention, reaction time, peripheral perception, stress reactivity, or time movement anticipation. However, the relatively poor experimental designs of many studies using VTS make it difficult to draw clear conclusions about its validity and feasibility.

IS THE LOW-COST COOSPO H808S AS RELIABLE AS THE POLAR H10 CHEST STRAP HR MONITOR?

PROTZEN, G., RIESCO-VILLAR, J., GONZÁLEZ-FERNÁNDEZ, A., ESCRIBANO-PASCUAL, A., BOULLOSA, D.

UNIVERSITY OF LEÓN

INTRODUCTION: Heart rate (HR) and HR variability (HRV) are widely used in sport to assess training intensity, autonomic adaptation, and recovery [1]. Chest strap heart rate (HR) monitors are currently the most used sensors for HR measurements due to their high accuracy and comfort when compared to other sensors. However, differences in signal processing, electrode quality, and transmission protocols can affect measurement agreement between different brands. The Polar H10 is one of the most validated HR monitors, known for its high precision and reliability which is comparable to gold-standard ECGs [2]. Recently, the Coospo H808S chest strap has emerged as a low-cost alternative, but its accuracy and consistency remain unexplored. Therefore, this study aims to compare the agreement of the Coospo chest strap HR monitor with the Polar H10 during different conditions.

METHODS: Sixteen recreational runners (25±5 years) participated in this study. Participants simultaneously wore Polar H10 and Coospo H808S chest straps, with strap placement (upper or lower positions) randomized. HR and HRV data were recorded via a smartphone app (HRV Logger) in three conditions: supine, seated, and running at RPE 2-3 out of 10. Each condition lasted 5 min, and the last 4 min of recordings were analyzed using Kubios HRV in two ways: raw data and medium-filtered data. Agreement was assessed using intraclass correlation coefficient (ICC) and Bland-Altman plots.

RESULTS: In the supine position, Coospo and Polar showed excellent agreement for RR, RMSSD, and HR (>0.967) before filtering. After filtering, there was a slight reduction in agreement for RR (0.917), RMSSD (0.930), and HR (0.911). When seated, the devices maintained a high agreement, with RR, RMSSD, and HR presenting > 0.990 before filtering. Post-filtering, HR, RR, and RMSSD (>0.990) remained highly correlated. During running, RR showed a correlation of 0.930, and HR maintained an excellent correlation (0.944) before filtering; however, RMSSD demonstrated a poor ICC (-0.244; +17.6 ms; LoA = -73.8 – 109.0). After filtering, RR (0.917) and HR (0.909) remained similar but correlation dropped to 0.132 for RMSSD (-5.1 ms; LoA = -40.4 – 30.1).

CONCLUSION: The Coospo H808S showed excellent agreement with the Polar H10 for HR and HRV measures in resting conditions, and excellent agreement for HR during low-intensity running. However, agreement for HRV measures decreased in running condition, especially for vagal modulations. Unexpectedly, filtering reduced agreement between devices, therefore suggesting that these monitors may have some differences in internal signal processing methods.

THE VALIDATION OF AN ORAL WEARABLE SENSOR FOR MEASURING HEART RATE IN COMBAT SPORTS

SILVA, D., STAMFORD, J., COOKE, K.

ORB INNOVATIONS; ST MARY'S UNIVERSITY, TWICKENHAM

INTRODUCTION: Combat sports (Boxing, MMA, Wrestling) often have a high aerobic demand with high heart rates between rounds [1], and elevated blood lactate concentrations [2]. Applied research and athlete monitoring in combat sports face significant barriers due to restrictions imposed both by the nature of the sport and its governing regulations. Since combat sports involve intense physical contact—such as grappling, striking, and punching—most heart rate monitors cannot be worn safely during training and/or competition. Therefore, the purpose of this study was to determine the agreement of an oral wearable sensor (ORB Sport smart mouthguard, OS), against previously validated heart rate monitors and an electrocardiogram (ECG) [3].

METHODS: Twenty healthy volunteers (11 male, 9 female; age (mean±SD) 28.2±4.2 years) completed the protocol while wearing the OS (ORB Innovations, UK), Polar H10 heart rate monitor (Polar Electro, Finland) and Movesense MD ECG sensor (Movesense Ltd, Finland). The protocol consisted of 5 minutes of seated rest, incremental walking and running (from 4 km/h, increasing 1 km/h every 1 min) on a treadmill (Precor, UK) up to a mean (±SD) heart rate of 170 ± 7 beat/min, followed by 5 minutes of seated recovery. The OS, Polar H10, and Movesense MD data were processed using manufacturer applications and Kubios HRV Scientific (KHS) software (Kubios OY, Finland). Heart rate algorithms for Polar, Suunto, and KHS provided a total of three criterion heart rate measurements. Following inspection of each participant's data, three were excluded from the final analysis – two for errors in the heart rate monitor or ECG data and one for errors in the mouthguard data. Heart rate data were averaged (5 second intervals) and temporally aligned for statistical analysis. Mean Absolute Percentage Error (MAPE), Intraclass Correlation Coefficients (ICC) and Bland-Altman Limits of Agreement [4] were calculated.

RESULTS: The oral wearable sensor had MAPE (mean±SD) of 4.7±5.2%, 5.5±5.3% and 5.5±5.5%; ICC of 0.96, 0.95 and 0.96; Bias with Upper and Lower Limits of Agreement of 1.1[16.4, -14.2], 1.4[17.5, -14.7] and 1.0[17.5, -15.5] beat/min compared to Polar, Suunto, and KHS, respectively. For comparison, MAPE between criterion heart rate monitors and ECG were 2.7±2.8% and 2.5±2.8% for Polar versus Suunto and KHS, respectively, and 1.9±3% for Suunto versus KHS.

CONCLUSION: These results demonstrate that the oral wearable sensor has levels of agreement comparable with other wearable devices [5] and can provide a useful estimate of heart rate to determine the intensity of training and competition in combat sports.

WEARABLE TECHNOLOGY IN SPORT: A SCOPING REVIEW

READ, D., BARRACLOUGH, S., KIRKWOOD, A., WHITTAKER, N., SANDERSON, A.

MANCHESTER METROPOLITAN UNIVERSITY

INTRODUCTION: Wearable technology is defined as a wireless electronic device worn on the user's body and can transmit real-time data. Wearable technology within sport exists in many forms, such as smart jewellery (e.g., watches, rings), body-mounted sensors, and smart clothing, measuring a range of variables. These devices are used in sport to reduce injury risk, assist with rehabilitation, and optimise training load. With the exponential expansion in the field of wearable technology in sport, there remains a large degree of uncertainty regarding the breadth and depth of available technologies, and therefore, a review of the published literature is needed. The objective of this scoping review is to identify which wearable technologies have been developed, or are in development, for use in sporting activities to measure physiological variables.

METHODS: The scoping review was conducted in accordance with the Joanna Briggs Institute manual for scoping reviews and reported according to the PRISMA extension for scoping reviews (PRISMA-ScR). The review protocol was preregistered at <https://doi.org/10.51224/SRXIV.280>. Seven databases were searched (inception – September 2024), including four scientific databases (PubMed, Scopus, SPORTDiscus, and Web of Science), one grey literature database (OpenGrey), one conference database (IEEE), and one UK doctoral thesis database (EthOS). Only studies where human participants wore a wearable technology device on the skin that could measure a physiological variable (e.g., heart rate) during sport or structured exercise were included. Following screening, 217 studies were found eligible for inclusion.

RESULTS: All individual wearable devices were counted, including studies that assessed multiple devices. In total, wearable technology had been placed on 14 locations on the body, with the most frequently identified being: the wrist (n = 150), the thorax (n = 108), the abdomen (n = 32), the upper arm (n = 15), and forearm (n = 13). There were 15 categories of wearable technologies, with the most frequently identified being: wristbands (n = 164), chest straps (n = 85), patches (n = 48), shirts (n = 29), and armbands (n = 12). There were 10 physiological variables identified, with the most frequently identified being: heart rate (n = 282), energy expenditure (n = 63), sweat rate (n = 39), respiratory rate (n = 32), and skin temperature (n = 20).

CONCLUSION: The review identified multiple locations, categories, and physiological variables associated with wearable technology. The wrist was the most common location, wristbands were the most frequently categorized wearable type, and heart rate was the most common physiological variable. This synthesis of the literature will assist researchers who wish to review the wearable technologies that have been developed or are in development for use in sporting activities to measure physiological variables.

V'O₂MAX ESTIMATION VIA ONE-MINUTE WINGATE TEST AND MACHINE LEARNING MODEL

GASPARINI, A., GENTILIN, A., TAM, E.

UNIVERSITY OF VERONA

INTRODUCTION: Aerobic capacity is essential in sports science to optimize training, performance, and health monitoring [1]. Direct V'O₂max measurement through pulmonary gas exchange is the gold standard but requires expensive metabolic carts and controlled lab settings, limiting practicality. Indirect methods, estimating V'O₂max using standardized exercise tests and regression models, provide a more accessible alternative but often trade off accuracy. The current goal is to improve estimation while reducing test duration and participant burden. We previously showed that variables from the modified one-minute Wingate test correlate with aerobic capacity, and machine learning models outperform linear regression by capturing complex nonlinear relationships [2]. This study combines the Wingate test with machine learning models for a new V'O₂max estimation method.

METHODS: A sex-balanced cohort of 180 subjects (22.64 years, 69.59 ± 9.46 kg, 170.16 ± 6.62 cm) performed a progressive incremental test (25 W·min⁻¹) on a cycle ergometer, with breath-by-breath gas data collected via a metabolic cart. V'O₂max, determined by the gold standard, was the regression target. In a separate session, after a 5-minute warm-up at 50 W, subjects completed a 60s all-out Wingate test (final 5s warm-up at 160 rpm, test starting at minute 5, maintaining peak power for 1 min). Peak, mean, and minimum power, fatigue rate, and time-to-peak power, along with age, weight, and height, served as predictors. Multiple regression models (Linear Regression, Support Vector Machines, Gaussian Process Regression, Decision Trees, and Ensemble Methods) were trained and validated using leave-one-out cross-validation. The best model was selected based on the lowest root-mean-square error (RMSE) between reference and estimated outputs [2].

RESULTS: The subjects average V'O₂max was 3511 ± 426 mL O₂/min (range: 2769–4553). Among tested models, Gaussian Process Regression (GPR) with an exponential kernel best captured predictor-V'O₂max relationships (RMSE: 121 mL O₂/min). Combining the one-minute Wingate test with GPR yielded an R² of 0.93 vs. the gold standard. The bias between real and estimated V'O₂max was 0.41 ± 110.35 mL O₂/min, with LOA of 216.69 and -215.88 mL O₂/min.

CONCLUSION: Indirect submaximal tests for estimating V'O₂max typically yield R² values of 0.70–0.85 [2], while our model achieves 0.93, showing superior performance. These results pave the way for a rapid V'O₂max estimation test, with the core assessment completed in one minute.

BRIDGING THE GAP: CHALLENGES IN APPLYING BEST-PRACTICE TRAINING LOAD AND ATHLETE RESPONSE MONITORING IN ELITE AND SUB-ELITE SPORTS

MONDIN, D., COUTTS, A.J., PYNE, D.B., ETXEBARRIA, N., NATERA, A.O., MINEHAN, M.

UNIVERSITY OF CANBERRA

INTRODUCTION: Athletes are monitored routinely to optimize adaptation, performance, and health. Best practice involves tracking both prescribed and performed loads alongside athlete responses [1]. Monitoring should be efficient, use valid and reliable methods [2], and adopt a multifactorial approach [3]. However, ineffective monitoring can create skepticism among athletes and coaches, highlighting the need for clearer guidelines [4]. This study examines monitoring strategies in elite and sub-elite sports, identifying gaps between best practices and real-world applications.

METHODS: A total of 111 practitioners (48% strength and conditioning coaches, 18% physiotherapists, 14% coaches, 20% other) completed the survey. Participants worked with elite/sub-elite athletes (>=3 sessions/week, >=1 hour/session) and had >=2 years experience. Respondents represented 29 sports (48% Olympic, 38% professional, 14% development) across 15 countries. The survey consisted of 49 multiple-choice and open-ended questions across 6 sections: Participant, Load Monitoring, Response Monitoring, Womens Metrics, Communication, and Future Directions.

RESULTS: Of 111 practitioners, 66% monitored both load and response, 30% monitored only load, 2% did not monitor, and 1% only tracked responses. External load was objectively monitored by 85%, internal load by 40%, and subjective training load by 62%. Response was assessed objectively (55%), subjectively (50%), and 19% used biomarkers. Common load monitoring methods were RPE (57%), weight lifted (53%), and GPS (46%), while response was measured via isometric tests (28%), body weight (26%), and sleep quality survey (26%). Half of the practitioners used objective load monitoring every session, 46% used subjective monitoring each session, whilst 29% monitored internal load in selected sessions only. Practitioners tracking responses adjusted training more frequently compared to those who monitored load only (26% vs.

11%) and they also perceived monitoring to be more effective in preventing maladaptation (33%) and improving performance (46%). Only 3% used best practice approaches combining external and internal load with athlete response, and 9% used both subjective and objective data. Most practitioners (88%) expressed a desire to improve their monitoring practices.

CONCLUSION: Most practitioners monitor training load, yet fewer integrate response measures despite best practice recommending both. Communication gaps were noted between strength and conditioning coaches and physiotherapists, as under 40% shared data between them, potentially limiting best practice care. These findings reveal variability and critical gaps between best practice and current approaches. Improved education and interdisciplinary collaboration are recommended to align practices with best-practice guidelines.

SYNCHRONIZATION OF IMU AND GNSS IN TWO COMMONLY USED SPORTS TRACKERS

MENTZONI, F., JØLSTAD, P.

THE NORWEGIAN OLYMPIC AND PARALYMPIC COMMITTEE AND CONFEDERATION OF SPORTS

INTRODUCTION: Sports trackers are widely used to analyze performance in various sports, including alpine skiing, cross-country skiing, football, handball, rowing, and others. Typically, these devices record both GNSS (position) and IMU (accelerations and rotations) data. However, it is unclear if data from the two sources are perfectly synchronized or if a time offset should be considered when performing analyses using data from both sources.

METHODS: Three units from each of two brands of sports trackers, ASI AdMos and Catapult OptimEye S5, were mounted on a longboard that was suddenly accelerated from rest by pulling an attached rope. 11 repetitions were performed. The associated peaks in acceleration were identified in the IMU data and calculated using the second-order derivative of the position from the GNSS data. A 4th-order Butterworth low-pass filter, with cut-off frequency at 6 Hz, was applied to the raw IMU data. The 10 Hz GNSS data were upsampled to the same frequency as the IMU data (200 Hz with ASI AdMos and 100 Hz with Catapult OptimEye S5) using the `resample_poly` method of Scipy in Python [1]. The offset in peak acceleration was calculated for each of the six units and each of the 11 repetitions.

RESULTS: The GNSS data of the ASI AdMos units were delayed compared to the IMU data, with a mean difference in time, i.e., latency, equal to 0.19 s (lower quartile: 0.13 s; median: 0.20 s; upper quartile: 0.23 s). The mean of the standard deviation of the latency between the three ASI AdMos devices was 0.036 s. Contrary, the GNSS data of the Catapult OptimEye S5 were ahead of the IMU data, with a mean latency of -0.17 s (lower quartile: -0.28 s; median: -0.15 s; upper quartile: -0.11 s). The mean of the standard deviation of the latency between the three Catapult OptimEye S5 devices was 0.070 s. Moreover, the mean absolute difference in GNSS time for the peak in acceleration using GNSS data with the ASI AdMos units was 0.009 s, whereas with the Catapult OptimEye S5, the mean absolute difference was 0.064 s. Supplementary data and figures illustrating the results are made available on Figshare [2].

CONCLUSION: Practitioners should be aware that the GNSS and IMU data of commonly used sport trackers are not perfectly synchronized, but that an offset in time of approximately 0.2 s is likely. Somewhat surprisingly, which of the data sources (GNSS or IMU) that were delayed depended on the sports tracker brand. Practitioners working with both data sources and requiring high temporal accuracy should verify synchronization in their specific setup. Our study exemplifies a method for this.

REFINING DECELERATION TESTING IN FIELD SETTINGS: CROSS-VALIDATING GPS AND TIMING GATE DATA

DA SILVA, Y., ROMAO, D.

LUNEX

INTRODUCTION: Deceleration ability is critical for performance in multidirectional sports, yet accurately identifying the onset of deceleration remains challenging in field settings. This study introduces a novel method that cross-validates approach velocity at timing gates with GPS data to precisely determine deceleration onset. By integrating conditional formatting, the method classifies athletes responses as anticipatory or reactive, providing new insights into decision-making and decelerating ability.

METHODS: Twenty-one athletes performed acceleration-deceleration ability (ADA) tests, comprising a 20m sprint followed by maximal deceleration. Approach velocity at the timing gate was cross-validated with GPS-derived braking points to identify deceleration onset, with conditional formatting rules applied to classify standard errors as anticipation (negative values) or reaction (positive values). Metrics such as distance to stop (DTS), time to stop (TTS), and peak deceleration were calculated. Exponentially weighted moving averages (EWMA) were used to reduce GPS data noise and improve measurement reliability.

RESULTS: The cross-validating method identified a standard error of 0.25 ± 0.23 seconds between timing gate and GPS-derived braking points, revealing variations in athletes braking strategies. Conditional formatting revealed that 91% of athletes consistently delayed their braking points, providing insights into the quality of the instructions provided and the

individual decision-making tendencies. EWMA significantly reduced high-frequency noise, enhancing the interpretability of deceleration curves.

CONCLUSION: This cross-validating method enhances the accuracy of deceleration analysis in team sports by combining GPS and timing gate data with objective thresholds for anticipation and reaction classification. The approach is cost-effective, field-ready, and offers actionable insights for developing targeted training interventions to improve braking efficiency and decision-making under pressure. Future studies should validate this method against laboratory-grade tools and expand its application to unplanned deceleration scenarios.

CP-API0 Coaching I - Team Sports

VERBAL INSTRUCTIONS AND PERFORMANCE IN YOUTH SOCCER: POSITIVE OR NEGATIVE FEEDBACK?

MODENA, R., SCHENA, F.

CERISM, UNIVERSITY OF VERONA

INTRODUCTION: Communication between coaches and athletes is key to athlete development and performance. Verbal communication is the most used strategy by coaches to transmit suggestions and instruction to athletes and it was shown the nature of this feedback can influence the training and competition climate. [1] This study compares youth soccer players technical and physical performance when positive or negative feedback is provided.

METHODS: 41 young soccer players (15.5 ± 1.8) performed six bouts of 5vs5 small-sided games on two occasions during the teams regular training. Coaches provided standardised positive or negative feedback in a randomised order in each session. Several technical and physical outcomes were monitored during the game through video analysis, GPS, and heart rate monitoring. The two conditions (e.g., positive and negative verbal feedback) were compared. Data are presented as mean $\pm$ SD for continuous variables and median [interquartile range] for discrete ones.

RESULTS: The number of offensive passes (11 [7 to 14] vs 8 [5 to 11], $p = 0.014$) and kicks on the target (5 [3 to 5] vs 3 [1 to 4] $p = 0.044$) seems to be higher with positive than negative feedback. The type of feedback also influenced the external load, increasing the number of sprints (11 [6 to 17] vs 7 [5 to 15], $p = 0.004$), the number of accelerations at moderate (129 [111 to 145] vs 118 [107 - 137], $p = 0.043$) and very high-intensity (7 [4 to 13] vs 6 [4 to 9], $p = 0.012$), and the distance covered at moderate- (1004.7 ± 197.4 m vs 936.9 ± 219.0 , $p = 0.003$), high- (478.0 ± 122.7 m vs 438.1 ± 147.2 m, $p = 0.009$) and very high-speed running (131.3 ± 89.7 m vs 110.9 ± 71.5 m, $p = 0.028$), when coaches used the positive feedback. No difference in heart rate was found between feedback conditions.

CONCLUSION: Our results showed that coaches' communication style affects young soccer players physical and technical performance during small-sided games, highlighting the increase in the external load and attacking technical actions when positive feedback is used. These novel findings confirm the literature that showed the importance of a coach's positive behaviour in creating a more motivational climate and an optimal learning environment [2], suggesting the use of positive verbal feedback to push young soccer players to make more courageous decisions and to try more attacking actions, limiting at the same time the mistakes.

MAPPING THE ACCURACY OF SOCCER PLAYERS PERFORMANCE IN 11-M PENALTY KICKS: HEIGHT AND DIRECTION

HOOTA, C., LIDOR, R., BAR-ELI, M.

THE LEVINSKI-WINGATE ACADEMIC COLLEGE

INTRODUCTION: In recent decades, 11-m penalty kicks have become pivotal in determining soccer-match outcomes. Bar-Eli and Azar (2009) found that scoring is heavily impacted by the vertical dimension, since powerful, well-placed shots – particularly to the top corners of the goal – greatly reduce the goalkeepers chances of stopping the ball, leaving success almost entirely dependent on the kickers execution. Yet, kickers tend to avoid targeting these areas, likely due to the inherent difficulty of executing the kick with the necessary precision. The aim of this study, therefore, was to examine whether the accuracy of the 11-m penalty kick is consistent across all goal areas, while analyzing ball-flight speed – to gain deeper insights into player performance.

METHODS: Thirty soccer players (aged $M=17.9$ years, $SD=0.64$), from three clubs in Israels Youth Premier League, participated in three sessions, each spaced 2–7 days apart. Kicking accuracy and ball-flight speed – when aiming at different goal zones – were measured under three controlled conditions: no goalkeeper, no crowd, and no physical fatigue. Each player performed 15 penalty kicks per session, targeting nine randomized goal zones. All kicks were video recorded, and

accuracy was analyzed after the sessions. Ball-flight speed (km/h) was measured using a radar gun. After the third and final session, each player completed a survey regarding their attitudes towards penalty kicks.

RESULTS: The vertical direction of penalty kicks significantly impacted kicking accuracy ($p < .01$), with the highest accuracy (61%) seen in the lower third of the goal. Horizontal direction, session order, and trial sequence did not significantly influence accuracy. Ball-flight speed varied across goal zones, with the highest speed recorded in the central zones (96 km/h), and the lowest speeds in the right-hand zones. Analysis of the self-reporting questionnaires revealed players' challenges in aiming at the upper corners of the goal, the impact of pressure on performance, and the crucial role of penalty-kick training.

CONCLUSION: Kicks aimed at the upper corners of the goal, which are considered optimal for scoring, are notably more challenging in terms of accuracy. As the participants were youth players rather than professional experts, their performance likely reflects a lack of preparation and focused training. These findings highlight the need for dedicated training – especially in youth leagues – to improve accuracy in targeting upper corners, combined with mental training – to better manage pressure that is associated with such situations.

POSITIONAL EFFECTS ON TECHNICAL CHARACTERISTICS IN PROFESSIONAL GREEK MALE SOCCER PLAYERS

SOUGLIS, A., KALIARNTAS, K., ANDRONIKOS, G., APOSTOLIDIS, A., NOUTSOS, K., MELETAKOS, P., TRAVLOS, A.K., BOGDANIS, G.

1. UNIVERSITY OF ATHENS, 2. UNIVERSITY OF PATRAS, 3. EDINBURGH NAPIER UNIVERSITY, 4. UNIVERSITY OF PELOPONNESE

INTRODUCTION: The physical and technical demands on soccer players are determined by their positional role in the team (1) and the style of play of the team. Studies investigating the positional differences in technical characteristics in soccer are limited (2). The purpose of this study was to investigate the technical demands across different playing positions of Greek professional soccer players.

METHODS: The study included 125 elite soccer players allocated into 5 groups according to their position: Attackers (A) ($n=25$, age 23.2 ± 0.5 yrs, Training Experience 15.1 ± 0.5 yrs, Body Mass 79.8 ± 0.6 kg, Height 183.0 ± 0.7 cm), Centre Backs (CB) ($n=25$, age 23.5 ± 0.3 yrs, Training Experience 15.0 ± 0.4 yrs, Body Mass 82.0 ± 0.3 kg, Height 185.2 ± 0.5 cm), Fullbacks (FB) ($n=25$, age 22.5 ± 0.5 yrs, Training Experience 14.5 ± 0.5 yrs, Body Mass 73.5 ± 0.7 kg, Height 175.9 ± 0.7 cm), Wide Midfielders (WM) ($n=25$, age 23.0 ± 0.5 yrs, Training Experience 15.0 ± 0.5 yrs, Body Mass 73.1 ± 0.6 kg, Height 176.5 ± 0.6 cm), Central Midfielders (CM) ($n=25$, age 22.8 ± 0.4 yrs, Training Experience 14.7 ± 0.5 yrs, Body Mass 76.1 ± 0.7 kg, Height 179.3 ± 0.7 cm). Technical performance characteristics were measured during a football match (i.e. passes, successful passes, dribbles, ball touches, shots, headers). One-way between groups ANOVA models were used. A statistical level of $p < 0.05$ was accepted and all descriptive data are expressed as Mean $\pm$ SEM.

RESULTS: The groups were similar in terms of age and years of training experience. However, CB were significantly heavier (82 ± 0.3 kg) and taller (185 ± 0.5 cm) compared to most other groups. CM completed significantly more passes (42 ± 0.4) and with higher accuracy ($81\% \pm 0.5$) as compared to all other groups. Wingers touched the ball significantly more times (128 ± 1.6) compared to all other groups, while Attackers performed significantly more dribbles compared to CB/FB, but not when compared to CM/WM. CB performed significantly more clearances (3.9 ± 0.2), headers (13.5 ± 0.5) and tackles (3.6 ± 0.2) compared to all other groups. Attackers performed significantly more shots (2.2 ± 0.2) compared to CB/FB but not compared to CM/WM. Also, CB won significantly more ball possessions (23.1 ± 0.5) and lost the ball significantly less times (15 ± 0.3) compared to all other groups, while Attackers won significantly less possessions (8.3 ± 0.2) compared to all other groups, and FB lost significantly more possessions (22.8 ± 0.4) than most of the other positions.

CONCLUSION: As expected, professional soccer players have different technical demands determined by their playing position. Central midfielders, as the play makers, complete more passes and with higher accuracy. Centre backs are involved in significantly more headers, clearances and tackles as well as winning significantly more times the ball and losing it significantly less. This evidence can inform position specific coaching interventions.

EXPLORING PERFORMANCE METRICS OF THE DUAL-TRACK GAME-ENDING MECHANISM IN 3x3 BASKETBALL

LAN, Y.C., LIU, Y.T.

NATIONAL YANG-MING CHIAO-TUNG UNIVERSITY

INTRODUCTION: The 3x3 basketball game is derived from traditional 5x5 basketball but demonstrates significant differences in its rules and competition formats. Notably, the "dual-track" game-ending mechanism stands out as its most unique feature. According to FIBA regulations, each game lasts 10 minutes and ends early if a team scores 21 points; otherwise, the team with the higher score at the end of regulation wins. These distinct game-ending mechanisms significantly influence the offensive pace and the technical and tactical performance of winning and losing teams. This study utilizes indicators derived from the ball possession formula to examine the differences in performance between winning and losing teams under dual-track game conditions.

METHODS: The game-ending rate was calculated as the ratio of score-end (time-end) games to total games in a given tournament. An independent samples t-test compared the two rates. The boxscores from the 2019, 2022, and 2023 World Cup 3x3 mens basketball games and the 2021 and 2024 mens 3x3 Olympic basketball games were utilized. A total of

152 games from the World Cups and 68 games from the Olympic Games were analyzed. A 2 (endings) by 2 (outcome) mixed design MANOVA was used to analyze the number of possessions (POSS), field goal attempts (FGA), free throw attempts (FTA), scoring rate, 1-point and 2-point FGA rates, and the turnover rate to POSS, with game outcome as the repeated factor.

RESULTS: The independent samples t-test revealed a significantly higher score-ending rate of 72.71% than a time-ending rate of 27.29% across the five tournaments, $p < .001$. The MANOVA results indicated a significant interaction effect, $p < .001$. Further examination of the ANOVA results pointed to significant interactions regarding the scoring rate, 2-point field goal attempt rate, and turnover rate ($ps < .05$). The differences were generally greater between winning and losing teams in score-ending games than in time-ending games, with winners from the score-ending teams performing significantly better than those from the time-ending games.

CONCLUSION: The dominating score-ending games observed in the World Cups and the Olympic Games indicate that 3x3 mens basketball promotes a performance-driven, high-intensity style of play. The 2-point scoring rate based on the number of possessions is the key performance indicator for winning the game. The higher scoring and lower turnover rates observed from the winning teams of the score-ending games further emphasize the importance of offensive efficiency in support of performance-oriented play.

COMPRESSION GARMENTS AND ADAPTATIONS TO PLYOMETRIC TRAINING IN SOCCER PLAYERS: A RANDOMIZED-CONTROLLED STUDY

GOSSET, M., COQUART, A., DELAVAL, B., CATALANO, J., BOZOK, D., DOUCHET, T., ABAIDIA, A., JAFFRÉ, C.

UNIVERSITY OF PICARDIE JULES VERNE

INTRODUCTION: In soccer, players may be exposed to a congested schedule of training sessions leading to fatigue accumulation. To avoid an increased risk of injury and a decrease of performance, it is of importance to limit fatigue without interfering with training adaptations. Studies have shown the beneficial effect of compression garments on post-exercise recovery. However, to our knowledge, no study focused on the effects of a chronic use of compression garments on training adaptations. This study aimed to analyze the impact of a chronic use (6 weeks) of compression garments on training adaptations following plyometric training in soccer players. It was hypothesized that compression garments will have a beneficial effect on training adaptations, compared to a placebo.

METHODS: Twenty soccer players from a reserve team of a professional club were randomly assigned to receive either compression garments (Elite Compression Tight, RVE, Deinze, Belgium) or a placebo for 24 hours following a plyometric session. The players participated to a plyometric training program: 2 sessions per week during 6 weeks. The groups were tested before and after the training program on the following parameters: countermovement jump performance, one-leg sprint power, pennation angle of the calf muscles, creatine kinase levels, soreness and recovery perception. The results were analyzed using a two-factor mixed linear model.

RESULTS: All the performance parameters were significantly improved following the training program ($p < 0.001$). No significant condition effect was observed when comparing compression garments and placebo. However, countermovement jump performance showed a moderate improvement in the compression garments condition ($ES = 0.578$), and a small improvement in the placebo condition ($ES = 0.427$). No significant effect of the condition was observed for the other parameters.

CONCLUSION: The results did not confirm our hypothesis, as no significant effect of condition was detected for performance evolution. However, the larger amplitude of increase observed in the compression garments condition for countermovement jump height shows that wearing compression garments following each training session may lead to better results compared to a placebo condition. Wearing compression garments had no detrimental effects on training adaptations.

THE IMPACT OF H:Q RATIO ON KNEE JOINT MECHANICS DURING LUNGE IN MALE COLLEGIATE BADMINTON PLAYERS

PUNTHIPAYANON, S., PARIYAVUTH, P., TANTIKANOKPRON, N., PHROMSAK, P., TADTHONG, S., SIRAYAKORN, W., CHOPSUNGNOEN, P.

SRINAKHARINWIROT UNIVERSITY

INTRODUCTION: Hamstring-to-Quadriceps (H:Q) ratio is a key indicator of knee injury risk in athletes [1]. While badminton lunges create substantial knee loads [2], the relationship between the H:Q ratio and knee joint mechanics during these movements remains unclear [3].

METHODS: Sixteen male collegiate badminton players (20.3 ± 1.2 years) performed isokinetic strength testing (HUMAC-NORM) at $60^\circ/s$ and $180^\circ/s$. Three-dimensional motion analysis of 60-degree sidestep lunges was captured (Motion Analysis Corp., 200 Hz). Knee joint reaction forces were calculated using ANYMOCAP across three axes. Pearson correlations examined relationships between H:Q ratios and joint forces.

RESULTS: H:Q ratio significantly correlated with Y-axis (medial-lateral) joint reaction forces ($r = 0.674$, $p < 0.05$), but not with X-axis ($r = 0.183$, $p > 0.05$) or Z-axis forces ($r = 0.025$, $p > 0.05$). Mean H:Q ratios at $60^\circ/s$ were 0.62 ± 0.08 .

CONCLUSION: The significant correlation between the H:Q ratio and medial-lateral knee forces suggests its importance in maintaining knee stability during badminton-specific movements. These findings have implications for training program design and injury prevention strategies.

OPTIMIZING HIIT PRESCRIPTION IN TEAM SPORTS: A COMPARISON OF ANAEROBIC SPEED RESERVE AND VIFT-BASED APPROACHES

GULIN, J., JURICIC, T., VUCETIC, V.

UNIVERSITY OF ZAGREB FACULTY OF KINESIOLOGY

INTRODUCTION: Managing exercise intensity is crucial for optimizing endurance training, particularly in team sports where time constraints demand efficient prescription methods. Various methods refine training prescriptions to enhance performance efficiently. Interval training, specifically different modalities of HIIT (short and long), is among the most effective strategies. The primary goal of these approaches is to maximize the time spent above 90% of $\text{VO}_{2\text{max}}$, a key stimulus for aerobic capacity enhancement. Traditionally, maximal aerobic speed (MAS) has been used to prescribe HIIT sessions, particularly for short- and long-format intervals. However, this prescription model does not account for individual differences in locomotor profiles, leading to significant variability in acute training responses among athletes. A more individualized approach, incorporating anaerobic speed reserve (ASR), may offer a more homogeneous acute response. This approach could improve the effectiveness of interval training programs by ensuring that athletes experience a more consistent and targeted training stimulus.

METHODS: The sample comprised fifteen male semi-professional football players. Testing included a 40-meter sprint test (MSS), the VAM-Eval test (MAS), and the 30-15 intermittent fitness test (vIFT). Participants completed two randomized 10-minute HIIT sessions involving straight-line running. Acute training responses were evaluated using a paired t-test, comparing session rating of perceived exertion (sRPE), blood lactate [La], and time spent above 90% HR_{max} ($t > 90\% \text{HR}_{\text{max}}$) between sessions. Additionally, the effect of training prescription on intersubject variability was assessed through a paired t-test by comparing mean residuals for each training condition. In the ASR-based session (20% ASR), intensity was prescribed as a percentage of the difference between MAS and MSS, while the vIFT-based session was set at 95% of the final velocity reached during the 30-15 IFT. Testing and training sessions were conducted on a football field, with a minimum of 48 hours between sessions.

RESULTS: No statistically significant differences were observed between sessions in $t > 90\% \text{HR}_{\text{max}}$, sRPE, or [La]. However, residual analysis revealed significant differences in $t > 90\% \text{HR}_{\text{max}}$ and sRPE ($p < 0.05$), while no significant difference was found in [La] between sessions. Notably, sessions prescribed based on 95% vIFT resulted in a lower cardiac response ($t > 90\% \text{HR}_{\text{max}}$), whereas sessions based on ASR elicited a lower perceptual response (sRPE).

CONCLUSION: Contrary to previous research, our findings suggest that ASR-based HIIT prescription may not necessarily reduce intersubject variability. A possible explanation lies in the methods used to prescribe training, as the 30-15 IFT is likely more familiar to football players than the VAM-Eval test. Since ASR-based prescription accounts for both MAS and MSS assessments, it inherently introduces more variability, which may explain the differences observed in intersubject response.

CP-AP13 Coaching II - Mixed

BEING COACHED DOES NOT IMPROVE ADHERENCE TO PLANNED TRAINING LOAD IN TRIATHLETES: DIFFERENCES BETWEEN SEXES, AGE CATEGORY & RACE DISTANCE PREFERENCE

DWYER, D., WELLS, L.A., BRUCE, L., HOFFMANN, S.M., KREMER, P.

DEAKIN UNIVERSITY

INTRODUCTION: Optimal training for aerobic endurance sports is based on a planned program that specifies load in each session and variations between micro and macrocycles that align with the concept of periodisation (Bull et al., 2001). Although adherence to training has been studied (Santos et al., 2023) it is usually measured as proportion of sessions in a program that were completed, rather than the proportion of each session. This more precise measure of adherence is unknown triathlon (Clemente-Suárez et al., 2021). The current study aimed to quantify adherence to planned training load in age-group triathletes.

METHODS: Data representing all training sessions over 6 months from 37 triathletes were analysed (4,040 sessions in total). Adherence was based on the percentage difference between planned training and actual training, for total duration and total distance in each session. Adherence was calculated as mean bias and root mean squared error.

RESULTS: Triathletes completed less training than planned (duration; mean bias -5.4% , rmse 18.9% , and distance; mean bias -1.3% , rmse 16.9%). Focussing on training duration, adherence was not different ($p=0.56$) between females (mean bias -7.1% , rmse 15.8%) and males (mean bias -5.1% , rmse 19.3%) and not different ($p=0.40$) between the younger (≤ 39 years, mean bias -12.0%) and older age categories (≥ 40 years, mean bias -0.7 to -8.3%). Adherence to planned

training duration not different ($p=0.94$) between athletes that race both Long and Short course (mean bias -7.9%) compared to those that race only Long (-4.9%) or only Short course (-5.2%). Adherence was also not different ($p=0.42$) in athletes who were coached (mean bias -4.7%) compared to those who were not (-6.6%).

CONCLUSION: There are small differences in adherence to planned training that are not statistically significant, but they may be practically important. The imperfect adherence reported here represents the equivalent of 3-5 weeks of missed training per year. Furthermore, the large rmse's represent the magnitude of both over and under training, which may undermine important variations in training load between different phases of a program. Coaches should monitor and manage adherence carefully as targeted periodisation objectives may not be achieved, leading to sub-optimal adaptations.

INSTRUMENTATION OF A CONTROLLED-MANUFACTURING SURFBOARD DURING SURFING IN ORDER TO QUANTIFY THE INFLUENCE OF FLEX IN THE OVERALL PERFORMANCE OF THE MATCH ATHLETE-BOARD.

CHARLES, P., ALGOURDIN, P., OSTRE, B., JOLIFF, Y., BOUFFIER, L., FLEURY, S.

UNIVERSITÉ DE TOULON LABORATOIRE MATÉRIAUX POLYMÈRES INTERFACES ENVIRONNEMENT MARIN ; WYVE

INTRODUCTION: Despite the last OGs and a recent interest for cutting-edge training, surfers and equipment manufacturers don't have any tool guaranteeing them a consistent board-athlete match, mostly due to the incapacity to control the mechanical behavior of the board (McCagh 2013). The aim of this research is to develop a tool and gather data about the board's mechanical behavior to help define the factors of the performance match. It is proposed to make an instrumented surfboard, measuring its rigid-body motions and deformations, synchronized with biometric data from an instrumented surfer.

METHODS: A Wyve surfboard is made with a built-in electronic system made of 5 strain-gauges, IMU (Inertial Measure Unit), Bluetooth (BT) communication governed by an Arduino Nano v3. It measures and acquires at 15hz, communicates at 50Hz.

The board is calibrated on a 3-points static bending bench with tunable value and position of the input force. Data is calibrated with the inversion method (Kern 2002). Torsion is calibrated with the same method.

A surfer is surfing this board in oceanic waves from 0.8 to 1.5m. The experiment lasts for 10min or until 2 waves caught, repeated 5 times (Lestrade 2016).

The surfer is instrumented with EMGs (Electromyograph) (Cometa MiniWave Infinity) at a sample rate of 2000Hz. SENIAM references are followed to place the electrodes after skin preparation. The muscles activity (Trapezius Descendens (upper), Triceps brachii, Biceps femoris, Gastrocnemius Medialis) were recorded (Ruess 2013). The legs and lower body position was measured with IMUs (Cometa WaveTrack) calibrated using standing T-pose (Cordillet 2019).

RESULTS: On the 3-point bending bench, the system gives the application point positions and force value with this precision: 1% in x (longwise), 13% in y (in width) and 13.5% in F (force value).

In-situ, the surfboard shows good qualitative data in bending. However, due to the ever-changing limit conditions on the nose, bending calibration is irrelevant. Torsion-wise, data was calibrable. It shows that the tail tilts toward the heel of the surfer when he is standing up. On a trimming phase, the tilt-angle is around 0.4°, near 0° during a frontside bottom turn, around 0.5° during the top turn, up to 0.8° during some turns (for an intermediate surfer).

About physiognomy, we have the following proportion of the cited-before muscles activity (%), considering a wave being the phases: Paddling (2.4s) 33%. Take-off (0.5s) 12%. Trimming (2.2s) 20%. Bottom turn (0.5s) 6%, Top turn (0.8s) 9% and finish (1s) 20%.

CONCLUSION: An instrumented surfboard has been made. It shows interest in measuring the tail torsion in-situ. Further methods will be tested.

A physiognomic protocol has been validated and tests with different stiffness boards and pro-athlete will follow.

RECREATING THE NORDIC HAMSTRING EXERCISE USING A NOVEL ADAPTIVE RESISTANCE TRAINING MACHINE TO REDUCE ACUTE SORENESS AND EXTEND RANGE OF MOTION.

MUIRHEAD, P., ZAMBOLIN, F., MCPHEE, J.

MANCHESTER METROPOLITAN UNIVERSITY

INTRODUCTION: Hamstring injuries are a common and significant problem for athletes. The Nordic Hamstring Exercise (NHE) has been shown to reduce hamstring injury risk, but its application is limited when athletes lack the knee flexor eccentric torque needed to perform NHEs through the full range of motion, leading to extensive muscle damage that

hinders subsequent athletic performance. The purpose of this study was to test the efficacy of a novel adaptive resistance training machine (Akuis Sintesi, Italy) in assisting the NHE to enhance its effectiveness as a training intervention.

METHODS: The study was approved by the Research Ethics and Governance Committee and participants signed informed consent. Sixteen participants were randomized into assisted-NHE or non-assisted NHE groups to complete 15 NHE repetitions. Assessments before NHE included maximal voluntary knee flexion isometric torque (MVC) and biomechanical analysis of NHE using the Noraxon Portable lab, integrating electromyography (EMG) of bicep femoris and semitendinosus, knee and hip goniometry, shoulder and trunk accelerometry, ankle force and 2D videos. Assessments were repeated 48h later. Sintesi partially off-loaded body mass in the assisted-NHE group via a chest harness, proportional to the athlete's anthropometry, body mass and strength. Two-way repeated measures ANOVA was used for group and time interactions, with significance set at $p < 0.05$.

RESULTS: Assisted-NHE resulted in a greater range of motion ($P < 0.05$), with similar peak EMG and ankle force compared to non-assisted. Assisted NHE had lower muscle soreness at 48h and better preservation of MVC (both $p < 0.05$).

CONCLUSION: The Sintesi machine can enhance the effectiveness of NHE by allowing greater range of motion and reducing muscle soreness and damage. This has applications for optimising hamstring training and rehabilitation.

THE EFFECTS OF CHALLENGE AND THREAT APPRAISALS ON MOTOR PERFORMANCE UNDER PRESSURE

LU, C., CHEN, L.1, LIN, F.1, CHENG, M.Y.2, ELBANNA, H.3,4,5, HAGAN, J.E.3,4

¹ THE MASTER PROGRAM OF SPORT FACILITY AND HEALTH PROMOTION, NATIONAL TAIWAN UNIVERSITY ² DEPARTMENT OF SPORT SCIENCE RESEARCH, TAIWAN INSTITUTE OF SPORTS SCIENCE ³ CENTER OF COGNITIVE INTERACTION TECHNOLOGY, BIELEFELD UNIVERSITY ⁴ FACULTY OF PSYCHOLOGY AND SPORTS SCIENCE, BIELEFELD UNIVERSITY ⁵ DEPARTMENT OF SPORTS PSYCHOLOGY, FACULTY OF PHYSICAL EDUCATION, MANSOURA UNIVERSITY, MANSOURA, EGYPT

INTRODUCTION: Previous studies have established a relationship between stress-induced psychological states and motor performance, with high-pressure conditions often associated with performance deterioration. However, according to the cognitive-affective motor neuroscience (CAM) model of performance under pressure, stress may not necessarily lead to performance decline; rather, it may enable performers to achieve superior performance. Nevertheless, there is currently no research that directly tests the CAM model. This study aimed to examine the role of stress perception in motor performance by testing CAM model under pressure. Specifically, we investigated whether individuals who perceive stress as an opportunity (PO) exhibit enhanced motor performance, while those who perceive it as a threat (PT) demonstrate impaired performance.

METHODS: A total of 38 novice golfers were recruited and divided into two groups (PT group, $n = 20$; PO group, $n = 18$). Two conditions were manipulated during the experiment. Only the high-pressure condition included manipulations such as leaderboards, feedback, and cash prizes, while the low-pressure condition had no pressure-related manipulations. Within the high-pressure condition, participants received different types of feedback. Feedback was provided every five trials. PO received encouraging feedback, emphasizing that their performance was close to surpassing or slightly above 50% of others, reinforcing a sense of opportunity. In contrast, PT received negative feedback, highlighting that their performance was well below 50% and required significant improvement, cultivating a sense of threat. To assess the effectiveness of the pressure manipulation, participants completed the State Anxiety Inventory (STAI-S) before putting tasks before both high- and low-pressure conditions. Additionally, a visual analogue scale (VAS) was used to ensure that participants anxiety level remained consistent throughout the experiment. Mean radial error (MRE) was measured using the Vicon Motion Systems to evaluate putting performance.

RESULTS: The STAI-S results in both groups showed higher pressure levels in the high-pressure condition compared to the low-pressure condition. In addition, the results confirmed that VAS-measured anxiety levels remained consistent. In the MRE analysis of putting performance, PO had lower MRE as better putting accuracy under high-pressure conditions. Conversely, PT exhibited higher MRE as poorer putting accuracy under high-pressure conditions. However, there was no significant difference between the two groups under low-pressure conditions.

CONCLUSION: These findings suggest that pressure does not necessarily impair performance; rather, individuals who perceive stress as an opportunity may experience enhanced motor performance. This research provides new insights into the interaction between stress and motor performance, highlighting the potential to stress as a tool for improving athletic outcomes.

THE RELATIONSHIP BETWEEN CENTRE OF PRESSURE DATA AND ARCHERY PERFORMANCE

SANTOS, J., ATALAIA, T., ALEIXO, P.
UNIVERSIDADE LUSÓFONA, LISBOA

INTRODUCTION: Postural stability plays a pivotal role in archery performance, particularly during the aiming phase (i.e., the critical period between anchoring and releasing the arrow).1 Centre of pressure (CoP) data have been used to assess postural stability in archery. Previous research has identified key findings: a) maximum CoP sway velocity is a predictor of shooting performance;2 b) an inverse relationship between body sway and expertise level was observed;3 c) both CoP and bow sway are likely to influence shot accuracy.4 Given the scarcity of studies addressing this topic, this study aimed to further investigate the relationship between shooting performance and CoP data during the aiming phase.

METHODS: Thirty-one archers aged 18 and over were selected (19 men; 32.7 ± 17.1 years; archery experience: 13 with less than 2 years, 10 with 2-5 years, 3 with 5-10 years, and 5 with more than 10 years, age categories: 3 juniors, 20 seniors, 8 veterans). Each archer shot 10 sets of 3 arrows at a target (18 m; official competition indoor distance) with recurve bows. Shooting performance was assessed based on the target score and the distance between the arrow and the centre of the target. CoP data was collected using a RSscan pressure plate (50 Hz). In order to achieve the CoP data of the aiming phase, a camera (CANON EOS 550D; 25 Hz) was used. The following CoP parameters were computed: amplitudes of the anteroposterior and mediolateral displacements; maximum anteroposterior and mediolateral velocities; ellipse area (95%). Spearman test was used to analyse the correlation between CoP and shooting performance variables. Mann-Whitney test was used to compare subjects with more than 5 years of archery experience to those with less.

RESULTS: The data did not reveal any correlation between CoP data and shooting performance variables. However, when an individualized analysis was conducted, it was found that 10 subjects (8 with less than 5 years of archery experience) exhibited a correlation between CoP parameters and shooting performance variables ($p < 0.05$). The group with more than 5 years of archery experience exhibited better shooting performance ($p < 0.05$); however, no differences in CoP data were observed between this group and those with less than 5 years of experience.

CONCLUSION: The findings of the present study did not align with previous research that linked CoP data to shooting performance. This suggests that other variables, such as centre of gravity or bow sway, may be more closely related to archery performance and could serve as more accurate predictors. However, based on our results, CoP data may still hold value as a performance-enhancing parameter in individualized analyses, particularly for individuals with less archery experience.

A STUDY ON CAREER TRANSITION ANXIETY AND SOCIAL SUPPORT NEEDS OF PROFESSIONAL E-SPORTS PLAYERS

YU, M.Y., NAZARUDIN, M.N., MA, T., JIANG, S., ZHANG, G., SUI, X.

TIANJIN UNIVERSITY OF SPORT

INTRODUCTION: The explosive growth of the e-sports industry has spawned a group of young professional players. However, the short career of this group (average retirement age is 25 years old) makes them face multiple challenges during the transition period. Retired players not only need to deal with the rupture of identity, but also need to reposition themselves in the traditional job market. The existing support system is mostly focused on psychological counseling or financial assistance, but ignores the deep needs of skill reshaping and social recognition.

METHODS: This study uses qualitative research methods to deeply explore the sources of anxiety and unmet social support needs of e-sports players during the transition period, and provides a theoretical basis for building a more targeted career transition mechanism. The study takes 20 former professional e-sports players who have retired for 1-3 years as the research subjects, covering mainstream game type. Through in-depth interviews and participant observation, the focus is on the players career transition experience, psychological experience and social interaction. The interviews were semi-structured and focused on four core dimensions: career planning, skill application difficulties, social prejudice perception, and support needs. Each interview lasted 60-90 minutes and was supplemented by textual materials such as players social media content. The research design emphasizes contextual understanding to capture the diversity and contradictions of individual experiences.

RESULTS: The data analysis adopted the three-level coding process of grounded theory. The study found that the core of transition anxiety stems from three aspects of tension: the disconnection between the professionalism and universality of skills, the lack of social recognition of e-sports identity, and self-doubt about professional values. Most respondents said that although e-sports training has cultivated the ability to make quick decisions and teamwork, these skills are difficult to identify in the traditional recruitment system. The study also revealed that existing support policies are often misaligned with the actual needs of players.

CONCLUSION: Thereby, this study proposes that an e-sports skill certification system should be established to transform abilities into assessable workplace competitiveness. At the industry level, the study suggests that clubs should be encouraged to cooperate with vocational education institutions to develop customized courses for retired players, and all sectors of society can reconstruct the image of e-sports through public publicity, emphasizing the universal value of soft skills. The study is not only about the transformation of individual career paths, but also involves the reconstruction of cultural capital and the renegotiation of social identity. At the practical level, the research conclusions provide a roadmap for the e-sports industry association to shift from "crisis response" to "preventive support."

EXPERT OPINION ON THE ROLE OF SKILL ACQUISITION SPECIALISTS IN APPLIED SPORT SCIENCE: A DELPHI STUDY

RUNSWICK, O., UIGA, L., FORD, P., SMEETON, N., MILLER-DICKS, M.

KINGS COLLEGE LONDON

INTRODUCTION: Skill acquisition is a rapidly evolving field of sport science, but its definitions, roles, and professional practices remain inconsistently articulated. Despite growing recognition of its importance, there is a lack of consensus regarding the core competencies and responsibilities of skill acquisition specialists, which creates barriers for the development of professional accreditation and development pathways. The aim of this study was to consult with experts to establish a consensus definition of the field of skill acquisition, clarify the roles of its specialists, and understand the needs and requirements of effective applied practice.

METHODS: A panel of 22 international experts in skill acquisition (15.2 ± 8.4 years' experience) took part in a Delphi study using online surveys following the Guidance on Conducting and Reporting Delphi Studies (CREDES). The panel included some of the most noteworthy skill acquisition researchers in the world, practitioners in professional sport across three continents, successful early career skill acquisition specialists, and other roles including high performance managers and coach developers. The survey comprised seven sections: (i) panellist information; (ii) definitions of the field of skill acquisition; (iii) definitions of the role of the skill acquisition practitioner; (iv) the need for skill acquisition specialists in MDTs; (v) knowledge requirements; (vi) technical skills; and (vii) professional competencies. Consensus was set at 75% (17 out of 22 respondents agree).

RESULTS: The panel reached consensus that skill acquisition specialists represent a unique and currently underrepresented role within multidisciplinary support teams in sport. The panel developed and agreed upon a clear definition of the field: 'an applied science addressing the performance, learning, and refinement of perceptual, cognitive, and motor skills across the spectrum from novice to expert performers.' There was also consensus on the definition of the role of skill acquisition specialists: 'skill acquisition specialists work in partnership with key individuals and groups (e.g., coaches, athletes) to apply research-led and theoretical principles to enhance and measure the perceptual, cognitive, and motor skills of performers.' Key responsibilities of a skill acquisition specialist were identified as practice design, individualised skill development, and education at the organisational level. Furthermore, the panel reached consensus on the essential knowledge and professional skills required to fulfil this role effectively.

CONCLUSION: Findings present a first step towards establishing a framework for professional development and accreditation in skill acquisition as a standalone discipline of sport science. This is key for the integration of high-quality, evidence-based skill acquisition practices within sport organisations.

DUAL-TASK LANDING CHALLENGES ON DYNAMIC POSTURAL STABILITY IN ATHLETES DURING DROP JUMP

CHANG, Y., HUNG, M., YU, C., LIN, J.

NATIONAL TAIWAN UNIVERSITY OF SPORT

INTRODUCTION: Athletes often perform motor and cognitive tasks simultaneously during sports events, which inevitably involve dual-task. According to the attention demand theory, dual-task challenges can impair athletes postural control and coordination, resulting in suboptimal and even injury [1], and dynamic postural stability can be used to assess the extent to which athletes are disturbed by motor tasks [2]. Few studies have investigated the effect of unintended landing combined with dual-task. This study aims to examine the dynamic postural stability during drop-jump with or without dual-task, simulate a distraction scenario and assess postural control.

METHODS: This study recruits 8 college female athletes. The dual-task intervention consisted of using a hand-held wireless grip strength meter to control 30% of maximum grip strength while performing a 30 cm platform drop-jump with single-leg balance test, collecting 3 successful movements for analysis. Data were collected using 12 Vicon cameras and 2 Kistler force plates to analyze the dynamic postural stability index (DPSI), center of pressure (CoP), center of mass (COM), and lower extremity joint kinematics. A paired-sample t-test was used to compare dual-task (DT) and non-dual-task (NDT).

RESULTS: According to the results of the paired-sample t-test, no significant differences were found in lower extremity kinematics and ground reaction forces. However, the CoP total sway distance ($p = 0.035$), Medial-Lateral sway velocity ($p = 0.007$), and the vertical range of the COM ($p = 0.046$) were significantly lower in the DT compared to the NDT.

CONCLUSION: This study found that the dual-task had less total sway and slower velocity at the CoP with less vertical range of COM.

This highlights the heightened challenge athletes face when encountering unexpected landings combined with DT. A restricted lower limb cushioning preparatory posture adopts a more conservative postural stability control strategy and exhibits poorer dynamic postural stability characteristics compared to the NDT. Research indicates that when athletes face threats to postural stability, they tend to adopt a more stable landing strategy while sacrificing secondary task performance to optimize postural stability[3]. Dual-task challenges may vary among athletes at different levels, and further studies are needed to explore the influence of athletic proficiency.

COMPARISON OF OPEN AND SQUARE STANCE IN THE FOREHAND AMONG COMPETITIVE TENNIS PLAYERS: A PRELIMINARY STUDY

CAPRIOLI, L., ROMAGNOLI, C., CARIATI, I., CAMPOLI, F., EDRISS, S., BONAIUTO, V., PADUA, E., ANNINO, G.
TOR VERGATA UNIVERSITY OF ROME

INTRODUCTION: The kinetic chain in tennis originates from the legs, and a proper stance is crucial for effective energy transfer to the ball [1,2]. Among the stances, the open stance forehand has gained popularity in the last twenty years despite the traditional square stance [3,4]. Hypotheses favoring open stance were supported by a study [5] that argued that this stance offers more power in strokes, allowing athletes to generate more spin and reach wider angles, however, the results in the literature are sometimes discordant [6,7] and many studies have linked the open stance to increased injury risk [8,9,10], but a clear understanding of the performance differences between the square and open stances remains elusive. This study aims to compare the effectiveness between forehand played in open and square stance, in terms of performance: 1) ball speed, 2) accuracy, 3) gesture economy.

METHODS: Ten healthy competitive players (8 males, 2 females) were involved in the study. Eighty forehands were played by each subject with open and square stance, in lateral and diagonal-inside running structured situations, receiving the ball from a ball-throwing machine, and aiming to play in a square-shaped target with 2 m sides. The ball's speed, accuracy of the shot and heart rate were acquired. Kruskal-Wallis's tests and Dunn Post Hoc tests were used to compare the effect of stance and tactical situation on these performance variables. Wilcoxon signed-rank t-test was applied for a separate comparison of each between the two types of stances. Jasp (Version 0.18.3) and R software (Version 4.4.2) were used for the statistical analysis of the data.

RESULTS: Square stance consistently resulted in significantly higher ball speeds in both lateral running (Δ Median: 8 km/h) and diagonal-inside running (Δ Median: 8.5 km/h), while differences in accuracy and metabolic demand were not significant.

CONCLUSION: This preliminary study found that, in the examined group of competitive tennis players, square stance technique provided a clear advantage in terms of generating ball speed. Although the higher accuracy found was not significant, so was the difference in metabolic effort, it follows that the advantages in performance, together with and reduced risk of injury seem to make the square stance the preferable choice. A larger survey of a greater number of subjects is required.

THE IMPACT OF OPEN AND SQUARE STANCES ON THE PERFORMANCE OF FOREHAND DRIVES IN FAVORABLE TENNIS SITUATIONS

TRIOLET, C., HYBOIS, S., DOURRIEU, B., GUIGUI, K., LEGÉ, C., OBERTAN, M., TEULIER, C.
UNIVERSITÉ PARIS SACLAY

INTRODUCTION: In tennis, open and square stances are both used to produce forehand drives, especially when players are not under time pressure [1], like in offensive situations. Interestingly, even though some biomechanical differences between these stances have been found [2;3], studies about their impact on performance are sparse. Indeed, a few studies showed no differences in racket speed [4;5] between square stance and open stances among high-level players, while the impact on shot accuracy has never been studied.

Hence, the objective of our study was to examine the impact of using open or square stances during the execution of forehand drives in offensive tennis situations in terms of ball speed and shot accuracy.

METHODS: Thirteen tennis players (two women and eleven men), at the regional to national level, performed a laboratory task that involved executing winning down-the-line forehand drives with the highest possible speed and accuracy.

Subjects were required to perform 8 series of 5 strokes (4 series with open stances and 4 series with square stances) aiming at a target integrated into the projection of a tennis court image.

A radar (Stalker Pro II) was used to record ball speed. Stroke accuracy was assessed through the distance between ball impact and the center of the target, using video footage processed with the Kinovea software.

RESULTS: Wilcoxon paired samples T tests showed a significant effect for ball speed ($W=8$; $p=.006$) but not for accuracy ($W=65$; $p=.191$). Stroke speed was higher when players used square stance ($130.46 \text{ km.h}^{-1} \pm 13.49$) than when they used open stance ($123.3 \text{ km.h}^{-1} \pm 11.46$).

An additional analysis examined whether players tended to hit higher or lower, more to the left or to the right depending on the stances used. It did not show any accuracy bias based on stance modality.

CONCLUSION: While looking at the two key factors of performance in tennis forehand drives (ball speed and accuracy), only ball speed varied based on stances used. Previous studies showed no difference in terms of racket speed [4;5] but did not put players in specific situations (hitting an offensive shot within a target), hence probably hiding the overall differences. Moreover, these differences may be attributed to the players level of expertise, the controlled laboratory setting of our experiment, or the fact that all their drives occurred under favorable conditions, i.e., without time constraints. Hence it

seems worthwhile to continue studying these strokes in favorable situations to analyze which stance is the most effective in a real-life situation on the tennis court.

EFFECT OF VIBRATION DAMPENERS ON PLAYERS PERCEPTION AND PERFORMANCE IN TENNIS: A PILOT STUDY

NAJLAOUI, A., CAPRIOLI, L., CHADEFaux, D., DANey, T., PADUA, E., PATÉ, A., BONAIUTO, V., ANNINO, G.5

TOR VERGATA UNIVERSITY

INTRODUCTION: Traditional tennis vibration dampeners (VD) are small devices placed between the strings of a tennis racket to reduce vibrations [1], with the purpose of providing a more comfortable playing experience. However, some studies [2,3] found that VDs reduce some high frequencies, but do not reduce racket frame vibration transfer to the forearm. Thus, we hypothesize that VDs are relevant mainly to players acoustic preferences and, to a lesser extent, to proprioceptive comfort. The relevant question is whether VDs influence players' perception and performance.

