Methods: In this randomized controlled trial, 129 adults (18-45 years) with no RT experience were assigned to either APART or a standard RT group. After baseline testing and familiarization, both groups completed three weekly RT sessions for 12 weeks, performing three sets on six RT machines per session. Under APART, trainees selected their preferred loads and completed repetitions until reaching an RPE of 7-8. Under the standard approach, trainees followed a fixed load protocol, using 65%-75% of their one-repetition maximum (1RM) for 10 repetitions per set. Performance, health, psychological measures, and adherence were assessed at baseline, during, and after the intervention. Group differences were analyzed using confidence intervals and compared against predefined non-inferiority margins.

Results: 101 participants completed the intervention, with similar adherence rates in both groups (69.5% in APART vs. 71.2% in the standard group). Both groups improved all performance outcomes, including 1RM (percent change range: 19%-38%), muscle endurance (51%-85%), and isometric (21%-24%) tests. APART was found to be non-inferior to the standard approach in performance measures. Additionally, both groups improved in most health outcomes, including systolic blood pressure (-1% to -2.5%), waist circumference (-2.1% to -2.6%), fasting glucose (-1.1% to -3.3%), total cholesterol levels (-1.4% to -1.8%) and fat-free mass (1.1%-1.4%), yet non-inferiority could not be established. Finally, participants in both groups reported similar positive experiences (average > +40 on a -50 [negative] to +50 [positive] scale).

Discussion: APART led to improvements in performance, health, and psychological outcomes. While non-inferiority was established for performance outcomes, it was not established for health outcomes, potentially due to insufficient statistical power. APART's ease of implementation, ability to accommodate performance variability, and integration of trainees' preferences make it a viable alternative to the standard RT approach. Future studies on APART should use larger and more diverse samples alongside longer interventions and follow-up periods to further explore its real-world applicability.

IMPROVING SPORT OPPORTUNITIES, PARTICIPATION, AND EXPERIENCES FOR CHILDREN IN OUT-OF-HOME CARE

SIMPSON, A., BUDDEN, T., WILLIS, C., DIMMOCK, J., LIN, A., THORNTON, A.L., FURZER, B., JEFTIC, I., ROSENBERG, M., JACKSON, B.
THE UNIVERSITY OF WESTERN AUSTRALIA

Background: Participation in sport offers significant physical, psychological, and social benefits. However, children in out-of-home care face complex barriers that limit their involvement, resulting in lower participation rates compared to their peers in other household arrangements. We aimed to identify carers' recommendations for improving sport participation and experiences for children in care.

Methods: A total of 42 foster and kinship carers in Western Australia participated in the study. Data were collected through online surveys and interviews using a sequential explanatory mixed-methods approach, integrating both quantitative and qualitative analyses.

Results: Three key recommendations—along with corresponding implementation strategies—were identified for policy-makers, researchers, peak sporting bodies, and sporting organisations: (1) embedding inclusive practices within existing

sport programs; (2) developing education and training for sport program providers; and (3) enhancing support for carers to facilitate children's sport participation.

Conclusions: This study provides actionable guidance for increasing sport participation among children in care, helping to maximise their opportunities for physical, psychological, and social development.

A THREE-ARM RANDOMIZED CONTROLLED TRIAL COMPARING LIFESTYLE INTERVENTIONS WITH DIFFERENT INTENSITY ON AVERAGE DAILY STEPS AMONG PRE-DIABETIC ARAB ADULTS LIVING IN EAST JERUSALEM

ZUAITER, L., BAR-ZEEV, Y., BITAR, D., BASSAL, R., KAUFMAN-SHRIQUI, V., LAHAD, A., MANOR, O., RAUCH, O., ZUAITER, S., PALTIEL, O.

THE HEBREW UNIVERSITY OF JERUSALEM-HADASSAH MEDICAL CENTRE

Background:

Individuals with prediabetes face a higher risk of developing Type 2 Diabetes Mellitus, but targeted interventions that incorporate physical activity (PA) can help prevent progression [1]. However, no prior PA intervention studies have been conducted among prediabetic Israeli Arab adults residing in East Jerusalem. This study aimed to compare the effects of lifestyle interventions with varying intensities on daily steps and self-reported PA habits. We hypothesized that higher-intensity interventions would lead to greater increases in PA.