METHODS: Thirty experienced tennis players (> 4 years of playing experience) wore during the test an earmuff (30dB attenuation) and used a racquet where the presence of the VD was masked. Unaware of the situation, they participated crosswise in 2 groups: Vibration Damper (VD) and Control Group (CG). The subjects performed 2 sets of 10 long line fore-hand shots for each situation on the same day, receiving the ball from a ball-launching machine, aiming to play as fast as possible into a 2mx2m area on the other side of the court. A speed radar (Pocket Radar Inc., Santa Rosa, CA, USA) measured the ball speed. A questionnaire regarding the presence or absence of VD and playing comfort was filled. Repeated measures MANOVA was used to detect changes in ball speed, accuracy of the shots and players comfort between the two groups. Statistical analysis was carried out with Jasp software (Version 0.18.3). Preliminary results are presented.

RESULTS: The results of one participant are shown. The player perceived no difference in the sound of impact. However, being used to playing with the same racquet model of the experiment with VD, he recognized his usual situation as a playing feel and correctly guessed when the racquet had the VD. In terms of performance, there was no significant difference in accuracy between the two situations (VD: 56%; CG: 50%) and a difference of almost 3km/h, but still not significant occurred in ball speed with VD compared to the other condition: (VD: 127.3; CG: 124.5 km/h).

CONCLUSION: The preliminary results provide initial insights into the potential effects of VDs on tennis performance. These findings suggest that the presence of VD, where the player was accustomed, might have subtly influenced his gesture, potentially leading to a slight increase in swing speed; highlighting the role of subjective perception and player familiarity in influencing performance and comfort feel. The analysis of the full sample size, as well as the use of inertial sensors, handle pressure sensors, and video cameras, may contribute in future studies to understanding the impact of VD on tennis performance.

LONGITUDINAL MONITORING OF SHOULDER STRENGTH ASYMMETRIES IN ELITE YOUTH TENNIS PLAYERS

CHAPELLE, L., DHONDT, J.

VRUE UNIVERSITEIT BRUSSEL

INTRODUCTION: Longitudinal monitoring of shoulder strength asymmetries in athletes is essential, as these imbalances are associated with reduced sports performance and increased injury risk. Tennis players, who frequently perform repetitive overhead motions, are particularly susceptible to strength discrepancies in the shoulder complex. Identifying and quantifying these asymmetries in elite youth tennis players can provide valuable insights for optimizing performance and reducing injury risk. This study aimed to examine longitudinal changes in shoulder strength asymmetries in elite youth tennis players.

METHODS: Twelve elite youth tennis players (5 males, 7 females; mean age: 14.5 ± 1.8 years) underwent two isokinetic strength assessments, separated by a 12-month period, using a Biodex dynamometer. Measurements included peak torque, peak torque/body weight, and peak power for internal and external rotation at 90° shoulder abduction and a velocity of 60°/s. Asymmetry magnitudes were calculated using the percentage difference method: $((\text{dominant value} - \text{non-dominant value}) / \text{dominant value}) * 100$. Data normality was assessed with the Kolmogorov-Smirnov test. Repeated-measures ANOVA's analysed changes in dominant and non-dominant internal and external rotation strength, as well as the asymmetry magnitudes, over time separately for male and female players. Statistical significance was set at $p < 0.05$.

RESULTS: All data were normally distributed. Strength measures were significantly higher ($p < 0.05$) in the dominant shoulder except for external rotation peak power, which showed no significant difference. Most strength metrics increased significantly over time, except for peak power/body weight in both internal and external rotation. Male players exhibited significantly greater internal and external rotation power than females. Asymmetry magnitudes ranged from 12.8 % to 34.1 %, with internal rotation asymmetry decreasing significantly over time, while external rotation asymmetry remained unchanged.

CONCLUSION: These findings confirm the presence of significant shoulder strength asymmetries in elite youth tennis players, which evolve over time. Given the potential impact on performance and injury risk, targeted strength and conditioning programs are essential to address these imbalances. Due to the considerable variation in asymmetry magnitude, individualized assessments are recommended. Additionally, as the young age of participants precluded testing at higher angu-

lar velocities (e.g., 180°/s), future research should investigate whether significant asymmetries persist at greater angular speeds.

PREVALENCE AND FACTORS ASSOCIATED WITH PATELLAR TENDINOPATHY AMONG YOUNG TENNIS PLAYERS

ASPANDI, Y., SKY, B., STEINBERG, N.

THE ACADEMIC COLLEGE LEVINSKY-WINGATE, WINGATE CAMPUS

INTRODUCTION: Tennis is a sport in which proficiency begins at an early age. It differs from other sports in the duration of matches, the rigid playing surface and the fact that it is an asymmetrical activity. Additionally, tennis players must combine various physical abilities, such as short and rapid sprints, changes in direction, agility and muscle strength, to achieve high performance levels. These factors may create significant loads on the joints and may lead to injuries. This study was aimed to identify the prevalence and the factors associated with patellar tendinopathy among young tennis players.

METHODS: Eighty-six young tennis players (29 girls), aged 8-18 years (12.7 ± 1.9), members of the youth national teams participated in the current study. Measurements for both legs included: A Training Load Questionnaire, anthropometric measures, age, dynamic balance (Y-Balance test -YBT), agility (Hexagon Hop Test), bone strength (Quantitative Ultrasound Speed of Sound), muscle strength (by Handheld Dynamometer) and range of motion (ROM) (by Goniometer). Additionally, each participant underwent a clinical examination (Royal London Hospital Test) by a physiotherapist to identify patellar tendinopathy.

RESULTS: One hundred seventy-two legs were evaluated. For patellar tendinopathy only 165 legs were clinically examined (7 legs were excluded), with 83 legs (50.3%) identified with patellar tendinopathy. Significant differences were found between the injured and uninjured legs indicating that dynamic balance ($p < 0.01$), hip abductors ($p < 0.01$), hip flexors ($p = 0.001$) and knee extensor muscle strength ($p < 0.01$) were reduced in the injured legs compared to the uninjured legs. Additionally hip abductors ROM ($p < 0.01$), hip flexor ROM ($p < 0.01$) and knee flexors ROM ($p = 0.01$) were higher in the injured legs compared to the uninjured legs. Other examined variables were not significantly different between injured and uninjured legs ($p > 0.05$). Logistic regression analysis indicated that greater hip abduction ROM ($OR = 1.14$, $p < 0.001$), greater hip flexion ROM ($OR = 1.05$, $p = 0.02$) and fewer training hours per week ($OR = 0.93$, $p = 0.01$) were associated with an increased risk of patellar tendinopathy.

CONCLUSION: About fifty percent of the legs were diagnosed with patellar tendinopathy. Reduced dynamic balance, lower hip and knee muscle strength and greater hip and knee joint ROM were found in the injured legs compared with the uninjured legs. Additionally, greater hip ROM and reduced training hours were associated with increased risk for patellar tendinopathy. It might be suggested that a combination of insufficient weekly training hours, which are insufficient for building muscle strength and achieving optimal range of motion, along with poor dynamic balance, may increase the risk of patellar tendinopathy. These findings may contribute to the development of prevention and intervention programs aimed at reducing patellar tendinopathy in young tennis players.

THE EFFECTS OF A 4-MONTH MOVEMENT THERAPY TREATMENT ON YOUTH SHORT TRACK SPEED SKATING ATHLETES

BAJZIK, É., TÖRÖK-SZABÓ, B., VETO-SZABÓ, G.

FONTANUS CENTER LTD.

INTRODUCTION: When developing the Balance² movement therapy training method, our goal was to harmonize muscle balance disorders present in the body at any age, regardless of their cause. The foundation of the method lies in revisiting basic infant reflexes and fundamental movements within a comprehensive training framework. This approach enhances motor coordination skills, thereby improving fundamental movements and posture.

For competitive athletes, it is essential to recognize that sport-specific movements place unique demands on the body and the musculoskeletal system. Finding an appropriate complementary movement form alongside these specialized movements poses a challenge.

In our study, we tested the Balance² method as a supplementary movement form for short track speed skating.

METHODS: Examined Group:

Short track speed skating athletes aged 11-16

Baseline Assessments:

Stabilometric measurements

Balance² assessment

Starting Point:

All participants had been competing in short track speed skating for at least one year and followed a corresponding training program, including on-ice practice, strength training, and speed workouts.

Before the assessment, we assumed that flexibility deficits would be the primary issue. However, the evaluation revealed that overall coordination skills needed improvement. Athletes approaching peak growth showed satisfactory lateral stability, while those in the midst of or past their peak growth phase exhibited significant instability.

Method:

Participants attended Balance² movement therapy training sessions twice a week as a supplementary exercise.

RESULTS: All athletes participating in the study showed significant improvement over four months. After an average of two Balance² movement therapy sessions per week, enhancements were observed in static and dynamic balance abilities, the overall coordination of the anterior and posterior muscle chains, and core stability. Postural alignment also improved significantly, as assessed by the weight-bearing line analysis.

CONCLUSION: Based on the measurement results, the Balance² movement therapy training method could also be suitable as a complementary exercise for other sports. Additionally, it may serve as an effective movement form for adolescents who do not compete in sports, helping to improve overall posture.

SEASONAL CHANGES IN BODY COMPOSITION AND PERFORMANCE IN MALE AND FEMALE ICE HOCKEY PLAYERS

JUNGMAALM, J., GUSTAFSSON, M., PETTERSSON, S.
UNIVERSITY OF GOTHENBURG

INTRODUCTION: Recent developments in women's ice hockey such as allowing tackles suggest that physical demands will increase and be more similar to men's game. Yet, research indicates that female players may exhibit suboptimal strength and physical capacity training compared with their male counterparts (1,2). We were therefore interested in comparing seasonal changes among top-level Swedish ice hockey players. This prospective study aimed to examine seasonal changes in body composition, strength, and on- and off-ice performance in male and female ice hockey players, focusing on potential sex differences and time-dependent variations.

METHODS: Male (n=25) and female (n=23) elite ice hockey players underwent measurements at three time points (May/June, August, December) within one season. Body composition was assessed by DXA, and performance tests included both on-ice (e.g., sport-specific drills/sprints) and off-ice measures (back squat, power clean, bench press, 10/30-meter sprint, and broad jump). Repeated-measures ANOVA was used to analyze the effects of sex (between-subjects) and time (within-subjects), as well as their interaction.

RESULTS: Analyses consistently showed a strong main effect of sex ($p < 0.001$), indicating higher overall performance scores and lower body fat percentages in male players. By contrast, the effect of time (month) on outcome measures was either non-significant or of smaller magnitude, suggesting limited seasonal fluctuation in tested variables. Where tested, the interaction between sex and time was generally non-significant ($p > 0.05$), implying that changes over time did not differ substantially between male and female players.

CONCLUSION: These findings support earlier indications that physical and performance discrepancies persist between male and female hockey players. Although both groups undergo similar seasonal training and match demands, the data suggest that sex differences, rather than seasonal fluctuations, predominantly drive variations in body composition and performance. However, the small changes over time in this sample contrast with some previous reports of greater seasonal body composition shifts in female players (3). The present results underscore the need for tailored strength and conditioning programs that address specific performance demands of both male and female ice hockey players.

THE IMPACT OF PHYSICAL FITNESS ON PERFORMANCE IN THE EMERGING OLYMPIC SPORT OF IQFOIL: INSIGHTS FROM JUNIOR WINDSURFERS

LO, K.K., TAI, C.H., CHAN, Y.Y.
HONG KONG SPORTS INSTITUTE

INTRODUCTION: The debut of IQFoil as an Olympic event at the Paris 2024 Games has marked a significant evolution in competitive windsurfing. This new class, characterized by its unique hydro-foiling design, imposes distinct physical demands on athletes, necessitating a comprehensive understanding of how physical fitness influences performance outcomes. Effective fitness training not only enhances athletes capabilities but also helps in injury prevention, which is crucial given the physically demanding nature of windsurfing. This study aims to investigate if any correlation between physical fitness metrics and competitive results within the context of junior windsurfers, providing insights that could inform future training strategies and improve competitive performance in the IQFoil class.

METHODS: Seventeen junior windsurfers (10 males and 7 females; mean age 15.7 ± 0.62 years) participated in the study. Pre-competition assessments measured rowing power profiles, maximal aerobic running speed, and VO_2 max. Performance rankings were derived from the cumulative results of five races over two days. Descriptive statistics and Pearson correlation analysis were employed to explore relationships between competition rankings, fitness metrics, body weight, and height, with statistical significance set at $p < 0.05$.

RESULTS: The maximum race duration was 5 minutes and 13 seconds, during which competitors sustained 90% - 100% of HRmax for maximum of 2 minutes and 28 seconds. Analysis revealed significant positive correlations between competition ranking and maximum rowing power metrics for males: ten-second power ($r = 0.90$), one-minute power ($r = 0.67$), and four-minute power ($r = 0.84$). However, no correlations were observed for female participants regarding rowing power. A significant correlation was also found in body weight ($r = -0.88$) for males. No correlation was found between competition ranking and relative maximum power metrics, nor between maximal aerobic running speed and $\text{VO}_2 \text{ max}$ for either gender. These findings suggest that race intensity is high, and enhancing absolute rowing power is crucial for success in IQFoil, particularly for effective pumping throughout races.

CONCLUSION: IQFoil presents high-intensity physical demands with shorter competition durations. Due to the design changes of IQFoil, body mass and absolute rowing power significantly influence performance. Further investigation is warranted to evaluate the impact of technical skills, as prioritizing technical proficiency may be essential before optimizing fitness levels to meet the sports rigorous demands.

SINGLE-LEG LATERAL JUMP TESTS DISCRIMINATE GENDER AND COMPETITIVE LEVEL IN TABLE TENNIS PLAYERS

GUARNIERI, A., LAURENTI, F., PRESTA, V., MAZZEI, S., GOBBI, G., CONDELLO, G.

UNIVERSITY OF PARMA

INTRODUCTION: Table tennis (TT) requires explosive and reactive actions in the frontal plane. Therefore, this study aims to assess mediolateral movement patterns in TT players.

METHODS: Fifty-three TT players (Males=43; Females=10) of different age categories (Senior=32; Under 19=21) and competitive levels (High=12; Medium=20; Low=21) executed 3 single-leg lateral jumps: for the Maximal Lateral Rebound Jump test (MLRJ), players stood on one leg, performed a lateral jump, and rebounded with the opposite leg as fast as possible returning to the stance leg, reaching the maximal lateral jumping distance [1]; the Lateral Squat (LSJ) and Countermovement (LCMJ) Jump tests were executed on the mediolateral direction pushing with one leg and landing on the opposite leg [1]. The leg corresponding to the playing hand was defined as the Playing Side (PS), while the opposite leg was identified as the Non-Playing Side (NPS). Each test was repeated three times per leg and the average value was used for the statistical analysis. Contact Time (CT) of the rebounding leg was registered for MLRJ, and jumping distance was measured for MLRJ, LSJ, and LCMJ. The trochanterion height (TH) was measured for each participant from the floor to the trochanterion landmark [2].

RESULTS: A significant difference in the TH emerged between genders ($p < 0.001$; $d = 1.474$), and among competitive levels only for female sample ($p = 0.015$; $\eta^2 = 0.129$).

No differences emerged between age categories, whilst gender differences were found for jumping distances (normalized by TH) in the MLRJ (PS: $p = 0.003$, $d = 1.091$; NPS: $p = 0.001$, $d = 1.209$), LSJ (PS: $p = 0.001$, $d = 1.380$; NPS: $p = 0.016$, $d = 0.905$), and LCMJ (PS: $p < 0.001$, $d = 1.614$; NPS: $p < 0.001$, $d = 1.340$), with males outperforming females.

Differences among competitive levels emerged only in the MLRJ. In male group, high (169.3 ± 12.4 cm; $p = 0.031$, $d = 1.105$) and medium (167.2 ± 11.9 cm; $p = 0.035$, $d = 0.936$) level players reached longer jumping distances for the PS leg than low level players (157.4 ± 8.8 cm), even if no differences emerged for CT. For the NPS leg, high level players (171 ± 13.9 cm; $p = 0.013$; $d = 1.099$) performed longer jumping distances than low level players (158.8 ± 7 cm), without any differences for CT. In female group, the only difference emerged in the NPS leg, with longer jumping distances (normalized by TH) reached by high level players (1.79 ± 0.09 AU; $p = 0.036$; $d = 2.980$) compared with medium level players (1.56 ± 0.06 AU), without any differences for CT.

CONCLUSION: The preliminary analysis on gender demonstrates the capability of the 3 jump tests to discriminate differences between male and female TT players. However, only the MLRJ is able to discern differences among competitive levels. The greater performance demonstrated by the high level players highlights their higher ability in reactive strength, specifically in the application of an efficient stretch-shortening cycle.

CP-AP16 Combat Sports and Strength

TRAINING AT ALTITUDE: PREPARING AN ELITE JUDOKA FOR THE OLYMPICS

TILL, J., CLOAK, R., LANE, A.M., KONS, R.L., ROBINSON, D.

UNIVERSITY OF WOLVERHAMPTON

INTRODUCTION: Hypoxic training is frequently used to enhance sea-level exercise performance (Bonetti and Hopkins, 2009). Recently, the application of hypoxic training for accelerating return to play has gained popularity (Narang et al.,

2024). The use of hypoxic training for aiding in return to play whilst simultaneously preparing an athlete for the Olympic Games is yet to be explored. Therefore, the aims of this study were: (1) to examine data collected from a 12-week hypoxic training programme on exercise performance of an elite judoka returning from injury and preparing for the Olympics; (2) to explore the practices and perceptions of an elite judoka on the efficacy of hypoxic training for return to play and Olympic preparation.

METHODS: This study adopted a single-subject case-study research design which allowed for a detailed analysis of the individual physiological changes and responses to hypoxic training in an elite judoka. An elite female judoka completed a 12-week hypoxic training programme developed and implemented by British Judo. Exercise testing (2,000 m time-trial) was completed throughout the programme to measure aerobic performance. A 20-minute semi-structured interview was conducted by the primary researchers post-Olympic Games to explore the judoka's experiences and perceptions of hypoxic training. Data collected from the testing sessions were reported using relative percentage change. Interview data was analysed using a 6-step thematic analysis (Braun and Clarke, 2006).

RESULTS: Time-trial performance was improved after 6 weeks of training (07:36 (-3.8%) ~95% maximum heart rate (MHR)) and was further improved at week-10 (07:28 (-5.49%) ~96% MHR) of the programme when compared to pre-altitude time-trial performance (07:54). Eight sub-themes were organised into three higher-order themes: Altitude Training Practices, Altitude Training Benefits and Altitude Training Drawbacks. The first theme was used to describe previous and current altitude training methods adopted by the judoka (e.g. 'we definitely did some interval sessions'). The second theme captured the judoka's perception of the advantages that altitude training provided her with (e.g. 'I've never felt that fit in a competition ever'). The final theme encapsulated the judoka's views on the negative effects of altitude training (e.g. 'we realized we go away a lot, so it was kind of interrupted training').

CONCLUSION: Findings demonstrate that hypoxic training is an effective strategy for improving fitness during return to play and for enhancing exercise performance during Olympic preparation in an elite judoka. Hypoxic training was viewed as a beneficial aid to improving fitness, exercise performance and psychophysiological responses from training. Despite potential scheduling issues, applying an adaptable, athlete-led approach to coaching was suggested to overcome this concern. Additionally, improved motivation, enjoyment and athlete buy-in may enhance adherence to future training programmes in judokas.

LOCAL MUSCULAR OXIDATION: A KEY COMPONENT OF COMPREHENSIVE ENERGY SYSTEM PROFILING IN PROFESSIONAL MIXED MARTIAL ARTISTS

GRELLE, B., FOMIN, R.

THE UFC PERFORMANCE INSTITUTE

INTRODUCTION: Mixed Martial Artists (MMA) performance relies on a complex interplay of anaerobic power, aerobic capacity, and local muscular performance. However, traditional energy system assessments focus largely on systemic metabolism, often overlooking local muscular metabolism. This study investigates local muscle oxygenation in conjunction with systemic metabolism to better understand sport-specific energy system demands in professional MMA fighters.

METHODS: Twenty-eight male professional MMA fighters completed comprehensive Energy System Profiling (ESP) using an Air-Bike Elite (Assault Fitness), following a protocol developed by the UFC Performance Institute (2021). This protocol consisted of two assessments: (1) a 1-minute all-out maximal glycolytic power (MGP) test followed by a 2-minute active recovery, and (2) a maximal aerobic power (VO2 Max) test using an 8-minute incremental protocol to exhaustion, during which assessments were taken before exercise, during exercise, and one-minute post-exercise for both assessments. Data was collected from the Air-Bike, recording absolute and relative power output (PWR). Near-Infrared Spectroscopy (NIRS) devices (Train.Red) were positioned on m. rectus femoris to assess muscular oxygenation, with a primary focus on Tissue Saturation Index (TSI, %) to evaluate oxygen extraction rates in the lower body. Respiratory gas exchange was measured using a metabolic analyzer (K5, COSMED) to assess oxygen uptake (VO2), carbon dioxide production (VCO2), respiratory exchange ratio (RER), and ventilation parameters throughout the testing protocols.

RESULTS: For both assessments, baseline TSI was 71 +/- 6.2%. The MGP results showed a mean PWR of 10.3 W/kg, with a minimum TSI of 41%, VO2 of 48 ml/kg/min, and a peak RER of 1.3. The 1-minute post-recovery TSI was 63%. The VO2 Max test showed a mean PWR of 6.6 W/kg, a minimum TSI of 43% at Peak VO2, VO2 of 52 ml/kg/min, and a maximum RER of 1.3, with a post-recovery TSI of 61%. A TSI of 48% at Threshold 2 during the VO2 Max test showed a strong correlation ($r = 0.85$) with the minimum TSI value reached in the MGP test.

CONCLUSION: The MGP results showed a significant drop in TSI, followed by a rapid recovery, indicating that athletes can quickly restore muscle oxygenation after short, intense glycolytic bouts. This suggests that their recovery is more efficient following high-intensity efforts compared to prolonged aerobic exertion, as reflected by slower recovery rates during the VO2 Max. Strong correlation between the minimal TSI during the MGP and the TSI at Threshold 2 in the VO2 Max highlights the interconnected relationship between the shift to anaerobic metabolism during the VO2 Max test and the oxygen utilization demands observed during the MGP test. This emphasizes the often-overlooked role of local muscular performance and monitoring within ESP, providing a more comprehensive evaluation of an MMA fighters energy systems strengths and deficiencies.

FACTORS DETERMINING KICKING PERFORMANCE IN TAEKWONDO: THE ROLE OF ISOKINETIC KNEE AND HIP STRENGTHS

YÜKSEL, B., ACAR, S.T., ÖLMEZ, C.

INSTITUTE OF HEALTH SCIENCES

INTRODUCTION: The movement dynamics of the knee and hip joints emerge as a crucial component among the key biomechanical parameters that determine kicking performance. The influence of hip and knee isokinetic strength on the biomechanics of the kicking motion is significant, as these forces contribute to the overall effectiveness and accuracy of the strike [1]. The coordination of these muscle groups is essential for generating the necessary power and stability during the kicking action [2]

METHODS: The study was conducted with the voluntary participation of 20 elite taekwondo athletes. The isokinetic strength performance of the athletes knee and hip joints was assessed using a Cybex (Humac Norm) isokinetic dynamometer (CSMI, Stoughton, MA). Knee extension (EXT) and flexion (FLX) torques were analyzed at 60°/s, 180°/s, and 300°/s angular velocities, and hip FLX and EXT torques were analyzed at 60°/s and 180°/s angular velocities. Kicking speeds were measured using Kinovea (0.9.5).

RESULTS: The analysis of the relationship between athletes left kick speed and isokinetic knee strength revealed statistically significant correlations in the dominant limb at 60°/s FLX ($r = 0.463$), 180°/s FLX ($r = 0.647$), 300°/s EXT ($r = 0.506$), and 300°/s FLX ($r = 0.704$). In contrast, no significant relationships were found between the dominant limb isokinetic strength and right kick speed ($p > 0.05$). On the other hand, significant correlations were identified between left kick speed and the non-dominant limb at the hip joint for 60°/s EXT ($r = 0.527$), 180°/s EXT ($r = 0.517$), 300°/s EXT ($r = 0.575$), and 300°/s FLX ($r = 0.471$). Similarly, statistically significant relationships were observed between right kick speed and the non-dominant limb at 60°/s EXT ($r = 0.566$), 180°/s EXT ($r = 0.468$), and 300°/s EXT ($r = 0.506$).

Goncalves, 'Are isokinetic leg torques and kick velocity reliable predictors of competitive level in taekwondo athletes?', Plos One, vol. 16, no. 6, p. e0235582, Jun. 2021, doi: 10.1371/journal.pone.0235582.

[2] N. Hammami, B. Zinoubi, F. Hamdi, A. Nouri, A. Zouita, and C. Dziri, 'Isokinetic profile of knee muscles in Olympic elite taekwondo practitioners', Sci. Sports, vol. 28, no. 4, pp. 188–195, Sep. 2013, doi: 10.1016/j.scispo.2013.01.003.

CONCLUSION: The results revealed significant relationships between right and left kicking velocities and knee and hip isokinetic torques. Significant relationships were observed especially at 180°/s angular velocity in hip isokinetic strength and at 60°/s, 180°/s, and 300°/s angular velocities in the knee. These findings indicate that lower extremity isokinetic strength contributes to kicking performance and suggest that focusing on these angular velocities in training programs may be beneficial.

THE EXTERNAL AND INTERNAL LOADS AND INTENSITIES OF SIMULATED BRAZILIAN JIUJITSU TOURNAMENT

KIRK, C., FINLAY, M., ANGELL, P., MATHER, J.

SHEFFIELD HALLAM UNIVERSITY

INTRODUCTION: Brazilian jiu-jitsu (BJJ) is a grappling based combat sport contested in one-day knockout tournaments of consecutive 5 min bouts with relatively short recovery time between bouts. The internal loads of BJJ bouts have been previously explored, but the external loads have not. Additionally, reported measurements have occurred at the end of each bout without quantifying changes in loads within the bout. The aim of this study was to measure changes in internal and external loads and intensities of BJJ simulated tournaments between bouts, and between minutes within bouts.

METHODS: N = 8 male BJJ athletes were recruited (age=39±6; mass=85±14kg; stature=176±7cm) and paired based on mass and belt. Participants took part in 5x5 mins BJJ bouts under tournament rules against the same opponent in each bout. If any submission occurred participants were instructed to immediately continue the bout from a neutral position. Each bout was interspersed by a 10 min recovery period. Throughout each bout participants wore a Catapult Vector accelerometer (Catapult Innovations, AUSTRALIA) on the T3-4 vertebrae in a secure harness to measure Playerload as external load (PLdACC) and external intensity (PLdACC-min-1), both in AU. Each participant also wore a Polar H9 heart rate (HR) monitor (Polar, FINLAND). Following each bout participants reported rating of perceived exertion (RPE) using the Foster 0-10 scale and had fingertip capillary blood lactate measured using Lactate Plus (Nova Biomedical, USA). Between min and/or between bout differences were determined for external and internal load and intensity using repeated measures ANOVA and omega squared effect size (ω^2). Inference was provided by Bayes factors ≥ 3 supporting either the hypothesis (BF10) or the null (BF01).

RESULTS: PLdACC per bout = 19.3±3 – 21.6±3AU. Differences in PLdACC between bouts was inconclusive (BF10<1, $\omega^2=0.04$). PLdACCmin-1 was different between mins within bouts (BF10=24, $\omega^2=0.09$), with min 1 being greater than all other mins (BF10=4 – 92). Post hoc analyses supported the null hypothesis of no differences between bouts 1, 3, 4 or 5 for PLdACCmin-1 profile (BF01=4). End of bout HR=164±11 – 172±6 beats·min⁻¹ (HRmax% = 91±6 – 96±5%). HR was different between mins within bouts (BF10=11, $\omega^2=0.18$), due to min 1 being lower than all other mins (BF10=12,766 – 1.079x10+6). Bouts 1 and 2 were the only bouts to have post hoc HR profile differences to each other (BF10=3). Between bout changes in lactate (9±3 – 11±4 mmol·L⁻¹; BF10<1, $\omega^2<0.01$) and RPE (5.8±1 – 7.3±2.6AU; BF10<1 $\omega^2=0.04$) were inconclusive.

CONCLUSION: Neither external or internal load or intensity differs between successive BJJ bouts, despite performance occurring in the aerobic-anaerobic transition zone. BJJ participants may be using external load pacing strategies to minimise the onset of fatigue during successive bouts, allowing intensity to be maintained.

PHYSIOLOGICAL TRAINING IN STRIKING COMBAT SPORTS: A SYSTEMATIC REVIEW

KIRKWOOD, A., STEBBINGS, G., BIRDSEY, L., READ, D.

MANCHESTER METROPOLITAN UNIVERSITY INSTITUTE OF SPORT

INTRODUCTION: Combat sports can be characterised as grappling, striking or mixed combat. Striking combat sports (i.e., boxing, karate, kickboxing, muay Thai or taekwondo) incorporate strikes such as kicks, punches, elbows, and knees aimed at various body-parts of the opponent. Despite technical and tactical differences between these sports, the requirement to repeatedly execute strikes results in similar energy system demands. Physiological training is used to improve athletic performance. However, no study has reviewed the scientific literature regarding physiological training programmes for striking combat sports.

METHODS: Following the PRISMA guidelines, four databases (PubMed, Scopus, SPORTDiscus, and Web of Science) were searched for peer-reviewed original investigation articles that were written in English. Only studies that included healthy tier 2 or higher-level participants aged 16-40 years in boxing, karate, kickboxing, muay Thai or taekwondo were included. In addition, selected studies included a physiological training intervention lasting 2-12 weeks in which there was a validated pre- and post-physiological test. Following the screening process, nine studies were deemed relevant for data extraction. Risk of bias was assessed using a modified Downs and Black assessment tool.

RESULTS: Studies involved athletes from taekwondo ($n = 3$), karate ($n = 3$), boxing ($n = 2$), and kickboxing ($n = 1$). Physiological training interventions were between 2-8 weeks and included 2-4 sessions per week. High-intensity interval training (HIIT) was the most popular type of training ($n = 8$) with continuous training also utilised ($n = 1$). The most popular method of measuring physiological capacity pre- and post-intervention was an incremental exercise test ($n = 8$), with some studies also using a Wingate test ($n = 4$) and steady-state test ($n = 1$). Five outcome variables were measured across the nine studies and included VO_2max ($n = 7$), VO_2peak ($n = 1$), peak power ($n = 4$) and mean power ($n = 2$) in the Wingate test, and skeletal muscle oxygen saturation at exhaustion (SmO_2 ; $n = 1$). The interventions increased VO_2max by $3.3 \pm 2.2 \text{ ml.kg}^{-1}\text{min}^{-1}$ ($7.2 \pm 6.1\%$). In addition, peak power and mean power increased by $3.1 \pm 2.8 \text{ W.kg}^{-1}$ ($8.3 \pm 2.3\%$) and $0.4 \pm 0.1 \text{ W.kg}^{-1}$ ($4.6 \pm 1.7\%$) respectively. SmO_2 increased by 5.4%.

CONCLUSION: Physiological training interventions, predominantly consisting of HIIT lasting 2-8 weeks in striking combat sports demonstrated positive physiological adaptations in the measured variables. Coaches and practitioners can use the data collated in this review to optimise the type, frequency, intensity, duration, and content of each physiological session to improve athletic performance in striking combat sport athletes.

GENOME-WIDE ASSOCIATION STUDY ON GRIP STRENGTH IN ELITE ATHLETES: FINDINGS FROM THE IN:PROVE PROJECT

REICHERT, L., HACKER, S., KRÜGER, K., ZENTGRAF, K.

GOETHE UNIVERSITY FRANKFURT

INTRODUCTION: Grip strength (GS) serves as a widely recognized proxy measure for overall muscular strength, with higher levels being linked to enhanced athletic performance and a lower risk of injury (Suchomel et al., 2016). Previous research has frequently explored the relationship between GS and genetic polymorphisms, suggesting a genetic relation (Willems et al., 2017). However, evidence within elite-athlete populations remains limited. Therefore, this study aims to conduct a genome-wide association study to investigate the genetic correlates of GS in elite athletes.

METHODS: A genome-wide association study on GS was conducted with a sample of 419 elite athletes (187 female). DNA was extracted from human whole blood using the Chemagic Magnetic Separation Module I (Perkin Elmer Chemagen). Genotyping was performed with the Illumina GSAv3.0+MD+Psych array. Genetic data underwent quality control, including, e.g., ancestry and Hardy-Weinberg equilibrium checks. GS was assessed using a hand-held dynamometer [N]. Age, gender, weight, height, and three genetic principal components were included as covariates. The genome-wide significance threshold was set at $p \leq 5 \times 10^{-8}$, with suggestive polymorphisms considered at $p \leq 1 \times 10^{-5}$.

RESULTS: We identified 57 polymorphisms associated with GS levels below the suggestive significance threshold ($p \leq 1 \times 10^{-5}$) including, for example, SNPs on genes *DIO2* (rs225010, on chromosome 14), *FOSL2* (rs9309662, on chromosome 2), or *PEPD* (rs153701 and rs4239576, on chromosome 19). However, no polymorphism reached genome-wide significance level ($p \leq 5 \times 10^{-8}$).

CONCLUSION: Our findings reveal new polymorphisms on genes that may be associated with grip strength levels in elite athletes as *DIO2*, *FOSL2*, or *PEPD*. This should be validated in larger elite athlete samples. Further steps in the project include calculating polygenic scores to validate and compare results with similar studies (Willems et al., 2017). Our findings help to elucidate the relationship between strength and genetics in elite athletes.

A KINETIC COMPARISON OF CONVENTIONAL AND SUMO DEADLIFTS.

HANEN, N., BEN MANSOUR, K., ERTEL, G.N., DUCHENE, Y., GAUCHARD, G.C.

UNIVERSITÉ DE LORRAINE

INTRODUCTION: The deadlift is a strength exercise used in powerlifting, muscle-strengthening and rehabilitation. The deadlift generates significant forces, particularly in the lower limbs (1). There are two competitive techniques, the conventional deadlift and the sumo deadlift. This study aims to determine the kinetics differences between the two techniques from a lower limb. We hypothesized that in the sagittal plane, ankle and knee internal moments during the sumo deadlift would be relatively larger compared to those generated in the conventional deadlift, which, in contrast, would produce greater hip internal moments. Moreover, in the frontal and transversal planes, sumo deadlift would generate greater lower limb internal moments in three joints.

METHODS: Thirty healthy men (age: 26 ± 4.6 years; weight: 81.3 ± 8.7 kg; height: 178.5 ± 6.2 cm) and actively engaged in strength training performed three repetitions at 85% of 1-RM in conventional and sumo deadlifts. Kinematic data from 34 reflective markers placed on lower limb and pelvis and ground reaction force data, were recorded using an Optoelectronic system and two force plates, respectively. The ascending movement, which begins at lift-off and ends when the athlete reaches a fully upright position, was divided into two phases with the knee passing serving as the delimiter. The mean peak values of lower limb's joint moments in the three planes were compared between the two deadlifts techniques in each phase. Paired t-tests assessed the techniques effects on joint moments

RESULTS: The hip extension moments were more important in conventional deadlift, whereas in frontal and transversal plane hip moments were greater in sumo deadlift ($p < 0.001$). Knee moments were larger for sumo deadlift on the two phases ($p < 0.001$) except in the frontal plane on phase 2 where no difference was observed. Ankle eversion moment was observed on the two phases in conventional deadlift, while ankle inversion moment characterized sumo deadlift, the first showed greater moments. In transverse plane, ankle moment was more important in conventional deadlift on phase 1 before switch with the other on phase 2 ($p < 0.001$).

CONCLUSION: It can be interesting to favor one technique over the other in order to focus on a specific joint while performing a multi-joint exercise. The forces varied according to the technique adopted. As a result of the wider stance, the knee abduction moment in the frontal plane was greater in the sumo deadlift in the first phase, where the moments were greatest, in parallel with a greater hip adduction moment compared to the conventional technique. So, to put an accent on the knee or to implement a work on frontal plane, it will be interesting to favor the use of sumo deadlift, whereas conventional deadlift will be more interesting to focus on the hip, which is relevant for exercises such as sprints.

WEIGHT VEST DURING PARKOUR TRAINING: IMPACT ON FATIGUE AND EXPLOSIVE STRENGTH PERFORMANCE

DE PAUW, K., GROSPRÊTRE, S.

VRUE UNIVERSITEIT BRUSSEL

INTRODUCTION: Weight vest training already showed relevancy for explosive strength, endurance and coordination tasks. A sports discipline involving all these parameters is Parkour, in which the athletes need to overcome obstacles, primarily in urban settings. The immediate impact of weight vest training on movement efficiency, fatigue and recovery remains unclear. Therefore, this study aims to investigate the acute effects of weight vests during Parkour sessions on lower-limb performance, subjective fatigue, and delayed onset muscle soreness.

METHODS: Seventeen young, healthy, sportive participants (age: 21.7 ± 2.8 y; 6.0 ± 2.3 hrs of physical activity/week for the past 10.1 ± 5.8 years; 6 women; novice Parkour runners) underwent three familiarization sessions followed by two experimental sessions, each lasting two hours and separated by one week of rest. Each session started with participant preparation, warm-up, pre-tests, a 1-hr Parkour session, and post-tests. Two experimental conditions were included: Parkour without additional weight (PK) and Parkour with an additional weight vest (PK WV), representing 10% of body mass of each individual. Rating of Perceived Exertion (RPE) and delayed onset muscle soreness (DOMS) (24h to 72hr after each session) were obtained. Different physical tests were included, i.e., vertical jumps (squat jump, countermovement jump, drop jump, standing long jumps, 10-m sprints with or without obstacles).

RESULTS: RPE and perceived fatigue were higher after PK WV compared to PK ($p < 0.05$). Between conditions, DOMS were significantly worsened at the level of quadriceps 24 hours and calves 72 hours after the PK WV session compared to PK.

Several significant differences were observed for performance measures, such as standing long jump and 10m sprint with obstacles. These parameters significantly reduced after PK WV, whereas no significant differences were observed in the PK condition ($p < 0.05$). Other performances were not affected by PK WV: squat jump, counter movement jump, classic 10-m sprint. Finally, we did observe an unexpected significant improvement of drop jump height in the PK WV condition ($P < 0.001$).

CONCLUSION: As expected PK WV fatigued participants substantially more compared to PK, resulting in decreased jump and sprint performance. The most affected performances were those requiring the highest level of motor control (long

jump, sprints with obstacles), while squat jump or classical sprint remained unaffected. Overall, this might show that, while not affecting muscle power, WV might alter motor control. Interestingly, drop jump height increased despite fatigue in the PK WV condition. This might be due to an enhanced neuromuscular potentiation. The drop jump heavily relies on the stretch-shortening cycle, which benefits post-activation potentiation. The weight vest might have induced neural alterations to recruit motor units more effectively during explosive movements after removing the weight vest, thus temporarily enhancing neuromuscular efficiency.

APPLICATION OF THE YMCA STEP TEST TO INDIVIDUALS WITH VISION IMPAIRMENT

ERVUZ, E., EFLATUN, K., ESATBEYOGLU, F.

YOZGAT BOZOK UNIVERSITY

INTRODUCTION: The purpose of this study was to examine whether the YMCA step test is suitable to determine aerobic fitness in individuals with vision loss.

METHODS: 52 males between the ages of 19-36 participated in the study voluntarily. 15 of the participants were goalball players (age: 27.20 ± 4.07 years; height: 181.36 ± 7.18 cm; body weight: 84.54 ± 9.09 kg) and 20 of them were athletes without vision loss (age: 26.85 ± 4.04 years; height: 176.07 ± 6.00 cm; body weight: 77.11 ± 7.64 kg). As a control group, 17 male sedentary individuals with visual loss (age: 27.23 ± 5.00 years; height: 176.11 ± 5.63 cm; body weight: 82.21 ± 7.89 kg) were included in the study. Initially, physical characteristics were determined and PAR-Q questionnaire was applied. Afterwards, YMCA step test was applied to assess the aerobic fitness of the participants. One-way ANOVA was used to determine the differences in physical characteristics (age (years), height (cm), body weight (kg), body mass index (kg/m²), body fat percentage (%), body fat mass (kg), fat-free mass (kg)) and physiological responses (maximal heart rate (HR_{max}), RPE, recovery heart rate (HR_{recovery})) to YMCA step test among the three groups. If overall statistical difference was observed for the dependent variable ($p < 0.05$), the Bonferroni post hoc test was used to identify the location of pairwise differences.

RESULTS: The results revealed significant differences in height (cm) (F (2,49)=3.78, $p=0.03$), body weight (kg) (F (2,49)=3.86, $p=0.02$), body fat percentage (%) (F (2,49)=30.85, $p=0.00$), body fat mass (kg) (F (2,49)=21.33, $p=0.00$), fat-free mass (kg) (F (2,49)=39.11, $p=0.00$) whereas no statistically significant difference was found in the variables of age (F (2,49)= 0.04, $p=0.95$) and BMI (F (2,49)= 2.00, $p=0.14$). A statistically significant difference was found in HR_{max} (bpm) (F (2,49)=4.55, $p=0.01$), RPE (F (2,49)=26.62, $p=0.00$) and HR_{recovery} (bpm) (F (2,49)=38.12, $p=0.00$) as physical responses to YMCA step test ($p < 0.05$).

CONCLUSION: This study showed that the YMCA step test can be applied in individuals with vision loss to determine aerobic fitness.

PHYSICAL PERFORMANCE TESTING IN TEAM HANDBALL: A COMPARATIVE ANALYSIS ACROSS EXPERIENCE LEVELS

ALNEAMA, A., DHAHBI, W., VAN DEN TILLAAR, R., HERMASSI, S.

QATAR UNIVERSITY

INTRODUCTION: Team handball requires multiple physical attributes including strength, speed, and agility for competitive success. However, the relationship between specific performance tests and playing experience levels remains incompletely understood, particularly when comparing experienced versus less-experienced players.

METHODS: This cross-sectional study examined thirty-one male handball players divided into experienced (EP; $n=14$; age: 27.9 ± 4.3 years; playing experience: 8.4 ± 2.1 years) and less-experienced (LEP; $n=17$; age: 29.4 ± 4.1 years; playing experience: 3.2 ± 1.4 years) groups. A comprehensive testing battery assessed: (1) lower-limb power: squat jumps (SJ) and countermovement jumps (CMJ), (2) sprint capacity over 15m and 30m, (3) change-of-direction ability via T-Half test, (4) throwing performance using medicine ball throw, (5) aerobic fitness through Yo-Yo intermittent recovery test, and (6) muscle volume measurements of upper and lower limbs.

RESULTS: EP demonstrated significantly superior performance in agility (T-Half test: EP: 5.91 ± 0.15 s; LEP: 5.56 ± 0.40 s, $p=0.002$, $\eta^2=0.28$), explosive power (CMJ: EP: 42.3 ± 4.8 cm; LEP: 36.7 ± 4.2 cm, $p=0.002$, $\eta^2=0.28$), and throwing ability (medicine ball throw: EP: 12.8 ± 1.4 m; LEP: 10.9 ± 1.2 m, $p=0.009$, $\eta^2=0.21$). Linear sprint performance showed no significant differences (30m sprint: EP: 4.20 ± 0.17 s; LEP: 4.21 ± 0.14 s; $p=0.662$, $\eta^2=0.01$). Muscle volume measurements revealed similar values between groups for both upper (EP: 2856 ± 423 cm³; LEP: 2789 ± 398 cm³, $p=0.724$) and lower limbs (EP: 6234 ± 856 cm³; LEP: 6198 ± 812 cm³, $p=0.892$).

CONCLUSION: The findings demonstrate that handball-specific movements requiring complex motor control and power production (agility, jumping, sprinting) better differentiate experience levels than linear sprinting or muscle volume. This aligns with recent research showing sport-specific testing batteries are more sensitive to playing level than general athletic measures. The similar sprint times between groups likely reflect the limited occurrence of maximum-speed linear running in handball compared to multidirectional movements. Practitioners should prioritize specialized training regimens targeting these discriminating performance markers while considering experience level in training prescription.

FUNCTIONAL TESTS FOR UPPER LIMB STRENGTH AND POWER TO PREDICT THROWING PERFORMANCE IN HANDBALL

SPAGNOLLO DA SILVA, M., FONTANETTI, G., LIMA, L., EXEL, J., PAVAN, J., PUGGINA, E.

SÃO PAULO UNIVERSITY

INTRODUCTION: In Handball, athletic performance is closely tied to the execution of technical movements, like throwing the ball. Two key aspects contribute to an effective throw: accuracy and ball speed. Our aim was to evaluate if throwing speed can be predicted by upper-limb strength and power assessed as Ballistic Push-ups (BPU), bench press one repetition maximum (1RM) and power at different intensities (30, 60 and 90% RM).

METHODS: Nine handball athletes with strength training experience (five men and four women; age: 21.5 ± 2.2 years; height: 1.7 ± 0.1 m; body mass: 75.2 ± 12.1 kg; body mass index: 24.8 ± 1.8 ; fat-free mass: 57.8 ± 13.4 kg; fat mass: 23.9 ± 6.2 kg) participated in the study. Following two familiarization sessions, they attended four laboratory visits. During the first visit, body composition was assessed, followed by the 1RM test for the bench press. The second visit involved the submaximal acceleration test in the bench press (with loads of 30%, 60% and 90% of 1RM). On the third day, they performed the BPU test and on the fourth day, they completed the specific handball throwing tests, consisting of ball speed (BS) in standing throw (ST) and jump throw (JT). All sessions were preceded by a warm-up (stationary bike, mobility exercises, and horizontal arm abduction using an elastic band). On days involving the bench press, participants also performed two sets of twelve and eight repetitions at 50% and 75% respectively of their one-repetition maximum (1RM). Correlation analyses were conducted aiming to analyze associations between the weight lifted in the 1RM test and the power generated in the acceleration and BPU tests with ball speed during ST and JT. Correlation coefficients were considered as strong, very strong and nearly perfect according to the Pearson's product-moment correlation coefficient ($r = 0.5-0.69$, $0.7-0.89$, and $0.9-0.99$, respectively). Additionally, a simple linear regression technique was used to evaluate the prediction level of the tests. Statistical significance was set at $p < 0.05$.

RESULTS: Strong associations were observed between ST together with 1RM ($r = 0.67$) along with BPU and ST ($r = 0.60$). Very strong associations were observed between ST and 30%1RM ($r = 0.712$) and 90% 1RM ($r = 0.817$), and between JT and 90% 1RM ($r = 0.704$). Linear regression analyses revealed that all the loads in the acceleration test can predict BS for ST: 30%1RM [$F(1,7) = 7,212$, $p < 0,05$; $R^2 = 0,363$]; 60%1RM [$F(1,7) = 6,818$, $p < 0,05$; $R^2 = 0,493$]; 90%1RM [$F(1,7) = 14,008$, $p < 0,05$; $R^2 = 0,667$]. Furthermore only the 90%1RM load was able to predict BS for JT [$F(1,7) = 6,860$, $p < 0,05$; $R^2 = 0,495$].

CONCLUSION: Our results reveal that it is possible to predict handball throwing performance by employing general tests aiming to assess upper-limb strength and power. Considering that these tests are highly reproducible, they can be used as assessment tools for athletes, thereby enabling the development of parameters for training, which can be useful for all coaches.

INVESTIGATION OF THE INTRA AND INTER-DAY RELIABILITY OF THE ATHLETIC SHOULDER TEST USING THE WII BALANCE BOARD IN VOLLEYBALL PLAYERS

ÇİFTÇİ, M., ÇELİK, S., ÇABUK, S., INCE, I., ULUPINAR, S.

ANKARA YILDIRIM BEYAZIT UNIVERSITY, ERZURUM TECHNICAL UNIVERSITY

INTRODUCTION: The athletic shoulder test (IYT test) has been widely used to assess shoulder stability and strength in athletes, particularly in sports requiring overhead movements such as volleyball. Reliable measurements are crucial for both injury prevention and performance assessment. This study aims to evaluate the intra-day and inter-day reliability of the IYT test using the Nintendo Wii Balance Board (WBB) in volleyball players.

METHODS: Research Design

The study followed a prospective cohort design, measuring the reliability of the athletic shoulder test over two separate days. Measurements were taken at specified intervals, and both intra-day and inter-day reliability were assessed using the Wii Balance Board. The study adhered to the Helsinki Declaration guidelines, with ethical approval from Erzurum Technical University (Date: 06.06.2024, No: 7/13).

Participants

Twenty experienced volleyball players (age 14.48 ± 1.327 years) participated in the study. Inclusion criteria included no chronic health problems, no acute injuries, and at least 3 years of regular volleyball training. Exclusion criteria included acute neck or shoulder injuries, pain lasting over 20 minutes after the test, or an inability to assume test positions due to limited range of motion.

Athletic Shoulder Test (IYT Test)

Anthropometric measurements were taken using a stadiometer (0.01-meter precision) and a calibrated Weighing Digital Platform (0.01-kg precision). Participants performed the IYT test in a prone position with the forehead resting on a foam block. The Wii Balance Board (WBB) was used for data collection, connected to specialized software (IzWii) developed by Ince (2024b). The I test involved shoulder abduction to 180° , the Y test to 135° , and the T test to 90° , with full elbow extension in all positions. Force data from the WBB was recorded during the tests.

RESULTS: Intra-day reliability showed excellent consistency, with ICC values ranging from 0.908 to 0.969, while inter-day reliability also demonstrated strong results, with ICC values between 0.819 and 0.948. SEM values ranged from 1.996 to 6.781 N, indicating minimal measurement error, and MDC values ranged from 5.533 to 18.708 N, suggesting the test's ability to detect meaningful changes. Coefficient of Variation (CV) values were within acceptable limits, further supporting

the stability and consistency of the test. Overall, the IYT test showed good to excellent reliability for both intra-day and inter-day measurements in volleyball players.

CONCLUSION: The IYT test demonstrates excellent intra-day and inter-day reliability in volleyball players. The use of the Wii Balance Board as a measurement tool ensures accurate and consistent data collection, making it a valuable method for assessing shoulder function in athletes.

LONGITUDINAL PRELIMINARY DATA ON CHANGES IN PHYSICAL FITNESS IN YOUNG FEMALE VOLLEYBALL PLAYERS

PAULO, A., SANTOS, C., TEIXEIRA, D., ALEIXO, P., PEREIRA, S.

UNIVERSIDADE LUSÓFONA

INTRODUCTION: Physical fitness (PF) has been identified as a critical health marker in youth and is significantly influenced by environmental factors, such as the specificity of training [1]. While sports participation generally enhances PF levels [2], the relationship between training, lifestyle behaviours and fitness improvements is complex and multifaceted [3]. Volleyball is one of the most played sports worldwide, particularly among women. Given the specific characteristics of the volleyball game, it is essential to understand how regular practice influences physical fitness over time. Therefore, this study aims to investigate changes in motor, muscular and cardio-respiratory PF of young female Portuguese volleyball players over a one-year period, after adjusting for age.

METHODS: A total of 51 female Portuguese volleyball players from the same club, aged 12 to 19, were sampled. The athletes practised volleyball for an average of 7.45 hours per week (SD: 0.27 hours), 47 of which as their single sport participation (92 percent). Two assessments were conducted: one at baseline and another at a one-year follow-up. PF was assessed using four tests: the hand-grip strength test (muscular fitness component, MFC), the three-minute step test (cardio-respiratory fitness component, CRFC), and the shuttle-run and 30-meter run tests (motor fitness component; MoFC). Analysis of covariance (ANCOVA) was used to examine yearly changes in PF across each test, with age included as covariate. Statistical analysis was performed using SPSS 29, with the significance level set at 5 per cent.

RESULTS: Over the one-year period, changes in the volleyball players' PF varied, depending on the PF component assessed and the test used. While the 30-meter run performance showed no significant changes ($p > 0.05$), the shuttle-run test performance improved significantly ($F = 7.056$, $p = 0.011$, $\eta^2 = 0.13$). Athletes reduced their shuttle-run test times by -0.327 s (SE: 0.074 s; $p < 0.001$). Hand-grip strength also showed significant improvement ($F = 7.545$, $p = 0.008$, $\eta^2 = 0.13$), with an increase of 0.918 kgf (SE: 0.448 kgf; $p = 0.046$). Finally, the CRFC did not change over a one-year period ($p > 0.05$).

CONCLUSION: Young female volleyball players improved their PF over a one-year period, but dependant on component evaluated and test used on that regard. On performance-related PF, in the evaluation of this type of population, the shuttle run seems to be a better fit when evaluating the MoFC, than the 30-meter run. On health-related PF, though there was an improvement on the MFC, the lack of improvement in CRFC is concerning and warrants further investigation. Caution should be taken in the generalisation of this results given small-sample size overestimation risks.

THE INFLUENCE OF CIRCUIT TRAINING EXERCISE SEQUENCING ON LEG STRENGTH DEVELOPMENT IN YOUTH VOLLEYBALL ATHLETES

KHEMTONG, C., CHANNARONGSAK, T., SAWAENGWISAYASUK, S., KAMUTSRI, T., CHOODAM, C.

MAHIDOL UNIVERSITY

INTRODUCTION: Circuit training (CT) is widely recognized as an effective training method for athletes with limited equipment to enhance muscular endurance and general strength during the pre-season phase. Previous studies have demonstrated that an 8-week CT program can improve muscular strength and endurance in volleyball players. However, to date, no research has directly compared the effects of manipulating bodyweight exercise sequencing patterns for improving the general strength of youth volleyball players. This study aimed to compare the impact of a 6-week bodyweight CT program, using two different sequencing patterns, on leg strength in female youth volleyball players.

METHODS: Twenty-nine female volleyball players (mean age: 14 ± 1 years) were randomly assigned to either an IN-PLACE-CT group ($n = 15$) or a STAGE-CT group ($n = 14$), with both groups work-matched. Each CT program consisted of 12 exercises, performed for 20 repetitions across 3 total sets, three times per week. In the IN-PLACE-CT group, participants performed the exercises sequentially (from exercises 1 to 12) with 30 seconds rest between exercises and 3 minutes of rest between sets. In contrast, the STAGE-CT group completed each exercise in 3 sets, with 30 seconds of rest between sets, and 3 minutes of rest between exercises. During the 6-week training period, participants were instructed to maintain a consistent diet and adhere to their specific training program. Pre- and post-training assessments of knee extensor and knee flexor peak torque, and hamstrings-to-quadriceps (H/Q) ratio, were conducted using an isokinetic dynamometer at a velocity of 90 deg/sec for both the dominant and non-dominant legs.

RESULTS: After 6-weeks of training, the IN-PLACE-CT group showed a significant increase in peak torque of the knee extensors ($p < 0.001$) and flexors ($p < 0.001$) in the dominant leg, while only knee flexion peak torque increased in the non-dominant leg ($p < 0.001$). In the STAGE-CT group, a significant increase in peak torque was only observed for knee flexion in the non-dominant leg ($p = 0.011$). However, no significant between-group differences were found in peak torque at the

end of the training period. Similarly, the H/Q ratio did not differ between groups in either the dominant ($p = 0.176$) or non-dominant ($p = 0.926$) leg.

CONCLUSION: The programming of CT exercises, whether sequentially or in sets, did not result in a marked difference in leg strength between groups. However, the IN-PLACE-CT group led to significant pre-to-post test changes in knee extensor and flexor strength, particularly in the dominant leg. Therefore, our results suggest that the structure of bodyweight CT exercises may be an important consideration for optimizing the strength development of youth volleyball players. Based on our findings, IN-PLACE-CT may offer a more efficient approach for enhancing general strength in this population.

EEG ANALYSIS OF NEUROMOTOR PROCESSES IN SUCCESSFUL SOCCER PENALTY KICKS: A PILOT INVESTIGATION

WANG, K., LI, D., ELBANNA, H., CHEN, L.J., LIN, F.Y., LU, C.J.

NATIONAL TAIWAN UNIVERSITY

INTRODUCTION: Understanding the neuromotor processes underlying successful and unsuccessful performance in lower limb movements, such as football kicking, is essential for athletes. However, there has been a knowledge gap in research regarding whether higher activation of the prefrontal and central cortices that are associated with motor programming, such as motor planning and motor control, negatively influence motor performance in a difficult task. To address this issue, this pilot study aimed to investigate neuromotor processes in skilled football players performing penalty kicks under a difficult condition.

METHODS: 10 skilled football players were recruited and asked to perform 30 kicks under a difficult condition where the target size was adjusted to maintain a kicking success rate between 40% and 60% for each player while we recorded EEG data during motor preparation. Afterwards, EEG power in the 8-13 Hz frequency band was analyzed at frontal (Fz) and central (Cz) regions before action.

RESULTS: The main results indicated that successful penalty kicks were associated with lower 8-13 Hz power at frontal and central regions before action, suggesting efficient neural activation for motor planning and control during motor preparation.

CONCLUSION: These findings support the model of attention allocation and the psychomotor efficiency hypothesis, aligning with similar neuromotor processes observed in golf studies that manipulate task difficulty. This underscores the importance of motor planning and control in successful athletic performance in lower limb movements.

THE INFLUENCE OF MATURITY ON PLYOMETRIC TRAINING RESPONSES IN YOUTH SOCCER PLAYERS

HOLÍK, R., LEHNERT, M., KREJCI, J.

PALACKÝ UNIVERSITY OLOMOUČ, FACULTY OF PHYSICAL CULTURE

INTRODUCTION: The role of biological maturation in the effectiveness of plyometric jump training (PJT) remains unclear, with studies suggesting that both pre- and post-peak height velocity (PHV) athletes may benefit from neuromuscular adaptations [1]. However, the impact of PJT on speed, power, reactive strength and stiffness may differ across maturation stages due to growth-related changes in muscle architecture, tendon properties, and motor control [2]. This study examines how plyometric training influences these performance attributes in adolescent soccer players, considering a dependence on maturity offset.

METHODS: This 12-week randomized controlled trial included 39 male soccer players (aged 10–17 years), categorized into pre-PHV and post-PHV groups using the Mirwald method. Participants were randomly assigned to either a PJT group, performing two weekly plyometric sessions, or a control group following standard soccer training. Performance was assessed pre- and post-intervention. Sprint speed (20 m sprint), change of direction (L-run), explosive power (counter-movement jump (CMJ), broad jump), reactive strength (triple jump), reactive strength index (drop jump), and leg stiffness (20-hop test) were measured. A quadratic regression model was applied to relative performance changes to examine non-linear interactions with biological maturation. Regression analysis with linear and quadratic terms was used to analyse relationship between changes during training (Δ between pre- and post-test) and maturity offset.

RESULTS: PJT significantly improved sprint speed ($p = 0.014$) compared to the standard training with non-significant maturation dependence ($p = 0.083$). Leg stiffness significantly increased in the plyometric group ($p < 0.001$) with significant U-shape relationship on maturity offset ($p = 0.048$). The quadratic model showed that improvements in leg stiffness were less pronounced around PHV but more likely to occur at earlier or later maturity. CMJ height followed a reverse U-shape relationship, with the greatest relative improvements occurring near PHV and minimal changes at extreme maturity offsets ($p = 0.041$). Reactive strength, measured via the triple jump, showed a linear relationship ($p = 0.046$) on maturity offset, with greater improvements in less biologically mature athletes. The plyometric group also experienced a significant reduction in body fat ($p = 0.003$) compared to the standard training.

CONCLUSION: Plyometric training enhances sprint speed, leg stiffness, and explosive power in adolescent soccer players, but its effectiveness varies non-linearly with biological maturation. Adaptations in leg stiffness were less evident near PHV, while CMJ height gains peaked around PHV. These findings emphasize the importance of maturity-specific plyometric training to optimize athletic development.

DESCRIPTIVE ANALYSIS ON INJURIES IN YOUTH ELITE FEMALE SOCCER PLAYERS.

QUATTRUCCI, E., CAPRIOLI, L., ROMAGNOLI, C., EDRISS, S., ANNINO, G., TANCREDI, V.
UNIVERSITÀ DEGLI STUDI DI VERONA

INTRODUCTION: Soccer is a widely practiced sport among young female athletes, but it also presents a high risk of injuries that can impact their careers and the prevention of future injuries. Understanding the role of the first injury, its mechanism, and its potential influence on subsequent injuries is crucial for developing effective prevention strategies and screening tests. The aim of the study is to describe the first injury and to investigate whether it plays a role in subsequent injury.

METHODS: This study is a retrospective cohort study designed to investigate the first injury in elite young female soccer players. Data were collected using a questionnaire distributed to 137 athletes from the U15, U17, and U19 categories of several professional Italian teams.

RESULTS: 110 (80.3%) athletes reported experiencing at least one injury. The first injury occurred at a mean age of 13.2 ± 2.1 years and in 104 (94%) athletes who have been practicing soccer for more than 4 years.

Findings indicate that most injuries occurred through a non-contact (NC) mechanism (56%) compared to a contact (C) mechanism (44%). The main locations of the first injury were the knee joint (31%) and the ankle (29%) and the principal reported injury types were ligament (29%), muscle (21%) and tendon (13%).

Regarding the injury mechanism involving the most affected joints of the knee and ankle, NC injuries account for 68% and 38%, while C injuries account for 32% and 62%, respectively. Following the first knee injury, six athletes sustained an ACL rupture, with 83% occurring through a NC mechanism and 17% through a C mechanism.