METHODS: A three-arm parallel randomized controlled trial (RCT). Adult participants were recruited through primary care settings and randomly assigned (1:1:1) into low (arm A)-, moderate (B)-, and high-intensity (C) PA intervention groups. Arm A received an activity tracker and general PA recommendations. Arm B also received a personalized PA prescription. Arm C additionally received a motivational interview and a Mediterranean diet consultation. Baseline data were collected one week post-recruitment, with follow-up after ~7 months (SD=3.1) due to COVID-19 delays. Primary outcome was the change in daily steps, assessed via activity trackers. Secondary outcomes included self-reported PA. ANOVA and post-hoc pairwise comparisons evaluated pre- and post-intervention changes, while multiple regression controlled for baseline steps and sex. Sensitivity analyses combined arms B and C to assess trends.

RESULTS: A total of 175 participants [mean (SD) age 55.0 (7.5) years, mean BMI 32.4 (6.0) kg/m², 32.6% male] were randomized. Baseline daily steps averaged 6,391.4 (SD 3,268.1). At follow-up, n=130 completed assessments (A=45, B=41, C=48). No significant differences were observed across groups. Post-hoc analyses revealed significant step increases in arm C vs. arm A (p=0.04) and in arms B and C combined vs. arm A (p=0.02). Regression analysis showed an inverse association between baseline steps and step change (p=0.015). Arm C participants had a significantly higher step increase (+1,294.4 steps; p=0.016), while arm B and sex had no significant effects. Self-reported PA habits increased slightly but results were not statistically significant.

Conclusions:

In this three-arm RCT assessing PA interventions in the prediabetic Arab population of East Jerusalem, high-intensity PA interventions significantly improved PA levels, even during COVID-19 lockdowns, while moderate-intensity interventions showed no significant effect. PA interventions could be integrated into primary care to enhance cost-effective diabetes prevention strategies.

CP-PN01 Muscle Metabolism

THE OCCURRENCE OF REDS INDICATORS WAS NOT ASSOCIATED WITH PERCEIVED SLEEP QUALITY BUT WAS LINKED TO AN INCREASED USE OF SLEEP MEDICATION

AHOKAS, E., MIKKONEN, R.S.2, IHALAINEN, J.K.1

UNIVERSITY OF JYVÄSKYLÄ

INTRODUCTION: Sleep disturbances are a potential negative consequence of problematic low energy availability [1]. For instance, four weeks of energy restriction impacted the sleep patterns of non-athletes [2]. Additionally, athletes reported, via interviews, that their subjective perception was that weight reduction negatively affected their sleep [3]. The aim of this study was to investigate the association of perceived sleep and primary indicators of Relative Energy Deficiency in Sport (REDS).

METHODS: National and international level female athletes (n=128; 23.3±4.8 years) representing various sports participated in the study during their preparatory season. Athletes' sleep quality was assessed by the Pittsburgh Sleep Quality Index (PSQI). Seven components of sleep (quality, latency, duration, efficiency, disturbance, sleep medication use, and daytime dysfunction) were calculated from the PSQI. REDS indicators included primary and secondary amenorrhea assessed via

LEAF-Q (low energy availability in females questionnaire), low serum free triiodothyronine concentration, history of bone stress injury, low bone mineral density (Z-score <-1) at the lumbar spine analysed by Dual-energy X-ray absorptiometry, and an elevated score for the EDE-Qs (eating disorder examination questionnaire short). Participants were divided into groups based on the use of hormonal contraception: naturally menstruating (NM, n=80) and hormonal contraceptive users (HC, n=48), and further based on the primary indicators of REDs: no-risk (0 indicator), risk (1 or more indicators). The differences in PSQI points between groups were analysed with Mann-Whitney U Test and the differences of prevalence with Chi-Square Tests (SPSS 28.0.0).

RESULTS: REDs indicators were observed in 50% of NM and 54% of HC, while poor sleep (5 or more points in PSQI) was observed in 45% of NM and 40% of HC. There were no differences between no-risk and risk groups in total PSQI score or the PSQI components (NM: $p=0.104-0.897$; HC: $p=0.367-0.791$), but medication use was higher in NM-risk ($p=0.023$). Medication use was more prevalent in NM-risk (23%) than in NM no-risk (5%; $p=0.026$). Additionally, there was a trend for higher medication use ($p=0.073$) and prevalence of medication use ($p=0.081$; 21% vs. 4%) in HC-risk compared to HC-no-risk.

CONCLUSION: The primary indicators of REDs were not linked to perceived sleep quality. However, female athletes with more indicators of REDs were more likely to use sleep medication. The relationship between energy availability and sleep should be further explored.