Considering athletes who experienced their first injury at the knee or ankle ($n=66$) and analyzing the second injury, the most affected anatomical areas were the ankle (29%) and the knee (15%). NC injuries occurred in 32% of cases at the ankle and 64% at the knee, while C injuries accounted for 68% and 36%, respectively. Following the second injury, a total of five athletes sustained an ACL rupture. Among them, 60% had their first injury at the ankle and 40% at the knee. Additionally, 67% and 50% of these injuries, respectively, occurred without direct contact.

CONCLUSION: This study highlights the prevalence of injuries among elite young female soccer players, with NC mechanisms being the most common, particularly in knee injuries. ACL ruptures were strongly associated with NC mechanisms, suggesting a potential pattern in injury recurrence. The findings emphasize the need for targeted prevention strategies focusing on neuromuscular training and biomechanical assessments to reduce the risk of severe NC injuries. Future research with larger cohorts and prospective designs should be conducted to establish cause-and-effect relationships between the mechanism and anatomical location of the first injury and subsequent ones to enhance injury prevention programs.

CP-AP18 Power and Strength I

IMPACT OF THE MENSTRUAL CYCLE PHASE ON BARBELL VELOCITY IN A MULTI-EXERCISE VELOCITY-BASED STRENGTH TRAINING

DEL COSO GARRIGÓS, J., GARCÍA-ALVÍN, D., GARCÍA-ORTIZ, C., TRUJILLO-COLMENA, D., FERNÁNDEZ-SÁNCHEZ, J., RODRÍGUEZ-CASTAÑO, A., COLLADO-MATEO, D.
REY JUAN CARLOS UNIVERSITY

INTRODUCTION: Most studies investigating the effects of different menstrual cycle phases on maximal strength have focused on maximal performance tests (e.g., 1RM tests). However, the influence of the menstrual cycle on performance in more practical, real-world settings, such as training sessions utilizing submaximal loads (%1RM), remains largely unexplored. This study aimed to investigate the effect of the menstrual cycle on strength performance variables during a velocity-based strength training session.

METHODS: Twenty healthy, young, naturally menstruating women with strength training experience completed three identical velocity-based strength training sessions. These sessions were conducted during three distinct phases of the same menstrual cycle: (a) early follicular, (b) pre-ovulatory, and (c) mid-luteal. These menstrual cycle phases were individually determined using a combination of procedures, including a mobile application that tracked menstruation onset for four months prior, as well as continuous monitoring of body temperature and body weight throughout an entire menstrual cycle. During each strength training session, participants performed two sets of six repetitions at 80% 1RM in the semi-squat, bench press, deadlift, and barbell row exercises. They were instructed to execute each repetition at maximal velocity. Barbell velocity values for each repetition were recorded using a rotary encoder. The rating of perceived exertion (RPE) was measured at the end of the strength training session. A two-way analysis of variance (ANOVA; 2×12 , menstrual cycle $\times$ repetition) was conducted to compare the effects of the menstrual cycle phase in each exercise (one-way ANOVA for RPE values). A Bonferroni post hoc analysis was performed when a significant F-value was detected.

RESULTS: There was a main effect of the menstrual cycle on mean velocity during semi-squat ($F= 4.91$, $P= 0.01$), and bench press ($F= 5.91$, $P< 0.01$), with no effects on deadlift ($F= 2.98$, $P= 0.06$) and barbell row ($F= 2.17$, $P= 0.13$). The post hoc analy-

sis revealed that for semi-squat exercise, mean velocity was lower during the early follicular than pre-ovulatory (0.36 ± 0.10 vs 0.39 ± 0.11 m/s, $P=0.02$) and luteal (0.40 ± 0.10 , $P < 0.01$). Likewise, mean velocity was lower during early follicular than pre-ovulatory (0.29 ± 0.10 vs 0.31 ± 0.10 m/s, $P=0.01$) and luteal (0.31 ± 0.10 m/s, $P < 0.01$) during the bench press exercise. Finally, there was a main effect of the menstrual cycle on RPE ($F = 15.56$; $P < 0.01$) which was higher in the early follicular phase with respect to the preovulatory phase ($P < 0.01$) and the mid-luteal phase ($P < 0.01$).

CONCLUSION: These findings suggest that barbell mean velocity may decrease, while RPE values increase, during velocity-based strength training in the early follicular phase compared to the pre-ovulatory and mid-luteal phases. This information could be valuable for strength and conditioning professionals working with women to optimize strength training sessions across the menstrual cycle.

PHASE ANGLE AND PHYSICAL FITNESS IN ADOLESCENT GIRLS: ASSOCIATIONS WITH STRENGTH, POWER, AND AGILITY

LOVECCHIO, N., TORNAGHI, M., CUDICIO, A., ZAMBELLI, S., GIURIATO, M.

UNIVERSITÀ DI BERGAMO

INTRODUCTION: Phase Angle (PhA), derived from bioelectrical impedance analysis as the arctangent value of the ratio of X_c (reactance) to R (resistance) (Martins et al., 2023). PhA, in fact, is considered an indicator of cellular integrity and muscle quality (Ballarin et al., 2022). Its association with physical fitness parameters such as muscular endurance, power, and agility in adolescent is unclear and, in particular, in girls samples is not well established (Akamatsu et al., 2022). This study aims to investigate the relationships between PhA and key physical fitness components, identifying its potential role as a predictor or affecting the performance in this population.

METHODS: A total of adolescent girls 65 (mean age 12.52) were evaluated for core endurance (sit-ups), lower-limb power (Sargent vertical and standing broad jump [SBJ]), and agility (using T-agility test). PhA and anthropometric variables (i.e. weight, height and waist circumference) were also measured in different and dry location. The biological maturation was determined as the menarchal status (age). Stepwise regression analysis was conducted to identify predictors of physical performance while ANOVA was used to assess differences among PhA quartiles.

RESULTS: Stepwise regression identified PhA as a significant predictor of sit-ups (adj $R^2 = 0.274$), Sargent jump (adj $R^2 = 0.21$), T-agility test (adj $R^2 = 0.273$), and SBJ (adj $R^2 = 0.297$). Waist circumference and fat mass (FM) also contributed to Abalakov, t-test, and SBJ performance. ANOVA revealed significant differences across PhA quartiles. Post-hoc analyses showed that girls in the highest quartile (Q4) outperformed those in Q1 in agility ($p = 0.009$), power ($p = 0.003$), and muscular endurance ($p = 0.026$), with notable Q1-Q4 differences. The stratification according to manarchal tempo did not show any significant differences (adj $R^2 = 0.274$).

CONCLUSION: PhA is positively associated with strength, power, and agility in adolescent girls, suggesting its potential role as a functional marker of physical fitness. These findings highlight the importance of considering PhA in athletic performance assessments and during the plan of training periodization because we can included the biological condition of people within the training progression.

DIFFERENCES IN MINIMUM VELOCITY THRESHOLD AMONG ATHLETES OF SIMILAR LEAN BODY MASS, BUT DIFFERENT TRAINING BACKGROUND

TROMARAS, K., METHENITIS, S., ZARAS, N., TERZIS, G.

NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS

INTRODUCTION: Powerlifters have the lowest minimum velocity threshold (MVT) among strength trained individuals [1]. This may be related to either neural adaptations or the size of the lean body mass (LBM). The aim of the study was to investigate the relationship between MVT and LBM among experienced athletes who have similar lean body mass but train with either high or low external loads.

METHODS: Nine powerlifters (height 1.77 ± 0.05 m, age 29.62 ± 7.54 years, body mass 92.52 ± 13.37 kg, resistance training experience 8.00 ± 2.39 years, competition experience 1.81 ± 1.80 years) and eight experienced gym trainees (height 1.85 ± 0.05 m, age 23.54 ± 4.64 years, body mass 89.31 ± 13.14 kg, resistance training experience 6.50 ± 4.11 years) participated in this study. Data collection occurred over three sessions. In the first session, maximum strength (1RM) was evaluated for the squat (SQ), bench press (BP), and deadlift (DL). In the second session, lean body mass (LBM) was assessed using dual-energy X-ray absorptiometry (DXA). In the third session, the force-velocity relationship was analyzed using external loads corresponding to 30%, 50%, 60%, 70%, 80%, 90%, and 100% of athletes' 1RM in each exercise. Statistical analysis included descriptive statistics, independent sample t-tests, and Pearson's r correlation coefficient ($p < 0.05$).

RESULTS: No significant differences in LBM were observed between the groups ($p > 0.05$). Powerlifters had a 36% higher performance in the total lift sum than the other group ($p < 0.05$). The MVT was 37% lower in powerlifters' DL ($p = 0.033$). No significant differences were observed in MVTs of SQ and BP between the groups ($p > 0.05$). In powerlifters, only MVT in SQ

was positively correlated with total and arms' lean mass ($r = 0.67-0.69$, $p \leq 0.05$). In experienced gym trainees, only MVT in DL was positively correlated with total, arms' and trunk's lean mass ($r = 0.77-0.82$, $p < 0.05$). When all participants considered as one group, only MVT in SQ was positively correlated with trunk's LBM ($r = 0.495$, $p = 0.043$).

CONCLUSION: In conclusion, according to the results of the present study, it seems that LBM is not consistently related to MTV, and it seems that the correlations between MTV and LBM depends on the exercise and on athletes' training background. Thus, it may conclude that LBM has only a minor impact on MTV, and other physiological factors, such as the function of neural system may determine MTV.

PERFORMANCE AND NEUROPHYSIOLOGICAL RESPONSES TO DECEPTION AND WITHHOLDING INFORMATION DURING THE BENCH-PRESS EXERCISE

SKEIN, M., MURRELL, B., BUZZA, G.

CHARLES STURT UNIVERSITY

INTRODUCTION: Deception and withholding information have both been shown to impact performance outcomes, regulation of pacing strategies, and neurophysiological responses. Although these approaches are used in a range of training and competition settings, previous research has focused on endurance exercise, leaving the context of resistance exercise unexplored. This study examined the effect of deception and withholding lifting load information on performance and neurological and physiological responses during to-failure resistance exercise.

METHODS: Ten moderately trained, regular gym attendees completed five sessions containing two sets of bench presses with concealed resistances. Set one was performed at 60% of one repetition maximum (1RM) and deemed the control (18 ± 2 repetitions). During set two, participants completed as many repetitions as they could during one of five randomly assigned conditions: 60% of 1RM with correct information provided (CONT), a misleading 10% increase (DEC-A) or a misleading 10% decrease (DEC-B), or no information provided while lifting 70% of 1RM (WITH-A), or lifting 50% of 1RM (WITH-B). Throughout sets one and two, pre-frontal cortex oxygenation (oxyhemoglobin (O2Hb), deoxyhemoglobin (HHb) normalised tissue haemoglobin index (nTHI)), and triceps, pectoralis major and anterior deltoid muscle activation (EMG) were recorded. Immediately after each set, heart rate (HR), rating of perceived exertion (RPE), and number of successful repetitions were recorded.

RESULTS: Total repetitions lifted were higher in WITH-B ($p=0.001$) and less in WITH-A compared to CONT ($P=0.001$). DEC-A and DEC-B repetitions were lower compared to CONT ($p=0.001 - 0.019$). Post-set RPE was higher in WITH-A ($P=0.007$) and lower in WITH-B compared to CONT ($P=0.049$). Prefrontal cortex HHb levels were significantly higher in set 2 during WITH-A and DEC-A, while lower in WITH-B and DEC-B at various intervals ($P= 0.007 - 0.033$). Muscle activation in both muscles and HR were not significantly different within or between conditions ($P>0.05$).

CONCLUSION: These findings indicate that deception of load during to-failure exercise can impact performance, however, changes in repetitions to failure when withholding information were reflective of changes in load. The changes in RPE appear to be reflective of load despite load information being withheld and may suggest some conscious contribution to workload. Neural activity also indicates greater activity in the pre-frontal cortex when athletes are deceived or are completing work at a higher load. Understanding how athletes respond to information delivery formats may provide useful insights for training and testing practices to maximise performance and manage neurophysiological and perceptual responses.

MUSCLE ACTIVITY OF AGONIST AND ABDOMINAL MUSCLES DURING RESISTANCE EXERCISE WITH ASYMMETRICAL LOADS

SHINZAKI, S., NAKATA, K., MAEO, S., KINOSHITA, M., EIHARA, Y., NISHIZAWA, N., KANEHISA, H., ISAKA, T.

RITSUMEIKAN UNIVERSITY

INTRODUCTION: The abdominal muscles, particularly the deep muscles such as the internal oblique and transversus abdominis, play a crucial role in stabilizing the trunk, maintaining posture in response to external perturbations, and enabling the limbs to generate significant force. Therefore, developing effective training methods for the abdominal muscles, including the deep muscles, is essential for improving quality of life and sports performance. One such training method involves performing resistance exercises in an unstable environment using specialized equipment (e.g., sling-based push-ups, Maao et al. 2014; Kohiruimaki et al. 2019) or using free weights with asymmetrical loads (e.g., asymmetrical bench press, Saeterbakken et al. 2020). However, it is beneficial to propose a more practical and safer method for implementation. Therefore, this study examined the muscle activity of agonist and abdominal muscles during resistance exercise using a conventional machine performed with asymmetrical versus symmetrical loads.

METHODS: Fifteen healthy young men performed chest presses using a chest press machine (Life Fitness) under four different load conditions combining 30% and 70% of their one-repetition maximum (1RM) load: two symmetrical (Right-Left: R30-L30, R70-L70) and two asymmetrical (R30-L70, R70-L30) conditions. Muscle activity during the exercise was measured from the pectoralis major, lateral head of the triceps brachii, rectus abdominis, and internal oblique on both sides (eight muscles in total) by using surface electromyography (EMG). The EMG values were normalized to those obtained during maximal voluntary contractions of each muscle (% EMGmax).

RESULTS: Muscle activity of the agonist muscles (pectoralis major and triceps brachii) was higher with a higher load in all conditions (e.g., right pectoralis major, 37.3% vs 76.2% [2.0-fold] in R30-L30 vs R70-L70, $p<0.001$). On the other hand, the

muscle activity of the abdominal muscles was the highest in the lower load side of the asymmetrical conditions, and this was prominent in the internal oblique (e.g., right internal oblique, 10.7% vs 26.4% [2.5-fold] in R70-L70 vs R30-L70, $P < 0.001$).

CONCLUSION: The internal oblique muscle activity was the highest in the lower load side of the asymmetrical conditions even compared to when lifting a higher load under symmetrical conditions, despite the lower total weight lifted. This supports the notion that the internal oblique plays a crucial role in stabilizing the trunk and suggests that its activity is specifically enhanced during exercises performed in an unstable environment. Thus, performing resistance exercises using a conventional machine with asymmetrical loads may serve as a practical and safe training method to strengthen the deep abdominal muscles.

3RM AND 10RM BACK SQUAT PROTOCOLS PROMOTE DIFFERENT BRAIN OXYGENATION RESPONSES

LEITAO, L., SILVA, M., FIGUEIREDO, T., MARINHO, D., NEIVA, H.S., PAREJA-BLANCO, F.

SUPERIOR SCHOOL OF EDUCATION OF POLYTECHNIC INSTITUTE OF SETUBAL

INTRODUCTION: Motor tasks are intricately associated with the prefrontal cortex (PFC), which is crucial for decision-making during physical activities (De Wachter et al., 2021; Orcioli-Silva et al., 2024). The capacity to sustain exercise relies on sufficient cerebral blood flow and oxygen delivery. Participating in physical exercises significantly boosts the brain's oxygen consumption compared to resting states (Teo et al., 2023; Orcioli-Silva et al., 2024). Notably, resistance training involves different loads that trigger distinct physiological adaptations. Our study aim was to analyze cerebral hemoglobin (Hb) consumption during two maximal protocols in the back squat exercise.

METHODS: Sixteen men (27.5 ± 5.1 years; 76.4 ± 4.1 kg; 1.74 ± 0.02 m) performed 3 (3RM) and 10 (10RM) repetitions until failure in back squat, with 72 h of rest between them randomly. PFC response was analyzed by near-infrared spectroscopy to measure the concentration of oxygenated Hb (O2Hb), deoxygenated Hb (HHb), total Hb (tHb), and tissue oxygenation index (TOI). In both the 3RM and 10RM protocols, the initial and final repetitions were examined to understand the PFC responses throughout these efforts.

RESULTS: The O2Hb was notably higher in the 3RM protocol compared to 10RM, both at the first (14.1 ± 3.3 $\mu\text{mol/L}$ vs. 5.3 ± 3.9 $\mu\text{mol/L}$) and last repetition (19.1 ± 6.2 $\mu\text{mol/L}$ vs. 7.4 ± 6.2 $\mu\text{mol/L}$). Likewise, O2Hb showed an increase in the final repetition compared to the initial one for both protocols ($p < 0.05$). No significant differences were observed in HHb and TOI between the protocols.

CONCLUSION: In conclusion, as fatigue accumulated during both 3RM and 10RM protocols, O2Hb progressively increased. This rise was more pronounced with heavier loads, becoming evident from the first repetition.

BILATERAL DEFICIT OCCURS IN KNEE FLEXION BUT NOT IN KNEE EXTENSION

KOBAYASHI, Y., MAEO, S., KANEHISA, H., ISAKA, T.

RITSUMEIKAN UNIVERSITY

INTRODUCTION: The bilateral deficit (BD) is the phenomenon that the force produced during simultaneous maximal contractions of both limbs is lower than the sum of the force produced by the left and right separately (Howard and Enoka, 1991). BD has been shown to be present in various, but not all, exercise tasks and is thought to influence training outcomes (Zelevnik et al., 2022). Thus, it is important to clarify whether BD occurs or not in exercises of interest. BD is reported to be greater in lower body than upper body exercises (Skarabot et al., 2016). However, there is large variability among studies targeting the lower body in the magnitude of BD, likely because different exercise tasks were chosen across studies. In addition, the magnitude of BD may be influenced by the posture even in the same exercise task (Magnus and Farthing., 2008). Thus, the purpose of this study was to investigate whether BD occurs in two commonly performed lower body resistance exercises, knee extension and flexion, with two postures for each exercise.

METHODS: Ten untrained healthy young adults participated in this study. Bilateral and unilateral one-repetition maximum (1RM) were measured for both legs in two postures of Knee extension (seated and supine, hip flexion angle of 80 and 0

deg) and two postures of Knee flexion (seated and prone, hip flexion angle of 80 and 30 deg). In addition, we calculated the bilateral index (BI (%) = bilateral / (right unilateral + left unilateral) *100-100) to quantify the magnitude of BD.

RESULTS: Bilateral force production was not significantly different from the sum of unilateral force production in two postures of knee extension (bilateral vs the sum of unilateral: seated, 133.2 ± 13.8 kg vs 131.1 ± 23.5 kg, $P = 0.746$, Cohen's $d = 0.106$, $BI = 3.46\%$; supine, 117.9 ± 19.1 kg vs 121.4 ± 21.8 kg, $P = 0.155$, Cohen's $d = 0.491$, $BI = -2.51\%$). On the other hand, bilateral force production was significantly lower than the sum of unilateral force production in two postures of knee flexion (seated, 92.1 ± 9.5 kg vs 110.8 ± 13.9 kg, $P < 0.001$, Cohen's $d = 1.648$, $BI = -16.50\%$; prone, 50.9 ± 7.8 kg vs 55.5 ± 9.5 kg, $P < 0.001$, Cohen's $d = 1.012$, $BI = -7.93\%$). In addition, BI was significantly lower (i.e. BD was greater) for seated knee flexion than the other three conditions ($P \leq 0.004$) and for prone knee flexion than seated knee extension ($P = 0.038$).

CONCLUSION: These results suggest that the bilateral deficit occurs in knee flexion, particularly when performed in the seated position, but not in knee extension regardless of the posture.

POST-ACTIVATION PERFORMANCE ENHANCEMENT DOES NOT REDUCE VELOCITY LOSS IN MULTIPLE SETS OF BACK SQUATS COMPARED TO A TRADITIONAL WARM-UP

GAMA, M., RODRIGUES, T., COSTA, R., BATISTA, A., DOS SANTOS, L., BOTTON, C.
FEDERAL UNIVERSITY OF CEARÁ

INTRODUCTION: Warm-up strategies are widely used to enhance performance [1]. Post-activation performance enhancement (PAPE) involves a high-intensity conditioning activity (CA) [2] that mimics the main task and may improve short-duration, high-velocity actions [3,4]. Since velocity decline indicates fatigue in sets to failure [5], it is unclear whether PAPE can counteract this effect. Velocity-based training uses 10–20% velocity loss for strength and 30–40% for hypertrophy [6,7], but no evidence links PAPE to repetition volume across these thresholds. This study aimed to determine if PAPE delays fatigue-induced velocity loss compared to a general warm-up.

METHODS: Twenty strength-trained participants (5 women and 15 men; 23.9 ± 3.6 years; 3.9 ± 2.7 years of training experience) completed three warm-up protocols on randomized days: (1) General Warm-Up (GW): 5 minutes of treadmill running, 2.5 minutes of stretching, and 10 back squats at 50% of one repetition maximum (1RM); (2) Conditioning Activity (CA): 3 back squats at 85% of 1RM; and (3) Combined (GWCA): GW followed by CA. After completing the warm-up, participants performed three sets of squats to failure at 75% of their 1RM, with individualized recovery intervals. A linear encoder was used to velocity measurements during the concentric phase of the movement. Mean velocity (MV), peak velocity (PV), initial (MVi, highest of the first two reps) and final (MVf, last valid rep) values were recorded per set, along with averages across sets. Repetitions performed before reaching 10%, 20%, and 30% velocity loss thresholds were assessed by the encoder. Repeated measures ANOVA were performed.

RESULTS: There were no significant differences in MV loss ($p=0.312$) among the three protocol sets mean values. PV for GWCA and GW was significantly different to CA between protocols in the mean of the three sets ($p=0.016$). Regarding the PV values of the separate sets, there was a set effect ($p<0.01$), with no effect of protocol ($p=0.359$) or interaction set*protocol ($p=0.787$). For MVi and MVf, there was a significant effect of the moment ($p<0.01$), but no protocol effect ($p=0.438$) or interaction with the sets ($p=0.865$). The only statistically significant difference was observed between the GW and GWCA protocols at the repetitions performed before reaching 10% threshold in the second set ($p=0.019$).

CONCLUSION: PAPE does not reduce velocity loss in sets to failure compared to GW and PAPE does not affect the number of repetitions performed before different velocity loss thresholds compared to GW. With caution, we could speculate that PAPE may help maintain repetition numbers across multiple sets when velocity is sustained up to a 10% loss threshold, which in velocity-based strength training is typically used for strength and power-focused training.

EFFECTS OF A DETRAINING PERIOD AFTER A RESISTANCE TRAINING INTERVENTION WITH DIFFERENT VELOCITY LOSS THRESHOLDS ON STRENGTH GAINS AND JUMP PERFORMANCE

MERINO PÉREZ, J., SÁNCHEZ-VALDEPEÑAS, J., PÁEZ-MALDONADO, J.A., GALLO-HIDALGO, J.M., JIMÉNEZ-ROLDÁN, M.J., SÁNCHEZ-MORENO, M., CORNEJO-DAZA, P.J., PAREJA-BLANCO, F.
SCIENCE BASED TRAINING RESEARCH GROUP, UNIVERSIDAD PABLO DE OLAVIDE, SEVILLE, SPAIN

INTRODUCTION: Velocity loss (VL) is established as a valid indicator to determine the level of effort attained during resistance training (RT) [1]. In long-term adaptations, it is well known that a low-to-moderate VL threshold optimizes strength gains and vertical jump performance [2]. However, there are no available data on the residual effects of VL on strength gains after a detraining period. Therefore, the aim of this study was to compare the effects of two RT programs with differ-

ent VL thresholds (i.e., 20% vs. 40%) on strength gains and jump performance after an RT intervention and a detraining period.

METHODS: Forty-four physically active men followed an 8-week RT program based on the full-squat (SQ) exercise (16 sessions). Subjects were randomly allocated into the two intervention groups that differed in the VL attained within the set (VL20: 20%; VL40: 40%). The relative intensity (65-80% 1-RM), inter-set recovery (4 minutes), and number of sets (3) were matched for both groups in each training session. The performance was evaluated on three occasions: pre-training (PRE), post-training (POST), and after 3 weeks of the detraining period (DET). The following battery of tests was performed in each testing session in the subsequent order: 1) countermovement jump (CMJ), 2) progressive loading SQ test, and 3) fatigue SQ test. The performance variables were: 1) CMJ height; 2) 1RM; 3) mean propulsive velocity (MPV) achieved with the common absolute loads performed at PRE (AV); 4) MPV achieved with the common absolute loads lifted faster than 1 m·s⁻¹ at PRE (AV $\geq$ 1), 5) MPV achieved with the absolute loads displaced slower than 1 m·s⁻¹ at PRE (AV<1), 6) number of repetitions completed in the fatigue test (MNR).

RESULTS: Significant main "time" effects were found for all performance variables analysed. However, no significant "group x time" interactions were observed. Both groups significantly improved strength performance against different loads (i.e., 1RM, AV, AV $\geq$ 1, and AV<1), without significant differences between them. Only VL40 significantly increased CMJ height at POST ($p = 0.002$). Likewise, VL40 achieved significantly higher performance in AV, AV $\geq$ 1, CMJ, and MNR than VL20 at DET.

CONCLUSION: Despite the VL40 experiencing a higher level of effort within the set, both groups achieved similar strength-derived adaptations after an RT intervention. However, the VL40 group maintained better strength and jump performances after a detraining period, suggesting that accumulating higher volume and fatigue levels during an RT intervention could result in longer residual benefits on strength performance.

CP-AP21 Football

ISOKINETIC ASSESSMENT OF THE KNEE JOINT EXTENSORS AND FLEXORS OF PROFESSIONAL SOCCER PLAYERS

LOMBARDI, S., COCILIO, L., D'ORIO, D., SCATTOLARI, C., MAZZOLI, D., PINTO, A.

UNIVERSITÀ DEGLI STUDI DI PARMA

INTRODUCTION: Muscle strength is a key factor in soccer, closely linked with performance and injury prevention (1). One of the most frequent test used to evaluate muscle strength in the limb is the isokinetic test for knee flexors and extensor (2). The aim of this study is to provide additional data to integrate normative values set for the strength profile of the thigh in professional soccer players.

METHODS: In 2024 at the beginning of the soccer season isokinetic tests were performed on 14 professional soccer players from Rimini Football Club first team using a dynamometer (Isomove, TecnoBody, Dalmine, Italy). Specifically, we selected the knee flexors isokinetic strength test and knee extensors isokinetic strength test, both of which were performed bilaterally.

The angular velocities used for the tests were 90°/sec and 180°/sec to obtain a more complete strength profile. The players were required to perform three maximal concentric contraction at 90°/sec to test maximal strength and ten maximal concentric contraction at 180°/sec to test muscle endurance.

Peak torque (in Newton meter, Nm) and conventional hamstring to quadriceps ratio (H:Q ratio) were recorded for both angular velocities. The Limb symmetry index (LSI) was calculated for the peak torque values.

RESULTS: The mean peak torque for the right and left limbs at 90°/sec was as follows: 152,1 Nm and 150,8 Nm for hamstring, 203,7 Nm and 209,1 Nm for quadriceps. Considering LSI, only three players had an LSI<90% for flexors and only two players had an LSI<90% for extensors. No players had a H:Q ratio >0,60 (3).

At 180°/sec the mean peak torque for the right and left limbs was 113,1 Nm and 110,5 Nm for hamstring, 142,8 Nm and 147,8 Nm for quadriceps. In this test five players shown an LSI<90% for both flexors and extensors. The H:Q ratio was >0,60 at this angular velocity as well.

CONCLUSION: This preseason evaluation showed better LSI results at the lower angular velocity and valid flexors peak torque values when considering the conventional H:Q ratio for the entire sample. Monitoring these values throughout the season enables club staff to identify and study potential correlations with player performance levels and injuries.

FOOTBALL PERFORMANCE MONITORING: INSIGHTS FROM A NATIONWIDE SURVEY OF ITALIAN FITNESS COACHES

CASTAGNA, C., PERONDI, F., CATTOZZO, A., FANCHINI, M.

PEGASO TELEMATIC UNIVERSITY

INTRODUCTION: Tracking and evaluating football players performance is fundamental to improving their training regimens and mitigating injury risks. Fitness coaches play a crucial role in employing effective monitoring strategies across different levels of competitive football, including professional, amateur, and youth categories. However, disparities in the adoption and perceived effectiveness of monitoring methods in Italian football remain underexplored. This study aims to

assess the perspectives of fitness coaches on external and internal load monitoring, recovery evaluation, and injury prevention approaches.

METHODS: A total of 401 certified fitness coaches participated in an online survey conducted between April and May 2024. Participants were drawn from mens professional teams (Serie A-B, Serie C-D), amateur football, youth divisions (Professional-Club, Amateur-Club), and womens football (analyzed as a single cohort due to sample size constraints). Responses were considered valid if at least 60% of participants per subgroup completed the survey. Chi-square tests were performed to analyze subgroup differences ($p < 0.05$). The prevalence of different monitoring techniques was categorized as trivial (0–20%), small (20–40%), moderate (40–60%), large (60–80%), very large (80–90%), or huge (90–100%).

RESULTS: The study revealed that external load monitoring tools, such as GPS, were widely utilized in mens Serie A-B and Serie C-D teams (both 52%) and were predominant in womens teams (87%). Key performance indicators included total distance covered (69%), speed thresholds (60–86%), and acceleration/deceleration patterns (62–69%). Internal load monitoring, specifically the session rate of perceived exertion (S-RPE), was highly prevalent, particularly in womens teams (64%) and youth teams (81%). Injury prevention methods predominantly focused on previous injury management (95–97%), load modulation (68–73%), strength and conditioning protocols (64–72%), and recovery strategies (63–66%). Variations in training methodologies emerged based on age, gender, and training flexibility.

CONCLUSION: The study identifies significant differences in monitoring practices between various football levels. Professional teams favor GPS-based monitoring, whereas subjective assessment tools are more common in amateur and youth football. These findings emphasize the necessity for customized monitoring strategies and improved resource allocation, particularly in sectors with limited access to advanced tracking technology. Additionally, observed gaps in fitness coaches knowledge highlight the need for updated certification programs to better align with contemporary football performance demands.

DETERMINATION OF PURE MAXIMAL GLYCOLYTIC RATE AMONG DIVERSE POSITIONS IN HIGHLY TRAINED FOOTBALL PLAYERS

KWAK, Y.J., KIM, Z.H., CHOI, H.Y., YANG, W.H.

CHA 대학 스포츠 의학 대학원

INTRODUCTION: Football matches involve a variety of movements that occur at a wide range of exercise intensities. Aerobic performance plays a dominant role in the football match, accounting for about 90% of the total football match duration. However, crucial moments, such as scoring goals, require maximal sprints. These powerful actions rely on phosphagen and glycolytic energy systems to meet their high metabolic demands. Due to the various match strategies, each player faces different movements and metabolic demands based on their position. Therefore, this study aimed to compare metabolic demands, including pure maximal glycolytic rate ($PvLa_{max}$), maximal oxygen uptake ($VO2_{max}$), energetic contributions, and lactate thresholds (LTs) among different positions in highly trained football players.

METHODS: Thirty male highly trained football players participated in this study. Three position groups of forwards ($n=10$), midfielders ($n=10$), and defenders ($n=10$) were separated. All participants performed a 10-s all-out sprint test. During the sprint test, oxygen uptake ($VO2_{peak}$) and blood lactate concentrations (resting $La-$, peak $La-$, and $\Delta La-$) were measured. These parameters were used to calculate three energy system contributions in kilojoules (kJ) and percentages (%) (phosphagen; WPCr, glycolytic; WGly, and oxidative; Woxi) and $PvLa_{max}$. Furthermore, $VO2_{max}$, LT1, and LT2 were determined during incremental ramp and step tests on a motorized treadmill, respectively.

RESULTS: Values of peak $La-$, $\Delta La-$ and WGly in kJ, and $PvLa_{max}$ were significantly lower in the group of midfielders than in the groups of forwards and defenders ($p = 0.0024, 0.0015, 0.0030$, and 0.0068 , respectively). These parameters between forwards and defenders indicated no significant difference ($p > 0.05$). In addition, values of $VO2_{max}$ and LTs showed no significant differences among different groups ($p < 0.05$).

CONCLUSION: Our study outcomes revealed differences in glycolytic demands among position-specific football players during a 10-s maximal sprint test. Forwards and defenders demonstrated higher values of $PvLa_{max}$ and WGly compared to midfielders. This higher glycolytic performance in forwards and defenders may support their ability to execute powerful actions, such as scoring goals during football matches. Consequently, football players require position-specific training sessions, such as repeated sprint training, which may improve explosive sprint performance and support successful performance at competitive moments.

INTER-LIMB ASYMMETRIES IN EVOKED KNEE EXTENSION STRENGTH EXACERBATE MUSCLE FATIGABILITY IN YOUNG AND ADULT PROFESSIONAL SOCCER PLAYERS

FRIGERIO, M., RAMPININI, E., BOSIO, A., INDUNI, M., DEMOLLI, L., CARLOMAGNO, D., MAFFIULETTI, N.A.

SPORT SERVICE MAPEI

INTRODUCTION: Inter-limb strength asymmetries and muscle fatigability are both suggested to be risk factors for non-contact related injuries (1), but they are rarely studied in conjunction. Large inter-limb asymmetries negatively affect change of direction (COD) and sprint but not jumping performance (2). However, little is known about the impact of strength asymmetries on muscle fatigability during soccer-specific tasks, such as CODs. The aim of this study was to compare the amount of muscle fatigability across a repeated COD test among soccer players with different degrees of asymmetries in evoked knee extension strength.

METHODS: A total of 3458 evaluations were conducted on 497 young (age: 17 ± 1 yrs; weight: 72 ± 7 kg; height: 181 ± 6 cm) and 619 adult professional soccer players (age: 25 ± 5 yrs; weight: 78 ± 7 kg; height: 182 ± 6 cm). Each player executed at least once (range: 1-25) an intermittent rectangular running test with multiple CODs over 8 m, consisting of four intensity levels. After each level, right and left knee extensors were electrically stimulated in resting isometric conditions to evoke a twitch response, from which peak twitch (PT) torque after the first (PT1) and fourth (PT4) levels as well as the highest absolute PT value (PTmax) were recorded for both sides. Percent asymmetries were calculated as (stronger-weaker)/stronger*100.

Players were then arbitrarily allocated to specific groups according to their degree of asymmetry (LOW: $\leq 5\%$, MID: 5-15%, HIGH: $>15\%$). Muscle fatigability was calculated as the mean percent decline from PTmax to PT4 (PTdec). A linear mixed model was used to calculate estimated marginal means ($\pm$ SE) and to detect differences among groups in PTdec. Effect sizes were expressed as Cohen's d. Significance was set at $p < 0.05$.

RESULTS: When considering PT1, HIGH showed higher fatigability than LOW (PTdec: $-31\pm 1\%$ vs $-29\pm 1\%$; $p=0.014$; $d = -0.13$, trivial). When considering PT4, HIGH showed higher fatigability than both LOW (PTdec: $-34\pm 1\%$ vs $-24\pm 1\%$; $p < 0.001$, $d = -0.69$, moderate) and MEDIUM (PTdec: $-25\pm 1\%$; $p < 0.001$, $d = -0.65$, moderate).

CONCLUSION: The main finding of this study was that professional soccer players with larger asymmetries in evoked knee extension strength during repeated CODs displayed higher levels of muscle fatigability, and vice versa for players with smaller asymmetries.

PERFORMANCE TESTING IN ITALIAN FOOTBALL: CURRENT PRACTICES AND LIMITATIONS OF CERTIFIED FITNESS COACHES

FANCHINI, M., CATTOZZO, A., PERONDI, F., CASTAGNA, C.

UNIVERSITY OF VERONA

INTRODUCTION: Player testing is a key component of athletic preparation in both elite and amateur football. However, its implementation can be influenced by coaches' knowledge and contextual factors across different teams. This study examines the perspectives of Italian fitness coaches on testing methods in professional men's (Men), women's (Women), and youth (Youth) football. The objective is to evaluate the effectiveness, challenges, and real-world application of physical performance testing in these contexts.

METHODS: Between April and May 2024, an online survey collected 401 responses from certified Italian fitness coaches (239 Men, 23 Women, 139 Youth). Items were analyzed if at least 60% of participants per group responded. Subgroups included Men: Serie A-B, Serie C-D, and Amateur; Youth: Professional and Amateur; Women: a single group due to the small sample size. Chi-square tests ($P < 0.05$) were conducted for subgroup differences, and response incidence was categorized as Trivial (0–20%), Small (20–40%), Moderate (40–60%), Large (60–80%), Very Large (80–90%), and Huge (90–100%).

RESULTS: During the previous season, 84% of Men's teams, 96% of Women's teams, and 83% of Youth teams conducted testing sessions. Testing was mainly performed pre-season (68% Men Serie A-B, 62% Men Serie C-D, 61% Women, 62% Youth). Fitness coaches found testing useful for assessing physical capacities (85% Men, 87% Women, 96% Youth), post-injury rehabilitation (89% Men, 91% Women, 94% Youth), and return-to-play readiness (79% Men, 90% Women, 83% Youth). The most commonly used tests were: 45-15 Intermittent Test for endurance (68%, Men Serie C-D), 5-30m Sprints for maximal speed (64% Women, 67% Youth), Jump-Based Tests for strength and power (66% Youth Amateur). However, resource constraints were found in Men's Serie C-D (65%), Amateur (68%), and Youth Amateur (79%) teams.

CONCLUSION: This study underscores the widespread use of performance testing among certified Italian fitness coaches, while revealing critical resource limitations, particularly in amateur and youth settings. The findings highlight the necessity for context-specific testing protocols and increased resource allocation to optimize player development. Additionally, these insights emphasize the need for enhanced educational programs that equip fitness coaches with the latest methodologies and evidence-based practices in performance assessment. Continuous updates to training curricula and professional development pathways can help bridge existing knowledge gaps and ensure that testing strategies are effectively adapted to various competitive levels.

ANALYSIS OF THE IMPACT OF ESPORT FOOTBALL ON REACTION TIME AND OCULO-PODAL COORDINATION IN ELITE ATHLETES

CERUSO, R., ESPOSITO, G., RAIOLA, G.

UNIVERSITY OF VERONA

INTRODUCTION: Football eSports are emerging as an innovative tool for motor development through cognitive challenges, improving decision making, concentration and eye-hand coordination. These aspects can benefit the neuromuscular system in the real game. However, there is a lack of evidence on the connections between post-training muscle reactivity with eSport and athletes perceptions of motor learning and its use in personalised teaching. The aim of the study is to explore the connection between the impact of the psychophysical effects of a training protocol for the development of reaction time and oculo-podal coordination, based on the use of football eSports, and the related perceptions, opinions and knowledge. It is also analysed how increased levels of cognitive-motor reactivity, achieved through the use of football eSports, can influence young peoples perception and awareness of psychophysical effects.

METHODS: Forty young male and female footballers (12-16 years old) were recruited and divided into a control group (CG) and an experimental group (EG), the latter integrating football eSports with traditional training. Ex ante and ex post proto-

col, both groups were evaluated with BlazePod, measuring reaction times, correct responses and adaptation to visual stimuli. The CG followed standard training, while the EG integrated football video games. Subsequently, a questionnaire consisting of 2 items was administered: the first on perceptions and opinions on the use of eSports, the second on the development of awareness with respect to cognitive-motor skills (Ceruso et al, 2024; Esposito, 2024). Data analysis includes Students t-test, descriptive statistics and Chi Square test (χ^2).

RESULTS: The EG showed significant improvements in reaction time and oculo-podal coordination compared to the CG ($P < .05$). The mean reaction time in the EG was significantly reduced, whereas the CG showed no significant change. Seventy-five per cent of the EG participants reported positive perceptions of eSports as support to traditional training. Furthermore, the Chi Square showed a significant relationship ($P < .05$) between improved cognitive-motor skills and acquired awareness.

CONCLUSION: The integration of football eSports into mainstream training can foster the development of reactivity and coordination in young athletes. Improvements in responses to visual stimuli indicate cognitive-motor enhancement, while participants perceptions and awareness highlight the positive impact of eSports on their development. eSports could be useful in personalised teaching to refine motor learning strategies.

ANAEROBIC ENERGY METABOLISM IS MORE USED BY THIRD-MAN-PASSING SMALL-SIDED GAMES THAN REGULAR-PASSING SMALL-SIDED GAMES IN FOOTBALL PLAYERS

YANG, W., PARK, S., KWAK, Y., KIM, Z., CHOI, S.

CHA UNIVERSITY

INTRODUCTION: Different human metabolic systems are simultaneously required during diverse exercises. However, the relatively predominant contributions of phosphagen (WPCr), glycolytic (WGly), and oxidative (WOxi) energy systems rely on exercise intensity and duration. In particular, coaches often adjust training rules to target specific external output during small-sided games (SSGs). However, the perspective of metabolic system contributions as internal outputs might allow for a better understanding of the real effect of tasks in preparing players. Therefore, this study compared the physiological profiles and energy system contributions of trained football players engaged in regular- and third-man-passing SSGs that included 4 versus 4 and a goalkeeper (GK).

METHODS: Ten male-trained football players participated in this cross-over study. All participants were randomly assigned to either regular-passing SSG or third-man-passing SSG (4 vs 4 with a goalkeeper, 35 m x 17 m pitch size, and 6-min match duration). During these SSGs, physiological parameters, including peak and mean heart rate (HRpeak and HRmean), oxygen uptake (VO2peak and VO2mean), metabolic equivalents (METs) in VO2peak and VO2mean, and blood lactate concentrations (peak La-, and delta La- [Δ La-]), were measured. Energy contributions (WPCr, WGly, and WOxi) and global positioning system variables (global positioning system, total distance, total acceleration counts, mean speed, and maximum speed) were also analyzed.

RESULTS: No significant differences in physiological parameters and global positioning system variables were observed between regular- and third-man-passing SSGs. WOxi in kJ and % were significantly higher during both SSGs than WPCr and WGly ($p < 0.0001$, respectively). WPCr and WPCr + WGly levels during third-man-passing SSGs were significantly higher than those during regular-passing SSGs ($p < 0.05$, respectively). Additionally, low-to-moderate positive correlations were observed between WOxi, WGly in kJ, VO2peak, VO2mean, peak La-, Δ La-, total acceleration counts, and mean speed ($r = 0.39 - 0.64$).

CONCLUSION: Our study demonstrated the effects of regular- and third-man-passing SSGs (4 vs 4 with a GK) on physiological responses and energy system contributions. The third-man-passing SSG compared with the regular-passing SSG induced higher WPCr and WPCr + WGly in trained football players. Therefore, third-man-passing SSGs may be useful for increasing anaerobic performance. More third-man-passing SSG sessions in preparation for football games may support high metabolic power and repeated powerful performances in trained football players.

EFFECTS OF UNILATERAL LEG BLOOD FLOW RESTRICTION (BFR) APPLIED DURING TRAINING ON THE MITOCHONDRIAL CAPACITY OF FOOTBALL PLAYERS

CAPELLI, C., TAM, E., POLI, A.

UNIVERSITY OF MILANO, ITALY; UNIVERSITY OF VERONA, ITALY

INTRODUCTION: Considering the numerous physiological and performance benefits of the blood flow reduction method called "Blood Flow Restriction" (BFR), used in both strength and endurance training [1], we aimed to investigate the effects of blood BFR on mitochondrial capacity and performance after 8 weeks of training in football players

METHODS: Twelve amateur football players aged between 17 and 33 (18.6 ± 4.6) participated in the study and trained 3 days a week for 8 weeks with pneumatic cuffs "The Occlusion Cuff-Elite®." The trained leg was assigned randomly to each subject.

In week 0 (pre-test) all subjects carried out a Mitochondrial Capacity test with a NIRS probe applied to the vastus lateralis of the trained and non-trained legs with BFR [2]. During this week, subjects were also familiarized with the training cuffs, using a pressure equal to approximately 40 % of the individual arterial occlusion pressure (AOP) assessed in a preliminary session. Afterwards, the percentage of AOP increased by 10% each training week, starting from 50% in weeks 1-2 to 80% in weeks 7-8. Tests were repeated during week 9 (post-test). The training intervention was structured in 8 weeks consisting

of 3 sessions a week, alternating (weekly) aerobic power to aerobic capacity on Monday, standardizing workouts with repetitions of 20" -20" at VAM and repetitions of 300m at Vi2 intensity. On Tuesday and Thursday, players performed lactate training (Z-L) and repeated sprint ability (RSA) at 80% of Vmax, plus TABATA 20" -10" bodyweight circuit training.

A one-way ANOVA for repeated measurements was applied to evaluate the differences in the time constant (τ) of muscular VO₂ kinetics during recovery after leg exercise.

RESULTS: τ of POST (BFR LEG; 28.2 s $\pm$ 5.0) was significantly shorter than before training PRE; 33.3 s $\pm$ 4.2); mean difference - 5.1 s; -15.4%; 95% CI of diff (1.46 – 8.8); P= 0.005. Significant difference also emerged in POST (BFR LEG; 28.2 s $\pm$ 5.0) vs POST (CONTROL LEG; 33.9 s $\pm$ 6.7); mean difference -5.7 s; -16.8%; 95% CI of diff (11.28 – 10.6); P= 0.005.

CONCLUSION: Our study showed a faster response in the time constant of mVO₂ recovery at the end of a moderate-intensity exercise test (50% VO₂max) after an 8-week training period with BFR. This results suggest that BFR associated with training was highly beneficial in improving mitochondrial capacity.

RELATIONSHIP BETWEEN JUMP AND RUNNING PERFORMANCE PARAMETERS IN U21 NATIONAL TEAM SOCCER PLAYERS

KALINA, T.1, LIPČÁK, A.1, HRUBÝ, M.1,2, PALUDO, A.C.3

1 MASARYK UNIVERSITY, 2 FOOTBALL ASSOCIATION OF THE CZECH REPUBLIC, 3 UNIVERSITY OF CYPRUS

INTRODUCTION: This study investigates the relationships between countermovement jump (CMJ) metrics, linear 40 m sprint (Lin40), the horizontal force-velocity profile (FVP) and change of direction (COD) ability in soccer players. The aim is to explore how CMJ parameters are associated with Lin40, FVP and COD parameters to optimize training strategies. Special attention is given to the interplay between horizontal and vertical force production and its impact on acceleration and deceleration phases, which are crucial for sprinting and rapid direction changes.

METHODS: Fifteen male U21 Czech national team soccer players participated in a training camp assessment, completing two trials of the CMJ, linear 40 m sprint (Lin40), and COD performance, with only the best individual results—jump height for CMJ, and time for Lin40 and COD—analyzed. Additional CMJ parameters, including braking-phase rate of force development (DecRFD) and maximal relative power (PP), were measured using K-deltas (Kinvent, France). Sprint (Lin40) and COD performances were assessed with the 1080 Sprint device (1080 Motion, Sweden) under a constant 3 kg isotonic resistance. In the COD test, athletes sprinted 15 m with 3 kg assistance, performed a 180° turn, and continued for 5 m with 3 kg resistance. COD metrics included maximal acceleration (MaxAcc) and maximal deceleration (MaxDec). Lin40 performance included maximal acceleration (MaxAcc) and horizontal force-velocity profile (FVP) metrics: maximal power output (Pmax), theoretical maximum force (F0) and maximum velocity (V0).

RESULTS: COD: 4.35 $\pm$ 0.08 s (time), 7.22 $\pm$ 0.72 m/s² (MaxAcc), and 8.71 $\pm$ 0.99 m/s² (MaxDec). CMJ: 43.4 $\pm$ 3.94 cm (jump height), 60.1 $\pm$ 5.5 W/kg (PP), and 10740.7 $\pm$ 4531.67 N/s (DecRFD). Lin40 and FVP: 5.9 $\pm$ 0.21 s (time), 7.8 $\pm$ 0.58 N (F0), 9.3 $\pm$ 0.47 m/s (V0), 17.86 $\pm$ 1.19 W/kg (Pmax), and 7.3 $\pm$ 0.62 m/s² (MaxAcc). CMJ height demonstrated a moderately strong positive correlation with Pmax ($r = 0.55$, $p < 0.05$) and F0 ($r = 0.51$, n.s.), as well as with CMJ PP (both $r = 0.66$, $p < 0.05$). No significant correlations were found between CMJ and COD parameters, although CMJ DecRFD was positively correlated with COD MaxAcc ($r = 0.21$), and COD MaxDec was negatively correlated with CMJ height ($r = -0.37$) but not with CMJ DecRFD ($r = 0.09$).

CONCLUSION: CMJ, Lin40 and COD performances share common neuromuscular determinants, while COD ability appears to rely more on acceleration and deceleration capacities. These findings highlight the necessity for targeted training strategies in elite U21 soccer players. Specific exercises designed to improve both explosive strength for CMJ and agility for COD are essential for optimizing performance across all facets of the game. Future research should further investigate how tailored training programs can enhance both vertical and horizontal power, thus improving overall athletic performance.

Conventional Print Poster Presentations

CP-AP24 Swimming

THE RELATIONSHIP BETWEEN TRUNK POWER AND UNDERWATER PERFORMANCE IN 400 M FREESTYLE FOR SWIMMING ATHLETES

GAO, S., ZHONG, J.1, YANG, C.2, WANG, H.3, WANG, D.1

1. SHANGHAI UNIVERSITY OF SPORT, SCHOOL OF ATHLETIC PERFORMANCE; 2. CHANGCHUN NORMAL UNIVERSITY, SPORTS DEPARTMENT; 3. ZIBO SPORTS SCHOOL, SWIMMING DEPARTMENT.

INTRODUCTION: The underwater phase (from wall contact to the head first break water after rolling rotation) during turns plays a crucial role in competitive swimming, as it enables faster speeds compared to surface freestyle swimming [1]. A longer and faster underwater phase is associated with better turn performance thus the overall swimming success. Trunk power may contribute to the two skills executed during underwater phase - the twisting rotation (twisting around the vertical axis of the body) and the undulatory underwater swimming. However, the relationship between trunk power and the underwater performance of turn is still unclear. 400 m freestyle requires athletes to have both speed and endurance,

and a large number of turns can be analyzed. Therefore, this study aimed to investigate the correlation between trunk power and underwater turn performance in 400 m freestyle.

METHODS: Ten national-level male swimmers (19.6 ± 3.8 yr, 185 ± 3.6 cm.; 74.9 ± 8.1 kg) participated in the study. Their average personal best performance was 92.29% of the current world record. Data were collected in 7 turns during a 400 m freestyle test, including average water break time (WBT), underwater velocity and water break distance (WBD), captured by two fixed cameras (HDR-CX680, SONY, Tokyo, Japan) for assessing underwater phase performance. The front and side abdominal power tests (FAPT and SAPT) were conducted using a 2 kg medicine ball by throwing forward and sideward respectively. Each test was performed three times per direction, with a 45-second rest interval between trials. The maximum throwing distance (m) was used for analysis. Pearson correlation coefficients were calculated to determine the relationship between underwater performance and trunk power.

RESULTS: Pearson correlation showed significant positive correlations between WBT and left SAPT ($r = 0.664$, $p = 0.036$) and right SAPT ($r = 0.644$, $p = 0.044$). Strong correlations were shown between underwater velocity and FAPT ($r = 0.808$, $p = 0.005$), left SAPT ($r = 0.747$, $p = 0.013$) and right SAPT ($r = 0.636$, $p = 0.048$). Similarly, WBD showed strong correlations with FAPT ($r = 0.711$, $p = 0.021$), left SAPT ($r = 0.717$, $p = 0.020$), and right SAPT ($r = 0.666$, $p = 0.036$).

CONCLUSION: The findings suggested that the underwater performance (WBT, underwater velocity, and WBD) are strongly correlated with trunk power (in the direction of front, left and right). Besides, stronger correlations were observed for left SAPT compared to right SAPT with underwater performance.

NEUROMUSCULAR TRAINING PARADIGMS FOR SWIMMERS: A SYSTEMATIC REVIEW OF THE RELATIONSHIP BETWEEN EXERCISE LOADING AND EXERCISE PERFORMANCE

CHEN, D., HAO, T., DENG, W., GUOPING, Q., QIANG, Y.

NANJING SPORT INSTITUTE

INTRODUCTION: Neuromuscular training is critical for optimizing swimming performance, yet evidence-based load prescription remains challenging [1-3]. Current research lacks consensus on: (1) dose-response thresholds for different training modalities, (2) valid load monitoring biomarkers, and (3) taper duration optimization. This systematic review establishes evidence-based guidelines for neuromuscular training periodization.

METHODS: The systematic literature search was conducted following the PRISMA-PERSiST guidelines across seven databases (PubMed, Web of Science, Scopus, SPORTDiscus, CINAHL, Cochrane Library, and EMBASE). Methodological quality was appraised via AMSTAR2 with dual-independent screening.

RESULTS: From 2,317 initial records, 42 studies met inclusion criteria (68% published 2019-2024). High-intensity training demonstrated superior performance correlation ($r = 0.69$, $p < 0.01$) versus volume-based approaches (NS). Strength loads at 70-85% 1RM elicited maximal sprint improvements (3.2-5.6%, $ES = 1.21$). A 3-week exponential taper optimized time gains ($\Delta 2.9$ -3.2%, $p < 0.01$) through fatigue reduction, whereas extended tapering diminished returns ($ES = 0.18$). Neuromuscular interventions revealed differential effects: core training enhanced stroke efficiency ($\Delta 9.2\%$, $p < 0.05$) while plyometrics improved start/turn power ($ES = 0.5$ -0.6). Session-RPE showed high validity for load quantification ($ICC = 0.92$), with HRV thresholds (< 50 ms RMSSD) effectively detecting overtraining states ($AUC = 0.89$).

CONCLUSION: Neuromuscular training efficacy in swimming depends critically on load modulation. High-intensity protocols, short-term tapering, and core/power training yield robust performance benefits. Personalized load monitoring using RPE or physiological biomarkers (e.g., HRV) is essential to balance adaptation and recovery. Future research should prioritize RCTs comparing periodization models in diverse athlete populations.

THE EFFECTS OF PULL-UP TRAINING ON SWIMMING PERFORMANCE AND PREDICTORS: A SYSTEMATIC REVIEW

LI, L., BI, C.

BEIJING SPORT UNIVERSITY

INTRODUCTION: pull-ups, are widely incorporated into swim training due to their biomechanical similarity to swimming strokes. Pull-ups strengthen the muscles associated with swimming (back muscles, etc.). Despite their relevance, limited research has directly investigated the effects of pull-up training on swimming performance. This systematic review aims to (1) examine the impact of pull-up training on swimming performance and (2) explore its potential as a predictor

METHODS: A comprehensive literature search was conducted in PubMed, Scopus, Web of Science, and Google Scholar for studies published between January 2014 and July 2024. The search strategy utilized the keywords ("pull-up" OR "chin-up") AND ("swimming" OR "swimmers"). Studies were excluded if they involved non-swimmers, lacked pull-up interventions, or exhibited low methodological quality. After screening, 11 studies were included and evaluated following PRISMA guidelines. Methodological quality was assessed using the PEDro scale.

RESULTS: The included studies primarily focused on freestyle/breaststroke. Pull-up velocity and power during the concentric phase showed significant correlations with short-distance swimming performance (50m and 100m). In contrast, the maximum number of pull-ups completed in a single attempt did not correlate with short-distance performance. Pull-up endurance (maximum repetitions within 30 seconds) was associated with middle- and long-distance freestyle performance. Training interventions targeting pull-up velocity effectively improved 50m freestyle performance, particularly in the first half of the race. However, high-intensity pull-ups ($\approx 3RM$) for post-activation potentiation (PAP) provided limited benefits. In breaststroke, athletes with greater pull-up endurance exhibited higher stroke frequencies during competitions. Females 1RM pull-up performance correlated with 50-yard freestyle performance, but no such correlation was observed in males. Pull-up velocity and power partially predicted short-distance performance, while velocity and repetition count moderately predicted middle- and long-distance performance. Pull-up performance remained largely unaffected by fatigue, limiting its utility as a condition indicator. Significant gender differences were noted, with 1RM pull-ups predicting short-distance performance only in females.

CONCLUSION: Pull-up training enhances upper body strength and swimming performance, especially in short-distance events. Swimmers should focus on improving pull-up quality (velocity, power) over increasing repetition count. Gender differences in 1RM pull-up performance indicate upper body strength is more critical for female swimmers. After achieving maximal strength, training for explosive power and endurance may offer greater benefits. Limitations include small sample sizes and limited stroke coverage. Future research should explore pull-up training across strokes, distances, and genders, and assess its efficacy as a predictive metric and warm-up tool.

EXPLORING NUTRITION AND BODY COMPOSITION CHANGES: THE CASE OF A SOLO SWIMMER ON A 100 KM JOURNEY

GHIANI, G., CATTÀ, G., RUGGIU, M., PORCEDDU, M., COCCO, A., TOCCO, F.

UNIVERSITY OF CAGLIARI

INTRODUCTION: Ultra-endurance swimming events challenge athletes with distances ranging from 10 km to over 100 km in natural bodies of water, where they face varying conditions such as currents, waves, and temperature fluctuations. Training for these events often requires months or years of preparation. Participants typically swim with support teams that provide nutrition, hydration, and safety assistance. The physical and mental challenges include fatigue, temperature regulation, and the psychological demands of long-distance swimming. A crucial aspect of performance is meeting the energy requirements during these events. This study examines changes in body composition and hydration of an athlete who completed a solo 100 km swim.

METHODS: A 22-year-old swimmer planned a solo open water swim of 100 km in September 2024 to raise money for charity and trained for about a year. He trained both in swimming pools and open sea, and added resistance training during the whole year before the event. To optimize physical and nutritional fitness, he sought support from the Sport Physiology Lab at Cagliari University. We assessed his body composition and energy intake during training and designed his diet for both training and the event. The energy cost of swimming 100 km was estimated through an incremental cardio pulmonary exercise test done in open water in which the most economical race pace was identified. A support boat accompanied him during the challenge, providing supplementation (liquid and solid) every 30 minutes. Pre- and post-race measurements of body mass, body fat percentage, skeletal muscle mass, and total body water were conducted using anthropometric methods and bio electrical impedance analysis. During the swim, the athlete used a device (Garmin Fenix 6) to track distance, heart rate, calories burned, and water temperature.

RESULTS: The athlete successfully swam 102 km in 32 hours and 40 minutes, maintaining an average pace of 1:40 min/100 m for the first 53 km and 1:54 min/100 m for the last 49 km. He ingested approximately 200 Kcal per hour from supplementation, totaling a fluid intake of about 8 liters. At the conclusion of the swim, he reported being in good health and high spirits. Body mass decreased by 4.6 kg, skeletal muscle mass by 0.4 kg, body fat by 2.6 kg, and total body water by 1.1 liters.

CONCLUSION: Our goal of supporting the athlete in preparing for and completing the ultra-endurance event while preserving his health was achieved. Despite the challenges demands, he successfully adhered to the planned schedule. Consistent with findings from other studies, we observed that body mass loss is not solely attributed to dehydration. These results warrant further investigation in larger field studies involving ultra-endurance swimmers.

SUBJECTIVE PERCEPTION OF PHYSICAL AND MENTAL FATIGUE IN ARTISTIC SWIMMERS DURING THE PRE-COMPETITIVE AND COMPETITIVE SEASON

KONTI, E., KAVVALOU, E., NTOMALI, S., ARSONIADIS, G., TOUBEKIS, A., BOTONIS, P.
NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS, GREECE

INTRODUCTION: Artistic swimmers (AS) participate in daily training sessions requiring in-water and dry-land training [1,2]. Previous research in high-level netballers has indicated that physical fatigue (PF) and mental fatigue (MF) demonstrate a shared variance of 14.3% [3], suggesting that several factors may affect the feelings of physical and mental fatigue. Excessive increases in training load (TL) may increase the subjective feeling of PF [4]. However, it is uncertain whether fluctuations in TL mirror changes in PF and MF, since MF might be influenced not only by training, but also by school commitments [5]. Therefore, the present study examined whether fluctuations in TL are reflected on changes in MF and PF of AS over a 10-week period including pre-competition and competition training.

METHODS: Fifteen female adolescent AS (age: 14.7 ± 1.6 years, body mass: 49.2 ± 7.0 kg, body stature: 166.0 ± 0.1 cm, competitive experience: 6.9 ± 1.7 years) participated in the study. Internal TL (rating of perceived exertion x training duration), and subjective PF and MF (visual analogue scale from 1 to 10), were daily recorded across three distinct phases: phase 0 (Easter holidays: two weeks with regular training and no school obligations), phase 1 (5 weeks of reduced training, but increased mental demands due to school exams), and phase 2 (3 weeks of preparation for competitions; no school commitments). The effect of each training phase on TL, PF and MF was examined using separate linear mixed models, where the three training phases were defined as fixed effects, while the athletes were defined as a random factor. The level of statistical significance for all tests was set at $p < 0.05$.