IMPACT OF 14 DAYS OF BED REST WITH OR WITHOUT EXERCISE ON CALF MUSCLE AND FAT VOLUMES, AND FIBER TYPE COMPOSITION

HAJJ-BOUTROS, G., DULAC, M., SONJAK, V., FAUST, A., GUDYMENKO, A., CHURCHWARD-VENNE, T., GOUSPILLOU, G., MORAIS, J.A.

MCGILL UNIVERSITY HEALTH CENTER

INTRODUCTION: Bed rest is a common occurrence in clinical settings, including hospitals and extended care facilities. The resulting inactivity leads to muscle mass loss, reduced strength, and diminished functional capacity, which can increase mortality risk, particularly in older adults. Muscle loss in this population is strongly linked to a higher risk of falls. While physical activity is known to mitigate age-related declines in muscle mass and function in older adults, its effectiveness in counteracting the detrimental effects of bed rest on skeletal muscle mass and fiber composition in older adults remains unclear. This study examined the effects of 14 days of six-degree head-down tilt bed rest (HDBR) on muscle volume, as measured by MRI, and muscle fiber composition, assessed through biopsy samples in older adults. Additionally, it evaluated whether an in-bed exercise countermeasure could mitigate the detrimental impact of bed rest on muscle mass.

METHODS: Twenty-two participants (aged 55–65 years) were randomized into two groups for a two-week HDBR: a control group (σ : 6, φ : 5) and an exercise group (σ : 5, φ : 6). The exercise group performed one hour of combined resistance and aerobic exercise daily while remaining in bed. Needle muscle biopsies from the vastus lateralis and calf muscle and fat volumes by MRI were conducted prior to, and after HDBR.

RESULTS: At baseline, no significant differences were observed between groups. Following 14 days of bed rest, both groups experienced a reduction in total calf muscle volume (control: $28.4 \pm 2.0 \text{ cm}^3$ to $25.1 \pm 2.0 \text{ cm}^3$; exercise: $29.3 \pm 2.2 \text{ cm}^3$ to $26.7 \pm 2.2 \text{ cm}^3$). However, a significant group effect was observed in calf fat volumes, with a decrease only in the exercise group ($18.1 \pm 2.0 \text{ cm}^3$ to $16.9 \pm 1.9 \text{ cm}^3$, $p = 0.001$), while no significant change was observed in the control group ($16.2 \pm 1.8 \text{ cm}^3$ to $16.4 \pm 1.7 \text{ cm}^3$). Our preliminary findings suggest that neither bed rest alone nor bed rest with exercise significantly alters muscle fiber composition.

CONCLUSION: HDBR resulted in a significant reduction in calf muscle volume in both the control and exercise groups, highlighting the rapid muscle loss associated with inactivity in older adults. However, a reduction in calf fat volume was observed only in the exercise group, suggesting potential metabolic benefits of in-bed exercise during prolonged inactivity. Further analysis will offer deeper insights into muscle fiber changes following HDBR.

LOCAL COOLING OF SKELETAL MUSCLE BEFORE ACUTE EXERCISE AND ENDURANCE TRAINING HAS A SYNERGISTIC EFFECT ON MITOCHONDRIAL ADAPTATIONS IN MICE

KANO, R., TAKEDA, R., POOLE, D., KANO, Y., HOSHINO, D.

UNIVERSITY OF ELECTRO-COMMUNICATIONS

INTRODUCTION: Cooling interventions after exercise have been used to enhance skeletal muscle mitochondrial adaptations to endurance exercise (1). Recently, we found that intermittent cooling of skeletal muscle for 1 hour modulates intramyocyte [hydrogen peroxide], which plays an important role in intramuscular signaling. This cooling pattern increases gene expression of Nrf2, a transcription factor that responds to altered [hydrogen peroxide]. Increased Nrf2 expression prior to endurance exercise enhances exercise-induced mitochondrial adaptations (2). Therefore, this investigation was

designed to test the hypothesis that local cooling of skeletal muscle prior to running exercise would enhance mitochondrial adaptations in mouse skeletal muscles.