RESULTS: Significant differences among the three training phases were observed in TL, as well as in the subjective scores of PF and MF (all, $p < 0.01$). TL was higher in phase 2 (581 ± 172 a. u.) compared to phase 1 (409 ± 91 a. u., $p < 0.01$) and phase 0 (449 ± 121 a. u., $p < 0.01$). PF was lower in phase 2 (4.2 ± 1.6 a. u.) compared to phase 1 (4.5 ± 1.2 a. u., $p < 0.05$), while MF was higher in phase 1 (4.8 ± 1.7 a. u.) than in phase 0 (4.1 ± 1.9 a. u., $p < 0.01$) and phase 2 (3.6 ± 1.9 a. u., $p < 0.00$).

CONCLUSION: This is the first study that examines the influence of three distinct training phases on TL, PF and MF in adolescent AS. It suggests that fluctuations in TL in this cohort of athletes does not mirror respective changes in PF and MF. These findings provide practical insights for coaches in optimizing TL management in adolescent AS and suggest that along with TL, PF and MF should be recorded in training procedure. However, the influence of TL on PF and MF warrants further investigation.

INFLUENCE OF INSPIRATORY MUSCLE PRE-ACTIVATION ON 400 M FRONT CRAWL PERFORMANCE IN YOUNG SWIMMERS: A COMPLEX NETWORK ANALYSIS

SOARES DE ARAUJO, L., PAPOTI, M.2, ORSI, J.1, HIRAI, D.3, ROSEGUINI, B.3, HILL, D.4, GOBATO, C.1, MANCHADO-GOBATTO, F.1

1UNIVERSITY OF CAMPINAS, 2UNIVERSITY OF SÃO PAULO, 3PURDUE UNIVERSITY, 4UNIVERSITY OF NORTH TEXAS

INTRODUCTION: Inspiratory muscle pre-activation using airflow restriction (IMPA) has been shown to benefit athletes [1]. However, it is uncertain if IMPA is effective in swimmers, whose activity is associated with high inspiratory demand in aquatic environments. This study investigated the effects of IMPA on 400m front crawl performance using complex network model.

METHODS: Nine swimmers (16 ± 1 yrs; 68.9 ± 4.5 kg; 1.7 ± 0.1 m) were evaluated in four sessions. In the first, anthropometric measurements, body composition, maximal inspiratory pressure (MIP), and the global strength index were assessed. In subsequent randomized sessions, athletes performed a 400 m front crawl time-trial under 3 conditions: with no pre-activation (Control, C), with IMPA at only 3 cm H₂O (Placebo, PLA), and with IMPA at 40% of MIP (Pre-activation, PA), using POWERbreathe K5 device. Blood lactate, skin temperature in target regions, and perceived exertion and dyspnea were assessed after each test. Data were analyzed by conventional statistics and by complex network. For this, undirected weighted graphs ($G=V,E,w$) were constructed for each scenario (C, PLA, and PA) to examine the degree (number of connections) and betweenness (intermediate nodes considering the shortest paths between two in a graph) centrality metrics [2]. The graphs were composed of 25 vertices (V, nodes) corresponding to the athletes profile, mechanical, and physiological parameters, and edges (E) denoted interactions based on Spearman's correlation coefficients ($r \geq 0.5$) to construct the weight function (w).

RESULTS: The Friedman test showed significant difference in the stroke length between C and PLA (1.45 ± 0.21 and 1.43 ± 0.24 m, $p \leq 0.05$). In parallel, the complex network highlighted athletes' profiles and inspiratory measures as important nodes in all cases. A total of 206 connections were observed in the C scenario, 123 in the PLA, and 176 in the PA. The C graph exhibited the highest density (0.69) and connectivity with nodes such as height, arm span, and MIP (21–22 connections); betweenness was distributed among athletes' profiles and mechanical nodes (height, arm span, stroke length). In the PLA, graph density was lower (0.41), with a reduced degree (16–15 for lactate, height, and arm span), and peak lactate exhibited the highest betweenness (0.08), while other values were ≤ 0.02 . The PA graph demonstrated an intermediate density (0.59), with a high degree (20–19 for arm span, height, and inspiratory values), and betweenness highlighted body fat (0.06), chest temperature (0.04), and arm span (0.03).

CONCLUSION: IMPA did not alter mechanical, physiological, and perceptual parameters in the 400m front crawl. However, the complex network indicated anthropometric, inspiratory values, and chest temperature as central nodes, suggest-

ing that after pre-activation, these parameters may play a key role in the interconnection among performance and physiological responses.

ISOLATED VS. SIMULATED TRIATHLONS: A COMPARATIVE STUDY OF PERFORMANCE, PHYSIOLOGY, AND BIOMECHANICS IN TRIATHLETES

PUGGINA, E., SANTOS, I., OLIVEIRA, L., TRAVITZKI, L.

UNIVERSITY OF SÃO PAULO

INTRODUCTION: Given the gap in the literature regarding the behaviour of different loads imposed by isolated events versus a triathlon and recognizing that clarifying this could impact the development and programming of training for triathletes, this study aimed to compare performance, physiological, and biomechanical variables between separate triathlon events (swimming, cycling, and running) and combined events (simulated triathlon) in triathletes.

METHODS: Nine triathletes were randomly evaluated in both conditions (isolated triathlon -swimming, cycling and running performed separately- vs. simulated triathlon -complete race-). Performance in each segment, heart rate (HR), muscle oxygen saturation (SmO₂), rating of perceived effort (RPE) and biomechanical indicators such as cycles, frequency and length of strokes in swimming; power and cadence in cycling, cadence, length and ground contact time in running were evaluated.

RESULTS: Swimming performance was worse in the isolated condition (1902.3 ± 262.1 s) compared to the simulated triathlon (1862.0 ± 229.1 s; $p = 0.02$). No significant differences were found in cycling (isolated: 4269.6 ± 321.1 s; simulated: 4464.6 ± 374.4 s; $p = 0.12$). Running performance, however, was poorer in the simulated triathlon (3044.6 ± 523.1 s) than in isolation (2676.3 ± 294.6 s; $p = 0.006$). Swimming in isolation led to reduced performance (~ 3%) and higher perceived effort.

CONCLUSION: Running after swimming and cycling resulted in worse performance (~13%) and shorter stride length. Therefore, incorporating full triathlon simulations in training is recommended to help athletes adapt to transitions. Such a strategy could enhance running efficiency following swimming and cycling, improving overall triathlon performance.

RELATIONSHIP BETWEEN BENCH PRESS AND IRON CROSS MAXIMAL ISOMETRIC CONTRACTION – A POTENTIAL PATH TO PERFORM THE IRON CROSS ON GYMNASTICS STILL RINGS

LECOCQ, T., GOUELLE, A., SCHÄRER, C., MOCHIZUKI, L., TORDI, N.

UNIVERSITÉ DE REIMS CHAMPAGNE-ARDENNE

INTRODUCTION: The last code of point ruling international artistic gymnastic competitions took another step toward the ubiquitous necessity of strength difficulty on still rings. The objective of the present study is to analyze the relationship between a bench press and an iron cross maximal isometric contraction. Based on this relationship, a theoretical model will be provided to help coaches with individual and personalized training recommendations relying on the gymnast's current general and specific training status.

METHODS: 52 sub-elite gymnasts (Mean $\pm$ SD 22.4 ± 5 years, 173 ± 5 cm, 68.5 ± 6 kg) were randomly assigned to start by one of two exercises: 1) Maximal isometric contraction in bench press position: The force applied by the athletes against an immobile bar in the bench press position was measured with a pair of handheld dynamometers. 2) Maximal isometric contraction in the iron cross position: Participants were standing on force plates to measure their body weight at rest and during a maximal contraction. The force developed was computed by subtracting the remaining weight to the initial body weight. Both maximal forces were normalized by body weight and expressed in percentages.

RESULTS: Maximal relative strength ranged between 62.2% and 230.47% in Bench Press and between 40.9% and 102.1% in Iron Cross. Contrary to the hypothesis, the relationship between the two measurements is only moderate (Pearson's $r = 0.41$; $p = 2.64e-3$; $IC = [0.15; 0.61]$). Nevertheless, by splitting the entire population according to Bench Press 20% interval (i.e. [60%; 80%], [80%; 100%], etc.) and analyzing the strongest individual in the iron cross for each subgroup, a threshold appears. Accordingly, iron cross relative strength can seemingly take any value between zero and a maximal theoretical value computed from the bench press: $\text{Iron Cross} = 0.5 \times \text{Bench Press} + 15$.

CONCLUSION: The main findings from the present study are twofold: First, the absence of a linear relationship between those two maximal isometric contractions. Second, the existence of a linear threshold rather than a linear trend between bench press and iron cross. Based on the present findings, a model has been developed to help coaches locate gymnasts and provide personalized guidelines to improve the performance of the iron cross depending on the athletes' current general and specific strength status. From the model, the threshold governing the interaction between those two relative strengths seems to stress the need to improve the bench press to improve the iron cross, while the absence of gymnasts with a low bench press and a high iron cross relative strength could highlight the necessities of the bench press

to perform the iron cross. In addition, the important number of gymnasts presenting a high bench press, and a low iron cross relative strength might emphasize that while being necessary, the bench press is not sufficient for the iron cross.

VALIDITY AND RELIABILITY OF A NEW ENDURANCE TEST ADAPTED TO CHILDREN AGED 4-7 YEARS

JIDOVTSSEFF, B., BERTRAND, D., HENN, A., LEGRAND, E., LEJEUNE, R., ABDELMOULA, A.

UNIVERSITY OF LIEGE

INTRODUCTION: Currently, there is no field test to assess aerobic endurance in children aged 4-7 years, while taking into account the physiological and psychological characteristics specific to this population. The main validated test is a 3-minute continuous, round-trip 10m run (Ayan et al, 2015). However, studies show that intermittent effort is better suited to the physiological specifics of young children, notably due to their greater ability to recover quickly between brief efforts (Baquet et al., 2010). Furthermore, the integration of playful elements, such as imaginative storytelling or dramatizations, could not only increase the pleasure felt during effort, but also improve children's motivation and engagement (Howells et al., 2023). These playful approaches seem particularly relevant for encouraging adherence to physical activity from an early age, and it seems worthwhile to propose a positively perceived endurance assessment test for younger children.

METHODS: To take into account the particularities of the target age group, we developed a 3x1 minute intermittent endurance test (recovery = 30 seconds) accompanied by a story to make it fun. To study the validity of the test and the influence of the variables "intermittent effort" and "playful context", 80 children will perform the test under 4 conditions: continuous non-playful test (reference test); continuous playful test; intermittent non-playful test; intermittent playful test. To study reliability, 80 children will perform both intermittent non-playful test and intermittent playful test twice. Children level of exhaustion and the level of amusement will be assessed using emoticons scales.

RESULTS: Preliminary tests have been carried out to arrive at a rigorous organization enabling the evaluation of a class (around 20 children) in a single session lasting less than 45 minutes. Measurements for validity and reliability are currently underway. Full results will be available at the conference.

CONCLUSION: We hypothesize that the playful intermittent test will be well suited to the 4 to 7 year-old population. We hypothesize that overall validity and reliability will be good, but influenced by the age of the children, and lower in the youngest age groups. We hypothesize that, at the end of the new test, children will report a level of exhaustion comparable to other tests, but will report a higher fun score.

EFFECT OF TRAINING FREQUENCY DURING HEAT ACCLIMATION ON THE PHYSIOLOGICAL ADAPTATION OF THOROUGH-BRED HORSES

EBISUDA, Y., KITAOKA, Y., SUGIYAMA, F., TAKAHASHI, Y., YOSHIDA, T., MUKAI, K.

EQUINE RESEARCH INSTITUTE, JAPAN RACING ASSOCIATION

INTRODUCTION: Heat acclimation, the repeated exposure to exercise in a hot environment, induces physiological adaptation with improved thermoregulatory and cardiovascular functions. In humans, daily training regimens in hot environments are recommended for improved adaptation and higher performance. While heat acclimation is also crucial for Thoroughbred horses, research on different training protocols for this species is scarce. This study compared the effects of consecutive and intermittent heat acclimation protocols in Thoroughbred horses.

METHODS: This was a randomized crossover study, including eight trained Thoroughbred horses. The horses were assigned to either a consecutive (CONS, 9 consecutive days) or an intermittent protocol (INT, 3 days/week for 3 weeks), involving 30 min exercise in hot conditions (Wet Bulb Globe Temperature [WBGT] 29.5°C). Both training protocols comprised alternate sessions of high-intensity interval training (3 × 1 min bout at 100% VO₂max with 2 min recovery) and moderate-intensity interval training (3 × 1 min bout at 70% VO₂max with 2 min recovery). Before and after the heat acclimation period, incremental exercise tests (IETs) were conducted in hot conditions (WBGT 29.5°C), with collection of arterial and venous blood samples to measure blood gases and plasma lactate concentration. Pulmonary artery temperature and heart rate were also recorded. Prior to IETs, muscle biopsy samples were obtained from the middle gluteal muscle for enzyme activity analysis. Data were analyzed using mixed models, and pairwise comparisons were performed using Tukey's test ($P < 0.05$).

RESULTS: Both protocols decreased pulmonary artery temperature after heat acclimation, both at rest (CONS, -0.2°C; INT, -0.3°C) and during submaximal exercise (CONS, -0.3°C; INT, -0.3°C). For IETs, time to exhaustion increased in INT (+11.6%, 8 of 8 horses improved) but not in CONS (+5.7%, 5 of 8 horses improved). For both protocols VO₂max remained unchanged (CONS, +7.5%; INT, +3.4%) whereas speed eliciting VO₂max increased (CONS, +6.5%; INT, +10.4%). For CONS only, maximal stroke volume increased (CONS, +11.8%; INT, +3.9%) while heart rate during submaximal exercise decreased (CONS, -5.5%; INT, -3.7%). Moreover, weight loss was observed after heat acclimation for CONS only (CONS, -1.8%; INT, -0.6%). Regarding enzyme activity, citrate synthase remained unchanged in both protocols (CONS, +2.0%; INT, -3.6%) whereas 3-hydroxy acyl-CoA dehydrogenase decreased in INT only (CONS, -30.2%; INT, -42.8%).

CONCLUSION: Both protocols elicited physiological adaptation to thermoregulation and aerobic energy metabolism. However, improved performance occurred only in INT, while cardiovascular improvement and weight loss occurred only in CONS. These findings suggest that consecutive heat acclimation training can induce robust physiological adaptations in a short period. However, care should be taken to prevent overreaching in Thoroughbred horses.

A SIMPLE METHOD TO DETERMINE THE SEVERE-EXTREME INTENSITY EXERCISE DOMAIN BOUNDARY USING THE VO₂ KINETIC RESPONSE

OZKAYA, O., JONES, A.M., BURNLEY, M., PEKER, A., AS, H.

FACULTY OF SPORTS SCIENCES

INTRODUCTION: The boundary separating the severe intensity exercise domain, wherein the maximal O₂ uptake (VO₂max) can be attained, from the extreme intensity exercise domain, wherein VO₂max cannot be attained, is not widely adopted in applied work with athletes due to its labour-intensive nature. The aim of this study was to propose an alternative, practical approach to estimate the severe-extreme boundary using VO₂ kinetics.

METHODS: Sixteen physically active males completed an incremental exercise test and a series of constant power output exercise tests on a cycle ergometer. The relationship between time to achieve VO₂max and time to task failure during severe-intensity exercise (PUPPERBOUND) was calculated to provide an estimate of the highest power output at which VO₂max was momentarily attained just before task failure. Separately, the highest power output that provided a time to task failure that was equal to or greater than four times the time constant (τ) describing the VO₂ kinetics during severe-intensity exercise (P4- τ) was calculated.

RESULTS: The PUPPERBOUND and P4- τ occurred at similar power outputs (379±60 vs. 380±57 W, respectively; $p=0.62$) and were closely related ($r: 0.99$; bias: 1 W; SEE: 7 W; limits of agreement: -14 W to 16 W).

CONCLUSION: Compared to PUPPERBOUND, the P4- τ method provides a simpler and more time efficient approach to identify the severe-extreme intensity exercise domain boundary.

THE EPIDEMIOLOGY OF DANCE-RELATED INJURIES AND EFFECTS OF 11+ DANCE NEUROMUSCULAR PROGRAM ON LOWER LIMB FUNCTIONAL PERFORMANCE IN PRE-PROFESSIONAL DANCERS

LI, L., WONG, L., TAO, J., LEUNG, H., CHEUNG, C., LEUNG, K., CHENG, F., LIMBU, F., NGO, J., HO, I., LUK, J.

TECHNOLOGICAL AND HIGHER EDUCATION INSTITUTE OF HONG KONG

INTRODUCTION: A systematic review shows a high injury rate among pre-professional dancers (17-90%) [1]. Most injuries occur in the lower limbs, with 21-34% in the ankle and 12-21% in the knee [2]. Nevertheless, there is limited research on dance-related injury epidemiology, especially on the type of injuries in non-Western pre-professional dancers. Studies on prevention specific to dancers are lacking. This study includes the epidemiology of dance-related injuries among ballet, contemporary, and Chinese pre-professional dancers in Hong Kong. It also examines the effects of the 11+ Dance neuromuscular program on the functional performance of the lower limbs of pre-professional dancers.

METHODS: Surveys focusing on dance training habits and injury history were distributed to dance students of a professional dance school in Hong Kong. 24 subjects participated in a 6-week non-randomized controlled trial. The intervention group engaged in the 11+ Dance program 3 times a week (hybrid mode of face-to-face and home-based training) for 6 weeks. The control group performed their usual training dance routine. Pre- and post-tests were conducted to assess the functional performance of all participants, including the single-leg hop for distance, side hop test, modified Balance Error Scoring System, and isometric strength (hip abduction and ankle eversion) tests using a hand-held dynamometer.

RESULTS: 49 pre-professional dancers responded to the survey. 83.7% ($n=41$) had previous dance-related injuries. The most common injured regions were the ankle (31.4%) and the knee (22.9%). The most common injury diagnosis included ankle sprain (37.1%) and plantar fasciitis (31.4%). 25.7% of dancers indicated a pain level of 8 out of 10 would lead to their absence from dance activities. 37.1% of injured dancers indicated a 50% recovery as their return to play threshold. The results also showed the positive effects of 11+ Dance on enhancing lower limb functional performance compared to the control group.

CONCLUSION: Ballet, contemporary, and Chinese pre-professional dancers are prone to lower limb injuries, especially in the ankle region. The 11+ Dance program using the hybrid mode as their warm-up is an effective intervention for improving lower limb functional performance.

EFFECT OF TRANSCUTANEOUS VAGUS NERVE STIMULATION ON HEART RATE RECOVERY AFTER INTENSE EXERCISE

MERATI, G., FORMENTI, D., CAVAGGIONI, L., CARRANTE, F., DE DONATO, S., MANENTE, A., CASTIGLIONI, P.
UNIVERSITY OF INSUBRIA

INTRODUCTION: Heart rate variability (HRV)(1) and recovery (HRR)(2) post-exercise are interesting metrics for understanding autonomic regulation and cardiovascular fitness. Non-invasive tragus stimulation of the vagus nerve (taVNS) has been hypothesized to influence recovery dynamics after an exercise bout by acutely enhancing vagal activity (3). This study aimed to evaluate the effect of tragus stimulation on HRR and HRV, compared to a sham condition, during post-exercise recovery phases.

METHODS: Nine healthy participants (all males; age 23.8 ± 2.0 yrs; weight 75.7 ± 5.7 kg; height 178 ± 5 cm) completed a cycling graded maximal exercise protocol, immediately followed by two conditions: taVNS and sham stimulation (placebo). Heart rate data were recorded using a Faros ECG device (sampling rate: 250 Hz) during the baseline, exercise and recovery phases. Typical HRR short-term indices (HRR30 and T30) and HRV indices, including RMSSD, HF power (indexes of vagal tone), and LF/HF ratio (index of sympathovagal balance), were analysed across different recovery intervals: very short-term (30 s), short-term (2-6 min), mid-term (7-11 min) and long-term (11-16 min). Differences between conditions were assessed using Wilcoxon paired tests and effect size analysis (Cohen's r).

RESULTS: Tragus stimulation exhibited trends of improved vagal recovery only during mid- and long-term recovery phases, as indicated by increased RMSSD and HF power values. While statistical significance was not achieved in all indices, Cohens r suggested medium-to-large effect sizes, favouring vagal dominance during tragus stimulation in the long-term phase. Similarly, sympathovagal balance (LF/HF ratio) displayed a significant shift towards vagal modulation during long-term recovery under taVNS compared to the sham condition ($p < 0.05$, $r > 0.5$). Surprisingly, in the first 30 s recovery HRR30 and T30 worsened under taVNS.

CONCLUSION: Tragus stimulation is a promising non-invasive approach that promotes parasympathetic recovery following exercise, particularly during prolonged recovery phases. It may enhance cardiovascular recovery and autonomic balance, offering potential applications in sports performance and rehabilitation.

OBSERVATION OF WALKING WITH DIFFERENT LEFT AND RIGHT TREADMILL BELT SPEEDS STRONGLY ACTIVATES THE ACTION OBSERVATION NETWORK COMPARED TO NORMAL WALKING WITH TIED-BELT SPEED

KITAMURA, M., HAMADA, T., ISHIKURA, T., KAMIBAYASHI, K.
DOSHISHA UNIVERSITY

INTRODUCTION: Observing others actions activates a brain network known as the action observation network (AON), which includes motor-related brain areas [1]. The AON activity has been reported to be stronger when observing an action that the observer has repeatedly practiced compared to an unexperienced action [2]. However, previous studies have mainly focused on how motor experience affects the AON activity during the observation of voluntary movements (e.g., dancing) and have not examined semi-automatic rhythmic movements such as walking. Therefore, the present study aimed to investigate brain activity induced by observing walking in a split-belt condition (where the left and right treadmill belts move at different speeds), which the observers had not experienced. Initially, walking under the split-belt condition becomes asymmetric, but it gradually approaches more symmetric over several minutes [3]. Using functional magnetic resonance imaging (fMRI), we investigated brain activity, while participants observed both asymmetric and symmetric walking at the initial and late periods of the split-belt condition, respectively.

METHODS: Nineteen healthy adults participated in the study. From the walking video recorded from the actors left side in a tied condition (left and right speed: 1.25 m/s) for 2 minutes and a split-belt condition (left speed: 1.0 m/s, right speed: 1.5 m/s) for 10 minutes, three video clips of the actors lower limb movements were created: 8 seconds during walking in the tied condition, as well as the initial and last 8 seconds (initial and late period, respectively) of split-belt condition. The actors step lengths in the video clips were almost symmetric in the tied condition and late period of the split-belt condition, but were markedly asymmetric in the initial period of the split-belt condition. The participants observed these video clips in a random order to examine brain activity during the observation using fMRI. The differences in brain activity between condi-

tions were analyzed using one-sample t-tests with a voxel-wise threshold of $p < 0.001$ (uncorrected) and a family-wise error rate-corrected extent threshold of $p < 0.05$.

RESULTS: While observing walking video clips, AON areas, including the parietal cortex, cerebellum, and inferior frontal gyrus, were significantly activated, irrespective of the condition. Furthermore, brain regions, including the supramarginal gyrus and inferior frontal gyrus, were strongly activated during the observation of walking in both periods of the split-belt condition compared to the tied condition.

CONCLUSION: Our results suggest that observation of walking under an asymmetric speed condition, which is unfamiliar to the observers, elicits stronger AON activation compared to observation of normal walking in a symmetric speed condition.

BALANCING AT THE LIMITS: AGE DIFFERENCES IN POSTURAL CONTROL STRATEGIES

WARGEL, A., REIMEIR, B., DEBERTIN, D., FEDEROLF, P.

UNIVERSITY OF INNSBRUCK

INTRODUCTION: Older adults experience more frequent falls due to sensory decline, reduced muscle strength, and other causes. While these risk factors are well-documented, less is known about how aging affects movement behavior near the stability limit. In particular, do older adults adjust their postural control strategies differently than young adults when balance becomes precarious? To investigate this, we instructed volunteers to lean forward as far as possible ("test your limits") from an upright standing position while maintaining a straight body posture. We hypothesized that older individuals would exhibit different characteristics in their corrective movements compared to younger individuals.

METHODS: Twenty young (10 males, 26 ± 3 years) and 21 older (11 males, 70 ± 7 years) healthy volunteers performed eight 30-second trials of forward leaning while their postural movements were recorded (Vicon™, 39 markers, 250 Hz). Postural movement characteristics were analyzed using principal component analysis (PCA), with relative movement variance (rVARk) reported for each principal movement. Depending on normality and variance homogeneity, group differences in rVARk were assessed using independent t-test, Welch's t-test, or the Mann-Whitney U test. Effect sizes were reported as Cohen's d ($d = 0.2$ – 0.5 : small, $d = 0.5$ – 0.8 : moderate, $d > 0.8$: large) or rank biserial correlation ($rbc = 0.1$ – 0.3 : small, $rbc = 0.3$ – 0.5 : moderate, $rbc > 0.5$: large).

RESULTS: PCA revealed no significant differences in the first two principal movements, which accounted for 71% of explained variance. However, older adults exhibited greater lateral sway (rVAR3, $p = .005$, $d = -1.79$), while younger adults showed higher contributions of an ankle strategy with arm movements (rVAR4, $p < .001$, $d = 2.22$), a hip strategy with arm movements (rVAR6, $p = .016$, $d = 1.51$), and elbow flexion, lateral trunk flexion, and ankle movement (rVAR8-12, $p < .038$, $d > 1.21$ / $rbc > .63$).

CONCLUSION: Our findings reveal age-related differences in corrective motor responses near the stability boundary. The lack of differences in the first two principal components, which account for most of the movement variance, suggests that fundamental movement strategies remain similar across age groups (Haid et al., 2018). However, younger adults exhibited greater variance in higher components, indicating more adaptable movement strategies. In contrast, older adults showed increased lateral sway, a pattern associated with a higher fall risk (Rogers & Mille, 2003).

THE EFFECT OF COMBINING NEUROMUSCULAR ELECTRICAL STIMULATION WITH TOWEL CURL EXERCISE FOCUSING ON THE ABDUCTOR DIGITI MINIMI MUSCLE ON STANDING BALANCE

NISHINO, A., KIBUSHI, B.

KOBE UNIVERSITY

INTRODUCTION: Foot stabilization for maintaining standing posture has been attributed to intrinsic foot muscles, particularly the abductor hallucis muscle (1). However, our previous study indicated that the towel curl exercise, which activates the abductor digiti minimi (ADM) along with other intrinsic foot muscles, improves balance during single-leg standing (2). Despite this, exercise alone struggles to effectively target ADM, making its role in balance control difficult to evaluate. Therefore, we combined exercise with neuromuscular electrical stimulation (NMES) to selectively activate the ADM and investigate its role in balance control. NMES enhances muscle strength, neural adaptations, and intermuscular coordination (3), with effects further augmented when combined with voluntary exercise (4). This study examined the effects of combining NMES with ADM-focused exercise and hypothesized that it would improve balance and activate extrinsic foot muscles during standing.

METHODS: Twenty-six participants were divided into two groups: NMES combined with towel curl exercise (NMES group) and exercise alone (CON group). They performed single leg standing tasks under eyes-open and eyes-closed conditions before and after intervention. NMES at 20 Hz for 20 minutes was applied to the NMES group before exercise. During the

exercise, they used their little toe side to gather the towel. Balance was assessed using the root mean square (RMS) of CoP displacement in the anteroposterior and mediolateral (ML) directions and rectangular area (RA). Electromyogram of the lower limb was recorded, and the RMS of each muscle were analyzed. They were analyzed by two-way repeated measures ANOVA ($\alpha = 0.05$).

RESULTS: During single leg standing with eyes closed, both groups showed reduced ML-RMS (CON: $p = 0.003$, NMES: $p = 0.003$) and RA (CON: $p = 0.037$, NMES: $p < 0.001$) after the intervention. Additionally, in the NMES group, RMS of the gastrocnemius ($p = 0.033$) and peroneus longus ($p = 0.003$) decreased with eyes open. With eyes closed, RMS of the tibialis anterior ($p = 0.024$) and peroneus longus ($p = 0.004$) decreased in the NMES group.

CONCLUSION: In single leg standing with eyes closed, ML CoP sway decreased in both groups, likely due to ADM activation supporting lateral stability (5). Furthermore, improvements in eyes-closed conditions, where somatosensory input dominates (6), suggest that NMES and exercise enhanced somatosensory function. The NMES group showed reduced extrinsic foot muscles activity, implying ADM activation minimized compensatory extrinsic muscles use (1). These findings indicate that activation of intrinsic muscles enhances stability and reduces reliance on extrinsic muscles. In conclusion, NMES combined with ADM-focused exercise improves standing balance and reduces extrinsic foot muscles activity.

BUILDING UP FOR SHORTCOMING: PARALLEL-FIBERED GRACILIS MUSCLE INHERENTLY HAVING LONG FASCICLES BECOMES "THICKER" RATHER THAN LONGER AFTER ECCENTRIC-ONLY STRENGTH TRAINING

TAKAHASHI, K., KAWAMA, R., OKUDA, Y., WAKAHARA, T.
DOSHISHA UNIVERSITY

INTRODUCTION: Muscle hypertrophy by strength training is accompanied by changes in internal architecture (1,2). It is well known that muscle increases fascicle length ($\propto$ speed/excursion potential) rather than physiological cross-sectional area (PCSA, $\propto$ force potential) by eccentric training (3,4), which likely matters in injury prevention and motor performance (5). However, our understanding is strongly biased toward "pennate" muscles with short fascicles and large PCSA. We still poorly understand architectural changes of "parallel" muscles inherently having long fascicles with small PCSA, because of the difficulty in capturing them in vivo. Overcoming this with an MRI-based approach, we tested our hypothesis that parallel muscle hypertrophy is attributed to an increase in PCSA rather than fascicle length after eccentric-only strength training.

METHODS: Eleven healthy males completed a 10-week strength training (3 sessions/week) for eccentric-only knee flexion. Each session included 3 sets of 10 repetitions at 50% of maximal voluntary contraction over 50–100% of the range of motion. Before and after the training, muscle volume/length/PCSA, fascicle length/angle, and aponeurosis length/width were measured for the gracilis (Gra) having the second-longest fascicles in human leg muscles, using diffusion tensor MRI (6). Also, eccentric knee flexion strength was measured with a dynamometer. The paired t-tests and linear regression analyses were performed.

RESULTS: The Gra had long fascicles (21 cm) attached to a small aponeurosis before the training. After the training, the eccentric knee flexion strength (+61%) and Gra volume (+31%) increased greatly ($p < 0.01$), but the muscle length did not. Notably, the Gra hypertrophy was mainly attributed to the increase in PCSA (+25%, $p < 0.01$) but not fascicle length. This PCSA increase was accompanied by elongation of the aponeurosis length (+11%, $p = 0.03$) but not the width or fascicle angle. Also, the PCSA increase tended to be greater in individuals with longer fascicle lengths relative to muscle lengths ($r = 0.65$, $p = 0.03$).

CONCLUSION: The parallel-fibered Gra became thicker rather than longer through aponeurosis elongation by eccentric training, contrary to the fascicle longitudinal growth of pennate muscle (3,4). Thus, architectural mechanisms underlying muscle hypertrophy and strength gain may differ depending on the inherent architectural type (pennate/parallel); muscles likely make up for their shortcoming (fascicle length/PCSA). Expanding the current understanding beyond pennate muscle, our findings motivate us to rethink muscle architectural/functional plasticity in response to chronic mechanical loading and provide novel insights into the design of training/rehabilitation programs for improving our physical function.

DOES STRETCHING IMPACT RUNNING ECONOMY? A SYSTEMATIC REVIEW AND META-ANALYSIS

ZECHNER, M., WARNEKE, K., KONRAD, A.

UNIVERSITY OF GRAZ

INTRODUCTION: Running Economy (RE), defined as oxygen consumption at a given running pace (1), is influenced by metabolic, cardiovascular, neuromuscular, and biomechanical factors (2). Literature outlines muscle-tendon properties in general and Achilles tendon stiffness in particular as a crucial parameter to increase energy storage and release, potentially lowering muscle activity to improve RE (1). Since stretching is known to decrease tissue stiffness (3), its effects on RE remain controversial. As the effects of stretching on running economy continue to be inconclusive, this meta-analysis aims to provide a comprehensive synthesis of current findings.

METHODS: In adherence with PRISMA 2000 guidelines a systematic search was performed in three databases. Inclusion and exclusion criteria were applied according to the PICOS guidelines. Only controlled acute and chronic studies on young, healthy participants assessing RE (O_2 /energy consumption at VO_{2max} -relative velocities) were included, while those without controls or metabolic outcomes were excluded. Data were meta-analyzed using robust variance estimation with subgroup analyses for stretching type and a meta regression for running velocity. Risk of bias was assessed via PEDro, and certainty of evidence was classified using GRADE. The protocol was registered on OSF (<https://doi.org/10.17605/OSF.IO/MA8D4>).

RESULTS: There was low certainty of evidence derived from 14 studies with a total of 169 participants, indicating that stretching did not significantly moderate RE ($ES=0.007$, $p=0.93$). This result remained consistent across different stretching types (dynamic, static, and proprioceptive neuromuscular facilitation), with no significant effects observed ($p=0.30-0.35$). Due to the limited number of chronic studies, long-term effects were assessed qualitatively with both studies indicating no significance effects (effects ES : -0.320 to 0.02 , $p>0.05$).

CONCLUSION: Stretching is often thought to reduce stiffness and impair RE (4,5), but current evidence does not support this. However, flaws in study designs and small sample sizes, varying test speeds, and unrealistic stretching durations limit conclusions and calls for future, well-designed studies with an urgent need for chronic studies.

IMPACT OF CHRONIC SLEEP RESTRICTION ON STRENGTH ENDURANCE AND TORQUE VARIABILITY DURING SUSTAINED ISOMETRIC CONTRACTIONS

SEYNAEVE, M., MANTINI, D., VANWANSEELE, B., DE BEUKELAAR, T.

KU LEUVEN

INTRODUCTION: Sufficient sleep is essential to achieve peak physical and cognitive performance. While insufficient sleep appears to have no impact on maximal force production, its effects on strength endurance and force control remain inconclusive. Therefore, we will measure these two parameters during sustained isometric contractions following a 4-night sleep restriction protocol. We will hereby focus on the muscles of the ankle, a crucial joint in everyday locomotion.

METHODS: Twenty-two healthy, young male subjects (21.33 ± 1.23 yrs) with a normal sleep pattern underwent two conditions: a sleep restriction condition (SR) and a control condition (CON). All subjects completed both conditions in a randomized order, interspersed by a 1-week wash-out period. In both conditions, subjects' habitual sleep was monitored for 7 nights before the first baseline session in the lab (SR-PRE or CON-PRE). After this first session, subjects in the SR condition were requested to sleep 5 hrs for 4 nights, while subjects in the control condition continued their normal sleep habits. Afterwards, all subjects returned to the lab for a second session (SR-POST or CON-POST). Sleep duration was monitored using wrist actigraphy and a sleep diary. Force control assessments comprised maximal and submaximal dorsiflexion (DF) and plantarflexion (PF) contractions of the ankle on an isokinetic dynamometer. Subjects performed (i) 3 maximal DF and PF contractions, (ii) 6 DF and 6 PF contractions of one minute at 40% of their maximal voluntary contraction (MVC), and (iii) 1 submaximal DF and PF contraction until failure. Force control was assessed by torque variability using both linear (i.e. coefficient of variation) and non-linear methods (i.e. sample entropy and detrended fluctuation analysis). During the contractions, muscle activity of the tibialis anterior and gastrocnemius medialis muscles was measured using electromyography. Additionally, vigilance was assessed using the Psychomotor Vigilance Task (PVT), and subjective workload via NASA-TLX scores. Data were analyzed using a linear mixed model.

RESULTS: After four nights of sleep restriction, time until failure during the submaximal DF contraction decreased significantly (SR-PRE: 242 ± 113 , SR-POST: 206 ± 81 , CON-PRE: 184 ± 105 , CON-POST: 200 ± 97 s, $p<0.05$). In addition, subjects scored significantly higher on the NASA task load index, with a significant difference on the mental load subscale (SR-PRE: 7.23 ± 4.62 , SR-POST: 10.8 ± 6.08 , CON-PRE: 7.64 ± 4.28 , CON-POST: 7.45 ± 4.52 , $p<0.01$). Vigilance was significantly affected as observed by increased reaction times during the PVT task (SR-PRE: 363 ± 34.9 , SR-POST: 408 ± 66.5 , CON-PRE: 379 ± 47.3 , CON-POST: 373 ± 37.5 ms, $p<0.001$). No changes were found for torque variability and muscle activity.

CONCLUSION: Four nights of sleep restriction reduces strength endurance of the dorsiflexor muscles, increases mental task load, and reduces vigilance of participants. Torque variability and muscle activity remained unaltered.

ULTRASOUND STIMULATION ACUTELY DECREASES DEEP MUSCLE STIFFNESS

UMEDA, T., SUGIYAMA, K., HIRASAWA, H., WAKAHARA, T., HOJO, T.
DOSHISHA UNIVERSITY

INTRODUCTION: In sports, muscle injuries frequently occur at both the medial gastrocnemius (MG) and soleus (SOL) [1]. Previous research shows that a higher risk of muscle injury is associated with higher muscle stiffness [2]. To decrease muscle stiffness, massage and superficial thermal stimulation are commonly used for the triceps surae in clinical practice [3]. However, applying these stimulations to SOL is difficult because of its deep location. In the present study, we focused on ultrasound stimulation, which has mechanical vibration and heating effects on the deep tissues, possibly leading to a decrease in the stiffness of deep muscles [4]. However, this possibility has not been directly tested yet. Thus, this study aimed to evaluate the effects of ultrasound stimulation on muscle stiffness of the triceps surae.

METHODS: Sixteen healthy adults (9 males) were recruited for this study. Ultrasound stimulation (1 MHz, 2.0 W/cm²) was applied for 10 minutes to the skin over the MG of one leg in the prone position, while the other leg served as the control. The shear wave velocity (SWV) of MG and SOL, which is an index of muscle stiffness, was assessed before and immediately after the stimulation using the shear wave elastography mode of an ultrasound device. The thickness of MG plus its superficial fat (MGF) was measured using B-mode ultrasonography before the stimulation. Two-way ANOVA (legs x time points) and Pearson's correlation analysis were performed.

RESULTS: The SWV of SOL after the ultrasound stimulation was significantly lower than that before the stimulation ($p = 0.005$) and that of the control leg ($p = 0.018$). In contrast, no significant interaction or main effects were observed for SWV of MG. A significant negative correlation was observed between SWV of SOL before ultrasound stimulation and changes in the SWV after the stimulation ($r = -0.742$, $p = 0.001$). However, such a correlation was not significant in MG. In addition, no significant correlations were found between the thickness of MGF and changes in SWV of MG or SOL.

CONCLUSION: This study showed that applying 1 MHz ultrasound stimulation for 10 minutes decreased the stiffness of SOL, but did not affect the stiffness of MG. It has been shown that applying 1 MHz ultrasound stimulation for 10 minutes increases the temperature of tissues 2.5 cm beneath the skin by 4.0°C [5]. In addition, an increase in tissue temperature decreases the stiffness of the tissue [6]. Thus, the heating effect of ultrasound stimulation may lead to a reduction in muscle stiffness of SOL. Notably, the effect of ultrasound stimulation was more significant in individuals with higher baseline muscle stiffness. These findings suggest that ultrasound stimulation is a promising approach to reducing the stiffness of deep muscles, potentially contributing to injury prevention.

MOVEMENT COORDINATION PATTERN DIFFERENCES BETWEEN LEFT- AND RIGHT-HANDED VOLLEYBALL SERVES

WEN-TING, W., YIN-HUA, C.
NATIONAL TAIWAN SPORT UNIVERSITY

INTRODUCTION: Previous studies have reported lower anticipation accuracy in predicting the spike direction and movement type for left-handed volleyball players (1). Similar tendency was observed in anticipating the tennis serve direction and depth for left-handed serves even they were mirrored from right-handed ones (2). This phenomenon is attributed to lower perceptual familiarity with left-handed movements. However, whether there are movement coordination differences between left- and right-handed players remains unexamined.

METHODS: Three left-handed and three right-handed skilled volleyball players were recruited to perform 3 standing overhead float serves. Two high-speed cameras (240 fps) were used to record their serves, and the best trial from each player was selected for analysis. The trajectories of bilateral shoulders, elbows, wrists, hips, knees, and ankles were digitized using Kwon 3D. The resultant 12 joint angle time-series, along with trunk rotation, were input to Principal Component Analysis (PCA) to examine the movement coordination patterns of each serve.

RESULTS: Compared to right-handed players, left-handed players showed larger dominant ankle angle ($130^\circ > 107^\circ$) and a smaller non-dominant ankle angle ($112^\circ < 128^\circ$) at ball contact. The 13 kinematic time-series were effectively represented by 3 components, explaining approximately 80% of the variance. The first component, which included six to nine kinematic time-series, was primarily contributed by bilateral shoulder and knee angles across all serves, highlighting their key role in this type of serve. For two left-handed and one right-handed player, the dominant hip angle, but not the dominant elbow angle, was included in the first component. This suggested that their arm posture remained relatively stable during preparation phase, while changes in the dominant hip angle characterized their movement coordination patterns. Additionally, the trunk rotation was not included in the first component for the two left-handed players. This was due to their shoulder and hip rotating in a similar manner, whereas other players exhibited greater shoulder rotation compared to hip rotation.

CONCLUSION: The findings of this study suggest that bilateral shoulders and knees movements play an important role in standing overhead float serves. The absence of trunk rotation and dominant elbow angle in the first component for the two left-handed players suggested that their movements provided fewer distinguishable cues compared to right-handed players. This may explain why the movements of left-handed players are more difficult to predict.

VISUAL REACTION TIME CANNOT DETECT EXPERTISE IN SOCCER GOALKEEPERS VERSUS CONTROLS

GRAMAGE MEDINA, K., SCHWARTZ, C., DELVAUX, F., CROISIER, J.L., KAUX, J.F.

UNIVERSITY OF LIÈGE

INTRODUCTION: Visual reaction time (VRT) has been shown to be an expertise factor in some sports, compared to controls without prior sports training.[1]

At the same time, it seems to play a relevant role in injury prevention, and return-to-play contexts.[2]

While VRT evaluation is commonly assessed with computer-based tools, there is a need to develop new methods that better recreate the sport reality.[2]

We investigated the reliability of a VRT test in athletes with high reaction time demands (soccer goalkeepers, GK) and a physically active population; and compared the differences between them.

METHODS: A group of 21 male semi-professional GKs and 19 male students (STUD) practicing sports without a strong VRT component, participated in the study. A subset of 17 GKs and another group of 18 STUD, participated in two different sessions, within a two-week period, for the reliability analysis.

Field VRT Test: Two pairs of two FitLight sensors were placed 160cm apart at 90 & 170 cm height.

Participants had to stand in the middle and "deactivate" a series of 12 visual stimuli (3 per sensor) as fast as possible by passing the side-matching hand <30cm in front of the sensor.

An additional sensor was placed in front of the participant to pace the two-second pauses between stimuli. The mean of all responses was used for analysis.

Computer-based tests: Simple Response Time Task (SRT); Four Choice Visuospatial Response Task (4Cho); and Go/No-Go Response Inhibition Test (GoNoGo). Mean response time and number of errors were used for analysis.

We used Two-Way Mixed ICC for test-retest reliability; Wilcoxon and T-test for group comparisons (for $p < .05$ and $> .05$ Shapiro Tested normality, respectively). Significance was set at $p < .05$.

RESULTS: The reliability of the proposed VRT test was "moderate" (ICC=.74).

GKs were not significantly faster than STUD (657 ± 96 ms vs 680 ± 69 ms, $p = .400$).

GKs were also non-significantly faster on SRT (317 ± 37 ms vs 329 ± 42 ms, $p = .531$), 4Cho (455 ± 98 ms vs 460 ± 122 ms, $p = .925$), GoNoGo (438 ± 42 ms vs 440 ± 3 ms, $p = .896$); and had fewer errors on GoNoGo (9.6 ± 7 vs 11.6 ± 6 , $p = .273$).

CONCLUSION: Non-significant group differences suggest that VRT is not an expertise factor for GKs.

Practitioners interested in performance assessment or talent identification are advised to prioritize the evaluation of other parameters.

A multifactor use of VRT for these purposes remains to be explored.

In this population, the field test appears to be a reliable measure of VRT. Further studies in injury prevention and return to sport could explore the use of this test to incorporate VRT into common field practices (preseason testing, rehabilitation protocols, etc.).

ACHILLES TENDON STIFFNESS IN THE PREFERRED AND NON-PREFERRED TAKEOFF LEG OF UNIVERSITY BASKETBALL ATHLETES: RELATION WITH PERFORMANCE, RANGE OF MOTION, AND INJURY

SOONTJENS, O., BUSNER, J., FORTIN, M.

CONCORDIA UNIVERSITY

INTRODUCTION: Achilles tendon (AT) stiffness is a key factor in athletic performance, particularly in high-impact sports such as basketball. Athletes generally exhibit higher AT stiffness than the general population, which can enhance force transmission and movement efficiency but may also increase injury risk if not balanced with adequate strength and control. Shear-wave elastography (SWE) has been used to assess AT stiffness, yet the relationship between AT stiffness, performance, range of motion (ROM), and injury in university athletes remains unclear. This study aimed to investigate these relationships in male and female university varsity basketball players.

METHODS: Thirty-two university level varsity basketball athletes (12 females, 20 males) participated in this cross-sectional study. SWE was used to assess AT stiffness in both the preferred takeoff leg (PTL) and non-preferred takeoff leg (NPTL). Functional assessments included a single-leg vertical jump, heel raise test, and ankle dorsiflexion ROM. Participants also completed questionnaires on demographics, injury history, and Victorian Institute of Sport Assessment-Achilles (VISA-A) scores. Testing was conducted in a standardized manner pre-training. Paired t-tests compared AT stiffness between PTL and NPTL, while independent t-tests examined differences in AT stiffness and asymmetry between athletes with and without a recent history of lower body injury. Pearson correlations were used to assess relationships between AT stiffness, performance, and ROM.

RESULTS: Mean AT stiffness was 455.4 ± 72.4 kPa in male athletes and 411.7 ± 48.5 kPa in female athletes ($p = 0.185$). No significant differences in AT stiffness were observed between PTL and NPTL in either males (448.2 ± 83.6 kPa vs. 462.6 ± 84.6 kPa) or females (407.9 ± 40.0 kPa vs. 415.5 ± 77.3 kPa). Male athletes who had sustained a lower body injury in the previous 12 months exhibited significantly lower AT stiffness than non-injured males ($p = 0.040$), while female athletes with a recent lower body injury displayed lower between-limb stiffness asymmetry compared to their healthy counterparts ($p = 0.027$). No significant correlations were found between AT stiffness and performance measures or ROM in either sex.

CONCLUSION: This study found no significant differences in AT stiffness between the PTL and NPTL or between male and female basketball athletes. However, male athletes with a recent history of injury demonstrated significantly lower AT stiffness, while female athletes with a recent injury exhibited reduced side-to-side stiffness asymmetry. Our findings suggest that injury history may influence AT stiffness, however, AT stiffness was not associated with functional performance or ROM in our sample of university level basketball players. Further research is warranted to explore the long-term implications of AT stiffness variations on injury risk and athletic performance.

EFFECT OF VARIOUS FOOTWEAR ON THE VISCOELASTIC PROPERTIES IN THE LOWER LEG SYSTEM THROUGH CHANGE IN MUSCLE FORCE OUTPUT

ODA, T., ISHIZUKA, S., ISHIHARA, S.

JUNTENDO UNIVERSITY

INTRODUCTION: During the contact phase of running, the visco-elastic properties of the muscle-tendon complex (MTC) play a crucial role in functional muscle-tendon interaction and the recycling of elastic energy [1]. In recent years, the use of thick-soled shoes in track and field events has led to improvements in running efficiency and competition records, but the effects of these shoes on the mechanical properties of the lower leg system, including MTC, are still unclear in many cases. In addition, the effects of the muscle force exerted by changes in running speed are also unknown. The purpose of this study was to clarify these changes experimentally.

METHODS: Eight male and female subjects participated in the study. The viscoelastic properties of the MTC were measured using the vibration method under multiple load settings (similar to Fukushima et al. [2]). The subject was placed in a seated position (ankle and knee joints 90deg), with the ball of the foot on a force plate edge. A weight was placed on the knee, and with the posture maintained by isometric contraction (the muscle force exerted was varied), the damped oscillation of the triceps surae muscle was induced. The waveforms were regressed by the least-squares method on the following equation to calculate the unknowns, γ , ω , a , b and M .

$$F(t) = e^{-\gamma t} (a \cos \omega t + b \sin \omega t) + Mg$$

where F is force, t is time, e is Napier number, γ is damping factor, a is amplitude, ω is angular frequency, M is effective mass, and g is gravitational acceleration. Then, after consideration of the moment arm of muscle, the elastic and viscous coefficients (k and b) of MTC were calculated.

$$k = M(\omega^2 + \gamma^2)$$

$$b = 2M\gamma$$

These measurements were taken in three conditions: barefoot (S0), conventional running shoes (S1), and thick-soled shoes (S2).

RESULTS: Elastic coefficients: k increased significantly with force increment in all shoes. k of S1 was greater than that of S0 in all force application conditions. S2 showed almost the same value as S1 up to 300N, but after that k decreased, and at 600N it was smaller than S0. Viscosity coefficient: b increased significantly with force application up to 300N for all shoes. The change trends for S0 and S1 were similar, but S2 showed much lower b than the other two conditions after 300N. In addition, the individual differences due to different shoes on both coefficients were substantial.

CONCLUSION: It was suggested that the effect of the shoes on the viscoelasticity of the lower leg system was related to the exerted muscle force, or, in other words, the strength of the kick during the contact phase of running. The effect of these shoes could be related to the intrinsic viscoelasticity of MTC in subjects.

VELOCITY-DEPENDENT SOLEUS COMPENSATION FOR GASTROCNEMIUS FUNCTION IN KNEE-FLEXED PLANTARFLEXION: EVIDENCE FROM NEUROMECHANICAL AND MORPHOLOGICAL SYNCHRONIZATION

YE, J., KOVÁCS, B., HORTOBÁGYI, T., GU, Y.

HUNGARIAN UNIVERSITY OF SPORTS SCIENCE: MAGYAR TESTNEVELESI ÉS SPORTTUDOMÁNYI EG

INTRODUCTION: When the knee is flexed, during plantarflexion the gastrocnemius muscles contribution to ankle torque is reduced. Literature reports are inconsistent whether soleus (SOL) compensates for this reduced gastrocnemius function. Therefore, the aim of this study was to investigate SOL fascicle behavior during plantarflexion with the knee flexed vs. knee extended. We hypothesize that the compensation of the soleus muscle is evident when the knee joint is flexed. However, we assume that at high angular velocities, the compensation of the soleus muscle is not significantly affected by changes in knee joint angle.

METHODS: Healthy physically active Chinese male university students ($n=17$) performed knee-flexed (90°) and knee-extended (180°) plantarflexions at $60^\circ\cdot s^{-1}$ and $120^\circ\cdot s^{-1}$ on an isokinetic dynamometer. During the measurements, electromyographic activity of the medial gastrocnemius (MG) and SOL were recorded with bipolar surface electrodes, and the fascicle behavior of these muscles were obtained by ultrasonography.

RESULTS: Plantarflexion peak torque performed with the knee flexed vs. knee extended was lower by 44% at $60^\circ\cdot s^{-1}$ ($p < 0.001$) and 18% at $120^\circ\cdot s^{-1}$ ($p = 0.0001$). SOL EMG activity was higher in knee-flexed plantarflexion by 44.9% at $60^\circ\cdot s^{-1}$ and by 21.6% at $120^\circ\cdot s^{-1}$. As expected, MG activity was lower in knee-flexed plantarflexion at both velocities ($22.9 \pm 9.8\%$ at $60^\circ\cdot s^{-1}$ vs $67.6 \pm 12.3\%$ at $120^\circ\cdot s^{-1}$, $p = 0.005$). MG fascicles operated at shorter fascicle length ($14.3 \pm 0.6\%$ at $60^\circ\cdot s^{-1}$ vs $46.7 \pm 0.6\%$ at $120^\circ\cdot s^{-1}$, $p > 0.005$) in knee-flexed vs. knee-extended plantarflexion. Knee joint position did not affect SOL fascicle shortening.

CONCLUSION: Consistent with previous literature, our findings indicate that a flexed knee joint position alters medial gastrocnemius (MG) fascicle behavior and activation patterns. Although the SOL exhibited higher electrical activity at lower contraction velocities in the knee-flexed position, this did not correlate with distinct fascicle behavior, and the differences were minimal at higher contraction velocities. Consequently, we cannot directly confirm that SOL compensates for reduced MG function during knee-flexed plantarflexion. Additionally, while EMG activity demonstrated statistical significance, muscle fiber performance did not, suggesting that changes in knee joint position increase muscle activation without providing definitive evidence of SOL compensation.

MUSCLE-TENDON MORPHOLOGICAL PROPERTIES IN RUGBY PLAYERS AND MIDDLE-DISTANCE RUNNERS

LA GRECA, S., VALENTE, M., MARINELLI, S., BARILE, A., TIHANYI, J., DI GIMINIANI, R.

UNIVERSITY OF LAQUILA

INTRODUCTION: Human knee joint extensor muscle-tendon and ankle joint plantar flexor muscle-tendon units play an important role in producing propulsive force in running and jumping. Muscle and tendon interactions and their biomechanical behaviours depend on their morphological characteristics. Recent research shows that tendon thickness does not correlate with muscle mass, suggesting that resistance training does not increase tendon thickness.

METHODS: This study was conducted to investigate the morphological characteristics of knee extensor muscle-tendon and ankle joint plantar flexor muscle-tendon units in rugby players and middle-distance runners. Furthermore, the maximum voluntary isometric contractions in different tasks were determined. Nineteen athletes of national level (9 rugby players; age: 25.67 ± 4.09 years; stature: 178.11 ± 6.21 cm; body mass: 89.78 ± 16.64 kg; BMI: 28.21 ± 4.39 kg/m²; and 10 middle distance runners; age: 24.80 ± 5.69 years; stature: 178.40 ± 4.30 cm; body mass: 6.90 ± 4.82 kg; BMI: 20.68 ± 0.91 kg/m²) participated in this investigation. The magnetic resonance imaging scan (MRI) was utilized to measure the cross-sectional areas of the Achilles tendon (AT), patellar tendon (PT), plantar flexors (soleus, lateral and medial gastrocnemius) and knee extensors (vastus medialis, vastus lateralis, vastus intermedius, and rectus femoris) on the dominant leg. Maximal isometric voluntary contractions (MVICs) were executed while pushing against a barbell locked in a Smith machine. Before starting the MVICs, the participants assumed a half-squat position and a calf rise. For each task, they conducted three trials, and the highest value was used for analysis.

RESULTS: The CSA of AT and PT was significantly higher in rugby players compared to middle-distance runners ($p=0.011$). The rugby players demonstrated a higher CSA in their knee extensors muscles compared to the middle-distance runners ($p=0.001$), but not in their planter flexors ($p=0.123$). Rugby athletes demonstrated weak correlations between CSA PT and CSA knee extensors ($r=-0.16$, $p=0.468$) and between CSA AT and plantar flexors ($r=0.29$, $p>0.05$). Conversely, middle-distance runners showed a strong correlation between CSA PT and CSA knee extensors ($r=0.51$, $p=0.132$) and between CSA AT and CSA plantar flexors ($r=0.63$, $p=0.052$).

CONCLUSION: The findings of the present study confirm that the morphological characteristics of PT and AT in rugby players do not correlate with their respective muscle sizes. One possible explanation could pertain to the diverse tissue responses to an exercise stimulus. Given the significant variation in tissue responses to the same stimulus, it is plausible that the optimal loading for muscle tissue may be suboptimal for the tendon tissue in rugby players. In this regard, a substantial training volume over a prolonged period may alter the ratio of muscle/tendon cross-sectional area and potentially increase the likelihood of tendinopathy.

MUSCLE GEARING IS INDEPENDENTLY AFFECTED BY THE FORCE, VELOCITY, AND ACTIVATION OF A MUSCLE.

WAKELING, J., ALMONACID, J.A., PINTO, M.D., BLAZEIVICH, A.J.

SIMON FRASER UNIVERSITY

INTRODUCTION: The velocity that muscle fibres shorten affect their potential to generate force and power (1). Fibres in pennate muscle typically shorten at slower velocity than the whole muscle belly, in a process known as belly gearing (2). Previous experimental studies showed that gearing depends on the muscle force (3), and structural models have suggested that gearing is influenced by the properties of connective tissue associated with the muscle (4). However, it has not been clear how the activation state, velocity of the muscle belly itself or properties of the muscle tissue affect this gearing phenomenon. This study aimed to establish a mechanistic link between the muscle tissue properties and the contractile conditions with the belly gearing.

METHODS: Muscle belly gearing was modelled for a block of muscle tissue (18.6 x 6.58 x 6.95 mm with an initial pennation angle of 26.1°) that was represented as a fibre-reinforced composite biomaterial, in a fully-dynamic implementation that was solved using the principles of continuum mechanics. The block was stretched (110%) from its initial length, activated to a set level (0-100%), and allowed to shorten at a prescribed isovelocity rate (0-120 mm s⁻¹) while it was still active. At the moment that the block passed back through its initial length, the mean fibre velocity was determined and related to the prescribed velocity of the block to determine the belly gearing.

RESULTS: When the muscle contraction was simulated, the fibres shortened and also rotated to increase in pennation as the muscle block shortened. The rate of fibre rotation increased with both muscle shortening velocity and increasing activation. The fibre shortening velocity increased with muscle velocity, but this velocity was lessened at higher activations. The muscle belly gearing decreased with muscle force, increased with muscle velocity, and increased with activation.

CONCLUSION: The simulations predicted similar gearing effects that have been reported for maximally activated muscles in animal studies but also now predict the more nuanced effects that occur at submaximal activations as is the case during human movement. All the general features of muscle belly gearing emerged from the physics of the contractile elements and the muscle tissue properties alone, and do not need effects from other tissues to occur (i.e. aponeurosis, ECM or intramuscular fat). Further, this simulation framework shows how force, velocity, and activation independently affect muscle gear. The exact state of the tissue when the measures were probed depends on the energy balance at each condition, which in turn depends on the complex interaction between tissue stiffness, compressibility, and mass as well as the activation state and fibre contractile properties.

TOWARD SELECTIVE DECREASE IN MUSCLE STIFFNESS: CAN STATIC STRETCHING COMBINING THREE-DIMENSIONAL HIP JOINT ROTATIONS DECREASE THE STIFFNESS OF TARGET HAMSTRING?

RINA, S., TAKAHASHI, K., KAWAMA, R., FUJII, N., TOZAWA, H., TANAKA, M., WAKAHARA, T.

DOSHISHA UNIVERSITY

INTRODUCTION: High passive muscle stiffness is related to a high risk of hamstring strain injuries [1]. To reduce hamstring stiffness, static stretching is widely used in the sports field. As the susceptibility of individual hamstring muscles to strain injury varies depending on the types of sports [2], selective reduction in stiffness of the target muscle by stretching may be a key to prevention of the injury. Previous studies have mainly tested the effects of static stretching on hamstring stiffness within the sagittal plane, such as hip flexion or knee extension [3,4]. However, the hip joint (a ball-and-socket joint) rotates in three dimensions, and the biarticular hamstring muscles run three-dimensionally across the hip joint. Thus, static stretching with the hip joint position outside the sagittal plane may influence its effects on hamstring stiffness. This study aimed to investigate whether static stretching combining three-dimensional hip joint rotations decreases the stiffness of target hamstring.

METHODS: Fourteen young males participated in three sessions (on separate days) of static stretching (five sets of 90 s), in which the hip joint was passively flexed until their pain onset with 0° knee flexion in different hip abduction and rotation positions: 1) 0° abduction and 0° rotation (N-N), 2) 20° abduction and 30° internal rotation (Abd-In), and 3) 20° abduction and 30° external rotation (Abd-Ex). Before and after the stretching, the maximal knee extension range of motion (ROM), and the shear modulus (an index of muscle stiffness) of right biceps femoris long head (BFlh), semitendinosus (ST), and semimembranosus (SM) were measured with shear wave elastography, and their changes were examined with the Wilcoxon signed-rank test. The Friedman test was used to compare change values in each variable across stretching positions.

RESULTS: The shear modulus of SM was decreased after stretching in the Abd-Ex position (-11.6%, $p < 0.01$), but not in the N-N or Abd-In positions. No significant changes were observed in the shear moduli of BFlh or ST in any positions. The ROM increased after stretching in all positions (all $p < 0.001$); however, no significant differences were found in the extent of ROM increase across positions.

CONCLUSION: The stiffness of SM was selectively decreased after stretching in the Abd-Ex position. As SM is susceptible to strain injury in dancers [2], this finding may help prevent it. The result showed that stretching in the N-N position did not always reduce hamstring stiffness, even though it is widely used in sports and clinical settings. Our findings highlight the necessity of combining three-dimensional hip joint rotations during static stretching to reduce the stiffness of target muscle and contribute to developing preventive programs for hamstring strain injuries.

ULTRASONOGRAPHIC ANALYSIS OF THREE SUB-TENDONS WITHIN THE HUMAN ACHILLES TENDON

ISHIKAWA, M., NOBUE, A.

OSAKA UNIVERSITY OF HEALTH AND SPORT SCIENCES

INTRODUCTION: The Achilles tendon (AT) consists of three distinct sub-tendons originating from the medial head of gastrocnemius (MG-AT), lateral head of gastrocnemius (LG-AT), and soleus muscle (SOL-AT). Previous cadaveric studies have classified the twisted structure of these three sub-tendons into three distinct patterns based on their calcaneal insertion sites (Edama et al. 2015; Pękala et al. 2017). Variations in the degree of this AT twisting could affect stress distribution patterns within the tendon. Thus, it is important to monitor the AT twisting in vivo from an injury prevention perspective in sports. AT injuries most commonly occur 2-6 cm proximal to the calcaneal insertion. Therefore, the purpose of the present study was to examine the AT twisting in vivo using ultrasonography and to demonstrate variations in the degree of the AT twisting in vivo and the spatial relationships among sub-tendons at 4 cm proximal to the AT insertion.

METHODS: Twenty healthy adults (age: 27.0 ± 6.6 years, height: 172.6 ± 7.6 cm, body mass: 61.8 ± 13.3 kg) participated in this study. Using high-resolution ultrasonography (ARIETTA 850, Fujifilm Healthcare, Japan), the cross-sectional images of the Achilles tendon from both legs were obtained in a standing position from the gastrocnemius muscle-tendon junction to the AT insertion on the calcaneus. The images were digitally enhanced for optimal visualization. The classification and the spatial relationships among the three sub-tendons (MG-AT, LG-AT and SOL-AT) were examined at 4 cm proximal to the AT insertion.

RESULTS: Analysis of the spatial relationships among the three sub-tendons classified three distinct anatomical arrangements through ultrasonographic imaging. The first type, observed in 6 limbs (15.0%), showed minimal twisting, where LG-AT and MG-AT positioned superficially and SOL-AT was located deep. The second type, found in 30 limbs (75.0%), demonstrated moderate twisting, where MG-AT was positioned superficially while LG-AT and SOL-AT deep. The third type, seen in 4 limbs (10.0%), exhibited pronounced twisting where MG-AT and SOL-AT was positioned superficially, and LG-AT deep. Analysis of bilateral symmetry using weighted Kappa coefficient with quadratic weighting revealed no agreement above chance level ($\kappa = -0.010$) between the left and right AT twist patterns.

CONCLUSION: Ultrasonographic analyses confirmed three distinct spatial arrangements of the human AT sub-tendons, with the moderate twisting pattern being most prevalent. Notably, more than half of the participants showed asymmetrical twisting patterns between legs. These asymmetrical patterns may have influenced the differences in the stiffness and length of the AT in the left and right legs (Bohm et al. 2015).

REGION-SPECIFIC PASSIVE STRETCH RESPONSE OF THE BICEPS FEMORIS LONG HEAD USING SHEAR-WAVE ELASTOGRAPHY: AN IN VIVO STUDY

NARA, G., NAKAO, G., ADACHI, R., ISHIYAMA, K., KOZAWA, K., SEKIGUCHI, K., TANIGUCHI, K.

GRADUATE SCHOOL OF HEALTH SCIENCES

INTRODUCTION: Understanding the passive mechanical properties of the biceps femoris long head (BFLh) will contribute to the development of accurate musculoskeletal models that can provide valuable insights into the mechanisms underlying strain injuries. The BFLh has intramuscular variability in fascicle and aponeurosis morphology and architecture (1), suggesting regional heterogeneity in passive mechanical properties during muscle elongation. However, whether passive stretch responses, such as the slack angle, differ regionally within the BFLh, in vivo, remains unclear. Therefore, this study investigated the region-specific stretch response within the BFLh during passive knee extension using ultrasound shear wave elastography.

METHODS: Nine healthy males (mean, 21.7 ± 2.3 years) participated. The shear modulus was measured using shear wave elastography at knee flexion angles ranging from 90° to 0° , in 5° decrements. Measurements were taken at three regions of the right BFLh: proximal (25%), middle (50%), and distal (75%) of the distance between the musculotendinous junctions (0% proximal, 100% distal). A piecewise exponential model was applied to the shear modulus-knee angle data to calculate the passive stretch response characteristics, including the slack angle, slack shear modulus, and the slope of the increase in shear modulus (2). The fit quality of the model was evaluated using the coefficient of determination (R^2), and data with $R^2 \geq 0.5$ were included in the statistical analysis. For passive stretch response characteristics, a one-way analysis of variance (sites: proximal, middle, and distal), followed by Tukey's honestly significant difference post hoc test ($p < 0.05$), was performed.

RESULTS: All data had an R^2 value ≥ 0.5 (distal: 0.93 ± 0.05 , middle: 0.91 ± 0.03 , and proximal: 0.86 ± 0.11). A significant main effect of the site ($p < 0.05$) was observed for slack angle (distal: $68.02 \pm 15.58^\circ$, middle: $59.80 \pm 12.18^\circ$, and proximal: $50.96 \pm 10.83^\circ$), with post hoc analysis revealing a significantly larger slack angle at the distal region compared to the middle region ($p < 0.05$). There were no significant main effects of the site for slack shear modulus (distal: 2.91 ± 0.39 kPa, middle: 2.96 ± 0.31 kPa, and proximal: 2.97 ± 0.17 kPa) or the slope of the increase in shear modulus (distal: 0.0110 ± 0.0045 , middle: 0.0081 ± 0.0021 , and proximal: 0.0087 ± 0.0061).

CONCLUSION: This study investigated regional variability in the passive stretch response within the BFLh, as quantified by the shear modulus–knee angle relationship. The distal region had a significantly larger slack angle than the proximal regions, indicating earlier development of passive tension during knee extension. These findings provide novel insights into the regional passive mechanical properties of the BFLh with implications for developing musculoskeletal models and understanding mechanisms underlying strain injuries.

VALIDATING THE MYOTONPRO: COMPARING DYNAMIC AND TENSILE STIFFNESS OF THE ACHILLES TENDON

WAUGH, C., FINNAMORE, E., SQUIER, K., SCOTT, A.

UNIVERSITY OF BRITISH COLUMBIA

INTRODUCTION: Stiffness is an important property of tendon and often investigated due to its functional relevance to injury and athletic performance. It is traditionally measured as the lengthening that results from tendon loading ('tensile stiffness') and until recently was limited to being obtained in a research setting. The MyotonPRO, a handheld device which imparts a small perturbation to the tissue of interest and measures the responding oscillations, now provides a fast and simple alternative ('dynamic stiffness'). As a result, stiffness obtained from the MyotonPRO is increasingly used as a surrogate for tensile stiffness, however it remains unclear if stiffness obtained using this device is comparable to tensile stiffness. We sought to evaluate the dynamic stiffness measured by the MyotonPRO in relation to tensile stiffness obtained through established methods.

METHODS: Tensile stiffness of the Achilles tendon was obtained from 18 healthy individuals using a combination of 3D motion analysis, passive ankle rotations performed on a dynamometer, and ultrasonography. Dynamic (transverse) stiffness was obtained from a standardized location superficial to the Achilles tendon mid-portion using tissue oscillations produced and recorded by the MyotonPRO. Both methods calculated stiffness estimates from a similar joint angle, under resting conditions (passive tension only). The coefficient of variation for obtaining tensile and dynamic stiffness was 12.6% and 1.47%, respectively.

RESULTS: Regression analysis demonstrated a low correlation (R^2 of 0.17) between stiffness values obtained using the two methods. Stiffness was consistently greater using the tensile method than MyotonPRO - mean tensile stiffness was 114 ± 63 N/mm and mean dynamic stiffness was 1.04 ± 0.27 N/mm. Bland-Altman analysis revealed limits of agreement ranging from -11.0 to 236.7 N/mm, indicating individual measurements differed substantially. A highly linear proportional bias ($R^2 = 1$) was also found simply because tensile stiffness values dominate the scale of measurement, rather than the difference between methods increasing systematically with measurement magnitude.

CONCLUSION: We found poor agreement between stiffness values obtained from the MyotonPRO and with tensile measurement techniques, indicating that the two methods are not interchangeable. The significant discrepancy in the magnitude of these values likely reflects a fundamental difference in how tendon stiffness is measured (rather than a simple scaling issue) and indicates that different aspects of tendon behavior are captured by each approach. Care must be taken to avoid confusing the reader and when referring to stiffness as an outcome measure using this non-tensile method.

PELVIC BELT-EQUIPPED GARMENT SUPPRESSES FATIGUE-INDUCED REDUCTIONS IN FORCE PRODUCTION DURING COUNTERMOVEMENT JUMP AND LANDING CUTTING

ENDO, Y., KAWAMURA, T., KIBUSHI, B.

KOBE UNIVERSITY

INTRODUCTION: Jump distance and rapid directional changes are crucial for athletic performance; however, fatigue reduces force production during these movements. For instance, fatigue decreases ankle power during countermovement jump (CMJ) push-off and knee extension force (1,2). Maintaining performance under fatigue during jumping and cutting maneuvers can reduce injury risk and improve athletic performance. Although pelvic belts are widely used for lower back support and have been shown to enhance hip energy absorption during landing (3), their effect on jumping and cutting

under fatigue is unclear. This study investigated whether a pelvic belt-equipped garment (PBG) can suppress fatigue-related declines in jumping and cutting performance.

METHODS: Ten male athletes (age: 20 ± 1 years; height: 1.70 ± 0.03 m; weight: 62 ± 8 kg), who participated in sports at least three times per week, performed tasks under two conditions, one with PBG and the other without PBG (CON). Participants performed a CMJ and a landing cutting (LC) maneuver before and after a fatigue protocol, which consisted of the Yo-Yo intermittent endurance test Level 1 and box jumps. Motion data and ground reaction forces were recorded at 100 Hz and 1000 Hz, respectively. We calculated CMJ jump height, concentric phase impulse, and LC peak lateral propulsive force. A two-way ANOVA was used to assess the effects of garment condition (CON vs. PBG) and fatigue (PRE vs. POST), and paired t-tests with Holm correction were performed for post hoc comparisons.

RESULTS: In the CON condition, the CMJ jump height significantly decreased (CON-PRE: 0.38 ± 0.08 m, CON-POST: 0.32 ± 0.07 m, $p < 0.01$), and the impulse during the concentric phase of the CMJ significantly decreased (CON-PRE: 2.83 ± 0.26 N/Body weight, CON-POST: 2.65 ± 0.25 N/Body weight, $p < 0.01$). Similarly, the LC peak lateral propulsive force significantly decreased (CON-PRE: 0.65 ± 0.18 N/Body weight, CON-POST: 0.56 ± 0.16 N/Body weight, $p = 0.04$). In the PBG condition, CMJ jump height, concentric impulse, and LC peak lateral propulsive force did not significantly decrease after fatigue.

CONCLUSION: In the CON condition, fatigue significantly reduced CMJ jump height, concentric impulse, and LC peak lateral propulsive force. However, these reductions were not significant in the PBG condition. These results suggest that the PBG may provide lumbar stabilization during repeated jumping and cutting maneuvers, thereby suppressing fatigue induced declines in force production. Consequently, the PBG could help maintain propulsion force production for CMJ and LC under fatigue.

THE DIFFERENCE IN LANDING SOUND AND MOVEMENT DURING SPIKE JUMP BETWEEN EXPERIENCED AND INEXPERIENCED VOLLEYBALL PLAYERS

KUMAMOTO, S., TASHIRO, T., ARIMA, S., ONOUE, S., TERAOKA, Y., KOYANAGI, M., HARA, T., MAEDA, N.
HIROSHIMA UNIVERSITY

INTRODUCTION: Volleyball players frequently sustain injuries during jump landings. Experienced volleyball players typically achieve higher jump height than inexperienced players. However, no significant differences are observed in vertical ground reaction force (vGRF) in each group. A previous study reported that experienced players mitigate landing impact by increasing the range of motion (ROM) in ankle joint during landing [1]. Furthermore, vGRF is positively correlated with landing sound. The quieter landing is associated with greater lower limb joint movement [2]. This study aimed to compare landing sound during spike jump landing in real-field scenario, and investigate differences in landing mechanics between experienced and inexperienced volleyball players.

METHODS: Twenty male university students (experienced, $n=10$; inexperienced, $n=10$) participated in this study. After measuring their maximum spike jump height, participants performed spike jump aiming to reach that height and landed on both feet. Landing sound, as well as knee and ankle joint angles were analyzed. Landing sound was measured using the Sonic Tools SVM app (Rikki systems, Japan), and joint angles were recorded from a lateral view using a smartphone. Initial contact and maximum flexion angles were calculated using Tracker 6.2.0 software (Open Source Physics, US), and ROM was determined as the angular displacement between these points. For statistical analysis, a paired t-test was conducted to compare the jump heights, landing sounds and joint angles between the two groups. In addition, correlations between landing sound and joint angles were analyzed using Pearson's correlation ($p < 0.05$).

RESULTS: Experienced volleyball players had significantly higher jump heights than inexperienced players (55.1 ± 5.6 cm vs. 46.1 ± 7.2 cm, $p = 0.009$), but no significant differences were observed in landing sound and joint angles. In experienced players, landing sound exhibited stronger negative correlations with joint movement, particularly with maximum ankle dorsiflexion ($r = -0.70$, $p = 0.02$), maximum knee flexion ($r = -0.61$, $p = 0.06$), and knee joint ROM ($r = -0.59$, $p = 0.07$).

CONCLUSION: While experienced volleyball players demonstrated greater jump heights, no significant differences in landing sound were observed in each group. Although joint angles showed no significant differences, stronger negative correlations observed in experienced players suggest that volleyball experience may influence muscle activity in the ankle and knee joints during landing. These findings suggest that volleyball experience may enhance the ability of joints to absorb landing impact more effectively. Additionally, coaching strategies that emphasize quieter landings may encourage greater joint movement, potentially reducing the risk of injury.

THE EFFECT OF REBOUND-JUMP LANDINGS WITH TRUNK ROTATION ON KNEE JOINT ANGLE IN FEMALE BASKETBALL PLAYERS

UEDA, M., TASHIRO, T., ARIMA, S., ISHIHARA, H., YOSHIARA, R., HARA, T., MAEDA, N.

HIROSHIMA UNIVERSITY

INTRODUCTION: The anterior cruciate ligament (ACL) injuries frequently occur in a slightly flexed and valgus knee position, during jump landings and directional changes. Basketball is characterized by jump landings with trunk rotations (rebound-jump landing) depending on the competitive scene, and especially women athletes have a higher incidence of ACL injuries. Previous study has examined the effect of rebound-jump landing with trunk rotation toward the takeoff leg (TL) and reported that the non-takeoff leg (NTL) exhibited smaller flexion and larger valgus angles of knee joint [1]. However, the direction of rotation was limited. Therefore, this study aimed to investigate the differences in knee joint angles during rebound-jump landings under multiple rotational conditions.

METHODS: In total 11 female basketball players with more than 3 years of experience were participated in this study. The 3-dimensional motion analysis was used to calculate the knee joint angles during rebound-jump landings in 3 conditions: (1) front-facing jump (Front), (2) with trunk rotation in 90° toward the TL (TL-side), and (3) with trunk rotation in 90° toward the NTL (NTL-side). The initial contact (IC) was defined as the point when the vertical ground reaction force exceeded 4 N. Measurements were taken at 5 points every 10 ms from IC up to 40 ms. In each condition, a paired t-test or Wilcoxon signed-rank test was used to compare knee angles between the TL and NTL ($p < 0.05$).

RESULTS: In the TL-side condition, the knee flexion angles were significantly smaller in the NTL compared to the TL at all time points ($p < 0.01$). In the NTL-side condition, the TL exhibited significantly larger knee valgus angles than the NTL at the IC, 10ms, and 20ms time points ($p < 0.05$). No significant differences in knee flexion or valgus angles were observed between the TL and NTL in the Front condition.

CONCLUSION: In case of jump landing with directional changes, it has been reported that the decreased knee joint flexion angle on landing in the front leg in relative to the jump direction is involved in deceleration [2]. Consequently, the knee flexion angles of the NTL were smaller in the TL-side condition. Regarding the knee valgus angle of the TL in the NTL-side condition, the centrifugal force which occurred during rotation may affect. The centrifugal force during rotation affected the outer leg (the TL in the NTL-side condition) relative to the direction of rotation, resulting in an increased knee valgus angle [3]. This study suggests that the risk of ACL injuries increases during jump landings with trunk rotation, such as rebound-jumps in basketball, and that differences in rotation direction may be a factor affecting the injured side.

NEUROMECHANICAL CONTRIBUTIONS OF SINGLE-JOINT FOCUSED MOVEMENT SYNERGIES TO VERTICAL JUMP PERFORMANCE: IMPLICATIONS FOR TARGETED EXERCISE SELECTION

SAITO, H., ENDO, N., SUGAWARA, R., TASHIRO, Y., MIURA, R., NAOKI, W., MATSUSHITA, K., SAKIKO, I., TAKAHIRO, O., TAKASHI, N.

TOKYO UNIVERSITY OF TECHNOLOGY

INTRODUCTION: Vertical jump (VJ) performance is a key indicator of explosive lower-body power in sports and an important measure in rehabilitation. Executing an effective VJ requires coordinated lower-limb and trunk extension, posing a complex neuromuscular control challenge. Despite the widespread use of targeted exercises to improve VJ performance, a clear neuromechanical framework for optimal exercise selection remains lacking, limiting the development of evidence-based training and rehabilitation strategies. This study systematically investigates the similarity between the muscle synergies of VJ and key single-joint focused movements (SFM).

METHODS: Fourteen healthy males (mean age: 20 ± 2 years) performed VJ (mean height: 49.0 ± 8.6 cm) and eight SFM—hip extension, abduction, active straight leg raise, knee extension/flexion, ankle plantar flexion, and trunk extension/flexion. EMG data from 16 lower-limb and trunk muscles were recorded wirelessly. Muscle synergies were extracted via non-negative matrix factorization (NMF) and clustered using k-means. SFM contributions to VJ synergies were evaluated using: (1) Similarity between synergy cluster centroids ($SP \geq 0.70$ indicating a direct match) and (2) Reconstruction of VJ synergies as linear combinations of multiple SFM synergies via non-negative least squares, requiring at least two synergies (scaling coefficient ≥ 0.2) and an overall $SP \geq 0.70$.

RESULTS: Six synergy clusters in the VJ were identified. The push-off module involved co-activation of ankle plantar flexors, knee extensors, and hip extensors. The thrust modules comprised two groups: one with hamstring and abductor activation, the other with the tensor fasciae latae, gluteus maximus, and adductors. The landing control module featured tibialis anterior and back muscle activation, while trunk stability modules corresponded to abdominal and back muscle activation. The thrust and trunk stability modules closely matched SFM synergies related to hip extension, trunk flexion, and trunk extension ($SP > 0.7$). However, the push-off and landing control modules were best reconstructed by merging multiple synergies: hip extension, knee extension, and ankle plantar flexion for push-off, and knee extension, ankle plantar flexion, and trunk extension for landing control. The thrust module with the tensor fasciae latae, gluteus maximus, and adductors did not correspond to SFM synergies.

CONCLUSION: VJ synergies serve distinct mechanical roles in jumping and landing, with specific SFM exercises contributing to corresponding movement patterns. The direct link between certain SFM synergies and VJ synergies supports the use of SFM exercises to target fundamental movement patterns. However, the push-off and landing control modules required multiple SFM synergies, suggesting that single-joint exercises alone may be insufficient for comprehensive VJ training. Future research should explore multi-joint exercises that integrate multiple SFM synergies to better replicate push-off and landing mechanics.

A LONGITUDINAL ANALYSIS OF PHASE-SPECIFIC PREDICTORS THAT IMPAIR COUNTERMOVEMENT JUMP PERFORMANCE AFTER A 3 X 12 BACK SQUAT FATIGUING PROTOCOL

GERVASI, M., FORMIGLIO, E., PATTI, A., GIUSTINO, V., FERNÁNDEZ-PEÑA, E.
UNIVERSITY OF URBINO

INTRODUCTION: Residual fatigue following intense exercise is known to impair athletic performance. This study aimed to assess the impairment of phase-specific predictors of vertical jump after a fatiguing resistance exercise protocol.

METHODS: Twenty-two participants underwent a back squat load/velocity profiling test. One week later, participants performed a set of three countermovement jumps (CMJ) at baseline (T0), immediately (T1), 30 minutes (T30min), and 24 hours (T24h) after completing a fatiguing protocol of 3 x 12 full squats at 70% 1RM with maximal intended velocity. A linear encoder measured the displacement velocity of the load, and a force platform recorded the vertical ground reaction force (GRF) of the CMJs. Duration and rates of force development (RFD) were assessed during the unloading, eccentric (yielding and braking), and concentric phases. Minimum position, force at minimum position, jump height, and modified Reactive Strength Index (RSImod) were also recorded.

RESULTS: Fatigue reduced unloading duration (from 0.195 ± 0.06 s at T0 to 0.161 ± 0.03 s at T24h, $p=0.008$). Although overall eccentric duration remained unchanged, yielding duration decreased ($p=0.024$) while braking duration increased ($p=0.007$). Unloading RFD increased ($p=0.007$) and yielding RFD increased ($p=0.002$), whereas braking RFD decreased ($p=0.003$). The minimum position was significantly lower at T1 and T30min ($p<0.001$) but returned to baseline at T24h, while force at minimum position decreased at T30min ($p<0.001$) and only partially recovered at T24h ($p=0.007$). Jump height and RSImod exhibited an acute impairment at T1 and T30min ($p=0.003$) with recovery at T24h.

CONCLUSION: These findings reveal that a common resistance training protocol (3 x 12 full squats) significantly disrupts phase-specific neuromuscular predictors of CMJ performance. Fatigue induces a compensatory strategy characterized by a reduced minimum position and an altered eccentric phase, specifically through an extended braking duration accompanied by a diminished braking RFD. Such adaptations suggest that the eccentric braking sub-phase is particularly vulnerable to fatigue, potentially compromising performance and increasing injury risk. These results highlight the need for optimized training programs and recovery strategies that specifically target the eccentric phase to mitigate fatigue effects. Future research should further explore the neuromuscular mechanisms underlying these changes and evaluate targeted interventions to enhance resilience during fatiguing conditions.

DOES A MUSCLE FATIGUE-INDUCING PROTOCOL ALTERS THE MAGNITUDE OF FUNCTIONAL INTER-LIMB ASYMMETRY IN HEALTHY ADOLESCENTS?

DHONDT, J., VANHOUDT, M., MALUTA, D., CHAPPELLE, L., AERENHOUTS, D.
VRIJE UNIVERSITEIT BRUSSEL

INTRODUCTION: Inter-limb asymmetry has extensively been studied in the context of sport performance. Research has shown that inter-limb asymmetry is a complex metric influenced by numerous factors (e.g., loading protocol). However, research on inter-limb asymmetry in a fatigued state is scarce. Therefore, the purpose of this study was to assess changes in jump asymmetry magnitudes in healthy adolescents over a 72-hour period following a muscle fatigue-inducing protocol.

METHODS: Twenty-two adolescents (age = 14.6 ± 1.8 years, 32% female) participated in the current study. The fatiguing protocol involved 10 sets of 10 maximal vertical jumps, with a one-minute rest interval between sets. The functional test battery consisted of the Single-leg 10-jump (SL10J), single-leg countermovement jump (SLCMJ), and single-leg hop jump (SLHJ) asymmetry, measured at baseline, immediately post-protocol, and at 24, 48, and 72 hours post- fatiguing protocol. Bioelectrical impedance analysis-derived phase angle was used to assess the level of muscle damage, while muscle soreness was evaluated using the Visual Analog Scale (VAS). Bilateral countermovement jump (BCMj) and bilateral horizontal jump (BHJ) were used to indicate changes in absolute jump performance across test occasions. Normality was assessed using the Shapiro-Wilk test. A one-way repeated measures mixed design ANOVA was conducted to examine differences in the magnitude of inter-limb asymmetry over time. For non-normally distributed data, Friedman and Wilcoxon tests were applied. Kappa coefficients were calculated to evaluate the consistency of the limb that performed better across tests (i.e., task specificity) and the consistency of the limb that displayed the highest jump performance over time (i.e., time specificity).

RESULTS: A significant increase in SL10J asymmetry was observed 48 hours post-protocol ($p<0.001$), while no significant changes were detected immediately post-protocol or at 24 and 72 hours post-protocol ($p=0.462-0.766$). No significant changes were found in SLCMJ ($p=0.714$) or SLHJ ($p=0.468$) asymmetry at any time point. BIA did not indicate significant muscle damage, although a significant increase in muscle soreness (VAS) was recorded. Kappa values indicated slight to

moderate agreement for task specificity ($\kappa=-0.123-0.493$) and slight to substantial agreement for time specificity ($\kappa=-0.137-0.732$).

CONCLUSION: SL10J asymmetry significantly peaked 48 hours after the fatigue-inducing protocol before returning to baseline values. In contrast, no significant changes were observed in SLCMJ and SLHJ asymmetry. Consistent with previous research, our findings indicate that inter-limb asymmetry is both task- and time-specific. However, the results show greater consistency in the direction of asymmetry between 24 and 48 hours post-protocol for both SLCMJ and SL10J. These findings suggest that repeated jump tests, such as the SL10J, may be more sensitive to detecting fatigue-induced changes in asymmetry.

KNEE TAPING FOR ENHANCED PERFORMANCE: KINETIC AND KINEMATIC COMPARISONS OF DYNAMIC, RIGID, AND KINESIO TAPING

SZELES, K., GREEN, A.

UNIVERSITY OF JOHANNESBURG

INTRODUCTION: The drop jump landing (DJL) evaluates reactive strength and jump performance across six phases: eccentric (0-20%), concentric (20-40%), flight (40-60%), loading (60-75%), attenuation (75-90%), and control (90-100%).(1) Continuous analysis of the full DJL cycle can reveal phase-specific effects of different knee taping types on performance. This study aimed to examine the impact of various knee taping conditions on lower limb kinetics and kinematics during DJL.

METHODS: Twenty-one athletes (age: 22 ± 2.69 years; height: 167.76 ± 7.47 cm; mass: 63.32 ± 10.57 kg) performed a series of 40cm drop jump landings under four taping conditions – no tape (NT), dynamic tape (DT), rigid tape (RT), and kinesio-tape (KT). Kinematic and kinetic data were captured using a 10-camera system and multi-axis force plates at 200Hz and 1000Hz, respectively. Discrete biomechanical data were analysed using repeated measures ANOVA ($p < 0.05$). Continuous biomechanical data were analysed using sphericity corrected repeated measures ANOVA ($p < 0.05$).

RESULTS: Significant differences in GRF occurred at 3–7% ($p = 0.001$) between NT vs. RT and NT vs. KT. Ground contact time (GCT) ($p = 0.003$) was significantly shorter for NT vs. RT, NT vs. KT, and DT vs. KT. No differences were found in jump height ($p = 0.92$), reactive strength index (RSI) ($p = 0.69$), or max take-off force ($p = 0.21$). Stability metrics (DPSI, VSI, APSI, MLSI) showed no differences ($p = 0.2-1.0$). SPM1D analysis revealed significant changes in ankle rotation (1-6%; 17-20%; 67-100%) in NT vs. KT, RT vs. KT, and DT vs. KT, knee abduction (14-16%; 49-51%) in NT vs. DT and NT vs. KT and rotation (1-15%; 17-40%; 51-100%) in NT vs. RT, RT vs. KT, RT vs. DT, and DT vs. KT, and hip rotation (16%; 71-100%) in NT vs. RT and NT vs. KT. Significant changes were seen in peak ankle abduction ($p = 0.035$) between DT vs. KT and peak knee flexion ($p = 0.004$) between DT vs. KT.

CONCLUSION: While the taping conditions influenced ankle, knee, and hip joint angles, the statistical differences were not substantial enough to observe that one taping condition outperformed the other. However, it can be noted that the DT condition followed a similar movement pattern to KT, and RT to NT. KT, RT, and DT reduced GCT but the overall reactive strength performance was highest in KT, with a significant increase in GRF in the eccentric phase, leading to the highest RSI. While KT did not affect force attenuation at peak GRF, it lowered loading rate, potentially increasing mechanical energy dissipation and reducing joint stress.(2) Given KT's neuromuscular stimulation properties, its performance benefits in DJL may stem from enhanced proprioception, optimising joint positioning sense to minimise energy loss in the eccentric phase and maximise force production in the concentric phase. These results highlight the potential of knee taping, which should form one part of a broader performance enhancement strategy.

EFFECTS OF ADDITIONAL LOADING AND VIBRATION FREQUENCY ON LOWER LIMB MUSCLE ACTIVITY DURING WHOLE-BODY VIBRATION EXERCISE

NAM, H., WANG, L.

SHANGHAI UNIVERSITY OF SPORT

INTRODUCTION: The effects of whole-body vibration (WBV) training are known to be influenced by multiple parameters. Optimizing these parameters is crucial for maximizing WBV's effectiveness in training and rehabilitation. This study examined how different vibration frequencies and loading conditions affect the electromyographic (EMG) activity of 11 lower limb muscles, providing a more comprehensive understanding of neuromuscular responses to WBV.

METHODS: Twenty-five healthy male participants performed dynamic squats during WBV exercise while EMG activity was recorded from the gluteus maximus, rectus femoris, vastus medialis, vastus lateralis, biceps femoris, semitendinosus, tibialis anterior, peroneus longus, soleus, gastrocnemius medialis, and gastrocnemius lateralis. The additional loading conditions consisted of either no load or a weighted vest equivalent to 20% of body weight. Vibration frequencies of 0Hz, 10Hz, 20Hz, 30Hz, 40Hz, and 50Hz were applied. EMG root mean square (EMGrms) values were statistically analyzed using a 2 (Loading) $\times$ 6 (Frequency) repeated-measures ANOVA.

RESULTS: No significant interaction effects between loading and frequency were observed. The gluteus maximus exhibited significant main effects for both loading ($p < 0.001$) and frequency ($p < 0.001$), with higher EMGrms under additional loading. EMGrms values at 10Hz, 20Hz, and 30Hz were significantly higher than at 0Hz. In the quadriceps (rectus femoris, vastus

medialis, vastus lateralis), only loading had a significant effect ($p < 0.001$), with higher EMGrms in the additional loading condition. The hamstrings (semitendinosus, biceps femoris) showed significant effects of both loading ($p < 0.001$) and frequency (semitendinosus: $p = 0.008$; biceps femoris: $p < 0.001$), with higher EMGrms in the additional loading condition. The semitendinosus showed significantly higher EMGrms at 10Hz than at 0Hz, while the biceps femoris exhibited significantly higher EMGrms at 10Hz and 20Hz than at 0Hz. The soleus demonstrated a significant loading effect ($p < 0.001$), with higher EMGrms in the additional loading condition. The gastrocnemius lateralis showed a significant frequency effect ($p = 0.016$), with EMGrms at 20Hz being significantly higher than at 50Hz. No significant effects of loading and frequency were observed in the gastrocnemius medialis, tibialis anterior, and peroneus longus.

CONCLUSION: Additional loading and vibration frequencies in the range of 10–30Hz significantly enhanced lower limb muscle activation during WBV exercise. This study provides a more comprehensive understanding of how these factors influence neuromuscular responses by examining a wider range of lower limb muscles. These findings highlight the importance of optimizing loading and frequency parameters to maximize the efficacy of WBV in both training and rehabilitation settings.

CP-BM14 Kinematics

THE EFFECTS OF CHRONIC ANKLE INSTABILITY ON JOINT KINEMATICS DURING A SIDE-CUTTING JUMP: A CROSS-SECTIONAL STUDY

KIM, C., JEON, K.

INCHEON NATIONAL UNIVERSITY

INTRODUCTION: Lateral ankle sprains (LAS) are a common musculoskeletal injury, particularly in sports that involve jump landings and rapid changes in direction [1]. Chronic ankle instability (CAI) affects the biomechanics and neuromuscular patterns of the ankle as well as the knee and hip, and these findings suggest that the mechanics of CAI may be multifactorial [2]. Consequently, this study aimed to investigate these factors by expanding the analysis to the upper limbs.

METHODS: Subjects who scored less than 25 on the CAIT and greater than 10 on the identification of functional ankle instability (IdFAI) were classified into the CAI group ($n = 11$), and those who did not qualify the criteria were included in the control group ($n = 12$). Participants performed a forward horizontal jump from a starting position set at 40 % of their height, landing with their right foot on the force plate, and then immediately jumping to the left with their right foot and landing. Kinematic data defined initial contact (IC) as the point when the ground reaction force (GRF) exceeded 10 N, toe-off as the point when the GRF fell below 10 N, and landing as the point when the ankle angle returned to neutral position. The interval from IC to one second after landing was normalized to 100 %. To evaluate the magnitude of the difference between groups, Cohens D effect sizes (d) were computed as the absolute mean difference between groups divided by the pooled standard deviation (SD). A frame-by-frame two-sample t-test using Statistical Parametric Mapping (SPM1D) was conducted in MATLAB (Math Works Inc., MA, USA) to analyze the group differences in mean values from IC (0%) to 1 second after Landing (100%). To address the issue of multiple comparisons, a Bonferroni correction was applied, and the statistical significance level was set to $\alpha = 0.05 / 100$ (number of frames).

RESULTS: The significant differences between the two groups primarily occurred from IC (0%) to Toe off (26.72%). Based on the CAI group, Neck left oblique ($p < 0.0005$), Neck anterior tilt ($p < 0.0005$), Neck left rotation ($p < 0.0005$), Pelvic left oblique ($p < 0.0005$), Pelvic left rotation ($p < 0.0005$), Right knee valgus ($p < 0.0005$), Right knee internal rotation ($p < 0.0005$) were small. While Trunk left oblique ($p < 0.0005$), Trunk anterior tilt ($p < 0.0005$), Trunk left rotation ($p < 0.0005$), Pelvic anterior tilt ($p < 0.0005$), Right Hip flexion ($p < 0.0005$), Right hip internal rotation ($p < 0.0005$), Right knee flexion ($p < 0.0005$), Right ankle external rotation ($p < 0.0005$), and Right ankle eversion ($p < 0.0005$) were large.

CONCLUSION: The results of this study suggest that CAI movements involving rapid changes in direction may influence the kinematics of both the lower and upper extremity joints. This indicates that the upper extremity may be a contributing factor in the CAI mechanism.

THE EFFECT OF UNSTABLE LOADS ON SCAPULAR KINEMATICS DURING SHOULDER PRESS: A PILOT STUDY

TSAI, Y., WENG, M.C., HUANG, T.S.

NATIONAL YANG MING CHIAO TUNG UNIVERSITY

INTRODUCTION: Unstable load is widely used in the fitness field, and the load is often made unstable by using flexible barbells. More unstable movements are generally believed to increase stabilizer muscle activation and strengthen these muscles more effectively than stable loads. Previous studies have mainly focused on investigating muscle activation during unstable and stable shoulder press exercises [1]. The differences in scapular kinematics between unstable and stable shoulder presses have not yet been studied. This pilot study aimed to analyze the differences in scapular kinematics during unstable and stable shoulder presses in recreationally active people.

METHODS: This pilot study recruited six recreationally active men with currently regular resistance training. The participants performed both unstable and stable shoulder press exercises in a randomized order. The unstable load was applied

using a Bandbell Bar with weight plates suspended by resistance bands on the bar. Unstable and stable shoulder presses each used their respective 15-repetition maximum (RM). During these movements, the electromagnetic motion capture system was used to analyze the scapular upward/downward rotation, anterior/posterior tilt, and external/internal rotation. The scapular kinematics were analyzed at 30°, 60°, 90°, and 120° of shoulder presses during both raising and lowering phases. Both types of shoulder press were tested five times, and the average value was calculated. The Mann-Whitney U test was used to compare differences between the two conditions.

RESULTS: The 15 RM of stable and unstable loads in six participants were 28.75 ± 2.09 and 22.47 ± 3.01 kilograms, respectively. The results indicated that shoulder press with unstable loads exhibited a significantly greater upward rotation at 120° of the raising phase compared to stable loads ($p = 0.020$). No statistically significant differences were observed in the other scapular kinematics.

CONCLUSION: Shoulder presses with unstable loads may exhibit greater scapular upward rotation at 120° of the raising phase compared to stable loads. Shoulder presses with unstable loads may be an effective re-education exercise for people with insufficient scapular upward rotation. More participants should be recruited to confirm the findings.

A COMPARISON OF BAR AND CENTRE OF PRESSURE HORIZONTAL PLANE MOTION DURING THE CONCENTRIC PHASE OF THE BACK SQUAT

SHORTER, K., LATSINOS, E., LAKE, J., BENSON, A.

SWINBURNE UNIVERSITY OF TECHNOLOGY

INTRODUCTION: Quantifying barbell motion during the back squat is a valid and reliable approach to monitor training performance[1]. When contrasted with force-velocity metrics obtained via integration of vertical ground reaction force (vGRF) from a force plate, the bar trajectory demonstrates a strong positive correlation in the vertical plane[2]. Whilst movement of the centre of pressure (COP), the point of application of the vGRF in the horizontal plane, is reflective of stability[3], there is a paucity of research considering the insight horizontal plane motion of the bar may afford. This study evaluated the similarity between the bar and COP to quantify horizontal plane motion during the back squat.

METHODS: Ten participants (age = 31.0 ± 10.1 years; mass = 82.7 ± 12.2 kg; height = 173.5 ± 7.82 cm; 1RM = 116.98 ± 18.32 kg) completed 3 sets of 8 full-depth back squat repetitions at 80%1RM emphasising maximal intent and velocity[1]. COP was derived from a Kistler 9281EA force plate sampling at 1000Hz synchronised to 8 Oqus 300 Qualisys cameras at 100Hz to quantify motion of the bar trajectory, defined as the midpoint between markers positioned on the bar ends. A 10Hz lowpass filter was applied to the bar trajectory with a bandpass filter applied to the COP within Visual3D. The concentric phase of each repetition[4] was extracted for analysis within Python 3.12, with horizontal plane motion defined by the range in the anterior/posterior (AP-Range) and medial/lateral (ML-Range) directions. Procrustes analysis[5] using Scipy.spatial assessed the similarity of horizontal plane motion between the bar and COP trajectories. Procrustes analysis applies an optimised transformation to minimise the distance between datasets with the associated dissimilarity measure implying the degree of similarity (0) or dissimilarity (1). Following exclusion of outliers (mean $\pm$ 3SD), statistical analysis was undertaken using descriptive statistics and Student's t-tests ($p=0.05$) using Scipy.stats.

RESULTS: From 234 back squat repetitions analysed, significant ($p<0.001$) differences with small-medium (AP-Range: bar = 8.87 ± 3.15 cm, COP = 7.92 ± 2.57 cm; $d=0.337$) and large effect (ML-Range: bar = 1.83 ± 0.97 cm, COP = 6.52 ± 2.85 cm; $d=-1.816$) were identified. Bar and COP trajectories had a dissimilarity score of 0.54 ± 0.24 .

CONCLUSION: Horizontal plane motion was significantly different for both AP-Range and ML-Range with Procrustes analysis establishing a lack of similarity between the bar and COP trajectories during the concentric phase of the back squat. Whilst the practical suitability of vertical plane motion of the bar to monitor training performance during the back squat is accepted [1], further research is required to elucidate horizontal plane contributions with results identifying that such motion should not be considered reflective of the COP or therefore stability during a back squat.

1.Thompson et al (2020) 2.Rahmani et al (2000) 3.Kohn et al (2021) 4.McMahon et al. (2018) 5.Krzanowski, W (2000)

EVALUATION OF KINEMATICS IN TENNIS FOREHAND DRIVES USING OPENCAP AND MARKER-BASED MOTION CAPTURE

HYBOIS, S., TRIOLET, C., EL MGHAZLI, I., TEULIER, C.

UNIVERSITÉ PARIS-SACLAY

INTRODUCTION: Biomechanical metrics derived from the analysis of 3D joint angles can provide relevant insights on tennis performance. Such methods have been extensively used to investigate tennis serve [1], but only a few studies focused on tennis forehand drives and the effect of stances [2]. One of the obstacles is that 3D biomechanical studies mostly rely on marker-based motion capture systems, that are difficult to use in ecological situations. The development of markerless tools like OpenCap [3] looks promising for democratizing 3D kinematic analysis directly on the court. The objective of our study was then to evaluate the accuracy of the OpenCap system for the assessment of kinematics during tennis forehand drives.

METHODS: Six tennis players (1 woman and 5 men), at the regional to national level, were recruited for this study. In lab conditions, they performed series of tennis forehand strokes, with open or square stances, aiming at a target integrated into the projection of a tennis court image. They also performed series of squats to have a baseline evaluation for a movement involving only flexion.

Trajectories of anatomical landmarks were collected with 3 iOS devices (OpenCap, Stanford University, USA) concurrently with a marker-based optoelectronic system (41 markers, 14 cameras, Qualisys, Sweden). Joint angles were computed with the OpenCap pipeline, and compared with the same angles inferred from 3D marker trajectories, using scaling and multi-body kinematics optimization tools from OpenSim.

RESULTS: For squat motions, differences in peak flexion angles between the two systems reached $12.3^\circ \pm 6.1^\circ$ for the hip and $6.8^\circ \pm 3.9^\circ$ for the knee. As expected, our preliminary analyses showed that differences between the two systems were higher for tennis strokes ($24.5^\circ \pm 15.3^\circ$ for arm flexion), with large errors occurring for rotations around the longitudinal axis ($31.1^\circ \pm 23.7^\circ$ for arm internal rotation).

CONCLUSION: Markerless motion capture tools like OpenCap allow to measure 3D kinematics on the tennis court, with the advantage of providing hands-on results. However, as reported in the literature [4], users should be aware that depending on the task and joint angles investigated, the magnitude of errors in comparison with marker-based motion capture can be high. In our case, the errors for squat movement were consistent with values reported in the literature [4] and drastically increased when investigating tennis strokes. This may be due to the specific movement of the tennis forehand, inducing upper and lower body dissociation and combinations of flexion, internal rotation, and adduction. Further investigations are required to compare this system to other embedded measurement tools like IMUs and OpenSense, in order to find the most suitable tool for 3D kinematics evaluation on the tennis court.

THE CONFLICT BETWEEN HORIZONTAL DECELERATION PERFORMANCE AND NON-CONTACT ACL INJURY

LIN, J., LI, W.

BEIJING SPORT UNIVERSITY

INTRODUCTION: Horizontal deceleration at high velocity imposes potentially hazardous knee mechanical loading, which may rupture the ACL. However, it is unclear whether horizontal deceleration performance concurrently increase knee joint loading and potential ACL injury risk.

METHODS: Thirty-eight males were recruited to participated in the study. Reflective markers were placed on the following bony landmarks: right and left shoulder top, anterior superior iliac spine, posterior superior iliac spine, medial and lateral epicondyles, medial and lateral malleolus, the first and fifth metatarsal head, and heel of the shoe. During the horizontal deceleration test, all athletes were instructed to perform a maximal horizontal deceleration following a 15 m linear sprint. To collect the velocity-time-distance profile, a radar device was positioned 5 m behind the start line at a height of 90 cm and sampling at 47 Hz as per manufacturer recommendations. All participants were instructed not to decelerate until passing the 15 m line, and any 15 m completion time which was 5% greater than the best 15 m sprint time recorded during the linear sprint test was discarded. Motion capture data and ground reaction force data of the first braking step were collected using an 8-camera set-up at 240 Hz. Ground reaction force data were recorded from two 40 cm × 60 cm Kistler force platforms sampling at 1200 Hz. Pearson's (parametric data) and Spearman's (non-parametric data) correlations were used to assess the correlations between horizontal deceleration performance and deceleration biomechanics, and non-contact ACL injury risk surrogates. The motion data and force data were low-pass filtered at 15 and 25 Hz, respectively [4]. Initial contact was defined as the instant when the vertical ground reaction force signal exceeded 20 N, and toe-off was defined as the frame where the vertical ground reactive force was less than 20 N [5]. For kinetic data, mean and peak multi-planar braking GRF (anterior-posterior, AP; medio-lateral, ML; vertical: V), horizontal braking GRF (horizontal = $AP^2 + ML^2$) [5].

RESULTS: Greater peak deceleration was significantly ($p < 0.05$) and moderately correlated with greater mean anterior-posterior braking GRF ($p = 0.39$ and 0.40) and greater horizontal braking GRF ratio ($p = 0.44$ and 0.46). Greater peak horizontal deceleration was significantly ($p < 0.05$) and moderately correlated with greater horizontal braking GRF ($p = 0.38$). There were non-significant correlations between deceleration performance (mean and peak deceleration) and KFM, KAM, and KRM ($p = 0.02$ - 0.20 , $p > 0.05$).

CONCLUSION: Therefore, there is no conflict between horizontal deceleration performance based on the first braking step, and non-contact ACL injury risk. As such, deceleration strategies which emphasize greater horizontal and posteriorly orientated forces during the first braking foot contact of deceleration appear effective for facilitating more effective deceleration, without concomitant increases in injury risk.

EVALUATING THE IMPACT OF STEP FREQUENCY MANIPULATION AND FEEDBACK MODALITIES ON RUNNING KINEMATICS AND STABILITY

BERNANS, E.

RIGA STRADINS UNIVERSITY

INTRODUCTION: Running kinematics and stability are critical components of athletic performance and injury prevention. Step frequency is a key variable that influences these aspects. Adjusting step frequency can alter running mechanics, potentially improving efficiency. This study explores the impact of step frequency manipulation on running kinematics and

stability, with a focus on different feedback modalities (auditory and visual). The Goal Equivalent Manifold (GEM) method is employed to assess running stability. GEM analysis provides a framework for understanding how runners maintain stability by allowing for variability in certain dimensions while constraining others. This method is particularly useful for analyzing complex motor tasks like running, where stability is maintained through dynamic adjustments rather than rigid control.

METHODS: Twenty trained and recreational runners (10 male, 10 female) took part in 13 treadmill trials, each lasting 2 minutes at a speed of 12 km/h with a 1% incline. Baseline kinematics were established from two initial runs without any feedback. Participants then completed trials with auditory (metronome) and visual (on-screen) feedback, adjusting their step frequency to predetermined targets of $\pm 3\%$ and $\pm 6\%$ from their baseline. The feedback was specific to the right leg, and participants were not informed of the frequency adjustments. Running kinematics, including step length and time, were recorded using the OptoJump Next system, and heart rate was continuously monitored. Stability was assessed using the Goal Equivalent Manifold (GEM) method, while kinematic variability and physiological responses were analyzed using descriptive and inferential statistics.

RESULTS: Preliminary analysis using repeated-measures ANOVA revealed significant differences in kinematic variability and stability between baseline and manipulated step frequencies. Visual feedback trials exhibited greater variability compared to auditory feedback, with more pronounced deviations at $\pm 6\%$ frequencies. Heart rate responses were correlated with step frequency deviations, indicating increased physiological effort with larger frequency changes. These results highlight also the importance of feedback modality.

CONCLUSION: The findings indicate that step frequency manipulation significantly impacts running stability and kinematics. The distinct responses to auditory and visual feedback modalities suggest that visual feedback may introduce greater variability in running mechanics. The correlation between heart rate and step frequency deviations highlights the increased physiological effort required for larger frequency adjustments. This suggests potential applications in training and rehabilitation. These insights can inform strategies for optimizing running mechanics, feedback methods, and physiological efficiency.

CP-BM16 Biomechanics - Mixed

EXPLORING THE TORQUE-VELOCITY RELATIONSHIP FOR LOWER LIMBS IN POSTMENOPAUSAL WOMEN: COMPARING THE GOODNESS OF FIT OF LINEAR AND NON-LINEAR MODELS AND ADDRESSING DATA PROCESSING ISSUES

RIAL-VAZQUEZ, J., CAMACHO-VILLA, A., RIVERA-MEJÍA, S.R., NINE, I., RÚA-ALONSO, M., FARIÑAS, J., ENRÍQUEZ-GONZÁLEZ, M.G., REVUELTA-LERA, B., IGLESIAS-SOLER, E.

UNIVERSITY OF A CORUNA

INTRODUCTION: Middle-aged women experience a decline in circulating estrogen levels, which affects muscle strength (1). Torque-velocity analysis allows us to monitor these strength alterations. The main aims of this study were to compare the goodness of fit and derived parameters of linear and non-linear models of fitting the torque-velocity (TV) relationship in postmenopausal women and to contrast the results using target or real maximum velocities as independent variable.

METHODS: 16 physically active postmenopausal women participated in a study funded by the Spanish Ministry of Science, Innovation and University (PID2021-124277OB). Knee extensors (KE) muscle strength was evaluated in the dominant limb using an isokinetic dynamometer. Range of motion was: 80° (knee flexed) to 0° (knee full extended). Isokinetic test was completed at 30, 60, 120, 180, 240, 300 and $400^\circ/\text{s}$. Peak torque was selected where $>90\%$ of the maximum target velocity was reached. Linear, polynomic and Hill regression models (2) were used to fit the TV data. Since the dynamometer reported a torque value even though the target velocity has not been reached, we obtained the TV relationship considering both real (i.e., the velocity achieved; TVR) and target velocity (i.e., the velocity preset on the dynamometer; TVT). The coefficient of determination (R^2), mean square error (MSE) and all the TV parameters derived from each model were obtained considering TVR and TVT relationships.

RESULTS: The isokinetic dynamometer failed to apply the preset target velocity, particularly at velocities $>240^\circ/\text{s}$. In those cases, the automatic report included a peak torque reached at a velocity much lower than the target velocity but indicating that it was achieved at the target velocity. The goodness of fit of linear, polynomic and Hill models for fitting TVR and TVT data was excellent ($R^2 > 0.915$). However, there were significant variations in both goodness of fit values and parameters derived from the linear and polynomial model, indicating that TVR and TVT were not similar ($p < 0.05$). No variations in those variables were detected using Hill model ($p > 0.056$). Considering TVR data, the best adjustment was obtained using Hill model ($R^2 = 0.991$; $\text{MSE} = 3.72 \pm 1.63 \text{ N} \cdot \text{m}^2$) and the worst with linear model. However, the theoretical maximum velocity (V_0) obtained from Hills model resulted physiologically incorrect ($6764.69^\circ/\text{s}$). The theoretical maximum torque (T_0) and velocity (V_0) obtained from Hill model resulted higher compared with the values obtained from linear and polynomial models.

CONCLUSION: Caution should be exercised when performing isokinetic assessment at high velocities in a population with low strength levels. Obtained data should be meticulously reviewed since TVR and TVT cannot be used interchangeably. The model choice can influence the parameters value. We recommend the polynomial model to fit the TV data for KE in postmenopausal women.

EFFECT ON STRENGTH PERFORMANCE AND MUSCLE ACTIVATION OF A PASSIVE EXOSKELETON DURING A MAXIMAL ISOMETRIC DEADLIFT TASK

FAVRO, F., PAVAN, D., BULLO, V., GOBBO, S., BORTOLETTO, A., DORO, B., BERGAMO, M., BERGAMIN, M.
UNIVERSITÀ DEGLI STUDI DI PADOVA

INTRODUCTION: Low back pain is the most reported work-related musculoskeletal disorder (WMSD), accounting for 21.8M disability adjusted life years (Fan & Straube, 2016). Exoskeletons designed for occupational use have the potential to reduce the risk associated with several work-related risk factors, including awkward postures and handling of heavy loads. Passive exoskeletons don't require an external power supply and are often lighter and less cumbersome but have been reported to provide less support (Schwartz et al., 2023). Therefore, the aim of this study was to investigate the efficacy of a commercially available back-support passive exoskeleton during a maximal effort lifting task.

METHODS: The exoskeleton adopted for this study was the Laevo V2.6 (Laevo Exoskeletons, Schiedam, Netherlands). Adult workers with experience in manual handling and with no history of low back pain in the last year were recruited for the study. After a short warm-up, the participants performed three trials of maximal isometric deadlift each with and without the exoskeleton, using a load cell to measure strength performance. EMG data were collected bilaterally for the iliocostalis, multifidus, biceps femoris and external obliques. RMS and envelope activation peak were computed for each acquired signal.

RESULTS: The sample consisted of 10 participants (23.6 ± 3.4 years old), 1RM without the exoskeleton was 173.7 ± 27.4 kg, and 173.3 ± 40.2 with the exoskeleton (p -value = 0.95). No significant differences were found for any muscle's EMG after applying Holm-Bonferroni correction.

CONCLUSION: The exoskeleton provided no support during the selected task, with 6 participants performing worse than without the device. It is possible that the additional torque provided by the exoskeleton was offset by the non-familiarity with the instrument and was masked by the relatively high level of maximal strength expressed by the participants sampled. Future studies could further explore the differences between passive and active exoskeletons.

ATTENTION TO WIND STRENGTH ENHANCES THE SKILL ADJUSTMENT IN RECURVE ARCHERS

CHEN, Y.H., CHEN, Y.L., CHEN, S.Y., KUO, W.J.
NATIONAL TAIWAN SPORT UNIVERSITY

INTRODUCTION: The influence of wind on archery performance remains underexplored (1). Research suggests that external and holistic attention improves performance over internal focus in experienced athletes (2). However, it remains unclear which types of external focus attention-skill-related (Ext-skill) or environment (Ext-env)-is as beneficial as holistic attention (H). Therefore, this study aimed to investigate the effects of these attentional foci on skilled archers.

METHODS: Eight recurve bow archers (4 females; 18.6-21.2 years; 5.5-11.2 years of experience; weekly training 15-25 hours; personal best: 625-662) were recruited. Each archer completed 12 ends of 6 arrows in a simulated competition across 2 sessions per attention condition (144 arrows per condition per archer). After each shot, archers rated wind strength, performance outcome, and overall feeling of the shooting movement (all on a 1-10 scale), corresponding to Ext-env, Ext-skill, and H condition, respectively. For data analysis, a generalized estimation equation (GEE) model was used to compare across attention conditions, with sex as a factor. Furthermore, actual wind strength, phase durations (setup, drawing, aiming, clicker reaction time [CRT]), aiming trajectory in the X and Y axes 0.5 s before and after clicker fall of each shot, and sex were input into separate GEE models to examine respective effects on score for each attention condition.

RESULTS: The first GEE model revealed no significant effects of attention condition ($p=.426$) and sex ($p=.400$) on score. However, separate analyses on each condition showed better model fit for Ext-env (QIC=1218) compared to Ext-skill (QIC=1389) and H (QIC=1551). All three models revealed that stronger wind negatively affected score ($\beta = -0.062$ to -0.128 , $p = .033$ to $<.001$). Specifically, in the Ext-env condition, CRT ($\beta = -0.002$, $p=.015$), aiming trajectory in the Y axis before ($\beta = -0.017$, $p=.017$) and after clicker fall ($\beta = -0.038$, $p=.003$), and sex (males > females, $p = .02$) had effects on score. These results suggested that when archers focused on wind strength, they adjusted their release timing and aiming trajectory in the Y axis. Such adjustments were not found in the Ext-skill or H conditions.

CONCLUSION: This study provided evidence that wind strength affects outdoor recurve archery performance. Focusing on wind conditions facilitated adjustments in release timing and vertical aiming, while focusing on skill or movement did not. These findings highlight the potential importance of attentional strategies in optimizing performance under varying environmental conditions in archery.

THE CURRENT STATE OF KNOWLEDGE ON PASSIVE BACK-SUPPORT EXOSKELETONS: A SYSTEMATIC REVIEW

GOBBO, S., BULLO, V., MULASSO, A., BERATTO, L., RAINOLDI, A., FAVRO, F., BERGAMIN, M.

UNIVERSITY OF PADOVA

INTRODUCTION: Back pain and musculoskeletal disorders are leading causes of disability among workers performing manual task. Passive back-support exoskeletons have been developed to reduce physical strain without relying on external power sources. Unlike active exoskeletons, which use motors or actuators, passive exosuits use mechanical elements such as springs and elastic elements to provide support. Although promising, the efficacy of these devices is still under investigation. This review aims to assess the current state of knowledge on passive back-support exoskeletons, focusing on their biomechanical impact and practical applications.

METHODS: A systematic literature search was conducted using databases such as PubMed, Scopus, and Embase. The following research search string was used on pubmed and adapted for the other search tools ("Exoskeleton Device"[mesh] OR "exoskeleton" OR "exoskeletons" OR "hybrid assisted limb" OR "wearable device" OR "wearable devices" OR "wearable robot" OR "exosuit" OR "ergoskeleton") AND (passive OR mechanical OR elastic OR "potential energy" OR "unpowered") AND ("back"[Mesh] OR "Shear Forces" OR "Compression Forces" OR "Back Muscles" OR "Lumbar" OR "multifidus" OR "longissimus dorsi" OR "iliocostalis" OR "spinalis" OR "low back" OR "lower back" OR "back support"). Inclusion criteria comprised peer-reviewed articles in english published in the last decade that examined passive back-support exoskeletons in any setting. Exclusion criteria included studies focusing exclusively on active exoskeletons or rehabilitation / medical applications.

RESULTS: Studies have consistently reported reductions in erector spinae muscle activity when using passive exosuits, particularly during lifting and sustained bending tasks. The most widely adopted devices (Laevo and HeroWear Apex) demonstrated significant reductions in lower back muscle activation across multiple tasks, although its effectiveness varied by task type and posture. User perception of exosuits is mixed, with most studies reporting positive feedback regarding reduced effort and fatigue. However, some users experienced discomfort due to fitment issues, increased heat, and restrictions on natural movement. Long-term usability studies are needed to assess adaptation and compliance in real-world settings.

CONCLUSION: Passive exosuits show promise in reducing muscle strain and perceived effort. However, their effectiveness depends on the task, and real-world adoption remains challenging due to user acceptance, comfort, and workplace integration. Future studies should explore long-term use, worker acceptance, and cross-industry applicability. While the biomechanical benefits are clear, optimizing the design for comfort and usability will be crucial for widespread adoption. With further research, passive exosuits could become valuable tools for injury prevention and ergonomic support in physically demanding occupations.

COMPARISON OF BICYCLE POSITIONING METHODS USING STATIC SIMULATION: TRADITIONAL FITTING TECHNIQUES VERSUS INDIVIDUALISED ADJUSTMENT

WINIARSKI, S., KUBIAK, A., PALUSZAK, A., ZADON, H., SZAFLIK, P., MICHNIK, R.

WROCLAW UNIVERSITY OF HEALTH AND SPORT SCIENCES

INTRODUCTION: Bicycle positioning significantly impacts cycling performance, injury prevention, and musculoskeletal health [1]. Traditional bike-fitting methods rely on standard anthropometric formulas or established procedures, whereas individualised adjustments using dynamic biofeedback aim to optimise biomechanics, muscular efficiency, and comfort [2]. This study compares these two approaches, assessing their impact on muscle activity, internal forces, and performance, with implications for sports medicine, physiotherapy, and injury prevention.

METHODS: A cohort of 35 healthy urban cyclists (19.5 ± 1.2 years, 15 female, 20 male) underwent bicycle fitting across five handlebar-saddle positions: (1) low handlebar & low saddle, (2) high handlebar & low saddle, (3) low handlebar & high saddle, (4) high handlebar & high saddle, and (5) a personalised position (P5). Key kinematic and kinetic parameters, including joint angles, saddle and pedal forces, and muscle activation patterns (EMG), were analysed using the Ultium Motion inertial system across all tested conditions. Anybody modelling system estimated reaction forces at L5-S1 and the lower limbs during four pedalling phases (0° , 90° , 180° , 270°). Noraxon insole force sensors and saddle pressure mapping provided additional reaction force data. Static optimisation identified muscle forces using a cost function that minimised the sum of cubes of the ratio of muscle forces to their maximum possible values. Muscle fatigue was assessed through a normalised muscle force ratio-based objective function. Statistical t-tests and statistical parametric mapping (SPM) analyses assessed differences in biomechanical efficiency, comfort, and performance outcomes between methods.

RESULTS: The experiment demonstrated optimised joint angles and reduced deviations in knee and hip alignment for the personalised position (P5) compared to traditional fitting (P1-P4). The lowest reaction force at L5-S1 was recorded in P5, with the highest forces at the start of the pedalling cycle (0°) and the lowest at 180° . P4 showed the highest L5-S1 force variability (177.5 ± 57.7 N), while P2 had the lowest (44.4 ± 4.4 N). Muscle fatigue, expressed as the normalised muscle load index, was lowest in the P5 position, averaging 0.56 ± 0.05 across all pedal stroke phases, suggesting reduced muscular strain and enhanced efficiency.