METHODS: Acute experiment: Male C57Bl/6J mice (9 and 10 weeks old) were divided into sedentary (n=7) and exercise (n=7) groups. Both groups were subjected to cooling stimulation (muscle temperature: 35~13~35°C x 6 sets, total 60 min) on the left leg. The sub-groups were Room temperature + sedentary (RT + Sed), ICE + sedentary (ICE + Sed), Room temperature + exercise (RT + Ex), and ICE + exercise (ICE + Ex). The exercise group performed a 60-minute treadmill running (15 m/min, slope 10 degree incline) immediately after the temperature intervention whereas Sed animals rested. Three hours after the the exercise or rest, tibialis anterior (TA) muscles of all groups were excised, and mRNA levels of PGC1 α , Ucp3, and pdk4 were measured. Training experiment: In 14 mice, the same cooling and exercise protocol as in the acute model was performed 4 times / week for 4 weeks, and 24 hours after the last training bout, TA and EDL muscles were harvested. Mitochondrial enzyme activity, mitochondrial and antioxidant-related proteins were measured. Statistical analyses using a paired two-way ANOVA, and multiple comparison tests were performed for interaction effects. A statistical level of p<0.05 was accepted.

RESULTS: Acute Responses: ICE + Ex showed significantly higher levels of PGC1 α mRNA than RT + Ex (+14%, p=0.012). Ucp3 and Pdk4 increased with exercise (p<0.001), but decreased with cooling stimulation (p<0.05). Training Responses: CS activity increased additively (+18%) with the combination of training and cooling as did β -HAD activity compared with training alone (+24%, p=0.017). There were no differences in the levels of mitochondrial-related proteins OXPHOS, PGC1 α , or antioxidant enzymes Sod1,2 among groups.

CONCLUSION: Local cooling stimulation of skeletal muscle prior to acute running exercise promoted an increase in PGC1 α mRNA levels. Running training under pre-cooling conditions increased the activity of the mitochondrial enzymes CS and β -HAD compared to training under normal conditions. This study demonstrates that pre-conditioning with local cooling has a synergistic effect on the mitochondrial adaptations induced by running exercise.

DESMINOPATHY-ASSOCIATED TLR4 DYSREGULATION AND MITOCHONDRIAL ALTERATIONS: POTENTIAL EFFECTS OF UROLITHIN A IN A TRANSLATIONAL MODEL

TAPIA-CURIMIL, G., VALERO-BRETON, M., DELDICQUE, L., ZBINDEN-FONCEA, H.
FINIS TERRAE UNIVERSITY - UCLouvain

INTRODUCTION: Desminopathy is a human myopathy characterized by the progressive loss of muscle fiber organization, leading to a reduction in muscle size, mobility, and strength. In desminopathy, inflammation disrupts muscle homeostasis and repair, contributing to progressive muscle deterioration. TLR4 signaling plays a critical role in mediating inflammatory responses and can induce structural changes in mitochondria. Mitochondrial dynamics and structure are closely associated with mitochondrial health and are involved in mitophagy. Mitochondrial morphology has also been implicated in desminopathy progression. Urolithin A, a recently identified natural compound, has been shown to induce mitophagy and potentially enhance mitochondrial homeostasis. Based on this rationale, our objectives were 1) To analyze TLR4 signaling in peripheral blood mononuclear cells (PBMCs) from desminopathy patients; 2) To determine the role of Urolithin A in TLR4 signaling and its effect on mitochondrial morphology in LPS-induced myotubes.

METHODS: 1) Five desminopathy patients and five healthy controls were included. Blood samples were collected to isolate PBMCs and assess health parameters. TLR4 signaling and mitochondrial dynamic proteins were analyzed by Western blot, while mitochondrial morphology was evaluated using transmission electron microscopy; 2) On day 6 of differentiation, C2C12 myotubes were stimulated with LPS (1 ng/ml) for three hours and/or Urolithin A (50 μ M) for 24 hours. Protein levels associated with TLR4 signaling and mitochondrial dynamics were determined by Western blot, and mitochondrial morphology was assessed using electron microscopy.

RESULTS: 1) Desminopathy patients exhibited higher CK-MB levels compared to controls. Additionally, proteins related to inflammatory signaling, such as JNK were elevated in desminopathy patients. Consistently, I κ B α and TLR4 protein levels were lower in desminopathy patients compared to controls; 2) Urolithin A reduced LPS-induced inflammatory signaling by downregulating TAK1, JNK, and ERK proteins. Moreover, LPS stimulation increased p-DRP1 levels, whereas Urolithin A treatment restored this protein to control levels. Furthermore, LPS reduced mitochondrial perimeter, while Urolithin A maintained a perimeter similar to that of control cells.