CONCLUSION: The findings suggest that dynamic simulation-based fitting results in lower spinal and muscular loads, reinforcing its superiority over traditional methods. The personalised position minimised muscle fatigue and spinal stress, emphasising the need for individualised bike-fitting in sports medicine and physiotherapy. These results support the inte-

gration of biomechanical modelling in bike-fitting practices to enhance performance and reduce injury risk. Future research should validate long-term effects in diverse cycling populations.

MEASUREMENT METHODS AND EVALUATION INDICATORS FOR TECHNICAL PERFORMANCE IN CLEAN SWIMMING: A SYSTEMATIC REVIEW

LIHANG, J.1, JIE, G.1, JIAWEN, L.2

1 BEIJING SPORT UNIVERSITY 2 YALE UNIVERSITY

INTRODUCTION: Swimming is an aquatic sport where race outcomes are determined solely by speed. During swimming, the swimmer technical performance is influenced by biomechanical and energetic factors. Overcoming hydrodynamic resistance while generating effective propulsion is critical for enhancing performance. Consequently, researchers require specialized measurement methods and biomechanical indicators to evaluate mid-race technical performance. With increasing demand for precise monitoring, advanced measurement tools have been integrated into training and competition. This study aims to comprehensively assess common measurement methods and evaluation indicators for technical performance during swimming, providing theoretical references for technical analysis.

METHODS: Literature review and expert interviews were employed to collate and analyze prevalent measurement methods and evaluation indicators in recent swimming research.

RESULTS: Common measurement methods for mid-race technical performance include video analysis, active drag systems, tethered swimming, and wearable devices. Biomechanical evaluation indicators are divided into kinematic and kinetic categories. Kinematic indicators encompass velocity, stroke rate (SR), stroke length (SL), coordination index (IdC), and joint range of motion (ROM). Kinetic indicators include propulsion and drag metrics. Propulsion metrics comprise average force, peak force, impulse, and rate of force development, while drag metrics focus on active drag coefficients.

CONCLUSION: Video-based analysis remains the primary method for swimming technical assessment. Current evaluations predominantly focus on upper limb and trunk movements, and limited studies on kicking dynamics. Measurement protocols should align with training and competition demands, simplifying data output and procedures. Future research should emphasize interdisciplinary integration to develop composite evaluation models, advancing swimming training practices.

DOES THE TRAJECTORY OF THE CENTER OF GRAVITY DURING THE BACK SOMERSAULT ANALYZED BY THE JUDGING SUPPORT SYSTEM (JSS) AGREE WITH THE 3D MOTION ANALYSIS?

ISHIKAWA, M., KOIZUMI, K., HATA, K., YAMAZAKI, Y., YANAGIYA, T.

JUNTENDO UNIVERSITY

INTRODUCTION: In international artistic gymnastics competitions, the AI-based judging support system (JSS, Fujitsu Ltd., Japan) has been introduced to assist in skill recognition. This system utilizes markerless motion capture technology to estimate the three-dimensional posture of athletes in real-time, supporting judges decisions. In addition to its role in judging, JSS has the potential to contribute to biomechanical research by offering kinematic data. However, its accuracy in providing positional data has not been thoroughly validated. To address this, we compared the Center Of Gravity (COG) trajectory obtained from JSS with that obtained from VICON, a widely recognized motion capture system for high-precision 3D motion analysis.

This study aimed to assess the accuracy of the COG trajectory obtained from JSS during back somersaults. We evaluated the similarity between JSS and VICON COG trajectories and analyzed estimation errors. The findings of this study provide fundamental insights into the applicability of JSS for biomechanical research in artistic gymnastics and its potential for advancing AI-based motion analysis.

METHODS: Five female gymnasts, all active competitors at the national level, participated in this study. Each performed a back somersault on a low balance beam. Four video cameras (30 Hz) were used, while VICON used 14 infrared cameras (250 Hz). COG was calculated using the body model for Japanese athletes proposed by Ae et al. (1992). The similarity between COG trajectories estimated by JSS and VICON was evaluated using Dynamic Time Warping (DTW) as trajectory similarity measures.

RESULTS: The results of this study indicate that JSS demonstrated high agreement with VICON in stable phases, with over 80% of the trials exhibiting a high level of agreement.

Time-series comparisons were performed using DTW and its derivative (DDTW) to assess trajectory similarity. Trials with lower agreement showed an error of 376 mm, while trials with higher agreement exhibited closer alignment with a baseline, indicating stronger consistency between JSS and VICON COG time series. The maximum error in trials with high agreement was 220 mm. Discrepancies increased after landing, suggesting greater estimation error in dynamic phases.

CONCLUSION: The results of this study indicate that JSS demonstrated high consistency with VICON in stable phases. However, larger discrepancies were particularly evident in the landing phase, indicating potential limitations in capturing rapid posture changes. Additionally, trials with lower agreement were performed by a single participant, suggesting that the AI's skeletal recognition may be influenced by individual physical characteristics as well as recording conditions.

In conclusion, this study demonstrated that the AI system exhibited a high level of agreement with VICON in back somersault trials. Further validation is needed to enhance the accuracy and reliability of AI-based motion analysis in artistic gymnastics.

INFLUENCE OF RIDER EXPERTISE ON MOVEMENT VARIABILITY AND STRIDE REGULARITY IN SHOW JUMPING

REGNAULT, N., BIDEAU, N., OLIVIER, A.

UNIVERSITÉ DE RENNES 2

INTRODUCTION: Movement variability is a key factor in the analysis of sports movements and motor skills, particularly in relation to expertise level [1]. In show jumping, such analyses can provide valuable insights into the underlying regulatory mechanisms of movement under different task constraints (i.e., the various zones of the jump). While coordination variability has been previously studied in show jumping [2], no research has examined variability in terms of both movement smoothness and inter-stride variability. This study investigates, under ecological conditions, how riders expertise level influences movement variability (rider's head and pelvis, horse) and stride regularity across different zones of the jump.

METHODS: 16 horse-rider dyads participated in a jumping task at a canter with Inertial Measurement Units (XSens MVN, The Netherlands) on the feet, shanks, thighs, pelvis, sternum, head, scapulae, upper arms, forearms, hands and horse's sternum. Participants were divided into 2 groups according to their expertise level: professional riders (PRO) and amateur riders (AMA). Stride regularity measured by the coefficient of variation (CV) [3] during approach zone and reception zone of jump. Jerk Cost (JC) [4] was computed stride by stride for head, pelvis and horse to assess the smoothness between kinematics of rider and horse. A repeated-measures ANOVA was conducted to compare the aforementioned variables for PRO and AMA riders on approach zone and reception zone. Significance was set at $p < 0.05$.

RESULTS: No significant results were observed between the PRO group and the AMA group for CV in the approach zone and in the reception zone, but a significant difference was observed between the two zones (approach 3.97 ± 1.68 ; reception 6.95 ± 3.13 ; $p = 0.008$). Regarding JC for the horse, no significant difference was noted between the PROs and the AMAs across strides, but the JC was lower for the approach strides in comparison with the reception strides (approach: $163 \pm 32.5 \text{ m}^2/\text{s}^5$; reception $198 \pm 39.3 \text{ m}^2/\text{s}^5$; $p = 0.001$). For pelvis and head JC, no difference was identified between the two groups between each stride, but JCs were higher in the approach zone than in the reception zone (JCHead approach: $327 \pm 139 \text{ m}^2/\text{s}^5$; reception: $188 \pm 65.7 \text{ m}^2/\text{s}^5$; $p < 0.001$ / JCPelvis approach: $361 \pm 111 \text{ m}^2/\text{s}^5$; reception: $292 \pm 71.6 \text{ m}^2/\text{s}^5$; $p = 0.024$).

CONCLUSION: The present results did not allow to discriminate the level of riders according to the CV of the horses stride or with JC on the horses overall movement or the riders head and pelvic movements. However, the results provide differences in terms of the change in the riders movement smoothness and stride regularity between the approach zone and the reception zone.

A SYSTEMATIC REVIEW OF AGE-SPECIFIC BIOMECHANICAL DIFFERENCES IN RUGBY TACKLING: IMPLICATIONS FOR SAFETY AND PERFORMANCE

EDGINGTON, H., MORAN, J., LIEW, B.X.W.

UNIVERSITY OF ESSEX

INTRODUCTION: Tackling is a critical skill in rugby, integral to both performance and injury risk. With tackling accounting for up to 72% of head impacts in rugby, including concussions and cervical injuries, the biomechanical execution of tackle techniques is essential for player safety[1]. This study systematically evaluates tackle biomechanics across age groups to identify differences in technique, injury mechanisms, and developmental opportunities, emphasising the importance of tailored coaching strategies for improving safety and performance.

METHODS: This systematic review adhered to PRISMA guidelines, utilising PubMed, SPORTDiscus, Web of Science, ScienceDirect, and Google Scholar databases. Studies analysing tackle biomechanics, injury prevention, and performance metrics in youth and adult players were included. Biomechanical data, including joint angles, kinematics, and head positioning, were extracted alongside injury rates and technical performance outcomes. Video analyses, motion capture systems, and accelerometer data were synthesised to compare tackle execution across age groups. The risk of bias was assessed using the Downs and Black checklist to evaluate the quality of included studies.

RESULTS: Youth rugby players exhibited higher rates of improper head positioning, increasing head and cervical injury risk (69.4 vs. 2.7 per 1,000 tackles)[2]. Youth players often performed high-risk tackles due to limited biomechanical control and experience. Adults showed better technique but faced higher injury rates from increased tackle volumes and forces. Though perceived as safer, low tackles increased head-to-knee impacts, while midsection tackles reduced risks. Age-specific training significantly improved technical proficiency, especially in the pre-contact and impact phases.

CONCLUSION: This review underscores the necessity of age-specific coaching strategies to optimise tackle safety and performance. Emphasising proper head positioning, pre-impact stabilisation, and midsection targeting can mitigate injury risks while enhancing skill acquisition. These findings support evidence-based training protocols to bridge the gap between safety and technical development, particularly in youth rugby.

RELIABILITY OF AN OPPONENT-INITIATED STIMULUS-RESPONSE SETUP FOR CHANGE-OF-DIRECTION MOVEMENTS IN FOOTBALL

GEHRING, D., EBNER, C., GRANACHER, U.
UNIVERSITY OF FREIBURG

INTRODUCTION: Change-of-direction (COD) movements play a key role in injury research and are often analyzed in stimulus-response situations, such as a light signal indicating the change of direction. To enhance ecological validity, attempts have been made to use real opponents instead of artificial stimuli [1]. Yet, control parameters, including approach speed and reaction time, are crucial factors to be considered [2]. Thus, ensuring reliable test conditions in opponent-initiated stimulus-response setups is essential for biomechanical research. Therefore, this study aimed to evaluate the reliability of a football-specific COD test setup using opponent-initiated stimuli under conditions with increasing task complexity.

METHODS: Twenty-nine female football players performed 90° CODs after an approach run targeted at 4.0 ± 0.3 m/s. COD directions were triggered by an experienced player (opponent) who kicked the ball in the targeted direction in four experimental conditions: anticipated COD, unanticipated COD with two options, unanticipated COD with three options including stopping, and unanticipated COD with four options including stopping or feinting. Kinematic data of the participants, the opponent and the ball were recorded via 3D motion capture. Variables of interest included approach speed, the position of the participant at the initiation of ball movement (PosBall), and the available time to react from initial ball movement (ATRBall) and from opponent movement (ATROpp) to force plate contact. Relative and absolute reliability were computed using intraclass correlation coefficients (ICCs) between conditions and coefficients of variation (CVs) within participants in each condition.

RESULTS: Approach speed showed excellent absolute reliability ($CV=2.2\%-3.0\%$) and high-to-excellent relative reliability ($ICC=0.89$ [$0.82, 0.94$]), with no significant main condition effect ($p=0.11$). For PosBall, we observed moderate-to-high relative ($ICC=0.73$ [$0.59, 0.85$]) and high absolute reliability ($CV=5.8\%-7.5\%$), without reaching the significance level for the factor condition ($p=0.71$). ATRBall and ATROpp exhibited moderate-to-high absolute reliability ($CV=11.6\%-15.7\%$; $6.5\%-8.9\%$) and high relative reliability ($ICC=0.79$ and 0.76), also with no significant condition effect ($p>0.05$).

CONCLUSION: Our findings confirm that an opponent-initiated stimulus-response COD setup in football demonstrated moderate-to-excellent reliability for all analyzed spatio-temporal parameters. Furthermore, we did not find significant condition effects, which supports the robustness of the setup and underscores its potential for use in ecologically valid test scenarios. Findings suggest that the test setup can be implemented in performance and/or injury-risk monitoring. Future studies should examine its applicability across male and youth players and different expertise levels to further establish the practical relevance.

YOUTH SPORT SPECIALIZATION, TRAINING VOLUME, AND INJURY HISTORY: ASSOCIATIONS WITH BALANCE, STRENGTH, AND MOVEMENT PATTERNS

WILCZYNSKI, B., BULER, J., BULER, R., GROCHOWSKI, M., PUCHALSKI, B., ZORENA, K.
MEDICAL UNIVERSITY OF GDAŃSK

INTRODUCTION: Physical activity declines from adolescence to young adulthood, potentially due to lifestyle changes or life transitions. This decline may be further exacerbated by youth sport specialization (YSS), which has been linked to an increased risk of injury and sports burnout. Moreover, YSS is often pursued as a pathway to elite athletic success and better sport performance. This study investigated the impact of YSS, training volume, and injury history on dynamic balance, isometric strength, and functional movement patterns in young athletes.

METHODS: A cross-sectional study of youth athletes in northern Poland adhered to STROBE guidelines, was approved by the Independent Bioethics Committee, and was registered on clinicaltrials.gov. Participants were classified into low, moderate, and high specialization. Data were collected through face-to-face questionnaires and interviews, anthropometric measurements, and performance tests, including the Y-Balance Test (YBT), Functional Movement Screen (FMS), and lower-limb isometric strength assessments using a handheld dynamometer.

RESULTS: Of the 373 participants initially enrolled, 235 young athletes (40% girls; 12.3 ± 1.8 yrs) met inclusion criteria, with 31% classified as highly, 53% moderately, 16% low specialized, and 37% reporting an injury history within the past year. No significant differences were observed in YBT, isometric muscle strength, or FMS scores across specialization levels ($p < .05$). Additionally, asymmetry analysis revealed a significant difference in anterior reach YBT scores between high (3.2 ± 10.5) and moderate (-1.9 ± 8.4) ($p = .0485$) and low (-1.03 ± 9.8) ($p = .0387$) specialization groups. Other asymmetry indices showed no significant differences ($p < .05$). Training volume correlated positively with isometric strength in knee flexors ($r = 0.16-0.21$) and hip abductors ($r = 0.21$, $p = .005$) and with FMS scores ($r = 0.21-0.22$, $p < .05$). Athletes training beyond their age showed higher strength in hip abductors, knee flexors, and ankle plantarflexors ($p < .05$) and better FMS scores (17.3 ± 1.66 vs. 16.2 ± 2.4 , $p = .027$). No significant differences were observed in sports performance between athletes with and without a history of injury ($p > 0.05$).

CONCLUSION: Contrary to common perceptions, higher specialization did not confer advantages in dynamic balance, isometric strength, or functional movement. Furthermore, it may be related to an asymmetry of dynamic balance in the anterior direction. Increased training volume was associated with strength improvements, particularly when exceeding age-related thresholds, but its impact on balance remained inconclusive, highlighting the need for balanced training approaches. Injury history was unrelated to sports performance. Given the increasing emphasis on evidence-based practice in youth sports, these findings provide valuable insights for coaches, parents, and sports scientists seeking to promote safe and effective training strategies for young athletes.

HIGH-INTENSITY RESISTANCE EXERCISE TRAINING AND PROTEIN SUPPLEMENTATION RESULT IN GREATER STRENGTH GAINS WHEN COMPARED TO STANDARD REHABILITATION IN PATIENTS RECOVERING FROM TOTAL KNEE ARTHROPLASTY

MONSEGUE, A., WILMS, E., KRAMER, C.S., MORWANI, J., VAN DER HAIJDEN, M., SINGH-POVEL, C.M., GROOTSWAGERS, P., DE GROOT, L.C.P.G.M., SLAGBOOM, P.E., VAN LOON, L.J.C., VERDIJK, L.B.

MAASTRICHT UNIVERSITY

INTRODUCTION: Despite successful surgery and standard rehabilitation practices, patients often remain with long-term deficits in muscle mass, strength, and physical functioning following total knee arthroplasty (TKA). We hypothesized that an optimized, combined exercise and nutritional intervention program would induce greater improvements in muscle outcomes than standard rehabilitation following TKA. We compared the effects of 12 weeks of high-intensity resistance exercise training (RET) with protein supplementation with 12 weeks of standard rehabilitation (SR) on muscle mass, strength, and physical functioning in older adults recovering from TKA.

METHODS: Thirty-three patients (70 ± 6 y; 28.7 ± 3.1 kg/m²) were randomized to the RET ($n=18$) or SR group ($n=15$). Starting 8 weeks after TKA, the RET group performed 12 weeks of supervised, high-intensity, whole-body resistance exercise training on standard exercise machines, 3x/week, progressing from 50% to 80% one-repetition maximum (1RM), and ingested a daily whey protein-based nutritional supplement (45g protein). The SR group underwent standard rehabilitation following individualized procedures from their own physiotherapist. Before and after the 12 weeks, muscle strength (1RM) was assessed on the leg press and leg extension, body composition and quadriceps cross-sectional area (CSA) were assessed using DEXA and CT-scan, respectively, and physical functioning was assessed with the short physical performance battery (SPPB), six-minute walk test (6MWT), chair-stand test (5CST) and timed-up-and-go test (TUG). Data were analyzed with 2-way repeated measures ANOVA ($\alpha=0.05$) and expressed as mean $\pm$ SD.

RESULTS: Leg press 1RM increased to a greater extent (P-interaction=0.026) in the RET vs SR group (RET: from 131 ± 38 to 174 ± 56 kg, $P < 0.001$; SR: from 124 ± 36 to 143 ± 49 kg, $P = 0.018$). Similar findings were observed for 1RM leg extension, with a tendency for greater improvements in RET vs SR (P-interaction= 0.074). Appendicular lean mass increased from 23.7 ± 5.0 to 24.2 ± 5.1 kg in the RET and from 23.4 ± 5.1 to 23.6 ± 5.4 kg in the SR group, with no differences between groups (P-time=0.009; P-interaction=0.390). Similarly, quadriceps CSA increased in both the operated and non-operated leg in both groups (RET: $+6.7 \pm 7.2\%$ and $+4.7 \pm 4.4\%$; SR: $+7.3 \pm 5.5\%$ and $+3.0 \pm 3.0\%$; P-time <0.001), with no differences between groups. While the SPPB significantly improved in the RET group (from 9.2 ± 1.5 to 10.4 ± 1.1 , $P < 0.001$), the SR group showed no changes (from 10.1 ± 1.3 to 10.5 ± 1.4 , $P = 0.150$; P-interaction=0.045). In contrast, improvements in the 6MWT were greater in the SR vs RET group (P-interaction=0.034), and both groups showed similar improvements on the TUG and 5CST.

CONCLUSION: High-intensity resistance exercise training with protein supplementation induces greater strength gains when compared to standard rehabilitation during recovery from TKA, but does not further augment gains in muscle mass and improvements in physical functioning.

INJURY EPIDEMIOLOGY: A SYSTEMATIC REVIEW OF REPORTING METHODS IN BASKETBALL

WING, K., BARDEN, C.1, MCMASTER, C.1, NEILL, M.2, AHERN, K.1, DE STE CROIX, M.1

1 UNIVERSITY OF GLOUCESTERSHIRE, 2 UNIVERSITY OF CALGARY, CANADA

INTRODUCTION: The international governing body of basketball (FIBA) reports nearly half a billion people play globally each year (1). The physical demands mean that injuries occur frequently (2). However, the injury epidemiological profile is largely unknown. This is attributed to a variety in reporting methods, making comparisons of injury rates between sports and contexts difficult (3). This review aims to summarise injury epidemiology and reporting methods in the literature to provide guidance for accurate reporting that aligns with IOC recommendations on injury surveillance.

METHODS: This review was conducted as per the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) guidelines and registered with PROSPERO (CRD42023487335). PubMed, SportDiscus, and Scopus were system-

atically searched up to December 2024 with no restrictions in place. Inclusion criteria specified peer-reviewed articles reporting injury rates (of any definition) per an exposure denominator, not intervention-based, in traditional 5v5 basketball of all age groups, sexes, levels or contexts in English. The abstract screening was completed by two pairs following calibration with raw agreement >0.80. A single author conducted data extraction, focusing on injury definitions, types of exposure, and the corresponding denominators. The quality of articles eligible for inclusion was assessed using the modified Downs and Black (DB) checklist (4).

RESULTS: A total of 2,879 articles were retrieved after the initial database search, of which 118 full-text articles were included. DB scores varied between 5 and 14 (mean 8.3). Key reporting methods included: injury definition, exposure type, and denominators. The majority of articles assessed injuries in North America (78%), with sparse data available for other continents. There were 12 different types of injury definitions. A total of 9 different exposure denominators were found, with athlete exposures being the most adopted (70%) followed by player-hours (17%). However, multiple different denominators were used, complicating any direct comparisons. Approximately one-third (36%) of articles reported no injury severity measures, limiting the understanding of an injuries impact.

CONCLUSION: This systematic review and the subsequent metanalysis in progress, provides a comprehensive overview of basketball injury epidemiology and highlights extensive heterogeneity across methods (injury definitions and reporting methods) making comparisons between studies difficult. These findings underscore the necessity for a consensus statement outlining standardised basketball injury surveillance protocols to advance research and promote player safety.

REGIONAL, SOCIO-ECONOMIC, AND HEALTH DETERMINANTS OF PHYSICAL FITNESS IN SCHOOL-AGED CHILDREN

NECHALOVÁ, L., DURCEK, P., ŠPÁNIK, M., BLEHA, B., BIELIK, V.

FACULTY OF PHYSICAL EDUCATION AND SPORT, COMENIUS UNIVERSITY IN BRATISLAVA

INTRODUCTION: The purpose of this study was to investigate the impact of critical predictors, such as school infrastructure, socio-economic factors, and health-related variables, on regional differences in physical fitness among school-aged children in Slovakia.

METHODS: Data were obtained from the Slovak Olympic and Sports Committee's National Physical Fitness Project. The study included 42,741 students in grades 6–9. Physical fitness was assessed using the EUROFIT test battery. Predictors included regional socio-economic indicators, health determinants, and school infrastructure variables. Four separate multiple linear regression models were developed, stratified by gender and age group.

RESULTS: BMI was identified as a significant negative predictor of physical fitness, while average life expectancy had a positive influence. Higher knowledge capital was associated with lower physical fitness, especially in younger students. Social vulnerability and gender equality had a strong negative effect on girls fitness, whereas insufficient school infrastructure notably diminished fitness levels in boys. The regression models explained 58% to 71% of the variance in physical fitness.

CONCLUSION: This study highlights the complex relationship between regional socio-economic, health, and environmental factors influencing physical fitness in school-aged children in Slovakia. The results emphasize the importance of targeted interventions to address systemic inequalities and enhance physical fitness and health equity among school-aged children.

Funding: This study was supported by the Slovak Research under Grant No. APVV-23-0062 , APVV-22-0047 and by the Development Agency, under Grant No. VEGA 1/0313/25.

BLOOD PRESSURE RESPONSE IN SPINAL CORD INJURY ATHLETES DURING STRESS TEST

PESTRIN, E., DEGANI, C., CANU, A., BARAZZONI, R., BIZZARINI, E.

UNIVERSITY OF TRIESTE, GERASUTTA INSTITUTE OF PHYSICAL MEDICINE AND REHABILITATION - UDINE, SANIRAD - TRICESIMO

INTRODUCTION: Spinal cord injuries (SCI) disrupt the nervous system's ability to regulate cardiovascular functions, leading to complications such as autonomic dysreflexia, orthostatic hypotension, and increased cardiovascular risk. These alterations increase the complexity of assessing cardiovascular health and exercise capacity in athletes with SCI, particularly in the context of sports eligibility evaluations. The unique cardiovascular challenges faced by SCI athletes need careful monitoring during exercise to prevent complications and ensure safety.

This study aimed to analyse blood pressure (BP) responses during stress test in SCI athletes, examining how factors such as lesion level, lesion completeness, and sport typology influence BP variations. A key aspect of the study was to assess whether recovery BP ratio (>0.9) could be used as an indicator of cardiovascular risk in SCI athletes, in line with findings from the general population.

METHODS: The study included 40 athletes with SCI, 27 paraplegic (23 males, 85%; 4 females, 15%) and 13 tetraplegic (10 males, 76%; 3 females, 24%), with lesion levels ranging from C5 to L3. The mean age was 43.3 ± 12.5 years for paraplegic

athletes and 43.4 ± 11.2 years for tetraplegic athletes. All athletes underwent sports eligibility evaluations, which included arm ergometry testing. During these tests, BP was measured at rest, peak exercise, and at recovery intervals. Data on lesion characteristics, sport type, and comorbidities were collected. The recovery BP ratio was calculated by dividing systolic BP at 3 minutes post-exercise by peak systolic BP. Delayed recovery (ratio >0.9) was considered an abnormal response and a potential marker of cardiovascular risk.

RESULTS: BP responses during exercise varied significantly depending on the level and completeness of the lesion. Athletes with tetraplegia or high thoracic injuries exhibited a reduced BP increase, with an average rise of 11.3% from baseline, and some even experienced a BP drop during exertion. In contrast, paraplegic athletes with lesions below T6 displayed a more typical BP response, with an average systolic BP increase of 23% and peak values reaching up to 210 mmHg.

The delayed BP recovery ratio was abnormal in 47% of SCI athletes (> 0.9), indicating a slower BP decline post-exercise.

In our data, a delayed BP recovery ratio (>0.9) was strongly associated with the presence of cardiovascular comorbidities, suggesting that a slow decline in BP after exercise may be a reliable indicator of elevated cardiovascular risk in SCI athletes, similar to the general population.

CONCLUSION: Lesion-specific cardiovascular assessments are essential to ensure the safety and effectiveness of sports participation for SCI athletes. Monitoring BP recovery dynamics during exercise testing provides valuable insights into cardiovascular risk, helping to identify athletes at higher risk and implement tailored management strategies to optimize health outcomes.

BIOMARKER VARIABILITY IN UNIVERSITY ATHLETES FOLLOWING CONCUSSION: INSIGHTS FROM NFL AND GFAP ACROSS THE RETURN-TO-PLAY PROTOCOL

PROSSER, S., STROM, A., I'ANSON, H., CASHMORE, I., DE MARCHI, A., WALTON, D., COE, J., O'HALLORAN, P., STEVENS, A., BELL, T., GASKELL, P., REYNOLDS, R., ALDRED, R., ELSWORTHY, R., LUCAS, S.

UNIVERSITY OF BIRMINGHAM

INTRODUCTION: Mild traumatic brain injury (mTBI) is one of the most common injuries in contact sports, with strong links to long-term neurological conditions such as post-concussion syndrome and an increased risk of Alzheimer's disease (1, 2). Despite its prevalence and severe consequences, mTBI diagnosis remains challenging, relying heavily on subjective assessments like the SCAT6, making diagnosis challenging. Previous research has highlighted promise in the ability of specific biomarkers to monitor brain injury (3). However, further research is required to better understand the relationships between these biomarkers and how they can be used together to advise return to play (RTP).

METHODS: This study investigated the changes in mTBI-related blood biomarkers across the RTP protocol. At initial concussion assessment (≤ 7 days post-injury) and RTP clearance, blood samples were collected from 34 university athletes (26 female) at the University of Birmingham Concussion Clinic. Biomarker levels were analyzed with Single Molecular Array (SIMOA) technology (Neuro 4Plex A assay) to assess changes in neurofilament light chain (NfL), glial fibrillary acidic protein (GFAP), ubiquitin c-terminal hydrolase L1 (UCH-L1), and total Tau levels across mTBI recovery. **RESULTS:** Between initial and RTP assessment, GFAP, UCH-L1 and Tau levels showed little to no change (all $p > 0.05$), although NfL decrease was near-significant ($p = 0.051$). There was marked variability among the athletes across all these outcomes (nested variability $p < 0.001$). Interestingly, a positive correlation was observed between NfL and GFAP levels ($R^2 = 0.286$, $p = 0.008$), suggesting a potential relationship between these biomarkers in mTBI recovery.

CONCLUSION: These findings highlight the potential link between neuronal damage (as indicated by NfL) and brain inflammation (GFAP release), given that $\sim 29\%$ of the variation in NfL levels were explained by changes in GFAP. However, the variability of individual biomarkers highlights the need for further investigation, particularly around the optimal timing of initial sampling in amateur sporting settings. Future research should aim to compare normative variability across a season, considering factors such as menstrual cycle phase and symptom severity during sampling, to improve the understanding of how blood-based biomarkers can have clinical application in the diagnosis and management of mTBI.

ARE SUPERVISED EXERCISE AND PSYCHOEDUCATION EFFECTIVE TO REDUCE CATASTROPHIC THOUGHTS IN INDIVIDUALS WITH CHRONIC PRIMARY LOW BACK PAIN? THE BACKFIT PROJECT.

TSIARLESTON, G., CASTELLOTE-CABALLERO, Y.M., DONOSO, B., DELGADO-FERNÁNDEZ, M., SEGURA-JIMÉNEZ, V.

INSTITUTO DE INVESTIGACIÓN BIOSANITARIA IBS.GRANADA

INTRODUCTION: Catastrophic thoughts such as pain magnification, rumination and pessimism are highly prevalent in individuals with chronic primary low back pain (CPLBP). A combination of supervised exercise and psychoeducational

program might be effective to reduce catastrophic thinking in these individuals. The aim of this study was to compare the effectiveness of a supervised exercise and a multimodal approach (supervised exercise+mindfulness) compared to a usual rehabilitation care group on catastrophic thoughts in individuals with CPLBP.

METHODS: 105 participants were recruited and randomized. A total of 53 individuals with CPLBP aged 52 ± 9 years attended >65% of the program: control group (CG, $n=20$), exercise group (EG, $n=14$) and exercise+mindfulness group (EMG, $n=20$). All groups received an 8-week intervention program twice a week for 45 minutes/session. The CG followed usual rehabilitation care (stretching, breathing and motor control exercises in different positions). The EG and EMG received a supervised exercise intervention focused on muscle strengthening exercises. Additionally, the EMG attended a mindfulness program once a week for 2.5 hours/session. Catastrophic thoughts were assessed with the pain catastrophizing scale divided into magnification, rumination and helplessness subscales. A total score of these subscales was calculated. Participants completed three assessments before (pre) and after (post) the intervention program and after a detraining period (re) of 3 months.

RESULTS: Repeated measures analysis of variance (ANOVA) showed that the EMG exhibited a reduction in catastrophic thoughts, rumination, magnification and helplessness following the intervention (post-pre mean difference (MD)=-7.3; 95% confidence interval (CI)=-12.16,-2.3; $p=0.06$; -0.4; -3.8, -0.95; $p=0.02$; -1.8; -3.1, -0.52; $p=0.09$ and -3.1; -6.1, -0.14; $p=0.41$, respectively). After the detraining period, the CG showed a reduction in catastrophic thoughts, rumination and helplessness (-6.60; -11.1, -2.1; $p=0.006$; -2.20; -3.9, -0.43 $p=0.17$ and -3.2; -5.39, -0.91; $p=0.08$, respectively). No significant differences were detected between groups for the remaining outcomes (all, $p>0.05$). Analysis of the covariance (ANCOVA) showed no significant differences between groups for catastrophic thoughts (all, $p>0.05$).

CONCLUSION: The multimodal approach effectively reduced catastrophic thoughts immediately after the intervention in individuals with CPLBP. Although no significant differences were found between groups, this was likely due to the small sample size and the consequently low statistical power. Future studies with larger samples are warranted.

A FEASIBILITY STUDY INVESTIGATING QUANTITATIVE AND QUALITATIVE EFFECTS OF EXERCISE IN THE WORKPLACE DURING WORK TIME FOR MENOPAUSAL WOMEN

DELETRAT, A., WALSH, G., SABIR, L., BAINES, K., FLETCHER, M., BIBBEY, A.

OXFORD BROOKES UNIVERSITY

INTRODUCTION: The menopause is associated with many physical (eg, hot flushes) and psychological (eg, anxiety) symptoms [1]. Physical exercise has some benefits to reduce these symptoms, however lack of time is cited as the main barrier to take part in physical exercise in this population [3]. Therefore our objective was to investigate the feasibility of exercise classes undertaken in the workplace during work time in healthy menopausal women, and to study the potential benefits of this intervention.

METHODS: Twenty-eight women (54.3 ± 6.5 years old; 162.6 ± 7.6 cm; 65.6 ± 12.5 kg) performed two testing sessions before and immediately after a 12-week exercise intervention including two exercise classes and two independent exercise sessions weekly. Feasibility outcomes were measured during the intervention, and semi-structured interviews were conducted post-intervention. Psychological (Menopause Rating Scale (MRS), 12-item Short- Form Health Survey (SF-12), Patient Health Questionnaire (PHQ-9), Generalised Anxiety Disorder (GAD-7) questionnaire, Self-efficacy for exercise (SEE) questionnaire, Behavioural Regulations in Exercise Questionnaire (BREQ-3) and the International Physical Activity Questionnaire (IPAQ)) and physical outcomes (body composition, balance, 30-s sit-to-stand (STS) test, and 6-min walk test (6MW)) were measured before and immediately after the intervention.

RESULTS: Participants' drop-out, retention and compliance were 14.3%, 78.6% and $70 \pm 32\%$, respectively. The exercise programme had a positive effect on the four main themes identified: positive organisation work culture, impact on menopausal physiological outcomes, impact on menopausal psychological outcomes, and improvements and growth for the program. Finally, significant improvements between pre- and post-intervention were observed in some MRS items ($p=0.007$ to 0.038), BREQ-3 ($p=0.001$ to 0.041), SF-12 ($p=0.028$), IPAQ ($p=0.039$), while body fat was significantly decreased ($p=0.026$) and STS (0.047) and 6MWT ($p<0.001$) were significantly improved.

CONCLUSION: A workplace physical activity intervention during work time for menopausal women is feasible and induces significant psychological and physical benefits after 12 weeks.

PHYSICAL ACTIVITY LEVEL MORE THAN MATURITY STATUS IS A KEY PARAMETER TO IMPROVING FATIGABILITY AND MUSCULAR FITNESS FOR HEALTH IN PREADOLESCENTS AND ADOLESCENTS

GALANTINE, P., HAYS, A., DEL SORDO, G., SUDLOW, A., MASO, F., BERTIN, D., DUCHÉ, P.

AIX-MARSEILLE UNIVERSITY

INTRODUCTION: Muscular fitness is a valuable indicator for monitoring the health of preadolescents (pre-peak height velocity (PHV)) and adolescents (post-PHV) [1]. To promote physical activity (PA) for health, it is essential to consider and understand how to develop the ability to resist fatigability and maintain muscular fitness during adolescence. This study aimed to assess the interaction effect between PA status (with regular and without regular PA) and maturity status (pre- and post-PHV) on fatigability and muscular fitness in preadolescents and adolescents.

METHODS: Fifteen pre-PHV boys (preadolescents) and seventeen post-PHV boys (adolescents) with regular PA, as well as thirteen pre-PHV boys (preadolescents) and twelve post-PHV boys (adolescents) without regular PA, participated in this study. Regular PA was defined as involvement for more than 4 hours a week (excluding physical education classes) and participation in organised systematic training. Each group performed a high-intensity intermittent protocol with 7 blocks (blocks 1 to 7) each comprising 1 x 30-m sprint and 5 min of high-intensity intermittent exercise with 1 min of passive recovery. Fatigability and short-term power output were measured. Linear mixed-effects models were used to analyse the interaction between PA status and maturity status on these parameters.

RESULTS: Fatigability increased significantly for all groups after the high-intensity intermittent protocol, but significantly more in preadolescents and adolescents without regular PA (blocks 4 to 7; CI 95% [-5.6;-0.2]; CI 95% [-5.6;-0.4]; CI 95% [-6.6;-1.4]; CI 95% [-6.7;-1.3], respectively). In addition, sprint time (block 4; CI 95% [0.8;18.8]; block 6; CI 95% [3.6;21.0]) and maximum velocity (block 6; CI 95% [-16.7;-3.2]) decreased significantly more during intense short-term exercises in preadolescents and adolescents without regular PA. Linear mixed-effects models showed no maturity status effect during the high-intensity intermittent protocol for all variables.

CONCLUSION: Independent of maturity status, preadolescents and adolescents who did not regularly take part in PA exhibited significantly greater fatigability than preadolescents and adolescents who did engage in regular PA during intense short-term exercises. This study confirms the importance of participating in regular PA from preadolescence and continuing through adolescence to improve resistance to fatigability and muscular fitness for health. When the level of PA is below the World Health Organizations recommendations (at least 60 min of moderate-to-vigorous intensity PA per day), greater exercise fatigability and poorer physical capacity are observed.

THE FEASIBILITY OF EXISTING GROSS MOTOR TESTS IN PRIMARY SCHOOL SETTINGS IN HONG KONG

KONG, Y., LAU, W.Y., SHEK, C.H., CHOW, C.C.G.

THE EDUCATION UNIVERSITY OF HONG KONG

INTRODUCTION: School physical education (PE) is important in assessing and promoting students' motor skills. In Hong Kong, a PE teacher typically manages dozens of students in class. Young students may struggle to understand complex instructions or have no prior experience in compound movements. This study evaluated the feasibility of some common gross motor tests of various areas in students aged 5–7 years in group settings.

METHODS: Thirty-nine typically developing children (1 withdrawal, 15 males and 23 females; grades: primary 1–3; age: mean $\pm$ SD: 6.70 $\pm$ 0.58) from two schools were recruited to perform physical tests in after-school sessions. Handgrip strength and eight tests selected from the Bruininks-Oseretsky Test of Motor Proficiency Second Edition (BOT-2), which assesses the developmental issues of those aged 4 to 21 years individually, were conducted with groups of 8 to 10 students. The data collection was video-recorded. The feasibility and performance of the tests were evaluated based on observations performed by the first author and two trained associates.

RESULTS: The feasibility index (percentage of participants who successfully completed the test out of the total number of participants ($n = 38$)) ranged from 94.74 to 100%. The sum of the maximum values obtained from three trials for each hand was 19.59 $\pm$ 5.70, similar to previous data collected from the same population. The raw scores of the BOT-2 items were converted to point scores. The students attained the highest scores in jumping in place—same sides synchronised (point score: 3.00 of maximal point 3) and walking forward on a line (4.00 of 4). Nearly the highest scores were achieved in standing on one leg on a balance beam—eyes open (3.82 $\pm$ 0.61 of 4), one-legged stationary hop (8.47 $\pm$ 1.27 of 10), and dropping and catching a ball—both hands (4.37 $\pm$ 1.08 of 5). A fair score was scored in dribbling a ball—alternating hands (3.11 $\pm$ 1.96 of 7). Notably, extremely poor scores were scored in knee push-ups (0.19 $\pm$ 1.17 of 9) and sit-ups (0.78 $\pm$ 1.46 of 9).

CONCLUSION: The test items appear highly feasible for group assessments using a video camera. Most participants in the current study could not perform knee push-ups (35 of 38 students) and sit-ups (27 of 38), suggesting two possibilities. Firstly, push-ups and sit-ups may exhibit floor effects for young participants. These exercises necessitate more than simply muscle force generation, a complexity that could hinder the differentiation of strength capabilities. Consequently, less skill-dependent test items, e.g. handgrip strength, could be more suitable for these participants. Secondly, the current typically developing participants exhibited underdeveloped muscle strengths, potentially due to the focus of the PE curriculum for

these grade levels in Hong Kong. In conclusion, the test items adopted in this study were highly practicable but are subject to floor effects when applied to groups of typically developing children.

WHAT CHARACTERIZES RESPONDERS TO AN EXERCISE INTERVENTION FOR LOW BACK PAIN?: FINDINGS FROM THE REVIEW RANDOMIZED CONTROLLED TRIAL

ESPIN, A., RODRIGUEZ-LARRAD, A.1,2, RUIZ-FERNÁNDEZ, A.1, ECHEVERRÍA, I.1, ARRINDA, I.3, MARTÍN-PÉREZ, A.1,2, IRAZUSTA, J.1,2

1. UNIVERSITY OF THE BASQUE COUNTRY, 2. BIOBIZKAIA HEALTH RESEARCH INSTITUTE, 3. IMQ IGURCO RESIDENCIAS SOCIOASISTENTIALES

INTRODUCTION: Exercise is one of the most effective interventions for low back pain (LBP). However, its effects vary, and not all patients experience improvement. Identifying factors that distinguish responders from non-responders could enhance therapeutic decision-making. Therefore, this study aimed to analyze differences between responders and non-responders to an exercise intervention for LBP addressed to eldercare workers, a population with high LBP prevalence.

METHODS: This study analyzed data from the ReVIEW randomized controlled trial, which was effective for reducing LBP (ClinicalTrials.gov: NCT05050526). Participants from the experimental group and the waiting-list control group were assessed. Inclusion criteria were having ≥ 2 average LBP intensity at baseline on the numerical rating scale (NRS, 0-10) and completing pre-post assessments after participation in a 12-week videoconference-supervised exercise intervention. The intervention consisted of two weekly 45-minute group sessions including whole-body resistance exercises performed with bodyweight and elastic bands at moderate-high intensity. Response was defined taking into consideration a clinically significant reduction of ≥ 2 points on the NRS [1]. Responders vs. non-responders were compared based on adherence to the intervention, sociodemographic data, and several baseline measures of muscle performance, psychological health, work-related parameters and musculoskeletal pain (including low back, neck, shoulder and hand/wrist pain). First, between-group comparisons were done with independent samples t-tests or Mann-Whitney U tests (depending on normality) for continuous variables and chi-squared tests for categorical variables. Later, variables with $p < 0.05$ in these analyses were entered into a binary logistic regression model, with response status as the dependent variable. Analyses were conducted using IBM SPSS Statistics 30.0.0.

RESULTS: 77 participants were included (39 responders, 38 non-responders). Between-group comparisons showed that responders had higher baseline LBP intensity (4.7 ± 1.8 vs 3.9 ± 1.7 in 0-10 NRS; $p = 0.045$) and lower anxious symptomatology (3.9 ± 2.4 vs 5.1 ± 2.4 in 0-9 Goldberg's scale; $p = 0.040$). Other comparisons were non-significant ($p > 0.05$). In the logistic regression model, higher LBP intensity (OR 1.37; 95%CI 1.03-1.81) and lower anxious symptomatology (OR 0.79; 95%CI 0.64-0.97) at baseline remained significant predictors of being responders.

CONCLUSION: This study highlights that baseline LBP intensity and levels of anxiety are significant predictors of response to a videoconference-supervised exercise intervention for LBP in eldercare workers. These findings suggest that tailoring interventions based on baseline characteristics could improve outcomes and enhance therapeutic decision-making for this high-risk population.

NECK STRENGTH IN ADOLESCENT ATHLETES: A COMPARISON OF NORMATIVE VALUES BY SEX AND SPORT

CRAIG, B., NORTHWOOD, K., DAVIES, J., COOPER, M., CROWFOOT, W., LEGG, H.

SOUTH GLOUCESTERSHIRE AND STROUD COLLEGE, ENGLAND, UK; UNIVERSITY OF GLOUCESTERSHIRE, ENGLAND, UK.

INTRODUCTION: Neck strength has been purported to be a modifiable risk factor in reducing the risk of sports related concussion. However, literature is sparse with most studies focusing on professional male athletes. Concussions are frequent across all playing levels and sports, particularly in adolescent and female cohorts. The neck strength profiles of these athletes are largely unknown. This study aims to describe and compare neck strength in high-school athletes across various sports.

METHODS: Male and female athletes participating in rugby, football and basketball academies, were recruited from an elite sports college in England, UK. All athletes completed a standardised warm-up followed by maximal isometric neck strength testing (VALD ForceFrame). In a randomised order, participants completed one submaximal practice attempt followed by three maximal isometric contractions (3 second push with 10 second rest) in a quadrupled position for neck flexion (FLEX), extension (EXT) and side flexion (SFLEX; rugby only), with a minimum of 10 minutes between directions. Absolute peak force values (Newtons (N)) and peak force normalised to body weight (N per kilogram of bodyweight) were gathered. EXT:FLEX and left:right SFLEX ratios were calculated to describe strength for opposing musculature. Significant

differences (significance $p < 0.05$) between sexes were analysed using an independent t-test, with a one-way ANOVA used to compare sex-specific sports academies.

RESULTS: 174 participants (125 males (81.0 ± 13.6 kg), 49 females (68.0 ± 13.5 kg)) from football (male $n=44$, female $n=20$), rugby (male $n=49$, female $n=29$) and basketball (male $n=32$) were included. Absolute and relative EXT values were greater than FLEX for both sexes and sports, with EXT:FLEX ratios of $1.39 \pm 0.3N$ for females and $1.34 \pm 0.3N$ for males. Males had significantly greater absolute force scores for each of the four movements compared to females as well as significantly greater normalised peak force FLEX and EXT scores ($p < 0.001$). Both male and female rugby athletes had significantly stronger FLEX and EXT scores (absolute and normalised) compared to their football counterparts ($p < 0.001$). In males, no differences were observed between basketball athletes and those from rugby or football for any absolute or normalised scores ($p > 0.05$).

CONCLUSION: Males had significantly stronger neck strength profiles compared to females, both with absolute and normalised force production. Lower neck strength could be one reason female athletes are at increased risk of concussion compared to male counterparts. Footballers had the lowest neck strength values across all sports, especially for neck flexion. This is interesting given football is the only sport with the involvement of intentional head movements through heading a ball, predominately stressing the neck flexors. Further work needs to focus on interventions to improve neck strength to aid performance and reduce concussion risk.

DOES INTERNAL OR EXTERNAL SHOULDER TORQUE RELATE TO SHIRT DRESSING SPEED IN COLLEGE-AGED WOMEN?

SHIM, A., MCCREADY, L., KOILE, C., HAGAN, K., CARLSON, R., BOWSER, S., DAUGHTRY, L., HIERHOLZER, K., SMITH, B.
CATAWBA COLLEGE

INTRODUCTION: The ability to dress a buttoned shirt is considered an Activity of Daily Living (ADL). These daily basic skills are considered necessary to maintain quality of life which include bathing and eating [1]. When one is unable to perform ADL's, their quality of life decreases which negatively affects their overall health [2]. The action of dressing oneself with a buttoned shirt requires flexibility and torque of the internal and external rotators of the shoulder joint. Previous research showed that peak torque of shoulder abduction was lower in older adults than compared to younger adults when performing ADLs [3]. However, there have not been studies demonstrating a relationship between internal and external torque of the dominant shoulder rotators and shirt dressing speed in either population. Therefore, the purpose of this investigation was to determine if dominant internal or external torque had a relationship with shirt dressing speed in college-aged women.

METHODS: 15 college-aged females with no history of shoulder injury (age: 19.5 ± 1.3 years; height: 169.7 ± 8.6 cm; weight: 69.8 ± 16.1 kgs) were selected for this study. The subjects were given a specific protocol on how to dress the button shirt sleeves using both arms without buttoning, starting with both hands on the chest. Two trials were provided for their best time in seconds using a hand-held timer. A Biodex III isokinetic dynamometer was then used to assess internal and external torque of the dominant shoulder in the standing position. Two trials of six maximal repetitions followed by one maximal repetition at 120 degrees/second was assessed. Peak torque for internal and external rotation were recorded for each trial.

RESULTS: Mean values of torque were analyzed (internal rotation 29.1 ± 12.01 ft-lb; external rotation 15.6 ± 6.99 ft-lb.). The average shirt dressing time for all subjects was 2.60 ± 0.50 seconds. Pearson correlations between external torque of dominant shoulder and shirt dressing speed was ($r = -0.19$; $p = 0.58$) compared to internal torque of the dominant shoulder ($r = -0.3$; $p = 0.14$).

CONCLUSION: Our results did not determine a significant relationship between the internal or external rotators and shirt dressing speed, but internal torque values and dressing speed were moderately related. A possible explanation could be due to participants lack of consistent effort, based on the specific shirt dressing protocol that all subjects were adhered to. If subjects were given adequate practice of the shirt dressing protocol, this potentially would have resulted in a stronger significant relationship. Utilizing an older population for future studies could result in consistency of scores.

MAXIMUM-SPEED SINGLE-LEG BRIDGE: A NOVEL APPROACH FOR ASSESSING AND REHABILITATING RECURRENT HAM-STRING INJURIES – A SINGLE CASE STUDY

MURASE, M., SANO, Y., KAWABATA, M., KENMOKU, T., WATANABE, H., TAKAHIRA, N.
KITASATO UNIVERSITY KITASATO INSTITUTE HOSPITAL

INTRODUCTION: The high recurrence rate of hamstring strain injuries (HSI) suggests that using only muscle strength and flexibility differences between the injured and uninjured sides may be insufficient. Recurrences are frequent during high-speed movements; however, no assessment method currently exists to evaluate high-speed functional performance. This case report aimed to highlight the use of the Maximum-Speed Single-Leg Bridge Test (MS-SLBT) in a rugby player with a

fourth recurrence of HSI to identify functional impairments that are not detectable with conventional assessments, and to demonstrate that these impairments can be improved by utilizing the test as an intervention.

METHODS: A 21-year-old university rugby player with a history of three prior HSI experienced a fourth recurrence in the semitendinosus. Magnetic resonance imaging (MRI) confirmed a Grade I injury (BAMIC 1a) 2, and musculoskeletal ultrasound imaging showed scarring and tenderness of the muscle fibers. At 1-month post-injury, the patient reported no pain during hamstring stretching, isometric or eccentric contractions, or sprinting. The patient was unable to complete the MS-SLBT because of severe pain and fear. After 2 months, the pain during the test decreased, but the buttock-raising speed and height remained limited. The patient then performed the MS-SLBT exercise as a daily intervention for 2 months and the effects of training and detraining were evaluated.

RESULTS: After the intervention, the buttock-raising height increased from 0.19 m to 0.35 m, and the buttock-raising speed improved from 0.83 to 1.46m/s during the MS-SLBT. The isometric knee flexor torque increased from 1.5 to 2.0 Nm/BW, and the flexibility, as measured by the active knee extension test, improved from 16.5 to 0.5°. These improvements were maintained even after a 1.5-month of detraining period. Ultrasound imaging showed reduced muscle fiber irregularities, improved centralization of muscle contractions, and increased contraction speed.

CONCLUSION: The MS-SLBT provides a specific and valuable tool to assess concentric contraction deficits in the hamstrings during high-speed movements in rugby athletes with HSI, even when conventional assessments such as muscle strength tests, flexibility measures, and Nordic hamstring exercises show no abnormalities. Additionally, using MS-SLBT as an intervention resulted in improvements in high-speed movement performance, muscle strength, and flexibility, along with a reduction in muscle fiber irregularities and enhanced coordination and centralization of muscle contraction during isometric hamstring contractions.

DYNAMIC KNEE VALGUS IN YOUTH SOCCER PLAYERS AFTER A FUNCTIONAL TRAINING PROGRAM. PILOT STUDY.

AMBRUS, M., MOLNAR, D.1, SOUSSI, B.1, UHLAR, A.1, HORVATH, T.1, TOVAR, O.1,2,3

1 HUNGARIAN UNIVERSITY OF SPORTS SCIENCE; 2 BIELEFELD UNIVERSITY, BIELEFELD, GERMANY; 3 SAARLAND UNIVERSITY, SAARBRÜCKEN, GERMANY

INTRODUCTION: Knee injuries are very common in athletes, especially soccer players and often take a long time to recover [1]. High loads on the knee during landing or changes of direction during soccer matches or training can lead to a valgus shift of the knee, known as dynamic knee valgus (DKV) [2]. Many studies have shown that a low dynamic knee valgus is a predisposing factor for knee injuries and disease, such as anterior cruciate ligament injury, patellofemoral pain syndrome or osteoarthritis [2;3;4;5;6]. Functional training based on dynamic stretching, balance, proprioceptive and stability exercises, has been developed to reduce the DKV.

METHODS: Nine male youth soccer players (mean age: 16.4 ± 0.2 years) from the same soccer team took part in six weeks of functional training program. DKV was measured in pre- and post-measurements during single leg squats using a three-dimensional Kinect Azure camera in combination with DynaKnee software [6]. In addition, maximal voluntary muscle contraction (MVC) was measured using a dynamometer and muscle activation amplitude (MAA) was measured using electromyography. Data were analysed using a non-parametric Wilcoxon signed rank test to assess differences in DKV, MAA and MVC at a 5% significance level.

RESULTS: Data showed a small improvement of DKV in dominant leg. MVC increased slightly in all measured muscle groups. MAA of the involved muscles in the single-leg squat had inconsistent results, but rather a decreasing trend. Nevertheless, none of the analyses showed significant changes.

CONCLUSION: Results showed influence on dominant leg on DKV. The small number of participants and the short duration of the training might have been a limiting factor. Further studies should repeat the procedure with a larger group of participants and a longer training period.

ANKLE STABILITY IN HIGH-SPEED RUNNING: FOOT PLANTAR PRESSURE, KINEMATIC, AND MUSCLE ACTIVATION CHARACTERISTICS IN ATHLETES WITH ANKLE INSTABILITY UNDER DIFFERENT TAPING

CHENG, T., CHANG, C., HSU, T., LIN, J.

NATIONAL TAIWAN UNIVERSITY OF SPORT

INTRODUCTION: Sports taping provides support and stabilization for the ankle during the rehabilitation phase while enhancing ankle stability to prevent re-injuries [1]. However, there is limited research on the effects of sports taping on ankle stability during high-speed running, and scientific validation remains insufficient. Therefore, this study compares the differences in joint kinematics and foot plantar pressure under different taping conditions during high-speed running.

METHODS: This study recruited nine athletes with chronic ankle instability (CAI) to perform a 20-seconds high-speed running test at 15 km/h of three conditions: no taping (NT), athletic taping (AT), and dynamic taping (DT). A quasars foot plantar pressure treadmill, nine EMG sensors, and nine IMUs were used to collect foot plantar pressure, muscle activation, and gait parameters. The analysis focused on different phases of running gait cycle, including the stance phase, swing phase, initial swing, mid-swing, and terminal swing. One-way ANOVA repeated measurement was conducted to compare the kinematic and kinetic and foot plantar pressure distribution across different taping.

RESULTS: The results of this study showed no significant differences between AT and DT across different stance phases during high-speed running. However, both AT and DT resulted in significantly greater ankle dorsiflexion during the stance phase compared to NT ($p=.014$). Additionally, during the swing phase ($p=.042$) and mid-swing phase ($p=.044$), the ankle dorsiflexion were significantly lower with AT and DT than with NT. No significant differences were observed in lower limb muscle activation, gait parameters, or foot plantar pressure across different taping during the various stance phases.

CONCLUSION: The findings of this study indicate that both athletic taping and dynamic taping effectively restrict the range of motion (ROM) of the ankle joint without affecting muscle activation or max foot plantar pressure. Additionally, CAI often exhibit excessive plantarflexion and limited dorsiflexion [2]. The findings suggest that DT is more effective than NT and AT in increasing the stance phase and reducing the swing phase of the ankle joint dorsiflexion angle. This modulation may facilitate shock absorption during initial contact of stance phase and promote a more neutral ankle position during the swing phase, optimizing landing preparation and potentially reducing the risk of repetitive high-speed running-related ankle injuries. Furthermore, when the ankle joint is in dorsiflexion, the elastic recoil effect of DT increases the storage of elastic energy, thereby reducing lower limb load [3]. Therefore, it is recommended that athletes with CAI in high-speed running-related activities consider using DT for injury prevention when athletic taping is necessary.

NEUROCOGNITIVE PERTURBATIONS IN NON-CONTACT ACL INJURIES IN ELITE FOOTBALL PLAYERS

NITRI, M., RANZINI, A., PELLEGRINI, A., TRECROCI, A., ESPOSITO, F., PIRLI CAPITANI, L., DELLA VILLA, F., ZAGO, M.

UNIVERSITÀ DEGLI STUDI DI MILANO

INTRODUCTION: Anterior cruciate ligament (ACL) injury is a severe concern in professional football, with persistently high incidence rates. While previous research focused on biomechanical aspects, a model incorporating playing situations and opponent interactions offers a more comprehensive understanding [1]. Lower cognitive function has been linked to higher non-contact knee injury risk [2], highlighting the value of including neurocognition in ACL injury studies. This study aims to investigate neurocognitive perturbations preceding non-contact ACL injuries in professional football players through video analysis.

METHODS: An established video analysis framework was adopted. Cases met the following inclusion criteria: (i) documented ACL injuries (2010-11 onwards) in (ii) top national and international competitions; (iii) available video coverage; (iv) non-contact ACL injury with (v) neurocognitive perturbations preceding the injury. Videos were analyzed using Kinovea to gather contextual factors: game situation, match score, minute, action preceding injury, body orientation, pitch location, playing position and opponent pressure. A gross biomechanical analysis was conducted using a custom form to extract data on injury mechanism, situational pattern, and biomechanics. Distributions homogeneity was tested with Chi-squared tests.

RESULTS: Preliminary data from 35 players were considered. Injuries predominantly occurred in defensive situations (66%), mainly during pressing (54%) and with a sidestep biomechanics (57%). A deceiving action preceded 51% of injuries, 94% of which were defensive. Time from the deceiving action to initial contact (IC) averaged 258 ms (range 34-490 ms). In offensive situations, injuries mainly occurred under tight opponent pressure (83%). At IC, the area around the injured player included the ball (86%), no teammates (89%), one opponent (83%) and no spatial constraints (63%). Scanning activity was present (68%) before the injury occurred but remained minimal (39% performed zero and 39% one scan in 3 s, and 50% and 19% in 5 s prior, respectively). Additionally, at perturbation, the visual focus was directed toward the ball (97%) rather than the motor task required.

CONCLUSION: This study describes neurocognitive perturbations, scanning activity and contextual factors associated with non-contact ACL injuries in elite football. Data align with existing literature indicating a high incidence of ACL injuries following a deceiving action. Results support the importance of efficient and rapid decision-making processes in unplanned

actions. Moreover, limited scanning activity may increase the risk of unexpected and subsequently altered movements. Findings highlight the role of neurocognitive errors and visual behaviours in the complex nature of ACL injuries, emphasizing the need for preventive strategies to include both biomechanical and neurocognitive aspects.

IS ACCELERATIONS DURING THE MARATHON PART OF A FULL DISTANCE IRONMAN ASSOCIATED WITH SKELETAL AND HEART MUSCLE DAMAGE?

DANIELSSON, T., CARLSSON, J., FRIDOLFSSON, J., AHNESJO, J., BERGMAN, P.
LINNAEUS UNIVERSITY

INTRODUCTION: It is well known that ultra-endurance races such as a full distance ironman triathlon causes damage to skeletal and cardiac muscles. However, the underlying factors causing these disturbances are less investigated. In this study we investigated if there is an association between ground reaction forces, measured with accelerometry, during the marathon part of an Ironman triathlon and markers of skeletal and cardiac muscle damage. Our hypothesis was that higher ground reaction forces are positively associated with skeletal and heart muscle damage with no gender differences. The overall results of the race have been reported previously [1, 2].

1. Danielsson T, Schreyer H, Woksepp H, et al. *BMJ Open Sport Exerc Med* 2019;5:e000486
2. Danielsson T, Carlsson J, Bergman P, et al. *Scientific Reports* 2020;10:901

METHODS: Twenty (8 women) participants completed a full distance ironman triathlon (3.8 km swimming, 180 km cycling and 42 km running) and provided a full set of data and were included in the analysis. As markers for skeletal muscle damage, creatine kinase (CK) and myoglobin was analysed. As markers for cardiac muscle damage cardiac troponin t (cTnT), the N-terminal of the prohormone brain natriuretic peptide (NT-proBNP) was analysed. Ground reaction forces were estimated using an accelerometer (ActiGraph GT3x). Based on the official transition times we sliced out the raw accelerations for the marathon part of the race and calculated the mean vector magnitude (VM) expressed in milliG per second (mG/s). Due to outliers among the dependent variables, Spearman rank correlations (ρ) stratified by sex was calculated.

RESULTS: No significant association between the biomarkers and mechanical stress was observed (all $p > 0.05$).

CONCLUSION: We did not find any support for our hypothesis of a positive association between ground reaction forces and markers of skeletal and heart muscle damage. The small sample size in the groups and the fact that we did not adjust for any potential confounder in this study warrants caution in the interpretation of the results.

VAGAL SUPPRESSION AND REACTIVATION IN THE ITALIAN MEDICAL CERTIFICATE: A FIRST APPROACH

LOPES STORNILO, J., TANZI, M., RIGOLON, M., MAZZOLA, V., RODRIGUES, G.D.
AUXOLOGIC ITALIAN INSTITUTE, IRCCS

INTRODUCTION: In incremental exercise tests, a significant decrease in vagal activity occurs as exercise intensity rises. This reduction in vagal tone results from the autonomic nervous systems (ANS) response to increased physical demands. As individuals move from rest to higher exertion levels, the sympathetic nervous system becomes more dominant, leading to an elevated heart rate (HR) and reduced heart rate variability (HRV). This shift in autonomic balance highlights the body's need to deliver more oxygen and nutrients to active muscles, showcasing the complex interaction between the cardiovascular and nervous systems during exercise. Despite this understanding, insights into HRV behavior during sports medical tests for issuing exercise certificates are limited. Thus, we aimed to assess the timing of vagal suppression and its recovery during maximal tests in the Italian clinical context.

METHODS: Following the Italian Ministry of Health's suggestion, the ECGs of twenty-three healthy men who underwent an incremental test on the cycle ergometer were recorded. The protocol involves a consistent load increase of 25 W every 30 seconds until reaching 85% of the theoretical maximum heart rate ($HR_{85\%theory}$). Tests were preceded by a 1-minute resting period and a 30-second warm-up at a fixed intensity of 50 W. The following recovery phase was divided into 30 seconds of pedaling without load and 2 minutes of rest. At each phase of the protocol, the root mean square of successive beats (RMSSD) and the HR were calculated.

RESULTS: A repeated measures Friedman test confirmed that RMSSD decreased along with the increased workload required (-42% from the rest phase to the end of the test, $p < 0.001$). However, the RMSSD at the final stage of recovery did not differ from the rest phase ($p = 0.85$), nor did the RMSSD observed during the first step of the test vary from that recorded at the beginning of recovery ($p = 0.08$). Moreover, the RMSSD during the resting phase also showed a significant correlation with its counterpart at the end of the test ($\rho = 0.47$; $p = 0.025$). In parallel, a paired t-test demonstrated that the maximal HR achieved at the end of the test presented values similar to those of the $HR_{85\%theory}$ ($p > 0.05$).

CONCLUSION: The lower RMSSD value observed during the incremental step test confirms that this protocol is sufficiently stressful for the ANS without compromising the cardiovascular system. As mandated by Italian authorities, this protocol aims to determine whether the participant is suitable for competitive sports, considering the underestimation of the actual maximal HR. From the ANS perspective, it was confirmed that there was greater reactivity at the end of the recovery,

demonstrating a similar autonomic balance to the results in the resting phase. Furthermore, participants with higher RMSSD values at rest maintained elevated RMSSD levels at the end of the test, reaffirming previous findings regarding the extent of vagal suppression in maximal tests based on resting values.

DECLINE IN LEFT ATRIAL BOOSTER FUNCTION DURING A MULTI-STAGE ULTRAMARATHON RACE

PRECHTL, L., KRUMPHOLZ, A.L., KLOEMPKEN, S., INFANGER, D., SCHUETZ, U., BEER, M., SCHMIDT-TRUCKSAESS, A.
UNIVERSITY OF BASEL

INTRODUCTION: The atria make a significant contribution to ventricular filling and thus to cardiac output.

Due to regular exercise-induced volume and pressure overload endurance athletes may develop atrial dilation, leading to a reduction in atrial reservoir and booster function. This reduction of atrial function can already be observed after 16 weeks of endurance training.¹ To investigate whether changes in atrial function may also occur during a single ultra-endurance event we analysed the atrial adaptations during the 64-day TransEuropeFootRace.

METHODS: 20 athletes (18 men, 2 women, age 26-65 (50.3 ± 10.0) years) ran 4,487 km at an average of 70.1 km/day. Cardiac magnetic resonance imaging (cMRI) was obtained at three time points: T1 after 294.3 $\pm$ 134.7 km, T2 after 1735.3 $\pm$ 85.7 km and T3 after 3369.8 $\pm$ 89.7 km. 8 months after the race (Tpost) 10 athletes returned for a follow-up scan. Atrial function was analysed by longitudinal strain analysis. Since atrial function is substantially influenced by ventricular filling pressures, we also analysed left ventricular diastolic function using the ratio of mitral peak early to late diastolic filling velocity (MV E/A). We fitted linear mixed models for all strain parameters. Means of the parameters were compared pair-wise by Tukey test at all time points. Multiple imputation was used to account for uncertainty due to missing data.

RESULTS: Left and right atrial reservoir strain and right atrial booster strain remained unchanged over the course of the race. MV E/A also remained unchanged. However, we found evidence for a significant change in left atrial booster strain in both 4- (F(3; 45.83) = 3.99, p = 0.013) and 2-chamber views (F(3; 45.74) = 3.77, p = 0.017). In the 2-chamber view, left atrial booster strain decreased significantly between T2 and T3 ($20.15 \pm 4.41\%$, $15.55 \pm 6.63\%$, p = 0.045). In the 4-chamber view, there was a significant increase in left atrial booster strain between time points T2 and Tpost ($10.19 \pm 4.76\%$, $17.07 \pm 11.03\%$, p = 0.039).

CONCLUSION: Cardiac imaging provides evidence of partial decline in left atria booster strain after approximately 45 days of the TransEuropeFootRace. As the left ventricular diastolic function remained stable this decline might be intrinsic to the left atrium. A possible regeneration of left atrial booster strain is suggested by the follow-up cMRI (Tpost) of a sub-sample.

AN INTERNATIONAL DELPHI STUDY OF CLINICAL AND EXERCISE PROFESSIONALS' OPINION OF EXERCISE PRE-SCREENING AND CONTRAINDICATIONS FOR PARTICIPATING IN POSTPARTUM PHYSICAL ACTIVITY.

DAVENPORT, M., CHRISTOPHER, S., DEERING, R.E., PREVETT, C., DUFOUR, S., FORTE, M., BEAMISH, N., ADAMO, K.B., BO, K., BROCKWELL, E., BRUNET-PAGE, E., CHARI, R., DE VIVO, M., FLEMING, K., HASSAN, A., HAYMAN, M., LANE, K.N., NEIL-SZTRAMKO, S.E., MOTTOLA, M.F., SANTOS-ROCHA, R., SZUMILEWICZ, A., RUCHAT, S.M.
UNIVERSITY OF ALBERTA

INTRODUCTION: To establish expert consensus on contraindications to moderate-to-vigorous intensity physical activity (MVPA) during the first year postpartum.

METHODS: A Delphi survey (up to three rounds) of clinical and exercise professionals working with postpartum women and individuals was conducted until consensus was reached ($\geq 75\%$ agreement). Round I consisted of questions about relative and absolute contraindications to MVPA. Rounds II and III included additional questions based on the thematic coding of open-ended responses from the previous rounds. Before conducting the Delphi study, a scoping review was performed.

RESULTS: 120 participants completed Round I, 105 completed Round II, and 95 completed Round III. Consensus was reached in 46/49 (94%) statements. Twenty-four relative contraindications to MVPA were identified (loss of consciousness; neurological symptoms; renal or kidney disease; calf pain or swelling suggestive of deep vein thrombosis; severe abdominal pain; vaginal bleeding not associated with menses; postpartum cardiomyopathy; caesarean section with symptoms that worsen with MVPA; unstable hypertension; an eating disorder; malnutrition; anemia; excessive fatigue; fractures or other significant musculoskeletal injuries; hemodynamic instability; breathing difficulties; acute systemic infection accompanied by fever, body aches, or swollen lymph glands; the new onset of chest pain, discomfort, and other angina-like symptoms with exertion; dizziness or lightheadedness during MVPA; new symptoms of heart disease, stroke; and other medical or physical conditions that may affect the ability to be physically active).

CONCLUSION: This Delphi study recommends relative contraindications to MVPA for the first year postpartum, as well as biopsychosocial screening to assess readiness to engage in MVPA.

ARTIFICIAL INTELLIGENCE-PREDICTED ELECTROCARDIOGRAPHIC AGE IN ATHLETES: PRELIMINARY FINDINGS

MARCOLINO, M., RIBEIRO, A.L., NEVES, A.N., SANTOS, A.G.R., ALEIXO, H.C., MELLO, D.B., SILVA, A.W.O., MAINENTI, M.R.M.
UNIVERSIDADE FEDERAL DE MINAS GERAIS

INTRODUCTION: Estimation of biological age using neural networks applied to electrocardiograms (AI-ECG) has been studied as a potential biomarker of accelerated aging, but studies assessing AI-ECG in athletes are lacking. This preliminary study aimed to estimate AI-ECG in athletes and compare it to chronological age.

METHODS: Cross-sectional study including athletes aged 18 years or older. A questionnaire was applied to assess demographic data, sports modality, weekly training volume, sleep and sports practice time, comorbidities, lifestyle and the Portuguese-adapted version of the "Depression, Anxiety and Stress Scale-21", in addition to recording a 12-lead digital ECG. An ECG-AI was estimated by the neural network. The Δ age was calculated as the difference between ECG-AI and chronological age. Data were presented descriptively as median and interquartile range (IQR). The multivariable linear regression model included as environmental variations predictors of Δ age: practice time, weekly training time, daily hours of sleep and DASS-2 score, obtained by adding the total score of the 14 items of the aforementioned scale. A p-value <0.05 was considered statistically significant

RESULTS: Forty-six athletes were recruited, with a median age of 27.8 years (IQR 24.5–35.5), 65.2% men, median time of sports practice of 13.0 years (IQR 10.0–17.0), median weekly training time of 20.0 hours (IQR 12.0–25.0), median daily sleep time of 7.0 hours (IQR 7.0–8.0). The median AI-ECG was 27.2 years (IQR 26.0–31.3), with no significant difference in relation to chronological age ($p=0.656$). Δ age was 0.32 years (IQR -4.35–4.66) and the median DASS-21 score was 5.50 (IQR 1.75–12.0). The multivariate regression model presented R^2 of 0.179, with a sample power of 55.2%. The time of sports practice ($B = -0.282$, $p = 0.085$) and the DASS score ($B = 0.215$, $p = 0.095$) presented associations close to significance, while the other variables were not statistically significant ($p > 0.05$).

CONCLUSION: This preliminary study suggests that sports practice may contribute to healthy biological aging, although variations in Δ age are observed depending on the sport modality and training intensity. However, the preliminary nature of the data highlights the importance of studies with larger samples and longitudinal methodologies.

THE IMPACT OF REPEATED TBIS ON THE HEALTH OF PROFESSIONAL RUGBY PLAYERS, WITH A FOCUS ON THE ROLE OF CIRCULATING MTDNA.

SELLERI, V., DALISERA, R., SINIGAGLIA, G., ZANINI, G., MICHELONI, G., SAVINO, G., MATTIOLI, A.V., PINTI, M., NASI, M.
UNIVERSITY OF MODENA AND REGGIO EMILIA

INTRODUCTION: Rugby is a high-contact sport with repeated traumatic brain injuries (TBIs), more in matches than in training, especially among forwards (FWD) players. Rugby players also experience contusions, muscular, and joint injuries, contributing to systemic inflammation. In this context, mitochondrial DNA (mtDNA) can be released into circulation as a damage-associated molecular pattern, regulating the inflammatory cascade. Since the biological role of mtDNA in contact sports remains unclear, we analyzed three mtDNA forms: within mitochondria (Fraction 1), bound to protein (Fraction 2), and naked (Fraction 3). Correlations between circulating mtDNA, soluble factors, blood parameters, and TBIs suffered were investigated.

METHODS: Thirteen male professional rugby players were monitored over two matches during the 2023-24 season. Venous blood samples were collected before (T0, T2), immediately after (T1, T3) each match, and one month post-season (T4). Fifty-two hematochemical parameters were analyzed, and plasma and PBMCs were isolated. Total DNA was extracted from 200 μ L of plasma, and mtDNA was quantified using Droplet Digital PCR (ddPCR). Neurofilament light chain (NFL) and several cytokines (IL-6, IL-8, TNF- α) were quantified using ELISA technology. Flow cytometry was performed to assess immune receptor expression (CD200R, CD36, CD11a) and monocyte subset distribution (classical, intermediate, non-classical). Correlations between circulating mtDNA, soluble factors, and blood parameters were evaluated using the Spearman correlation test and linear regression analysis.

RESULTS: MtDNA levels progressively increased from T0 to T4, in both the total population and the FWD players group. Data showed higher mtDNA levels after each match in both Fraction 2 and 3, and at T4 compared to T0. IL-6 and IL-8 levels significantly increased after each match, while TNF- α increased only at T3. NFL levels were significantly higher post-match in both the total population and the FWD players group but returned to pre-match values. Baseline mtDNA levels correlated with mean corpuscular hemoglobin, somatotropin, uric acid, triglycerides, LDL, glucose, cortisol, and key immune cells involved in the inflammatory response at T1 and T3. GPS data indicated that mtDNA levels at T2 ($p=0.0046$, $R^2=0.7061$) and T3 ($p=0.0291$, $R^2=0.4682$) correlated with the number of high-powered actions during the first match in the total cohort. In FWD players, mtDNA levels at T1 correlated with total contact involvement post-match ($p=0.0446$, $R^2=0.6761$).

CONCLUSION: Circulating mtDNA increased after each match and progressively over the season, suggesting a cumulative effect. The observed correlations between baseline mtDNA levels, blood parameters, and soluble factors depending on TBIs indicate that mtDNA, with other inflammatory markers, could serve as an early marker of cell damage, inflammation, and brain injury. This may be crucial for preventing the onset and progression of sports-related neurodegenerative diseases.

MISPERCEPTION OF OPPONENT SPATIAL INTERACTIONS AS A RISK FACTOR FOR DECISION ERRORS LEADING TO NON-CONTACT ACL INJURIES IN TEAM SPORTS

OGASAWARA, I., IWASAKI, S., NAKATA, K.

THE UNIVERSITY OF OSAKA

INTRODUCTION: Non-contact anterior cruciate ligament (ACL) injury is one of the most severe sports injuries. Although previous studies have quantified the mechanism of ACL injuries in biomechanical terms, the contribution of unquantifiable factors, such as the association between an athlete's ongoing cognition and eventual biomechanical risks, remains unexplored. This study aimed to identify the cognitive risks underlying non-contact ACL injuries in team sports through detailed video analyses conducted by experts, combined with semi-structured interviews.

METHODS: Six elite handball players (M:F = 3:3) and one elite female rugby player with a history of non-contact ACL injuries participated in this study. They provided videos capturing their injury events. Two experts—coaches of the Japan national handball team, each with over ten years of experience and biomechanics professional—reviewed these videos. In addition to analyzing biomechanical features (contact type: direct/indirect/non-contact, foot strike pattern, knee kinematics, and torso orientation) at the moment of ACL injury, the experts qualitatively assessed whether unreasonable decision-making (such as inappropriate strategic choices and associated body movements) based on their professional sports-specific knowledge. Additionally, semi-structured interviews were conducted to explore the athletes' reasoning for executing the final movement that led to their injuries.

RESULTS: In video reviews, the experts identified clear instances of unreasonable decision-making in six out of the seven cases. The most common decision error was attempting a one-on-one maneuver despite being positioned either too close to or too far from an opponent (six cases), followed by an attempt to break through a narrow space surrounded by opponents (two cases). In both scenarios, the space created by the opponents indirectly interfered with the athletes' body configurations, leading to risky biomechanics, such as loss of torso balance, and rapid heel strikes. The experts concluded that misperception of spatial interactions with opponents may predispose athletes to unreasonable decision-making, increasing the risk of ACL injury. During the interviews, the athletes were able to clearly describe their injury situations. They reported that, at the moment of the ACL injury, their attentional focus was entirely devoted to achieving game-specific success, such as scoring a goal with a preferred shooting style or evading opponents using quick change-of-direction techniques. However, video evidence did not always support the rationality of these decisions, as the spatial interactions with opponents suggested a mismatch between their situational perception and actual physical constraints.

CONCLUSION: This study aimed to explore cognitive risks underlying non-contact ACL injuries in team sports. The discrepancy between perceived spatial interaction with opponents and actual situation may have led to suboptimal movement choices, ultimately contributing to their injuries.

A SURVEY ON LIFESTYLE HABITS, GYNECOLOGICAL VISITS, AND MEDICATION USE IN FEMALE UNIVERSITY STUDENT-ATHLETES WITH DYSMENORRHEA

MAKIO, S., UCHINO, S., KOMATSU, T., SOMEYA, Y., AOYAGI, M., NARAOKA, Y., KAWASE, A., TANIGAWA, A., MATSUI, N., TAKAZAWA, Y.

JUNTENDO UNIVERSITY

INTRODUCTION: Dysmenorrhea is associated with lifestyle habits. However, the relationship between dysmenorrhea and lifestyle habits in female university student-athletes, as well as the actual measures taken to manage it, remains unclear.

Purpose: This study aims to clarify the relationship between dysmenorrhea and lifestyle habits (skipping meals, sleep duration, and exercise habits) in female university student-athletes, as well as the actual conditions of gynecological consultations and the use of medication.

METHODS: A survey was conducted using Google Forms targeting female university student-athletes participating in competitive sports. The survey examined the relationship between dysmenorrhea and lifestyle habits (meal skipping, sleep duration and exercise time), as well as gynecological visit history, oral medication use, and the impact of dysmenorrhea on daily life. Dysmenorrhea was evaluated based on whether individuals experienced symptoms such as lower abdominal pain or lower back pain that interfered with daily life. Participants who reported experiencing symptoms that affected their daily activities were classified as having dysmenorrhea.

RESULTS: A total of 316 responses were collected (age: 19.0 ± 1.0 years). The prevalence of dysmenorrhea was 23.4% (74/316). Comparisons based on the presence or absence of dysmenorrhea showed no significant differences in lifestyle habits (skipping meals: $p=0.127$, sleep duration: $p=0.544$) or exercise time ($p=0.601$). Among individuals with dysmenorrhea, 21.6% (16/74) had a history of visiting a gynecologist, and 85.1% (63/74) used oral medication. While 74.3% (55/74) of symptomatic individuals experienced no disruptions in daily life due to medication use, 25.7% (19/74) still faced difficulties despite using oral medication or because they were not using it.

CONCLUSION: 23.4% of female university student-athletes had dysmenorrhea, and there was no association between dysmenorrhea and lifestyle habits or exercise time. While about 75% of those with dysmenorrhea experienced no disruption in daily life due to medication use, approximately 25% experienced disruptions.

CP-MH04 Ageing I

EFFECT OF PROGRESSIVE MULTICOMPONENT EXERCISE PROGRAM ON PHYSICAL FITNESS, COGNITION AND QUALITY OF LIFE IN FRAIL ELDERLY

TU, G., LIAO, B., LIU, L., CHEN, W.

GUANGZHOU SPORT UNIVERSITY

INTRODUCTION: Frailty is a complex and age-related syndrome which leads to an increased risk of falls or other adverse events in the old adult. The characteristics of frailty include unintentional weight loss, self-reported exhaustion, weakness, slow walking speed, and low physical activity, which are highly associated with physical fitness. In addition, the physical decline of the frail elderly is frequently linked to cognitive impairments. Multicomponent exercise intervention is an effective strategy for improving both the physical function and cognitive ability. However, there is still a lack of best exercise prescription which is specific and implementable for frail elderly.

METHODS: A total of 130 enrolled frail elderly were randomly divided into the control group (CG, n = 68) and the exercise group (EG, n = 62) according to gender, age, Sports Self-Efficacy (SSE) and Short Physical Performance Battery (SPPB) by the matched group design. A 3-month progressive multicomponent exercise program which covering aspects such as gait training, aerobic exercise, resistance and flexibility training, balance, and cognitive training were conducted in the EG group while regular health education and care was conducted in the CG group. The SPPB and Senior Fitness Test (SFT), Chinese version of Montreal Cognitive Assessment-Basic (MoCA-BC), and the 36-Item Short Form Health Survey (SF-36) were adopted to assess the physical fitness, cognitive ability and quality of life respectively. Chi-square test was used to compare categorical variables. Independent sample t test was used for comparison between the two groups, and paired sample t test was used before and after intervention comparison.

RESULTS: After 3-month progressive multicomponent exercise intervention, the scores of gait speed, chair stand test and the total scores of SPPB, the walked distance, walking speed and step size of 6MWT, back scratch, chair sit and reach, 30s arm curl, 30s sit to stand and TUG test of SFT, the total score and the delayed recall domain of MoCA-BC, and the physical function (PF), vitality (VT), role emotional (RE) and mental health (MH) domains of SF-36 in the EG group were significantly improved both compared with baseline and CG group; the verbal fluency domain of MoCA-BC in EG group was significantly improved compared with CG group; the scores of balance test of SPPB in both the CG group and EG group, the 30s sit to stand and TUG test of SFT, the conceptual thinking domain of MoCA-BC in the CG group, and the role physical (RP), general health (GH) domains of SF-36 in EG group were significantly improved compared with baseline; while the verbal fluency of MoCA-BC in the CG group was significantly weakened compared with baseline.

CONCLUSION: The progressive multicomponent exercise program designed in this study increases the physical fitness, cognition ability and the quality of life in the frail elderly, which may provide a feasible program for the health management of local frail communities.

DEMONSTRATING THE EFFECTS ON FUNCTIONALITY AFTER 10-WEEKS OF TRAINING WITH BLOOD FLOW RESTRICTION COMBINED WITH LOW INTENSITY RESISTANCE TRAINING ON OLDER ADULTS.

PRESTA, D., CHEN, E., BERGDAHL, A.

CONCORDIA UNIVERSITY

INTRODUCTION: Blood Flow Restriction (BFR) training entails limiting perfusion to specific body areas, allowing low-intensity exercise to simulate the effects of high-intensity workouts. Combining BFR and online exercise classes is a novel approach of potentially improving both effectiveness and accessibility of training to an older population. It is essential to maintain strength as we age to avoid or manage physiological conditions like sarcopenia and osteoporosis. The goal of this study is to investigate if ten weeks of online low-intensity resistance training, will lead to greater improvements in functionality among older adults using BFR straps compared to those who do not.

METHODS: Men and women (N=25) with a mean age of 70 ± 5.6 were recruited in the Montreal area. They performed ten weeks of online, low-intensity resistance training twice a week using the Zoom platform. The study design was a randomized control trial with a pre, mid and post- testing session. Functionality was measured by: 30-second sit to stand (STS), 8ft timed up and go (TUG) and the calf raise senior (CRS) test

RESULTS: Both BFR and CON improved significantly at all intervals for the 30-second STS (BFR: pre-mid $p < 0.001$, mid-post $p = 0.023$, pre-post $p < 0.001$; CON: pre-mid $p = 0.028$, mid-post $p < 0.001$, pre-post $p < 0.001$). The CRS showed both groups improving significantly at all intervals (BFR: pre-mid $p < 0.001$, mid-post $p < 0.001$, pre-post $p < 0.001$; CON: pre-mid $p = 0.002$, mid-post $p = 0.003$, pre-post $p < 0.001$). The TUG revealed the BFR improved from mid-post ($p = 0.017$) and pre-post ($p = 0.003$), with no change in CON ($p > 0.315$). BFR showed no significant change pre-mid ($p = 0.096$).

CONCLUSION: The BFR group demonstrated significantly greater improvements in functionality compared to the control group, particularly in the TUG test, indicating enhanced mobility. These findings suggest that BFR training is an effective method for improving strength and functionality in older adults, offering a promising strategy to maintain independence and quality of life in aging populations

ENHANCING EXERCISE ADHERENCE AND PHYSICAL FUNCTION IN FRAIL OLDER ADULTS THROUGH A SMARTWATCH AND ISOKINETIC STRENGTH TRAINING

CHEN, T., HONG, S.W., WANG, S.Y., HUANG, S.F., HUANG, K.C.

TZU CHI UNIVERSITY

INTRODUCTION: Regular exercise is essential for preventing and alleviating disability-related symptoms by preserving muscle strength and mobility in older adults. This study assessed frailty risk through evaluations of daily life function, the Otassha 21-item questionnaire, and physical activity monitoring. Participants underwent physical fitness testing and gait analysis to establish baseline physical function. A whole-body isokinetic strength training program was implemented to enhance muscle strength and mobility in frail older adults.

METHODS: Individuals aged 65 and older with declining physical function were recruited through health screenings and questionnaires. Subjects were assigned to either a control group (CON, n=7) or a training group (TR, n=14) based on willingness and mobility levels. The CON group completed pre- and post-tests without training, while the TR group underwent a supervised 12-week isokinetic strength training program, followed by post-training assessments. A 12-week follow-up period without further intervention was conducted, culminating in a final assessment. The subjects heart rate (HR), steps and physical activity were recorded daily for 24 hours by a smartwatch for 24 weeks.

RESULTS: The TR group showed significant improvements in physical function. Among subjects with high fall risk decreased from 5 to 0 post-training ($p < 0.05$). Additionally, the number of subjects classified as low-risk for frailty increased from 0 to 10 after training and follow-up ($p < 0.05$). Muscle strength and mobility assessments revealed significant gains in single-leg stance duration, two-minute step test performance, and 6-minute walking distance in the TR group compared to the CON group ($p < 0.05$). However, these improvements were not sustained at the 12-week follow-up ($p > 0.05$). Heel-to-toe walking performance remained significantly better in the TR group post-training and at follow-up ($p < 0.05$), while the CON group showed a decline in step count. Daily step counts were consistently higher in the TR group at weeks 1, 4, 6, 8, and 18 ($p < 0.05$). Gait analysis showed that after training, the TR group had increased hip flexion and reduced hip joint torque ($p < 0.05$), indicating improved lower limb elevation and walking ability. HR monitoring revealed a downward trend in the average HR between 6:00-7:00 AM post-training and follow-up in the TR group but not in the CON group. This decrease may be linked to improved walking efficiency and reduced exertion levels during daily activities.

CONCLUSION: A 12-week isokinetic strength training program significantly improved walking ability and balance in older adults, preventing and delaying disability. These findings suggest that smartwatches are beneficial in maintaining exercise adherence and promoting long-term health in elderly populations.

GAIT ABILITY AND STRIDE LENGTH IN OLDER ADULTS: FOCUS ON HEEL CONTACT AND TOE-OFF

SAKAI, T., NAKANO, T., HAYASHI, Y., MURAYAMA, T., OYAMA, Y., KAMEYAMA, M., SAKAGUCHI, Y.

NAGOYA GAKUIN UNIVERSITY

INTRODUCTION: Falls and stumbling are major causes of reduced quality of life among older adults, which may be a result of a decline in physical function due to aging, disease, and the effects of medications. To prevent stumbling and falls, it is necessary to reduce the decline in physical functions such as walking ability, balance, and muscle strength. However, few studies have clarified the extent of such prevention. Therefore, this study focused on stride length as a measure of gait ability and examined the characteristics of the feet at contact and liftoff as a function of the difference in stride length.

METHODS: The participants were 31 men and women aged 65 years or older. Prior to the study, the participants were informed of the details of the study and protection of their personal information, and their consent was obtained. A simple gait analysis system (RehaGait) was attached to the dorsal surfaces of both feet. After calibrating the device, the participants performed two trials each of walking with stride lengths of 0 cm (stepping in place), 10 cm, 20 cm, 30 cm, 40 cm, 50 cm, 60 cm, and 70 cm, as well as normal walking and maximum walking, in random order on the floor. During the trials, the moving distance, stride length, speed, cadence, walking cycle, foot-to-floor angle with the heel as the axis of rotation at heel-strike, and foot-to-floor angle with the toe as the axis of rotation at toe-off (in both sagittal planes) were measured. The average of two trials was evaluated. In addition, a tape was placed on the floor to calculate stride length; however, trials in which the foot landed on the tape were invalidated. Kruskal-Wallis test and Bonferroni multiple comparisons were used to compare the conditions. Statistical analyses were performed using IBM SPSS Statistics version 26.0, and statistical significance was set at 5%.

RESULTS: Significant differences were observed in the plantar floor angle at the time of contact and lift-off when the stride length was less than 40 cm compared with normal walking. This suggests that as the stride length increases, the heel comes in contact with the ground, and at the time of liftoff, the heel can be lifted off the ground and the toes can contact the ground to kick off. The height of the raised foot was less than 10 cm, except in the 0 cm trial. In addition, the height of the raised foot in the 10 and 20 cm trials was lower than that during normal walking ($p < 0.05$).

CONCLUSION: In this study, individuals with a stride length of 50 cm showed that heel contact occurred and the ground could be kicked off. This highlights the importance of ensuring an appropriate stride length for gait assistance and fall prevention among older adults. In the future, more comprehensive knowledge can be gained by studying individuals with a wide range of characteristics, including those with impaired physical function, and by studying their relationships with physical functions other than walking in different regions.

RELATIONSHIP BETWEEN A REACTION STEP TEST AND HISTORY OR FEAR OF FALL IN THE ELDERLY

OYAMA, Y., KAMEOKA, M., SAKAI, T., SAKAGUCHI, Y., NAKANO, T., MURAYAMA, T.

TOIN UNIVERSITY OF YOKOHAMA

INTRODUCTION: To prevent falls, it is necessary to recognize obstacles, react to them, and apply appropriate strategies in relation to the concrete situation. A stepping strategy serves as the final measure for avoiding falls, and proper stepping movements can help reduce fall risk in older adults. Two abilities are essential for fall avoidance movements: agility, enabling a quick reaction to disturbances, and equilibrium, which later controls its posture. Previous studies have separately examined the relationship between falls and agility or equilibrium, but they have only considered individual abilities. To avoid falls, it is crucial to comprehensively evaluate movements, as fall prevention involves both rapid physical reactions and appropriate strategies of posture control. We developed a reaction step test that integrates agility and equilibrium and confirmed its reliability and validity. However, its relationship with falls has not yet been examined. This study is intended to investigate the relationship between the reaction step test and the history or fear of fall.

METHODS: A total of 57 elderly participants (24 men, 33 women; mean age 76.4 ± 6.1 years) performed the reaction step test. In this test, the participants stood upright on a pressure-sensitive mat in an upright position and were instructed to take a quick step forward onto a stabilometer following the onset of a visual stimulus. After stepping forward, they were required to stand on both legs for 10 s. The time from stimulus onset to foot-off was evaluated as agility, while the post-step center of pressure sway while standing on both legs was evaluated as equilibrium. An independent t-test was conducted to compare the results of the reaction step between groups based on history or fear of fall.

RESULTS: Both agility and equilibrium were significantly decreased in the group that had a history of falls. On the other hand, the group with fear of fall had significantly less agility, although it showed no difference in equilibrium.

CONCLUSION: The reaction step test, which evaluates agility and equilibrium in a series of movements, may be an effective method of assessing fall risk. In particular, agility and equilibrium were both lower in the group that had a history of falls, which indicates a decreased ability to avoid falls. In addition, only agility was decreased in the group with a fear of fall, suggesting that fall anxiety could influence the delay in the initiation of movement.

PHYSICAL ACTIVITY OF ANY INTENSITY PER DAY AS A PREDICTOR OF MORTALITY AND LONG-TERM CARE NEEDS AMONG COMMUNITY-LIVING OLDER PEOPLE IN JAPAN: A 7-YEAR FOLLOW-UP STUDY

KOZAKAI, R., UEDA, T., SASAKI, H., IDE, K., HANAI, A., ODA, S., TAKADA, S., HONDA, R., OGAWA, H., ODAJIMA, M., AIUCHI, T., OKITA, K.

HOKUSHO UNIVERSITY

INTRODUCTION: Physical activity is a crucial component of healthy aging. The WHO guidelines (2020) recommend regular physical activity and replacing sedentary time with physical activity of any intensity for older adults. However, research is still limited in demonstrating the association of physical activity engagement with mortality and long-term care needs as indicators of healthy life expectancy. The purpose of the present study was to assess different definitions of physical activity engagement and determine whether these physical activities predict mortality and long-term care needs over a 7-year period among community-living older people in Japan.

METHODS: Participants included 322 randomly selected men and women (aged 65 to 80 years at baseline) from a city in Hokkaido, the northern part of Japan. The participants had taken part in the baseline survey and had not relocated during the 7-year follow-up period. The incidence of death, long-term care needs and hospitalization was confirmed by city officials. Physical activity was assessed using a questionnaire, which included the following definitions: engagement in a local exercise class (multicomponent activities, once a week), exercise habits (moderate-intensity: at least 30 mins per session, twice a week; light-intensity: at least 5 mins per session, 4 times a week), and daily physical activity (moderate-intensity: at least 60 mins per week, every week; any-intensity: at least 40 mins per day, every day). Multiple logistic regression models were used to estimate odds ratio (OR) and 95% confidence interval (CI) for the incidence of death or long-term care needs. The study was approved by the Ethical Committee of Hokusho University, and all participants provided written informed consent.

RESULTS: During the follow-up period, 68 participants (21.1%) either died or required long-term care. Participants who engaged in at least 40 mins of physical activity of any-intensity per day had significantly lower incidence of death or long-term care needs compared to those who did not (40.0% vs. 54.8%, $p=.034$). The OR (95%CI) for developing long-term care or death among those who did not engage in at least 40 mins of physical activity of any-intensity per day were 1.82 (1.04-3.16, $p=.035$). After controlling for age and sex, the association was slightly attenuated but remained a trend [the adjusted OR (95%CI); 1.71 (0.96-3.04), $p=.067$]. No significant associations were found between other physical activity engagement and the incidence of mortality or long-term care needs.

CONCLUSION: Our findings suggested that engaging in at least 40 minutes of physical activity of any-intensity per day is more likely to prolong a healthy lifespan among community-living older people in Japan.

THE ACUTE RESPONSE OF BRAIN-DERIVED NEUROTROPHIC FACTOR IN PLASMA DURING EXERCISE AND RECOVERY IN DIFFERENT ENVIRONMENTS IN OLDER ADULTS

AHNESJÖ, J., BODÉN, J., BERGMAN, P., KARLSSON, P.S., AHNESJÖ, J.

DEPARTMENT OF SPORT SCIENCE

INTRODUCTION: Brain-derived neurotrophic factor (BDNF) is a protein which has been described as a marker of brain health, cognitive functioning, and neuronal plasticity. Physical activity promotes several aspects of health and upregulates expression of BDNF. Evidence also indicates positive effects on health measures from exposure to outdoors environments which sparks the question whether exercising outdoors have greater effects on BDNF than exercising indoors.

METHODS: A randomised clinical cross-over trial was conducted with 42 healthy participants over the age of 65 years who underwent 20 minutes of standardised ergometer cycling in three different settings (indoors, simulated outdoors, outdoors). BDNF was measured in plasma in advance of, immediately following exercise and at 60 and 120 minutes of recovery.

RESULTS: Levels of BDNF are elevated and thereafter reduced below baseline after exercising. BDNF-levels did not vary significantly between the three environments. No interaction between the two factors (environment, exercise) were found.

CONCLUSION: Our results suggests that brain health, cognitive functioning, and neuronal plasticity, measured as levels of plasma BDNF, may benefit from exercise. We could not detect any environmental effect on BDNF in this experiment, however, it is possible that BDNF may be influenced by environment but not measurable adjacent to physical activity.

THE RELATIONSHIP OF MUSCLE QUALITY WITH MUSCLE STRENGTH AND WALKING SPEED IN OLDER INDIVIDUALS.

OHTA, M., MITSUYAMA, H., YOSHIKO, A.

CHUKYO UNIVERSITY

INTRODUCTION: Muscle quality, which is determined by the content of adipose and connective tissues within skeletal muscle and muscle stiffness, has been assessed using ultrasound echo intensity and shear modulus. Recent studies have reported that aging is one of the factors that affect muscle quality negatively, implying that muscle echo intensity increases and muscle shear modulus decreases with aging. Therefore, in order for older individuals to live a healthy life with a high physical function, it is necessary to maintain and manage not only muscle quantity, but also muscle quality. However, few studies have investigated the relationship between muscle quality and physical function in older individuals using both muscle echo intensity and shear modulus. Thus, the purpose of this study was to investigate which of the two muscle quality indicators, muscle echo intensity and muscle shear modulus, is more strongly related to physical function, such as muscle strength and walking ability.

METHODS: Twenty-six men and women, aged 60 to 81 years, participated in this study. We focused on the thigh and lower-leg muscles and measured muscle thickness as the parameter of muscle quantity, and echo intensity and muscle shear modulus as the parameters of muscle quality using B-mode ultrasound image and ultrasound shear wave elastography. Knee extension peak torque and maximum walking speed were measured as the parameters of physical function. Stepwise multiple regression analysis was performed with knee extension peak torque and maximum walking speed as dependent variables, and muscle quantity and quality as independent variables.

RESULTS: For knee extension peak torque, muscle thickness of the vastus intermedius and the shear modulus of the rectus femoris were selected as independent variables ($R^2 = 0.309$). For maximum walking speed, only the echo intensity of the vastus intermedius was selected as an independent variable ($R^2 = 0.352$).

CONCLUSION: We showed that the higher muscle shear modulus was related to greater force exertion. As shown in previous studies, a higher shear modulus indicated a lower amount of adipose and connective tissues within the skeletal muscle. Although muscle thickness was not selected as an independent variable for maximum walking speed, echo intensity is negatively related to walking speed, implying that higher echo intensity indicated lower walking function. These results suggest that physical function is better explained by considering not only muscle quantity but also quality in the assessment of physical function. In conclusion, this study suggests that echo intensity and shear modulus contribute to physical function in older individuals; however, their relative contribution varies depending on the specific physical functions we assessed.

WATCH YOUR STEP! OLDER ADULTS INCREASE RELATIVE MUSCLE ACTIVITY DURING WALKING TASKS.

INNS, T., PINA, I., MACGREGOR, L., DUDCHENKO, P., CROCKETT, R., HUNTER, A.

NOTTINGHAM TRENT UNIVERSITY

INTRODUCTION: Age-related changes in walking performance are established risk factors for reduced independence and mortality (White et al., 2013). This study investigated age-related differences in muscle activation during walking tasks to highlight potential targets for future intervention.

METHODS: 31 young (18-29), 17 middle aged (40-59) and 35 older (60+) adults carried out 4-minute walking trials over a flat surface and separately over an uneven surface. A 10 m track was used with turns included, and triangular prisms placed at random under the mat to simulate an uneven surface. Surface electromyography (Biopac Systems Inc, Goleta US) was recorded during the trials on vastus lateralis (VL) and tibialis anterior (TA) muscles of the right leg.

RESULTS: There was a significant main effect of age for the TA during the loading phase ($F(2,77)=6.19$, $p<0.01$, $\eta^2=0.467$), with post-hoc testing showing older adults having greater activation during this phase vs. young ($t(77)=2.98$, $p=0.012$) and middle-aged ($t(77)=2.86$, $p=0.017$) adults. During the mid-stance phase, there were significant main effects of age for the VL ($F(2,77)=5.09$, $p<0.01$, $\eta^2=0.478$), with older adults displaying greater activation compared to young adults ($t(77)=2.87$, $p=0.016$). This was also the case in the TA, with a main effect of age ($F(2,77)=3.82$, $p=0.026$, $\eta^2=0.507$) reflecting greater activation in older compared to young adults ($t(77)=2.50$, $p=0.044$). A significant interaction was observed in the TA ($F(2,77)=4.74$, $p=0.011$, $\eta^2=0.110$), with older adults expressing a greater activation on the uneven surface than young adults ($t(154)=2.83$).

CONCLUSION: These findings highlight a greater muscle activation of knee extensors and dorsiflexors in older adults during normal gait cycles over a flat surface. Greater muscle activity during walking relates to increased muscular demand (Hortobágyi et al., 2011), in turn linked to decreased daily stepping time and sit-to-stand transitions in older adults (LaRoche et al., 2018). To combat this, muscle strengthening interventions are warranted to improve functional capacity to ensure prolonged mobility and crucially, independent living, in older age.

CP-MH05 Cancer I

CARDIOPULMONARY EXERCISE TEST AND FATIGUE OF CANCER PATIENTS RECEIVING IMMUNOTHERAPY

KRANJC, D., ZUBAC, D., NIELS, T.

SCIENCE AND RESEARCH CENTRE KOPER

INTRODUCTION: Cancer is acknowledged as the second greatest cause of death globally [1] and has enormous economic and societal impacts. Its treatments significantly impact patients physical and mental health, but it remains unclear how the novel treatment – immunotherapy, influences cardiorespiratory function and perceived levels of fatigue in cancer populations. Studies have shown that cancer-related fatigue (CRF) is associated with decreased cardiopulmonary performance, especially VO₂ peak [2]. Understanding the relationship between them can be beneficial for future exercise interventions for cancer patients undergoing immunotherapy.

METHODS: We conducted a cross-sectional study involving three age-matched groups: immunotherapy cancer patients (IMMU) (n=11; 36.36% females), cancer survivors (SUR) (n=12; 50% females), and healthy controls (HC) (n=16; 37.5% females). Cardiopulmonary exercise testing (CPET) was used to assess VO₂ peak, VCO₂, VE, maximal heart rate (HR_{max}), peak power output (PPO), and respiratory exchange ratio (RER). Self-reported fatigue was evaluated using the Multidimensional Fatigue Inventory (MFI-20). This study aimed to compare the CPET performance and fatigue levels among IMMU, SUR, and HC and search for possible correlations between fatigue and CPET parameters.

RESULTS: Significant differences ($p < 0.05$) were found between the IMMU and HC and SUR and HC when comparing the values of CPET (VO₂ peak, VCO₂, VE, PPO) and fatigue levels (general and physical fatigue, reduced activity). IMMU exhibited descriptively higher VO₂ peak values (mean: 31.09 ± 4.81 mL·kg⁻¹·min⁻¹) than SUR (mean: 28.33 ± 5.43 mL·kg⁻¹·min⁻¹) but lower than HC (mean: 39.75 ± 7.11 mL·kg⁻¹·min⁻¹). The highest fatigue levels were observed in IMMU compared to SUR, which showed fatigue levels comparable to HC. Increased VO₂ correlated with higher generalized fatigue ($p = 0.636$; $p = 0.048$), while VCO₂ ($p = 0.793$; $p = 0.006$), VE ($p = 0.652$; $p = 0.041$), and RER ($p = 0.688$; $p = 0.028$) correlated with higher mental fatigue in IMMU. Lower reduced activity was correlated to a higher VO₂ peak ($p = 0.590$; $p = 0.044$) in the SUR group.

CONCLUSION: The IMMU group showed tendencies of better CPET performance but significantly higher levels of fatigue than the SUR group, even though they were still receiving ongoing anticancer treatment. These findings indicate that CPET is not the only indicator of chronic fatigue development in cancer-affected populations, especially under immunotherapy treatment.

RESPONSE OF MYOKINES IN BREAST CANCER PATIENTS IS DEPENDENT ON THE MODALITY OF ACUTE EXERCISE

LAIZANE, L., KLAVINA, A., ZOLOVS, M., REIHMANE, D.

RIGA STRADIŅŠ UNIVERSITY

INTRODUCTION: Physical activity influences anticancer effects (ACE) indirectly by reducing cancer risk factors like sex hormones, body fat, and inflammation (doi:10.1038/nrc2325). Preclinical studies show direct effects on cancer cells, such as reduced proliferation (doi:10.1016/j.cmet.2017.09.015). These effects may be mediated by myokines like IL-6, which can inhibit proliferation and induce apoptosis in breast cancer (BC) (doi:10.1515/tjb-2020-0508) and colon cancer cells (doi:10.1002/ijc.33982). Oncostatin M (OSM) and SPARC can suppress or promote cancer growth depending on the type of cancer. Exercise also stimulates release of BDNF, and FGF21, which have systemic or direct ACE effects (doi:10.1016/j.bbcan.2022.188761). This pilot study examined effect of acute exercise on serum myokine levels in BC survivors. The focus was on markers associated with cancer progression, immune response, and metabolism, including cytokines.

METHODS: Seven women (age 44.7 ± 7.76 years, BMI 24.4 (23.1; 30.3), 6-12 months post-BC treatment). Modified Bruce protocol was used to assess HRpeak and VO2peak (UNCCRI Treadmill Protocol). VO2peak attainment was determined based on modified Borg scale (fatigue rating ≥ 8), and/or RER ≥ 1.1 , and tester's confirmation of protocol termination. In the following weeks subjects completed three high-intensity exercise protocols (85–95% heart rate reserve) with different modalities: interval, continuous, and incremental. Blood samples were obtained before and immediately after each exercise session. Levels of IL-6, OSM, FGF-21, SPARC, and BDNF were analyzed using the Human Myokine Magnetic Bead Panel (HMYOMAG-56K, Millipore, Billerica, MA, USA) on a Magpix analyzer (Austin, TX, USA). After checking normality mixed-design ANOVA and Post-hoc comparisons were used for data analysis.

RESULTS: During VO2peak estimation RER reached 1.14 ± 0.0698 , ventilation (VE) was 77 ± 7.47 L/min and VO2peak 29.1 ± 2.93 ml/kg/min. Data analysis revealed no significant interaction between intervention and time for any of the evaluated biomarkers ($p > 0.05$). Furthermore, post-hoc comparisons showed no significant differences between interventions or time points for any biomarker (all $p > 0.05$). However, each patient showed a different intra-individual response to various high-intensity exercise modalities, with varying trends and magnitudes of change. For example, BDNF values before vs after the training session for one of the patients were as follows: interval training - 18,914.8 vs 6,689.3 pg/mL; continuous exercise - 13,551.4 vs 14,891.5 pg/mL; incremental exercise - 6,813.5 vs 11,788.1 pg/mL, correspondingly.

CONCLUSION: None of the high-intensity exercise modalities resulted in significant systemic changes of myokines in breast cancer patients. However, intra- and inter- individual variability in response to different exercise modalities should be considered for development of proper research design and for personalized interventions in this patient population.

ASSESSING THE RELATIONSHIP BETWEEN BALANCE AND GAIT VARIABILITY IN CHILDREN WITH CANCER

KÜHN, M., WYPYRSCZYK, L., DREISMICKENBECKER, E., NEU, M.A., DIEL, H., FABER, J.

UNIVERSITY MEDICAL CENTRE OF THE JOHANNES GUTENBERG UNIVERSITY MAINZ

INTRODUCTION: The ability to walk safely and engage in daily activities and social interactions without restrictions relies on the coordinated interplay of sufficient muscle strength, ankle flexibility, and the effective acquisition and utilisation of sensory information essential for motor control and balance during walking. It is well-documented that cancer and its associated treatments can have a detrimental effect on physical performance, potentially resulting in limitations in parameters needed for normal gait, including balance. Therefore, this study hypothesises that balance impairments significantly influence gait variability in children with cancer, a factor recognised as a crucial contributor to increased fall risk in children. The present research aims to examine the relationship between balance and gait variability in children and adolescents with cancer.

METHODS: A total of 62 patients aged 4 to 20 years (mean age: 9.68 ± 4.02 years) during and after cancer treatment participated in the study. Spatio-temporal gait parameters (step length, base of support, step duration, velocity, step frequency) were measured using a 10 m OPTOGait walkway (Microgate S.r.l., Bolzano) and intra-individual gait variability was calculated using the coefficient of variance (CV). Balance was measured using the static stand test according to Bös et al. (2009), a balance test in which subjects maintain a one-legged stance on a thin T-bar for one minute and ground contacts are counted. Correlations between balance and gait variability were analysed using Spearman's correlation. The significance level was set at $p < 0.05$ and Spearman correlation coefficients were interpreted according to Cohen ($p = 0.1 - 0.3$: small correlation, $p = 0.3 - 0.5$: moderate correlation, $p > 0.5$: strong correlation).

RESULTS: The findings indicate moderate to strong significant correlations between balance performance and intra-individual variability in all gait parameters assessed, except for step frequency where only small significant correlations can be observed. Children with poorer balance ability in the static stand test had significantly greater variability in step length ($p = .402$, $p = .002$), base of support ($p = .305$, $p = .022$), step duration ($p = .375$, $p = .004$), velocity ($p = .353$, $p = .008$) and step frequency ($p = .263$, $p = .05$).

CONCLUSION: The findings of this study highlight the significant relationship between balance ability and gait variability in children and adolescents with cancer. Given the critical role of balance in maintaining stable and efficient gait, targeted interventions aimed at improving balance may help reduce gait variability. Future research should further explore the underlying mechanisms of balance deficits in childhood cancer patients and assess the effectiveness of tailored rehabilitation strategies to enhance mobility and overall quality of life.

PHYSICAL ACTIVITY, SLEEP QUALITY, FATIGUE AND QUALITY OF LIFE IN CHILDHOOD CANCER: THE IMPACT OF THE FIRST MONTH AFTER DIAGNOSIS

GALASSO, L., ZARDO, W.1,2,3, CASTELLI, L.1, CIORCIARI, A.1,4, SANTINI, L.1, MASSIMINO, M.2, ROVEDA, E.1, SPREAFICO, F.2

 ROCUORE,MILAN;4.FACULTY OF EDUCATION,FREE UNIVERSITY OF BOZEN-BOLZANO,BRIXEN-BRESSANONE,BZ

INTRODUCTION: Childhood cancer is a growing global issue, with increasing cases in recent years (1). Physical activity (PA) is an effective strategy to improve cardiorespiratory fitness and muscle strength, often impaired by cancer or bed rest in the hospital. Exercise programs also offer emotional and social benefits (2). Chemotherapy side effects, like fatigue and sleep disturbances, further limit participation in PA programs (3). The aim of this study is to assess physical activity (PA), sleep quality (SQ), fatigue (CRF), and quality of life (QoL) within the first month after pediatric cancer diagnosis.

METHODS: 12 patients with solid tumors (females=58%, median age=16.8 $\pm$ 1.6 years, range 14-19) were enrolled at Fondazione IRCCS Istituto Nazionale dei Tumori in Milan. They completed the Physical Activity Questionnaire for Adolescents (PAQ-A), Pittsburgh Sleep Quality Index (PSQI), Multidimensional Fatigue Scale, and Pediatric Quality of Life Inventory™ (PedsQL) at diagnosis (T0) and 30 days later (T1), when chemotherapy or radiation treatments begin. Data were analyzed using Prism GraphPad.

RESULTS: In the comparison between T0 and T1, significant reductions in PA ($p < .04$), SQ ($p < .0001$), parents CRF ($p < .03$), and adolescents CRF ($p < .002$) were observed. No significant changes were found in parents QoL ($p = .14$) or adolescents QoL ($p = .06$). SQ worsening, measured by the PSQI, was associated with changes in sleep ($r^2 = 0.45$, $p < .02$), fatigue ($r^2 = 0.69$, $p < .008$), and cognitive aspects ($r^2 = 0.44$, $p < .02$) as measured by the CRF questionnaire.

CONCLUSION: Levels of PA, SQ, CRF, and QoL underwent changes soon after cancer diagnosis in pediatric patients. Creating programs focused on the improvement of these aspects could be a useful strategy to improve outcomes in childhood cancer.

FITNESS AND QUALITY OF LIFE ASSESSMENTS AFTER DIFFERENT BREAST CANCER SURGERIES: WHICH TYPE OF TAILORED EXERCISE SHOULD BE PRESCRIBED?

GRAZIOLI, E., MURRI, A., MAURI, C., CERULLI C., MAGNO, S., ROSSI, C., SCHERC, N., IHOUT, P., TOLEDANO, A., MINGANTI, C., DIMAURO, I., PARISI, A.

UNIVERSITY OF ROME FORO ITALICO

INTRODUCTION: Although innovations in breast cancer (BC) treatments improved patients' outcomes, surgery often leads to physical and psychological challenges that can worsen over time. Exercise emerged as a promising intervention to mitigate these effects, but little is known about the optimal exercise interventions for BC patients immediately after surgery.

METHODS: The study aimed to assess and compare parameters, such as body composition, physical function (i.e. upper and lower limb strength), and health-related quality of life (QoL) in 50 BC patients (aged 45–65 years) who underwent mastectomy (MAST, n=13), quadrantectomy (QUAD, n=21), or tumorectomy (TUM, n=16)immediately after surgery. Moreover, potential correlations among these variables were identified to provide tailored exercise program recommendations.

RESULTS: Significant difference in PhA between the TUM and QUAD groups ($p < 0.000$) and between the QUAD and MAST groups ($p = 0.015$) were evidenced. FM difference was observed between TUM and QUAD ($p = 0.003$) and TUM and MAST ($p = 0.008$). The correlation analysis showed that Handgrip strength was positively correlated with emotional functioning ($r = 0.294$, $p = 0.038$) and with cognitive fatigue ($r = -0.284$, $p = 0.046$). Lower limb strength correlated with interference with daily life ($r = -0.367$, $p = 0.009$) and global health ($r = 0.292$, $p = 0.040$). Global health showed positive correlations with FFM ($r = 0.295$, $p = 0.037$) and BCM ($r = 0.327$, $p = 0.021$).

CONCLUSION: These results emphasize the importance of improving fitness parameters despite the type of surgery. Although aerobic training remains the most studied and commonly prescribed approach in cancer, strength training seems the most promising in improving those functional parameters related to health related QoL in BC patients.

DESIGN AND IMPLEMENTATION OF A PERSONALIZED EXERCISE PROGRAM FOR IMPROVING PHYSICAL FUNCTION IN CANCER SURVIVORS.

GUPTA, A.

UNIVERSITY OF GALWAY

INTRODUCTION: Cancer survivors suffer from long-term side effects of treatment which significantly reduces their functional capacity and quality of life (QoL). Exercise can improve functional capacity and can prevent long-term illness. Previous research and our preliminary study helped us to understand the patients' perspective on long-term illness following can-

cer treatment. A myriad of side-effects was identified of which chronic fatigue and loss of physical function (reduced cardiorespiratory capacity, flexibility, and muscle strength) was identified as the most debilitating effect that impacted the QoL of many patients. The severity and type of symptoms experienced by patients varied significantly. It was highlighted by the patients that the exercise intervention developed to address these issues needed to be tailored to the individual's symptoms and capacity. The intervention needed to be multi-modal targeting all the symptoms experienced by the patient. The current study aimed to develop a personalized, multimodal exercise-based rehabilitation program that will help to improve physical function amongst cancer survivors and reduce fatigue.

Purpose: To design, implement and evaluate the effectiveness of a "personalized" exercise program to improve physical function and reduce cancer-related fatigue in cancer survivors.

METHODS: Any person with a diagnosis of cancer, regardless of the stage of treatment, and no contraindication to exercise were eligible to take part in the study. Upon completion of a PAR-Q+ questionnaire and informed consent, participants performed a baseline exercise assessment and pre-intervention qualitative assessment of Fatigue and health related QoL performed via questionnaires. The exercise assessment measured the participants cardiorespiratory fitness, muscular endurance, flexibility, balance, and body composition. A 12-week personalized exercise program was developed for each participant based on their test results and symptoms. Each program contained aerobic exercise, resistance exercise and flexibility exercise that was tailored to the individual. An exercise physiologist/physiotherapist provided step by step guidance and supervised the weekly sessions and delivery of the exercise intervention. Each participant received weekly one to one advice and monitoring throughout the program via email, telephone, and weekly online exercise sessions. The intervention was adapted based on progress made which was assessed every 4 weeks during the program. At the end of 12 weeks, participants took part in a post-intervention exercise assessment and completed the questionnaires again.

RESULTS: 49 participants completed the exercise program including both the pre-intervention and post-intervention exercise assessment. Participants significantly improved their aerobic capacity and muscular endurance and reduced their symptoms of cancer-related fatigue from pre-intervention to post-intervention. A strong positive correlation was discovered between the participants post-intervention muscular endurance test scores and their post-intervention fatigue scores.

CONCLUSION: A personalized exercise program tailored to individuals' capacity and symptoms can significantly improve physical function and reduce the cancer-related fatigue experienced by cancer survivors. Future studies should focus on optimizing the process of assessing and prescribing exercise to cancer survivors to maximize their recovery from cancer and its treatment.

EFFECTS OF PHYSICAL EXERCISE AND PROBIOTIC SUPPLEMENTATION ON GUT MICROBIOTA IN PEDIATRIC PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA IN REMISSION

BIELIK, V., BABICOVÁ, M., ŠIMIAKOVÁ, M., HRIC, I., NECHALOVÁ, L., UGRAYOVÁ, S., KOLENOVÁ, A.
COMENIUS UNIVERSITY, FACULTY OF PHYSICAL EDUCATION AND SPORT

INTRODUCTION: Pediatric acute lymphoblastic leukemia (ALL) is the most common childhood cancer, often treated with intensive chemotherapy and antibiotic protocols that disrupt gut microbiota diversity and function. These disruptions can persist for years after treatment, leading to long-term health complications, including reduced microbial diversity, metabolic imbalances, and decreased physical fitness. This study investigated the impact of physical exercise and probiotic supplementation on gut microbiota, physical fitness, and overall health in pediatric patients with ALL in remission.

METHODS: This crossover study included 22 pediatric patients with ALL in remission (3–5 years post-treatment). Thirteen participants began as the experimental group and nine as the control group. The intervention consisted of an 8-week strength training program (3 sessions/week), followed by an 8-week probiotic intervention with daily consumption of *Lactobacillus casei* CNCM-1518. Strength and anthropometric measures were assessed alongside gut microbiota analysis using 16S rRNA sequencing.

RESULTS: Logistic regression analysis identified several variables significantly associated with probiotic intervention outcomes, identifying key predictors of gut microbiota improvements. The probiotic intervention increased gut microbiota diversity (Chao1 index, $p=0.065$) and beneficial taxa, including butyrate producers *Blautia caecimuris* ($p=0.007$) and *Blautia schinkii* ($p=0.024$), as well as *Lactocaseibacillus casei* ($p=0.011$) and Veillonellaceae ($p=0.054$). Physical exercise showed a modest effect on the shift in gut microbiome and handgrip; however, weight ($p=0.008$) and BMI percentile ($p=0.023$) improved.

CONCLUSION: This study demonstrated that probiotic supplementation significantly improved gut microbiota diversity and increased beneficial taxa. Physical exercise moderately influenced gut microbiota composition but significantly improved weight, BMI percentile, and handgrip strength in pediatric ALL patients. These findings suggest that probiotics can effectively restore gut health, while exercise supports anthropometric recovery in this population. This study was supported by the following granting schemes: APVV-22-0047 and VEGA 1/0313/25.

EFFECTS OF VIRTUALLY SUPERVISED EXERCISE IN PHYSICAL FUNCTION AND STRENGTH IN LATINA AND HISPANIC BREAST CANCER SURVIVORS: PRELIMINARY RESULTS FROM THE ROSA TRIAL

GONZALO ENCABO, P., ZHENG, Q., NGUYEN, D., WILSON, R.L., NORRIS, M.K., CHRISTOPHER, C.N., DIELI-CONWRIGHT, C.M.
UNIVERSITY OF ALCALA; DANA-FARBER CANCER INSTITUTE

INTRODUCTION: Latina and Hispanic breast cancer survivors (LHBCS) experience many treatment-related side effects compared to White counterparts. Previous studies have highlighted a high prevalence of impaired physical function among LHBCS, particularly those with obesity. Regular exercise has been shown to improve muscular strength and physical function in breast cancer survivors. However, most studies have focused on non-Hispanic white women, limiting our understanding of how exercise may benefit LHBCS. Therefore, we designed an exercise intervention that is culturally tailored to the needs of Latina and Hispanic women, aiming to address the unique barriers they face to engage in exercise (NCT04717050). This study aimed to assess the effects of a 16-week virtually supervised aerobic and resistance training intervention on physical function and muscular strength in LHBCS.

METHODS: Sedentary, overweight or obese ($BMI > 25.0$ kg/m²) LHBCS (N=64) were randomized to a combined aerobic and resistance exercise program (ACTIVAS; n=32) or waitlist control (n=32). The ACTIVAS intervention consisted of a thrice-weekly, 16-week home-based virtually supervised aerobic (50-85% VO_{2peak}) and resistance training (60-75% 1-RM) program via Zoom. The waitlist control completed a self-directed home-based stretching program. Physical function was measured at baseline and post-intervention (week 17) using the Sit-to-stand, Margaria stair climb and Timed-up and Go (TUG) tests. Upper and lower body muscular strength were measured by a 10-repetition maximum test using chest press and leg press, respectively. Repeated measures ANCOVA and paired t-tests were conducted.

RESULTS: Participants were 55 ± 10 years old, obese ($BMI = 30.7 \pm 5.6$ kg/m²), and 44% had received chemotherapy, radiation and surgery. Physical function data was available for 67% of participants, upper body strength for 69% and lower body strength for 66%. Baseline characteristics were similar between groups. At post-intervention, the ACTIVAS group showed a significant improvement in TUG (mean difference (95% CI): -0.5 s (-1.0, -0.1), $p=0.02$) compared with waitlist controls ($P_{group \times time}=0.01$). Upper and lower body muscular strength significantly increased within the ACTIVAS group at post-intervention (Upper: 4.4 kg (1.9, 6.8), $p=0.001$; Lower: 10.6 kg (0.1, 21.1), $p=0.04$). No significant within- or between-group changes were found for the Margaria stair climb or Sit-to-stand tests.

CONCLUSION: A virtually supervised exercise intervention improved upper and lower body strength, as well as physical function measured by the TUG among Latina and Hispanic breast cancer survivors. These results support the incorporation of virtually supervised exercise interventions into survivorship care plans for LHBCS, with the potential to improve physical function and strength. Future research is needed to optimize exercise strategies for this vulnerable population.