CONCLUSION: Desminopathy patients exhibited higher levels of proteins associated with TLR4 signaling, in parallel with increased markers of skeletal muscle damage. These findings suggest that Urolithin A effectively mitigates LPS-induced inflammation by modulating the TLR4 signaling pathway and mitochondrial dynamics. Thus, Urolithin A may represent a promising therapeutic agent for conditions associated with mitochondrial dysfunction and inflammation, highlighting its potential role in promoting skeletal muscle health.

HAMSTRINGS MUSCLE DAMAGE INDUCED BY FOOTBALL (SOCCER) TRAINING METHODS: CASE-SERIES

COSIO, P., MORENO-SIMONET, L., LLORET, M., PADULLES, X., PADULLES, J.M., CADEFEAU, J.A.
NATIONAL INSTITUTE OF PHYSICAL EDUCATION OF CATALONIA - UNIVERSITY OF BARCELONA

INTRODUCTION: Hamstring muscles play a key role in force production during sprinting biomechanics [1], and during shank deceleration before ground contact [2], so they are particularly susceptible to muscle strains in high-speed movements. Furthermore, the number of hamstring strain injuries has increased twofold over the last 20 years, due to highly

congested schedules [3]. Accordingly, several training methods have been implemented to reduce injury risk. Therefore, the purpose of the research was to compare the extent and time course of hamstrings muscle damage caused by repeated sprint training and inertial-based resistance training in comparison to a real football (soccer) match.

METHODS: Regional first-division football male players ($n = 4$, age = 23.0 ± 0.8 years, mass = 72.6 ± 5.7 Kg, height = 174.3 ± 4.2 cm, BMI = 24.0 ± 2.8 (mean $\pm$ SD)) participated in three common exercise exposures: (i) FM: a 90-minute football match; (ii) RST: a repeated sprints training (10-repeated 40-meter sprints, rest: 3'); and (iii) FRBD: a Flywheel Russian belt Deadlift training session (5 sets $\times$ 10 repetitions, rest: 3'). The extent of muscle damage was measured using the peak torque and perceived soreness in the hamstrings, through the 90°hip:20°knee test, together with serum biomarkers of structural damage (creatinine kinase [CK], sarcomeric mitochondrial CK [sMtCK]), oxidative stress (malondialdehyde [MDA]) and irisin, both at baseline and at +24, +48- and +72-hours post-exercise. Two-way repeated measures ANOVA (time (pre, 24h, 48h, 72h) $\times$ exercise (RST, FM, FRBD)) was conducted to identify the effect of time on neuromuscular and biochemical markers. Associations between variables were analyzed using Spearman's Rho correlation coefficient. The level of significance was set at $p < 0.05$.

RESULTS: All three exposures caused significant decreases in hamstrings peak torque [$F(3,27) = 9.923$, $p < 0.001$] and increases in perceived soreness [$F(3,24) = 6.768$, $p = 0.002$], CK [$F(3,27) = 10.632$, $p = 0.006$], sMtCK [$F(3,27) = 24.728$, $p < 0.001$], MDA [$F(3,27) = 7.283$, $p < 0.001$] and Irisin [$F(3,27) = 8.682$, $p < 0.001$] during the post-exercise recovery period. No significant differences were found between exercise exposures, nor correlations between neuromuscular and biochemical markers of muscle damage.

CONCLUSION: Both RST and FRBD training sessions produce a magnitude and time course of hamstrings muscle damage comparable to that of a real football match. Practitioners are required to consider appropriate recovery periods after sprint-based or inertial-based resistance training sessions during a competitive week.

THE EFFECT OF DL-HOMOCYSTEINE ON ENERGY METABOLISM IN C2C12 MUSCLE CELLS VIA INHIBITION OF KYNURENINE AMINOTRANSFERASE

TAKADA, H., SHION, O., RYOICHI, N.

TOHOKU UNIVERSITY

INTRODUCTION: In large-scale skeletal muscle metabolome analysis, kynurenine is increased in the skeletal muscles of the elderly, while its downstream metabolites, kynurenic acid (KYNA) and NAD⁺, are increased in active adult skeletal muscles (1). This suggests that the kynurenine pathway plays an important role in skeletal muscle energy metabolism. Kynurenine aminotransferase (KATs), the principal enzyme in this pathway, catalyzes the conversion of kynurenine to kynurenic acid. Recent studies have demonstrated that exercise increases the expression of KATs genes in mouse skeletal muscle and affects fatigue resistance and energy metabolism. However, the effect of KATs on the cell proliferation potential and energy metabolism of muscle cells themselves remains to be elucidated. The present study was thus designed to elucidate the impact of DL-Homocysteine, a KATs inhibitor, on the cell proliferation potential and energy metabolism of muscle cells.