IN VIVO MULTI-ORGAN ANALYSIS OF GLUCOSE UPTAKE, BLOOD FLOW AND BLOOD VOLUME OF THE EFFECTS OF PHYSICAL ACTIVITY AND CHEMOTHERAPY IN BREAST CANCER

LAITINEN, V.1,2, UURASMAA, T.M.1,2, KOIVULA, T.2, IHALAINEN, J.2, SHIMOCHI, S.2, LILJENBÄCK, H.2, HIDEHIRO, I.2, ROIVAINEN, A.2,4, RUNDQVIST, H.5, AUTIO, A.2, ANTTILA, K.1, HEINONEN, I.2

INTRODUCTION: We have previously shown that physical activity (PA) can benefit heart during doxorubicin (DOX) treatment in a breast cancer mouse model (1), but the effects in other tissues remain incompletely characterized.

METHODS: The effects of PA (voluntary wheel-running) and DOX were analyzed with positron emission tomography (PET) imaging with [¹⁸F]-FDG, [¹⁵O]-H₂O and -CO tracers in female FBV/N-mice (n=77) subcutaneously injected with breast cancer cells (I3TC). Glucose uptake (GU), blood flow (BF), blood volume (BV), and blood mean transit time (MTT) were analyzed using PET data from tumor, brain, liver, gastrocnemius muscle, bone marrow, and compact cortical bone. Tumor characteristics such as vasculature and hypoxia were analyzed by using histology. Mice were divided to four tumor-bearing groups: Control, DOX treated and further to PA and no-PA.

RESULTS: DOX significantly decreased BV in the whole tumor ($P=0.003$), tumor high flow areas ($P=0.005$), compact bone ($P=0.004$), bone marrow ($P=0.019$), brain ($P=0.011$) and BF in the brain ($P=0.01$). DOX significantly decreased MTT in bone marrow ($P=0.34$) and compact bone ($P=0.008$). GU increased over time in the brain ($P=0.001$) and liver ($P=0.0002$). Brain GU also significantly increased by PA when comparing all PA groups to sedentary groups ($P=0.037$). Analyses also revealed a significant DOX and PA interaction in the femur GU ($P=0.038$). No significant effects of time, PA or DOX were found in gastrocnemius muscle GU. DOX significantly decreased tumor maximal GU ($P=0.028$) and metabolic tumor volume (MTV) ($P=0.048$), but other factors observed by [¹⁸F]-FDG were not affected by DOX. Time reduced glucose uptake when tumor volume was used as a covariate, but PA significantly decreased the GU heterogeneity ($P=0.018$) when comparing the groups. A significant interaction was also found between PA and time on MTV ($P=0.035$), PA depressing over-time the decrease of MTV. PA significantly decreased large vessel ($<8\mu m$) density ($P=0.013$) in the tumor. Significant interaction was found between PA and DOX on α -sma-positive vessel proportion ($P=0.016$). Post hoc test revealed that PA and DOX alone significantly increased α -sma-positive vessel proportion, but not together. In addition, DOX alone significantly decreased α -sma positive vessel amount ($P=0.044$). No other differences were found in tumor vasculature or hypoxia. There were no statistical differences in tumor volume between the groups.

CONCLUSION: Particularly drug treatment of breast cancer appears to have many effects on circulatory function and glucose uptake in different tissues, but PA also affects some of these effects.

COMPARING SUPERVISED AND HOME-BASED EXERCISE INTERVENTIONS IN PERIPHERAL ARTERY DISEASE: CLOSING THE GAP ON FUNCTIONAL OUTCOMES

MCDONALD, T., KENYON, C., SOMANI, Y.B.

UNIVERSITY OF LEEDS

INTRODUCTION: Supervised exercise therapy (SET) is a first-line recommendation for improving walking performance in people with peripheral artery disease (PAD) and intermittent claudication (IC) [1]. However, low adherence and limited availability [2] often mean that home-based exercise therapy (HBET), usually consisting of basic walking advice, is recommended instead. Whilst SET leads to greater improvements in functional outcomes than HBET [3], recent studies have explored structured HBET interventions that incorporate more prescriptive walking advice and technology such as phone applications or smartwatches to track adherence and progress. In this systematic review and meta-analysis, we provide an update of the literature on the comparative efficacy of SET vs. HBET on maximal and pain-free walking outcomes. Within HBET, we further compare structured programmes to simple walking advice.

METHODS: A systematic literature search was conducted using Embase, Web of Science, and PubMed. Studies were included if they evaluated SET or HBET interventions lasting 12 weeks and reported outcomes related to maximal or pain-free walking distance or time. Structured HBET was defined as a home-based programme that included prescriptive walking advice, with or without additional support such as a fitness tracker or phone application.

RESULTS: A total of 27 studies were included in this review: 20 compared SET to HBET, 5 compared structured to unstructured HBET, and 2 compared all three interventions. 631 participants were included in the SET group and 509 in HBET. To further compare different types of HBET interventions, 197 participants were included in the structured HBET group and 191 participants were in the unstructured group. The mean age of participants was 65.7 years (65.9% men).

Compared with HBET, SET significantly improved maximal walking distance by a mean difference (MD) of 155.9 m [95% CI 110.8–201.0, $p < 0.001$]. Pain-free walking distance increased by an MD of 112.0 m [95% CI 73.9–150.1, $p < 0.001$]. When comparing the two types of HBET, structured HBET led to significantly greater improvements in maximal walking distance (MD: 53.5 m [95% CI 5.8–101.2], $p = 0.03$), but showed no significant difference in pain-free walking distance ($p = 0.09$).

CONCLUSION: Although SET remains the gold standard for improving functional outcomes in patients with PAD and IC, structured HBET programmes incorporating prescriptive walking advice and technology resulted in greater maximal walking improvements than unstructured programmes. These findings highlight structured HBET as a practical alternative to SET and its potential to help close the gap in functional outcomes between the two types of exercise programmes. Future research should prioritise optimising and scaling structured HBET interventions.

CARDIOVASCULAR RISK IMPOSED BY POLYCYSTIC OVARY SYNDROME APPEARS TO BE MITIGATED BY HABITUAL EXERCISE TRAINING

HUCKINS, W., VAN BERKEL, E.K., BERBRIER, D.E., USSELMAN, C.W.

MCGILL UNIVERSITY

INTRODUCTION: The prevalence of virtually all cardiovascular diseases are elevated in females with polycystic ovary syndrome (PCOS). While the pathophysiology of cardiovascular diseases in PCOS continue to be elucidated, a number of cardiovascular risk factors have been well-established as being common to PCOS. These include elevated blood pressures (BP), impaired endothelial function, and greater adiposity. Although these cardiovascular risk factors are effectively managed with exercise in other populations, short-term (e.g. 12-16 week) exercise intervention studies show conflicting results in females with PCOS. Thus, we used a cross-sectional approach to examine whether established differences in cardiovascular risk persist between females with and without PCOS (i.e. CTRL) who undertake habitual exercise training, defined as a minimum of 5 hours of structured moderate-vigorous physical activity weekly over the last year.

METHODS: Females with PCOS (n=7) and CTRL (n=7) were matched by age (24 ± 5 vs. 23 ± 6 yrs, respectively) and body mass index (BMI); 22.6 ± 2.2 vs. 22.6 ± 2.2 kg/m², respectively). Blood pressure was assessed via manual sphygmomanometry, endothelial function was quantified as %FMD according to standardized methodology, and body composition was assessed using dual X-ray absorptiometry.

RESULTS: Systolic BP (109 ± 6 vs. 105 ± 4 mmHg, $P=0.22$), and diastolic BP (69 ± 6 vs. 65 ± 4 mmHg, $P=0.26$) were not different between PCOS and CTRL. Likewise, %FMD was not different between PCOS and CTRL (7.6 ± 2.5 vs. $8.8 \pm 2.2\%$, $P=0.34$). Similarly, neither android fat (1.00 ± 0.36 vs. 0.94 ± 0.37 kg, $P=0.76$), gynoid fat (3.59 ± 0.94 vs. 3.40 ± 1.08 kg, $P=0.73$), android/gynoid ratio (0.28 ± 0.06 vs. 0.28 ± 0.07 g, $P=0.96$), or whole-body fat (29.86 ± 4.02 vs. $27.57 \pm 5.29\%$, $P=0.40$) were different between PCOS and CTRL.

CONCLUSION: These preliminary findings suggest that habitual physical activity may be effective in mitigating the established negative cardiovascular consequences of PCOS. Future research is warranted in investigating the most effective type and frequency of physical activity in reducing cardiovascular risk amongst females with PCOS.

THE CHALLENGES OF THE DIAGNOSIS AND MANAGEMENT OF EXERCISE-INDUCED ACUTE KIDNEY INJURY: A REVIEW OF THE CURRENT LITERATURE

OPARA, K.

FRIMLEY HEALTH NHS FOUNDATION TRUST

INTRODUCTION: Exercise-induced acute kidney injury (Also known as EIAKI or ALPE) is a significant, yet underrecognised and understudied cause of acute renal failure following exercise. It can be distinguished from rhabdomyolysis by normal or only mildly raised serum creatine kinase levels (CK) and is typically seen in activities that are predominantly anaerobic such as sprinting, weightlifting or military fitness testing and can be career ending. Dialysis is required in up to 20% of those with EIAKI and it is closely linked to renal hypouricaemia which has a reported prevalence between 0.15-1.39% in Asian countries like Japan and South Korea. Therefore an understanding of the pathophysiology, diagnosis, management and prevention of EIAKI is of the utmost importance to clinicians. A review of the literature was done to summarise the current knowledge of this condition.

METHODS: A literature review on Pubmed using the search terms "exercise induced acute kidney injury", "renal hypouricaemia" & "Acute Renal Failure with Severe Loin Pain and Patchy Renal Ischemia after Anaerobic Exercise". Case reports and reviews detailing the management and prevention of the condition were collected, with the results summarised below.

RESULTS: There were no randomised-controlled trials looking at the management of EIAKI found in the literature. However a case-report described an improvement in renal function in 2 cases after intravenous continuous infusion of $2 \mu\text{g/kg/min}$ dopamine. Another study reported that EIAKI was prevented in 5 patients with renal hypouricaemia by taking 300mg of allopurinol for 5 days. Management and prevention strategies in other studies included maintaining adequate hydration, avoiding NSAIDs, having a good baseline fitness and if feasible, avoiding the aggravating exercise.

Most patients had a spontaneous recovery in their renal function after 3 days and 25% of patients had at least one recurrence. There was no data on long-term ability to return to exercise or long-term effects on kidney function.

CONCLUSION: Exercise-induced Acute Kidney Injury (EIAKI) or Acute Renal Failure with Severe Loin Pain and Patchy Renal Ischemia after Anaerobic Exercise (ALPE) is marked by a significant rise in creatinine after intense anaerobic exercise, normal or mildly elevated CK levels and back or loin pain. Diagnosis is supported by a Computed Tomography (CT) scan showing wedged-shaped infarcts on the kidney.

The majority of patients with EIAKI have been found to have hereditary renal hypouricaemia and it is thought to be caused by either renal vasoconstriction due to oxidative stress which uric acid normally inhibits or uric acid nephropathy due to increased excretion by the kidneys. No definitive management strategy exists for EIAKI but dopamine infusion may reverse the vasoconstriction caused by anaerobic exercise, and allopurinol as a Xanthine oxidase inhibitor may prevent the formation and excretion of uric acid. Further research is required to better optimise the management of this condition.

THE EFFECTS OF EXERCISE ON IMMUNE CHECKPOINT INHIBITOR-RELATED CARDIOTOXICITY: IMPACT ON CARDIAC FUNCTION

CHENG, H., HUANG, Y.T., TSAI, K.L.

NATIONAL CHENG KUNG UNIVERSITY

INTRODUCTION: Immune checkpoint inhibitors (ICIs) significantly advance cancer immunotherapy, enhancing antitumor immunity by blocking the PD-1/PD-L1 pathway. However, their most severe immune-related adverse event (irAE) is cardiotoxicity, leading to myocarditis and heart failure due to off-target immune activation. T-cell and macrophage infiltration, oxidative stress, mitochondrial dysfunction, and endothelial impairment contribute to these effects. ICIs disrupt mitochondrial biogenesis and function, reducing ATP production and exacerbating oxidative damage, ultimately impairing cardiovascular function. Exercise exerts well-established cardioprotective effects by promoting mitochondrial biogenesis and reducing oxidative stress, thereby preserving cardiac function. This study investigated whether Exercise mitigates ICI-induced cardiotoxicity, focusing on cardiac structure and function through echocardiographic assessment. The findings highlight Exercise's potential to enhance ICI efficacy while reducing cardiotoxic effects, offering key insights for optimizing cancer immunotherapy while safeguarding cardiovascular health.

METHODS: Male 8-week-old C57BL/6 mice (n=18) were divided into three groups: Control, ICI, and ICI + Exercise. ICI-induced cardiotoxicity was modeled by administering nivolumab (10 mg/kg, i.p.) twice weekly for six weeks. The exercise group performed treadmill running (9 m/min, 5 days/week) for six weeks. Echocardiography was conducted at the study endpoint to assess cardiac function. Data were analyzed using one-way ANOVA with Tukey's post hoc test ($p < 0.05$ considered significant).

RESULTS: Exercise training preserved myocardial function, evidenced by significantly higher fractional shortening and ejection fraction in the exercise group compared to the ICI-treated group ($p < 0.05$, $p < 0.06$). The ICI group exhibited reduced end-diastolic and end-systolic volumes ($p < 0.0001$ vs. Exercise, $p < 0.006$ vs. control), indicating impaired ventricular filling and ejection. Left ventricular diameters in diastole and systole were significantly lower in the ICI group ($p < 0.0003$ vs. Exercise, $p < 0.01$ vs. control), suggesting contraction abnormalities rather than hypertrophy.

CONCLUSION: Exercise effectively mitigates ICI-induced cardiotoxicity by preserving mitochondrial function, reducing oxidative stress, and inhibiting apoptosis. It restores cardiac energy metabolism and enhances myocardial elasticity, ultimately improving heart function. These findings underscore Exercise's therapeutic potential as a complementary intervention in ICI therapy, offering a promising strategy to attenuate immune-related adverse events and optimize clinical outcomes in cancer immunotherapy.

EFFECTS OF BODY MAINTENANCE DEVICE-INDUCED PASSIVE LIGHT EXERCISE ON ARTERIAL STIFFNESS AND WALL TISSUE ELASTICITY

ISHIDA, T., KURIHARA, K., OI, N., KUME, D., GANDO, Y., NEMOTO, Y., KIKUGA, N., NISHIWAKI, M.
OSAKA INSTITUTE OF TECHNOLOGY

INTRODUCTION: Increased arterial stiffness due to aging and physical inactivity is a risk factor for cardiovascular diseases. Aerobic exercise or stretching is generally known to reduce arterial stiffness; however, in recent years, physical activity has declined due to the development of various technologies. Body maintenance devices can induce passive light exercise, such as stretching and/or massage, but its effects on arterial stiffness and arterial wall tissue elasticity remain unclear. The present study thus aimed to examine the effects of body maintenance device-induced passive light exercise on arterial stiffness and wall tissue elasticity.

METHODS: Fifteen healthy adults (mean age, 21.1 ± 0.4 years) participated in both body maintenance (BM) and control (C) trials in random order on separate days. In the BM trial, participants performed 30 minutes of passive light exercise using body maintenance devices, while in the C trial, they rested in the same body positions as in the BM trial. Arterial stiffness and arterial wall tissue elasticity were measured using the Cardio-Ankle Vascular Index (CAVI) and Shear Wave Elastography (SWE) before (Pre), immediately after (Post), and 30 minutes after (Post 30) each session.

RESULTS: There was no significant difference in heart rate between both trials. Furthermore, no significant changes were observed in resting heart rate, blood pressure, and pulse pressure. CAVI values showed no significant differences between the trials before starting, and no significant changes were found in the C trial. However, in the BM trial, CAVI significantly reduced at Post and returned to baseline at Post 30 (BM, Pre: 5.9 ± 0.2 ; Post: 5.7 ± 0.1 ; Post 30: 6.0 ± 0.1 , Control, Pre: 5.8 ± 0.1 ; Post: 6.0 ± 0.2 ; Post 30: 6.0 ± 0.2 , both $P < 0.01$). No significant differences were observed in the elastic modulus or shear wave velocity in either condition.

CONCLUSION: Therefore, our findings suggest that body maintenance device-induced passive light exercise reduces arterial stiffness but not arterial wall tissue elasticity. The observed reduction in arterial stiffness seems likely to be functional changes rather than structural changes in the arteries.

EFFECTS OF DIFFERENT EXERCISE MODES ON CARDIOVASCULAR DISEASE RISK FACTORS IN JAPANESE ADULTS

YAMAMOTO, M., FUJIE, S., ITO, R., KOJIMA, C., UCHIDA, M., TANQUE, Y., HASHIMOTO, T., TAKADA, H., MURAKAMI, H., IEMITSU, M.
RITSUMEIKAN UNIV

INTRODUCTION: The development and progression of cardiovascular disease (CVD) are the primary causes of overall mortality in the world. It is well known that habitual aerobic exercise is a promising first-line approach for preventing and managing CVD risk factors, such as arterial stiffness and blood pressure (BP) (1). Recent studies have demonstrated the effects of other modes of exercise training, including high-intensity interval training (HIIT) and sprint interval training (SIT), on CVD risk factors (2). However, these relative impacts of these modalities on the CVD risk factors remain unclear. This study aimed to elucidate the effects of the different modes on the CVD risk factors in Japanese adults.

METHODS: Fifty-four civil servants working in Japan (40 ± 13 years) were randomly divided into four groups; sedentary control (CON), moderate-intensity continuous exercise training (MCT; for 40 min at 60-70% maximal oxygen uptake [VO_{2max}] intensity), HIIT (8 sets of 2-min 80% VO_{2max} intensity and 3-min 40% VO_{2max} intensity), and SIT (8 sets of 20-s maximal exercise periods with 10-s rests) groups. Participants in the MCT, HIIT and SIT groups performed their respective training 3 days/week for 8-week. As indicators of CVD risks, carotid-femoral pulse wave velocity (cfPWV) and BP were measured before and after each intervention. The differences in the effects of each intervention on CVD risks were compared using one-way ANCOVA, adjusting for sex and age. Statistical significance was defined as $p < 0.05$.

RESULTS: No significant differences were found in VO_{2max} , cfPWV, and BP when compared among the four groups at baseline. Percent changes in VO_{2max} before and after the interventions were significantly greater in the MCT and HIIT

groups compared to the CON group ($p < 0.05$). Additionally, percent changes in cfPWV were significantly lesser than that in the CON group (CON: 59 ± 77 cm/sec vs MICT: -57 ± 76 cm/sec, $p < 0.001$, HIIT: -87 ± 76 cm/sec, $p < 0.001$, and SIT: -25 ± 77 cm/sec, $p = 0.007$). Moreover, the reductions in cfPWV in the HIIT group were significantly greater than that in the SIT group. Furthermore, percent changes in systolic BP in the MICT and HIIT groups were significantly lesser than that in the CON group (each $p < 0.05$). However, no significant differences of percent changes in diastolic BP were observed among the four groups.

CONCLUSION: Habitual exercise using different exercise modes, including MICT, HIIT, and SIT, may similarly reduce CVD risk factors in Japanese adults. However, the magnitude of the impact of each exercise mode on specific CVD risk factors may vary.

EFFECT OF 12-WEEK ISOMETRIC HANDGRIP TRAINING ON AMBULATORY BLOOD PRESSURE IN HYPERTENSIVE WOMEN: RANDOMIZED CONTROLLED TRIAL

MELO, P., FARAH, B., SILVA, M., LIMA, A., GERAGE, A., DOMINGUES, W., CORREIA, M., CUCATO, G., RITTI-DIAS, R.

NOVE DE JULHO UNIVERSITY

INTRODUCTION: Hypertensive woman has shown a higher risk of myocardial infarction, stroke, chronic kidney disease and hypertensive retinopathy than men. Isometric handgrip training (IHT) has shown to reduce blood pressure (BP) in hypertensive adults, although its effects on ambulatory BP is uncertain, especially in women. Therefore, the aim of this study was to evaluate the effects of 12 weeks of IHT on ambulatory BP in hypertensive women.

METHODS: Hypertensive women were randomly assigned to either an isometric handgrip training group or a control group (CG). The IHT group followed a protocol of 4 x 2-minute contractions at 30% of maximal voluntary contraction, with one-minute rest intervals among sets, alternating hands, three times per week for 12 weeks. The control group followed the same protocol as the IHT group and performed the sham training with a stress ball. The ambulatory BP (24-hour, awake and sleep) were measured before and after the intervention period.

RESULTS: A total of 59 hypertensive women were randomized and 40 participants (age: 56.7 ± 11.3 years; 29.8 ± 5.4 kg·m⁻²) completed the 12-week intervention. IHT significantly reduced 24h systolic BP (IHT: 123 ± 2 vs. 117 ± 2 mmHg; control: 121 ± 3 vs. 124 ± 3 mmHg, $p = 0.033$) and mean BP (IHT: 99 ± 2 vs. 94 ± 1 mmHg; control: 96 ± 2 vs. 99 ± 2 mmHg, $p = 0.033$). IHT decreased awake systolic BP (IHT: 125 ± 1 vs. 118 ± 2 mmHg; control: 122 ± 3 vs. 125 ± 3 mmHg, $p = 0.029$) and awake mean BP (IHT: 101 ± 2 vs. 95 ± 2 mmHg; control: 97 ± 2 vs. 100 ± 2 mmHg, $p = 0.035$). No significant effects were observed for 24-hour diastolic BP, awake diastolic BP and sleep BP ($P > 0.05$ for all).

CONCLUSION: Twelve weeks of IHT reduced awake systolic ambulatory BP, leading to a reduction in 24-hour systolic BP in hypertensive women.

EFFECTS OF STEP-BOX EXERCISE PROGRAM ON ARTERIAL STIFFNESS AND SYSTEMIC CARDIOMETABOLIC BIOMARKERS IN POSTMENOPAUSAL WOMEN

PARK, J., KIM, D., KANG, Y., LEE, E., SON, J., TAN, Y., RYU, B., LEE, S., PARK, Y., HWANG, M.

INCHEON NATIONAL UNIVERSITY

INTRODUCTION: Cardiovascular disease (CVD) is the leading cause of death, and arterial stiffness, a precursor of atherosclerosis, increases in postmenopausal women. With advancing aging, traditional cardiometabolic biomarkers such as lipids and glucose increase, whereas serum adropin, an emerging biomarker which is involved in cardiovascular health and regular physical activity, decreases. Regular physical activity is recommended as a biobehavioral strategy to improve cardiovascular and overall health. Step box exercise, a group aerobic movement with music of different beats, is preferred by postmenopausal women because it combines characteristics of interval training with the fun. To date, it is difficult to discover studies that comprehensively evaluate the effects of step box exercise on arterial stiffness, traditional cardiometabolic markers, and serum adropin levels in postmenopausal women. The purpose of this study was to assess the effect of 12-week of step-box exercise program on arterial stiffness, systemic lipids, glucose and adropin levels in postmenopausal women.

METHODS: Postmenopausal women ($n = 23$) were randomly assigned to step-box exercise group (SBE) or non-training control group (CON). The SBE group performed step-box exercises, 50 minutes a day, 3 days a week for 12 weeks. Arterial stiffness was assessed by aortic pulse wave velocity (PWV) and augmentation index (AIx) using a SphygmoCor Xcel system. For evaluating systemic cardiometabolic biomarkers, serum lipids, glucose, insulin and adropin levels were analyzed before and after the intervention.

RESULTS: After 12 weeks of intervention, Alx significantly decreased in SBE group (38 ± 3 vs. 34 ± 2 , $p=0.02$), while it did not change in CON group (33 ± 3 vs. 32 ± 4 , $p=0.80$). $AorPWV$ did not present any statistically significant changes in both groups. Twelve weeks of step-box exercise program significantly improved serum high-density lipoprotein cholesterol (HDL-c, 43 ± 1 vs. 50 ± 2 , $p < 0.01$). There was no significant group by time interaction in serum adipon level between SBE and CON group, but serum adipon level in SBE group was increased by approximately 13% (67 ± 1 vs. 76 ± 5 , $p=0.055$). In the whole group, change in serum adipon level was positively associated with change in HDL-c ($r = 0.46$, $p = 0.04$), and negatively associated with change in insulin level ($r = -0.54$, $p < 0.01$) and calculated homeostasis model assessment of insulin resistance (HOMA-IR, $r = -0.55$, $p < 0.01$). However, change in serum adipon level was not related to change in arterial stiffness measures.

CONCLUSION: Twelve weeks of step-box exercise program reduce Alx , a measure of arterial stiffness, and increase serum HDL-c level in postmenopausal women. Additionally, the increase in serum adipon through step-box exercise program is associated with the increase in serum HDL-c level and the decrease in insulin resistance. Step-box exercise program can be an effective behavioral strategy for reducing cardiovascular and cardiometabolic risk in postmenopausal women.

ACUTE EFFECTS OF ARM-CRANK EXERCISE ON THE ARM AND LEG VASCULAR FUNCTION OF PERIPHERAL ARTERY DISEASE PATIENTS: A RANDOMIZED CROSSOVER TRIAL

RITTI-DIAS, R., SILVA, G.O., CUNHA, P.M., OLIVEIRA, M.D., SILVA, J.K.T.N.F., KANEGUSUKU, H., WOLOSKE, N., CORREIA, M.A.

UNIVERSIDADE NOVE DE JULHO

INTRODUCTION: Arm-cranking exercise can be an interesting option for peripheral artery disease patients, because it minimizes the claudication symptoms and has shown to increase walking capacity. However, their effect on vascular function is poorly known. Our aim was to evaluate the acute effects of arm-cranking exercise on arm and leg vascular function in patients with peripheral artery disease and compare these effects to those of walking exercise.

METHODS: This randomized crossover trial employed single-blind data collection and included 17 patients with peripheral artery disease and intermittent claudication (53% male, 66 ± 7 years, 26.7 ± 4.4 kg/m²). Participants completed three experimental conditions—walking, arm-cranking (AC), and control—in a random order. The exercise conditions consisted of 15×2-minute bouts at an intensity corresponding to 4–6 on Borg's scale. Brachial and femoral artery flow-mediated dilation (FMD) were assessed before and after each condition.

RESULTS: No significant baseline differences in vascular variables were observed between sessions ($P > 0.05$ for all). There were no significant differences for neither brachial (Control: $4.5 \pm 2.8\%$ vs. $3.4 \pm 1.9\%$; Walking: $5.1 \pm 3.2\%$ vs. $4.8 \pm 3.8\%$; AC: $4.4 \pm 2.7\%$ vs. $4.0 \pm 2.1\%$; $P = 0.554$) nor femoral artery FMD (Control: 6.6 ± 4.7 vs. 7.0 ± 5.0 ; Walking: 7.4 ± 4.3 vs. 5.6 ± 4.3 ; AC: 6.8 ± 4.1 vs. 5.6 ± 4.3 ; $P = 0.339$).

CONCLUSION: A single session of arm-cranking exercise does not acutely affect arm or leg vascular function, showing a response similar to that of walking exercise. Funding: FAPESP #2023/00630-6; CNPq #308954/2021-1; CAPES#88887.986418/2024-00

WAIST-TO-HEIGHT RATIO AS A PREDICTOR OF CARDIOVASCULAR AND METABOLIC HEALTH IN CHILDREN

MAMEN, A., FREDRIKSEN, P.M., LINDBERG, M.

KRISTIANIA UNIVERSITY COLLEGE; INLAND NORWAY UNIVERSITY OF APPLIED SCIENCES AND ØSTFOLD UNIVERSITY COLLEGE; VESTFOLD HOSPITAL TRUST

INTRODUCTION: Understanding the relationship between central adiposity and health outcomes in children is crucial for early prevention of non-communicable diseases (NCDs). Waist-to-height ratio (WHtR) has emerged as a key anthropometric measure for predicting cardiovascular and metabolic health risks.

METHODS: This study investigates the association between WHtR, blood biomarkers (HbA1c, lipid profiles, ferritin, iron levels), blood pressure (systolic and diastolic), and overall cardiovascular and metabolic health in children aged 6–12 years.

RESULTS: A positive correlation between WHtR and unfavourable lipid profiles, with elevated total cholesterol and non-HDL cholesterol levels, alongside decreased HDL levels in the highest WHtR quartile, was displayed, suggesting increased cardiovascular risk. Similarly, the combination of high erythrocyte, low Reticulocyte Enumeration Assay (REA), high ferritin, and low iron, combined with high CRP, may imply chronic inflammation due to adiposities. Elevated systolic and diastolic blood pressure values further underscore this cohort's cardiovascular risks associated with central adiposity.

CONCLUSION: WHtR's ability to predict these metabolic and cardiovascular risk factors highlights its potential as a simple, non-invasive screening tool in public health settings, particularly in paediatric populations where invasive blood sampling and frequent testing can be ethically and logistically challenging. By using WHtR as a proxy for more invasive tests, health professionals could efficiently identify children at higher risk, enabling timely interventions that could significantly alter their long-term health outcomes.

CP-MH08 Exercise during Pregnancy / Obesity

COMPARISON OF TIME-MATCHED AEROBIC, RESISTANCE OR COMBINED EXERCISE TRAINING IN WOMEN LIVING WITH OBESITY: THE EXOFFIT STUDY

DAVIS, M., BLAKE, C., O'DONOGHUE, G.

UNIVERSITY COLLEGE DUBLIN

INTRODUCTION: Improvements in cardiorespiratory fitness (CRF) have been shown to largely attenuate the negative health risks associated with obesity. To date literature in women with obesity has focused upon the evaluation of aerobic-based exercise interventions. Hence, there is a need to evaluate resistance and combined interventions with this cohort. This study aimed to evaluate feasibility and efficacy of three exercise modalities in women with obesity for improving CRF, strength, body composition and other health outcomes.

METHODS: Sixty-seven women with obesity were randomised to the control (CON) or one of three exercise groups (aerobic [AE], resistance [RE], COM). Exercise groups trained x3 times/week for 12 weeks (up to 150-minutes/week). Feasibility outcomes included adherence, attendance, recruitment and retention rates and adverse events. Secondary outcomes were CRF (predicted VO₂ max), body composition (body weight [BW], waist circumference [WC], body fat percentage [%BF], fat mass [FM] and lean mass [LM]) and strength (5RM bench press, leg dynamometry, grip strength) and self-reported measures of physical activity, mood, sleep, pain and quality of life.

RESULTS: Findings support feasibility of all three exercise modalities in terms of adherence, attendance, and retention. Interventions with a resistance component (COM and RE) were associated with the greatest improvements across the broad range of health outcomes measured. Combined was the most promising for body composition outcomes including BMI (Effect size [ES]=0.79, p=0.04), BW (ES=0.75, p=0.05), %BF (ES=0.77, p=0.04), FM (ES=0.83, p=0.03) and WC (ES=0.90, p=0.02), physical activity (i.e. moderate PA [ES=0.69, p=0.07], mood (ES=0.83, p=0.03) and sleep (ES=0.78, p=0.04). Resistance was most promising for CRF (ES=1.47, p=0.002), strength (i.e. bench press [ES=2.88, p<0.001]) and pain (i.e. pain severity [ES=0.40, p=0.31]).

CONCLUSION: For health outcomes, these results indicate the importance of including a resistance component when prescribing exercise for women with obesity to achieve meaningful improvements.

USING A CO-PRODUCTION PROCESS TO REFINE AN EXERCISE SPECIALIST LED, MHEALTH FACILITATED, PHYSICAL ACTIVITY INTERVENTION FOR USE IN A PAEDIATRIC COMPLICATIONS FROM EXCESS WEIGHT SERVICE

DAVIES, A., HESKETH, K., BUCKLEY, B., MILLER, G., KINNAFICK, F., JONES, H., SENNIAPPAN, S., COCKS, M.

LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: To address the increasing prevalence of complications associated with severe childhood obesity, NHS England has established 21 Complications of Excess Weight (CEW) services. With the aim of improving physical activity (PA) provision within CEW services, our group developed an exercise specialist led, mHealth supported, exercise and PA intervention (MOTIVATE-CEW). A feasibility study to evaluate MOTIVATE-CEWs potential suggested it was well received by families and initial uptake and adherence to PA was good. However, there were concerns over the maintenance of PA. With the aim of improving long term engagement, we followed Medical Research Council (MRC) guidance on intervention development and utilised service users and stakeholder perspectives during a co-production process to refine the MOTIVATE-CEW intervention.

METHODS: The study was conducted within the Alder Hey Children's Hospital (AHCH) CEW service (England) and drew upon a conceptual model of healthcare service co-production to guide intervention development. An intervention co-production group was established, including young people receiving care from the AHCH CEW service, parents or guardians of young people and health care professionals (HCPs) from the multidisciplinary AHCH CEW team. Four workshops were conducted, with the intervention co-production group split to form separate young person and adult workshops. Workshop 1 refined the behaviour change techniques (BCTs) used in the original intervention. Workshop 2 introduced additional BCTs identified in the literature to enhance long-term PA maintenance. Workshop 3 focused on defining core research outcomes and study design. Workshop 4 invited feedback on the revised intervention and study procedures. Multiple qualitative methods documented the intervention development process, capturing audio and visual data. Emerging intervention components were iteratively mapped to a logic model.

RESULTS: Twenty-three stakeholders participated (7 patients, 5 parents/guardians, and 11 HCPs, all from the AHCH CEW service). The co-production process highlighted two key principles that were used to underpin the refined intervention: 1) personalisation is essential since every young person and family is different, and 2) young people value autonomy and flexibility in shaping their exercise and PA plans. Based on stakeholder insights, we developed a refined logic model that guided updates to the intervention's content, resources, and delivery. The revised intervention retained one original element, refined four elements, and introduced five new components.

CONCLUSION: By utilising MRC guidance and integrating stakeholder perspectives with existing research, we have refined MOTIVATE-CEW into a tailored exercise and PA intervention designed to meet the specific needs of the young people and

carers in CEW services. Future research will evaluate the feasibility of the revised intervention before progressing to a full-scale, multi-site RCT.

BODY FAT DISTRIBUTION AND METABOLIC ADJUSTMENTS SHAPE ENDURANCE PERFORMANCE IN OVERWEIGHT WOMEN

LETUKIENE, A., GINEVICIENE, V.

FACULTY OF MEDICINE, VILNIUS UNIVERSITY

INTRODUCTION: Excess adipose tissue influences metabolic efficiency, oxygen use and energy availability and therefore impacts endurance. Surplus fat, often seen as a limitation, may serve as an energy source during low-intensity exercise. In trained overweight individuals, higher fat oxidation delays fatigue by slowing glycogen depletion, depending on mitochondrial function and fatty acid availability. A lower insulin response improves fat mobilization for sustained energy. Despite an increased oxygen demand for basal physiological functions, overweight individuals often have high cardio-pulmonary capacity, raising the question of whether these adaptations offer endurance advantages. This study aims to evaluate body composition and metabolic response to endurance performance in metabolically healthy overweight women.

METHODS: Thirty-five metabolically healthy overweight women (BMI $32 \text{ kg/m}^2 \pm 4.2$, age 27-58, mean 41 years) participated in a 12-week exercise program: 3 weekly 50-minute aerobic sessions (60-70% max HR) and 2 weekly bodyweight resistance sessions. Endurance was assessed via a 5-minute cycle ergometer test (60 rpm, 70W), measuring (1) post-exercise heart rate recovery, (2) lactate concentration, and (3) leg muscle endurance (15 reps on an isokinetic dynamometer). Body composition was evaluated using BMI, fat mass (kg, %), excess fat percentage, and visceral fat, measured with body composition analyser. Data analysis included descriptive statistics and Pearson's correlation with SPSS.

RESULTS: BMI reduction ($0.8 \text{ kg/m}^2 \pm 1.8$) correlated with baseline BMI ($p < 0.05$), excess fat percentage ($15.4\% \pm 1.6$, $p < 0.05$), and visceral fat change ($0.1\% \pm 0.8$, $p < 0.05$), indicating greater reductions in BMI with higher initial adiposity. Cardiovascular endurance improvements were linked to lactate reduction (-0.1 ± 1.4) and faster heart rate recovery at 2 and 4 minutes (Pulse2mins after, 83.3 ± 12.9 , $p < 0.05$; Pulse4mins after, 80.1 ± 10.1 , $p < 0.01$). Faster recovery was associated with lower pre-intervention fat percentage ($38.2\% \pm 3.5$) and better muscle endurance post-training ($61.8\% \pm 7.2$, $p < 0.05$). Muscle endurance improvements were influenced by visceral fat and total fat loss ($0.7 \text{ kg} \pm 2.7$, $p < 0.01$). Enhanced leg work output was linked to fat loss and lactate clearance ($p < 0.05$), with balanced improvements in both legs ($p < 0.01$).

CONCLUSION: Body composition, rather than BMI alone, is a key factor in endurance improvements in overweight women. Visceral fat reduction most strongly correlated with cardiovascular recovery, lactate clearance, and muscle endurance. These findings suggest fat distribution, rather than total adiposity, drives metabolic and performance benefits. Future research should explore non-visceral fat stores as potential energy reserves and examine individual fat oxidation efficiency.

EFFECTS OF HIGH-INTENSITY INTERVAL TRAINING ON SELF-DETERMINED MOTIVATION TOWARD PHYSICAL ACTIVITY IN WOMEN WITH ABDOMINAL OBESITY

BLACKBURN, P., MARTEL, B., PLOUFFE, J.

UNIVERSITÉ DU QUÉBEC À CHICOUTIMI

INTRODUCTION: There has been growing interest in high-intensity interval training (HIIT) as an alternative to moderate-intensity continuous training (MICT) for reducing adiposity and cardiometabolic risk factors in patients with obesity. However, research on the impact of HIIT on self-determined motivation toward physical activity remains limited. The objective of this study was to compare self-determined motivation toward physical activity and cardiometabolic outcomes after 12 weeks of either HIIT or MICT, both matched for energy expenditure, in women with abdominal obesity.

METHODS: Twenty women with abdominal obesity (age range, 28-56 years) were submitted to 12 weeks of intervention and were randomly allocated into 2 groups: MICT ($n=10$) and HIIT ($n=10$). The MICT group performed a 38 to 62-minute continuous exercise at 70 % of the maximal heart rate. The HIIT group training performed 3 to 6 sets of 4-minute bouts at a running velocity corresponding to 90 % maximal heart rate, interspersed by a 4-min active recovery period at 50 % maximal heart rate. Self-determined motivation toward physical activity was evaluated with a validated questionnaire at the beginning and after 12 weeks. Adiposity indices, cardiorespiratory fitness ($\text{VO}_{2\text{max}}$) and lipoprotein-lipid profile were also measured.

RESULTS: Exercise adherence during the intervention was high, with no significant difference between HIIT and MICT. However, the HIIT group showed a greater increase in self-determined motivation toward physical activity compared to the MICT group ($p=0.016$). However, no significant improvements in $\text{VO}_{2\text{max}}$ and lipoprotein-lipid profile were observed in either the MICT or HIIT groups after the 12-week intervention.

CONCLUSION: Although we found the HIIT and MICT had no impact on cardiometabolic health, HIIT was associated with greater improvements in self-determined motivation toward physical activity. In this context, HIIT may be linked to better long-term adherence to exercise. This research further highlights the need for strategies aimed at helping women enhance their autonomous motivation toward physical activity.

IMPACT OF SPONTANEOUS PHYSICAL ACTIVITY ON GUT-ADIPOSE TISSUE CROSSTALK IN AN OBESE MOUSE MODEL.

BOISSEAU, N., COUVERT, A., GOUSTARD, B., KOEHLIN-RAMONATXO, C., DE CLERCQ, F., LECLAIRE, C., PERRIERE, F., COMBARET, L., CHASSAING, B., MARTIN, V., HOANG, H., NGUYEN, H.
CLERMONT AUVERGNE UNIVERSITY

INTRODUCTION: High-fat diet-induced obesity promotes intestinal inflammation, disrupts gut microbiota composition and compromises intestinal barrier function. Regular physical activity (PA) reduces adipose tissue accumulation, modulates gut microbiota (GM) composition and enhances metabolic health. This study aimed to examine the effects of spontaneous PA on gut-adipose tissue crosstalk in a mouse model of obesity and to identify specific bacterial strains as potential therapeutic targets.

METHODS: Forty-eight male C57BL/6 mice were initially fed either a control diet (CTRL, n=24) or a high-fat diet (HFD, n=24) for 12 weeks. Each group was then subdivided into two subgroups for an additional 12 weeks: sedentary (CTRL-SED, n=12; HFD-SED, n=12) or spontaneous PA (CTRL-PA, n=12; HFD-PA, n=12). Mice in the PA groups had access to a running wheel in their cage, whereas those in the SED groups had a locked wheel. Body weight and energy intake were monitored weekly and body composition was assessed at week 23 using EchoMRI. Blood, epididymal (EAT) and mesenteric adipose tissues (MAT) were collected at week 24. Fecal samples were collected at weeks 0, 12, and 23 to analyze GM composition by 16S rRNA gene sequencing. Short-chain fatty acid (SCFA) levels were analyzed on fecal samples collected at W23. Total running distance was recorded between weeks 12 and 24.

RESULTS: Preliminary results showed that 24 weeks of diet significantly impacted body composition, leading to increased body weight, fat mass (FM), EAT and MAT in HFD groups ($p < 0.001$). However, 12 weeks of PA mitigated FM accumulation and MAT expansion in HFD mice (PA effect $p < 0.02$). At W23, fecal SCFA analysis revealed a significant increase in butyric, valeric, and acetic acids in the HFD-SED group compared to CTRL-SED ($p < 0.01$), while these concentrations were lower in HFD-PA compared to HFD-SED ($p < 0.01$). Regarding gut microbiota composition, the relative abundance of Bacteroidales increased between W12 and W23 in PA groups ($p < 0.001$). Additionally, Bacteroidales abundance at W23 was negatively correlated with FM (g), suggesting that lower FM was associated with a higher presence of Bacteroidales. A negative correlation was also found between FM and changes in alpha-diversity from W12 to W23 ($r = -0.52$; $p < 0.001$).

CONCLUSION: These preliminary findings suggest that PA can modulate gut microbiota composition, particularly by modulating Bacteroidales, an order within the phylum Bacteroidota that is typically reduced in individuals with obesity. Further analyses on tissue inflammation and intestinal permeability will provide additional insights to better elucidate these interactions.

EFFECT OF POSTPARTUM ENDURANCE EXERCISE TRAINING ON CARDIOMETABOLIC HEALTH AMONG BREASTFEEDING PEOPLE WITH OVERWEIGHT/OBESITY: PRELIMINARY DATA FROM A RANDOMISED CONTROLLED TRIAL.

ASHBY, E., LEMOINE, M., ROSVOLD, G., MOHOLDT, T.
NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY

INTRODUCTION: Overweight/obesity during pregnancy is not only associated with adverse pregnancy outcomes, but also with postpartum weight retention which increases the risk of obesity-related complications later in life. Females have lower cardiorespiratory fitness one year postpartum, compared to their age-matched counterparts without a live birth. Since obesity and low cardiorespiratory fitness are major risk factors for chronic diseases, the postpartum period is a 'golden window' to modulate the future risk of adverse health outcomes. In the MILKSHAKE trial (1), we aim determine the effect of endurance training on breastmilk composition. Here, we report preliminary findings on maternal cardiometabolic health. We aimed to determine the effect of an 8-week exercise intervention that included high-intensity interval training (HIIT) on cardiometabolic outcomes among breastfeeding people.

METHODS: Exclusively breastfeeding people who were 6 weeks postpartum and had a pre-pregnancy body mass index of $\geq 25 \text{ kg/m}^2$ and/or postpartum $\geq 28 \text{ kg/m}^2$, were randomised (1:1) to an intervention group or a control group. The intervention group completed an 8-week supervised endurance exercise programme including moderate-intensity continuous training and HIIT, with 2-4 weekly sessions. We measured peak oxygen uptake ($\text{VO}_{2\text{peak}}$) using direct expired gas analysis, body composition (estimated with bioimpedance), waist circumference, blood pressure, resting heart rate, and circulating markers of cardiometabolic health (lipids, fasted glucose, glycated haemoglobin). The between-group differences were determined using a linear mixed model.

RESULTS: We have thus far included 57 participants (intervention 28, control 29). Participants in the exercise group increased their relative $\text{VO}_{2\text{peak}}$ from 30.8 (standard deviation [SD] 7.1) at baseline to 35.2 (SD 5.2) after 8 weeks, with an estimated between-group difference of 3.0 mL/kg/min (95% confidence interval [CI] 0.8 to 5.1, $p = .007$). In the exercise group, resting heart rate decreased by 4.9 beats/min (95% CI 1.1 to 9.0, $p = .012$), total cholesterol by 0.4 mmol/L (95% CI 0.1 to 0.7, $p = .004$), and low-density lipoprotein by 0.4 mmol/L (95% CI 0.1 to 0.7, $p = .005$) compared with the control group. There were no between-group differences in body composition measures, blood pressure, triglycerides, high-density lipoprotein, fasted glucose, or glycated haemoglobin.

CONCLUSION: Supervised endurance training improved $\text{VO}_{2\text{peak}}$, resting heart rate, total cholesterol, and low-density lipoprotein in breastfeeding people with overweight/obesity, but had no statistically significant effect on body composition, blood pressure, or the measured circulating markers of cardiometabolic health.

WOMEN AFTER GIVING BIRTH: TYPE OF DELIVERY AND PHYSICAL ACTIVITY-RELATED HEALTH COMPETENCE POSTPARTUM

ECKERT, K., CARL, J.

IST UNIVERSITY OF APPLIED SCIENCES

INTRODUCTION: Due to the health-promoting effects of physical activity, postpartum women are recommended to complete a weekly minimum of physical activity. However, only a small proportion of women achieve the level recommended by the WHO [1]. Postnatal phenomena such as physical limitations, fatigue, or depressive moods are discussed as significant barriers [2]. The aim of the present study was to investigate postpartum physical activity-related health competence (PAHCO) by 1) analysing corresponding differences between women after normal birth and women after caesarean section and 2) examining the role of time after birth for PAHCO.

METHODS: N=150 complete data sets were generated via an online survey (n=85 women giving birth normally, n=65 women after caesarean section). The assessment included socio-demographic data, specific questions about the birth (type, time), and the 42-item PAHCO questionnaire with its three subcompetence areas (movement competence, control competence, self-regulation competence) [3]. We calculated analyses of covariance (ANCOVA) to detect differences in PAHCO between postpartum groups.

RESULTS: Our study showed that women undergoing caesarean section rate significantly lower levels of PAHCO than women following normal birth. Significant differences were found in all three subcompetence areas ($F \geq 8.79$, $p \leq .004$, $\eta^2 \geq .058$). The greatest differences emerged in the cognitive and affective attitude components as part of self-regulation competence. The circumstance of a previous birth experience had no influence on PAHCO. However, the length of time since giving birth was significantly associated with the ability to master strength and endurance demands and the cognitive attitudes towards physical activity, favouring women who had given birth >12 months ago.

CONCLUSION: The results suggest that women who have had a caesarean section obviously have less competence in (a) ensuring the regularity of movement (self-regulation competence), (b) orienting activities towards health (control competence) and (c) performing at a high motor and fitness level than women with a normal birth. This indicates that aftercare and postnatal care services as well as advice on physical activity should be more specifically tailored to the needs of postpartum women by considering time since birth and how the child was born.

PHYSICAL ACTIVITY DURING PREGNANCY AND POSTPARTUM: PATTERNS, PERCEPTIONS, AND BARRIERS FROM A SOUTH AFRICAN PERSPECTIVE

MOSS, S.

NORTH-WEST UNIVERSITY

INTRODUCTION: The health benefits of regular levels of physical activity (PA) are well reported. In the last decade, the evidence for exercise during pregnancy and postpartum increased exponentially. In low-middle-income countries, as South Africa, where the burden of communicable and non-communicable diseases is increasing, more than 60 % of women at childbearing age are overweight and 35% obese (1). Mother and child mortality statistics and teenage pregnancies, therefore, overshadow the PA and exercise during pregnancy and postpartum agenda within the South African context. Hence, we aim to present evidence on physical activity patterns during pregnancy in South African women, and the perceptions and barriers to participating in regular physical activity.

METHODS: A systematic review of the literature was performed according to the PRISMA Guidelines. PubMed, PsycINFO, SPORTdiscus, Sabinet, and Medline were searched until January 2025. Studies included the search terms; pregnancy, postpartum, physical activity levels, exercise, perceptions, barriers and beliefs. Twenty-two articles were identified and abstracts and titles screened, data extracted and synthesised.

RESULTS: The relevant literature revealed that there is a scarcity of peer reviewed research on physical activity and exercise during pregnancy and postpartum for South Africa. The few studies identified, reported that the WHO guidelines for physical activity during pregnancy are not reached. PA levels decrease even more postpartum than during pregnancy. Women also tend to retain about 5 kg of body mass at three months postpartum. The systematic review targeting barriers and perceptions of PA during pregnancy and postpartum found that information related to exercise was mostly obtained from local media outlets. The available data indicate that cultural beliefs contribute to the perceptions about engaging with PA during pregnancy and postpartum. Barriers for participation in PA are mostly related to socioeconomic challenges, family responsibilities and lack of knowledge (2).

CONCLUSION: There is a scarcity of literature related to physical activity patterns of South African women. Understanding the perception about exercise and the barriers to increasing physical activity will assist in the co-creation of intervention programs that may lead to sustainable physical activity and exercise interventions during pregnancy for improved health outcomes. Exercise interventions may be a cost-effective alternative strategy to prevent pre-eclampsia and gestational diabetes in the region.

BARRIERS AND FACILITATORS TO PRENATAL PHYSICAL ACTIVITY: A CULTURAL PERSPECTIVE FROM CHINA AND POLAND

YU, H., XU, G., LI, X., SONG, G., LI, M., QIAN, G., OSSOWSKI, Z., SZUMILEWICZ, A.

SICHUAN UNIVERSITY OF SCIENCE AND ENGINEERING

INTRODUCTION: Prenatal physical activity (PA) supports maternal and fetal health, reducing risks of gestational diabetes, hypertension, and excessive weight gain [1]. Despite these benefits, cultural norms and societal attitudes significantly impact the adoption of PA during pregnancy. This study examines barriers and facilitators of prenatal PA in China and Poland from a cross-cultural perspective.

METHODS: A cross-cultural, mixed-methods study was conducted with 400 pregnant women (200 each from China and Poland). Quantitative data were collected using the Pregnancy Physical Activity Questionnaire (PPAQ) to assess PA levels (MET-min/week), awareness of prenatal exercise guidelines, and perceived barriers and facilitators. Semi-structured interviews explored cultural beliefs and practices regarding prenatal PA. Quantitative analyses, including ANOVA and logistic regression, compared PA levels and identified predictors, while qualitative data were thematically analyzed to uncover cultural patterns.

RESULTS: Chinese participants reported significantly lower PA levels (mean: 482 ± 217 MET-min/week) compared to Polish participants (mean: 1089 ± 300 MET-min/week; $p < 0.01$). In China, key barriers included traditional beliefs prioritizing rest during pregnancy (70%), fear of harming the fetus (57%), and limited guideline awareness (54%). In Poland, barriers were less pronounced, with time constraints (33%) and insufficient access to facilities (23%) being most cited.

Facilitators differed: in China, healthcare provider encouragement (41%) and family support (29%) were prominent, whereas in Poland, social exercise groups (58%) and tailored programs (49%) were key motivators. Urban participants in both countries exhibited greater PA levels and awareness of guidelines compared to rural participants ($p < 0.01$). Logistic regression analysis identified guideline awareness and positive attitudes as significant predictors of PA levels (China: $\beta = 0.54$, $p < 0.01$; Poland: $\beta = 0.67$, $p < 0.01$). Qualitative analysis revealed cultural themes, such as a strong belief in "energy conservation" during pregnancy in China and a focus on active lifestyles within urban Polish contexts.

CONCLUSION: Cultural norms and beliefs play a pivotal role in shaping prenatal PA behaviors. Chinese pregnant women encounter more significant cultural and informational barriers, while their Polish counterparts primarily face structural and logistical challenges. Raising awareness about prenatal exercise guidelines and addressing cultural misconceptions are essential steps in promoting PA in both regions. Culturally tailored interventions may prioritize dispelling traditional beliefs in China and improving access to prenatal exercise programs in rural Poland.

EFFECTS OF PRE-EXERCISE BASAL INSULIN MANIPULATION ON GLUCOSE DYNAMICS IN FEMALES VS. MALES WITH TYPE 1 DIABETES: A CROSS-OVER STUDY

BESOR, O., CONSTANTINI, K., BUHNIK, A., BIN, E., SCHILLER, T., PICK, H.

TEL AVIV UNIVERSITY

INTRODUCTION: Individuals with type 1 diabetes (T1D) are encouraged to engage in physical activity to improve health outcomes and glycemic control. However, fear of exercise-induced hypoglycemic events remains a major barrier to exercise. Various strategies, including basal insulin reduction before exercise, can be employed to mitigate hypoglycemia during physical activity. Notably, females are underrepresented in sports medicine studies, particularly studies on exercise among individuals with T1D. This study aimed to examine the effects of basal insulin adjustment on glucose dynamics and compare glucose variability between females and males with T1D during recreational exercise.

METHODS: The study consisted of three sessions: 1) a graded exercise test to volitional exhaustion to assess maximal O₂ consumption (VO₂max), 2+3) one hour of running or walking at 90% of heart rate at the first ventilatory threshold (based on VO₂max testing), basal insulin was either reduced by 50% or unadjusted, 90 minutes before exercise (session A vs. B, respectively). Participants arrived at the lab after a 4-hour fast. Blood glucose levels were measured before exercise and at 10-minute intervals. If a participant reached hypoglycemia (Glucose <70 mg/dL) they received oral glucose (16/22 g) and continued the effort. Data analysis was performed for the entire exercise session and until the first hypoglycemic event.

occurred. Longitudinal glucose changes were analyzed with adjustments for session and sex. The area under the curve (AUC) and glucose deltas between adjacent time points were calculated and compared.

RESULTS: A total of 16 individuals (7 females) completed the protocol (mean $\pm$ SD, age: 27.4 $\pm$ 6.7 years; BMI:24.5 $\pm$ 2.6 kg/m²; VO₂max: 45.4 $\pm$ 7.6 ml/kg/min). Ten hypoglycemic events were recorded during each session (A/B). Mean time to hypoglycemia was similar for each session (A 32.1 $\pm$ 12.5 min vs B 37.5 $\pm$ 17.4 min, $p=0.84$). Comparison of session A vs. B within sex also showed no differences ($p=0.32$ for both comparisons). The mean time to hypoglycemia for females in session A was shorter (30.9 $\pm$ 10.2 minutes) than during session B (42.8 $\pm$ 14.4). No significant differences in glucose deltas and AUC were found between sessions (adjusted basal insulin vs. unadjusted), for the entire cohort or each sex. Additionally, there was no difference in the interaction between sex and session.

CONCLUSION: Basal insulin reduction does not significantly mitigate hypoglycemia during an hour-long bout of aerobic exercise. There were no major differences in glucose dynamics between sexes within each session or between sessions. Future women-inclusive studies should focus on alternative strategies for hypoglycemia prevention during exercise.

THE KEY NEEDS OF CARDIAC PATIENTS TO STAY PHYSICALLY ACTIVE AFTER AMBULATORY REHABILITATION: A QUALITATIVE ANALYSIS

FAUDE, O., GERBER, M., BUR, L., KLEIN, A., BISCHOFF, C., HOHBERG, V.

UNIVERSITY OF BASEL

INTRODUCTION: Cardiovascular disease is the leading cause of mortality worldwide, representing a major global health burden. Physical inactivity increases cardiovascular risk, while regular physical activity supports health maintenance. In cardiac patients, the transition from structured rehabilitation to daily life is key for sustainable secondary prevention. Understanding patients exercise needs provides insights into experiences, barriers, and motivation, enabling tailored interventions that enhance adherence, safety, and well-being, while considering medical, psychological, and social factors. We conducted qualitative interviews with cardiac patients, therapists, and physicians to explore strategies for long-term physical activity support.

METHODS: We employed a qualitative research design with 11 semi-structured individual interviews with cardiac patients (55% female, aged 30-80 y) with coronary heart disease. They participated or had participated in ambulatory cardiac rehabilitation at our university hospital and were part of a secondary prevention program. Participants spoke and understood German at an adequate level. Additionally, we conducted a focus group interview with 5 rehabilitation center employees (therapists and physicians, 20% female). Thematic reflexive analysis was used to evaluate data.

RESULTS: In the individual interviews, four main categories emerged: attitude to sport, needs, barriers and motivation. All participants mentioned particularly motivation in the context of sports and physical activity. Intrinsic and extrinsic factors played an almost equal role in patient motivation, accounting for 49% and 51% of responses, respectively. Key intrinsic motivators were goal achievement (33%), body awareness/well-being (22%), challenge/enjoyment of movement (22%), and health awareness (20%). Extrinsically, patients were influenced by their social environment (55%), available programs (21%), and experiencing nature (16%). Psychological pressure from illness (7%) played a minor role. Professionals in the focus group identified barriers such as lack of social support, physical limitations, psychological issues, and daily life constraints. Additionally, inadequate education about the disease and the benefits of physical activity were frequently noted.

CONCLUSION: This qualitative study highlights motivation as a crucial factor in exercise behavior among cardiac rehabilitation patients. Both intrinsic and extrinsic motivation influence adherence, but sustaining lifestyle changes requires strengthening intrinsic motivation. Key factors potentially include social support, health awareness, daily life coordination, and diverse program offerings. Future research should further examine individual motivation, patient-professional relationships, family dynamics, and age-related differences. Qualitative studies and intervention trials should develop tailored exercise programs to enhance adherence and promote long-term health.

THE IMPACT OF DIFFERENT TYPES OF SCREEN TIME SEDENTARY BEHAVIOR ON DEPRESSION SYMPTOMS IN CHILDREN AND ADOLESCENTS

GUO, M.

BEIJING NORMAL UNIVERSITY

Objective: Previous studies have suggested that screen time sedentary behavior may contribute to depression in children and adolescents. However, the differential effects of various types of screen time on depression symptoms in this population remain unclear. This study aims to clarify the impact of different types of screen time sedentary behavior on depression symptoms in children and adolescents through a nationwide cross-sectional survey conducted over two years.

Methods: Based on the China Family Panel Studies, a total of 6,052 children and adolescents aged 10-18 were surveyed in 2020 and 2022. Depression symptoms were assessed using the Centre for Epidemiologic Studies Depression (CES-D) scale. Participants were surveyed on their frequency of screen time for activities such as online gaming, online shopping,

online learning, online socializing, and online entertainment. Three generalized linear regression models were used: Model 1 examined the effect of different types of screen time on depression symptoms; Model 2 controlled for gender, age, urban-rural type, and education level; and Model 3 further controlled for physical activity frequency and sleep duration.

Results: The results of Model 1 indicated that compared to children and adolescents who did not engage in online shopping, those who did were 24% more likely to experience depression (Odds Ratio [OR] = 1.24, 95% CI: 1.03-1.45). Similarly, those who engaged in online entertainment were 27% more likely to experience depression compared to non-users (OR = 1.27, 95% CI: 1.03-1.52), with daily users having a 44% higher probability of depression (OR = 1.44, 95% CI: 1.17-1.70). After controlling for gender, age, urban-rural type, and education level, the effect of online shopping on depression probability became non-significant, but the effect of online entertainment remained. Additionally, compared to adolescents who never used online socializing, those who did had a 31% lower probability of depression (OR = -0.31, 95% CI: -0.59 to -0.03). After further controlling for physical activity and sleep, the effects of online shopping, online socializing, and online entertainment on depression were no longer significant.

Conclusion: Among different types of screen time sedentary behaviors, online shopping and online entertainment are risk factors for depression symptoms in children and adolescents, while online socializing serves as a protective factor. Future policies should address the differential impacts of screen time behaviors on the mental health of children and adolescents and develop targeted interventions.

COMPARING THE AUTONOMY AND PERCEPTIONS APPROACH TO RESISTANCE TRAINING (APART) TO THE STANDARD PRESCRIPTION APPROACH: A NON-INFERIORITY RCT

SCHWARTZ, H., SILVERMAN, Y., KONFINO, SH., MARKUS, I., KOBI, O., HERSHTAIN, D., OBOLSKI, U., GEPNER, Y., HALPERIN, I.
TEL AVIV UNIVERSITY

Background: Resistance training (RT) provides numerous health and functional benefits, yet less than 30% of individuals meet RT guidelines. One potential barrier is the rigid structure of standard RT prescriptions, which use predetermined loads and repetitions, potentially limiting individualization. Consequently, there is a need for more flexible and personalized RT approaches. This study tested the non-inferiority of the Autonomy and Perceptions Approach to Resistance Training (APART). With APART, trainees select their preferred loads and perform repetitions until reaching a target rating of perceived effort (RPE) value on a 0-10 RPE scale.