METHODS: In this study, we utilized C2C12 myoblasts to assess the dynamics of cell proliferation and ATP synthesis during the proliferation phase, as well as the energy metabolism shift during the differentiation phase. These evaluations were conducted under varying concentrations of DL-homocysteine (10 μ M, 100 μ M, 200 μ M). The energy metabolism shift was determined by quantifying the inhibition of ATP synthesis derived from oxidative phosphorylation by oligomycin and the amount of lactic acid produced.

RESULTS: The groups administered 100 μ M and 200 μ M of the inhibitor exhibited a marked decrease in cell proliferation rate and total protein content compared to the control group. Conversely, the inhibitor significantly augmented the amount of ATP synthesis. On day 5 of differentiation, the groups administered the inhibitor demonstrated a substantial increase in ATP synthesis compared to the control group. In terms of changes in energy metabolism on day 5 of differentiation, the treatment group exhibited a significant increase in lactate production compared to the control group. Furthermore, in the treatment group, the rate of glycolysis was significantly higher than the rate of oxidative phosphorylation, indicating a shift towards glycolysis in energy metabolism.

CONCLUSION: In humans, KYNA has been demonstrated to be associated with the oxidative capacity of skeletal muscle (1). In this study, it was proposed that the inhibition of KATs from day 0 of myocyte differentiation increased the amount of ATP produced via glycolysis on day 5. This is attributable to the involvement of the kynurenine pathway in mitochondrial oxidative phosphorylation, and it is conceivable that the inhibition of this pathway may have activated the glycolytic pathway as a compensatory measure. These results underscore the necessity for further investigation into the mitochondrial function and oxidative capacity of muscle cells. Future research is anticipated to elucidate the underlying mechanisms through which KATs regulate these processes.

TOPICAL APPLICATION OF CANNABIDIOL FOR MUSCLE RECOVERY : A RANDOMIZED, DOUBLE-BLINDED PILOT STUDY ON RECOVERY OF MUSCLE FUNCTION AFTER EXERCISE-INDUCED MUSCLE DAMAGE

MENDES, A., CUVELIER, G., ANTHIERENS, A., LOCQUENIES, A., GAUCHET, N., MABOUDOU, P., HEYMAN, E., BERTHOIN, S., GAMELIN, F.X.

UNIVERSITÉ DE LILLE

INTRODUCTION: The purpose of this pilot study was to investigate the effects of Cannabidiol (CBD) gel compared to a placebo gel on muscle damage and recovery of muscle function over four days following a strenuous exercise. CBD has gained attention for its potential anti-inflammatory and analgesic properties, making it a possible aid for muscle recovery after exercise-induced muscle damage (EIMD).

METHODS: Fifteen physically active students (age: 21.4 ± 2.1 years; mass: 78.0 ± 9.5 kg; height: 181.7 ± 5.0 cm) participated in the study. Participants performed 10 sets of 10 drop jumps from a 0.6m box, with 2 minutes of rest between sets, to induce muscle damage. In a randomized crossover design, 2 grams of either CBD gel or a placebo gel were applied to the quadriceps and hamstrings immediately after exercise and over the next 72 hours. Muscle function recovery was assessed by measuring maximal isometric and isokinetic concentric peak torque of the knee extensor, plasma myoglobin concentration, and Delayed Onset Muscle Soreness (DOMS) (via visual analog scale) at baseline, immediately post-exercise, and at 24h, 48h, and 72h intervals.

RESULTS: ANOVA revealed a significant interaction between time and condition for isometric torque ($p < 0.02$). In the CBD condition, maximal isometric peak torque was restored within 24 hours, compared to 72 hours in the placebo condition ($p < 0.05$ for both). No significant differences were observed between the CBD and placebo conditions for plasma myoglobin concentrations or Delayed Onset Muscle Soreness scores.

CONCLUSION: The topical application of CBD gel may accelerate the recovery of muscle strength following strenuous exercise, as evidenced by faster restoration of isometric peak torque compared to placebo. However, CBD had no significant effect on plasma markers of muscle damage or subjective soreness. These findings suggest that CBD could be a useful tool for improving muscle strength recovery, although further research is needed to fully understand its mechanisms and broader impact.

DO AGE OR SEX MEDIATE THE EFFECTS OF IMMOBILIZATION-INDUCED DECLINES IN MUSCLE VOLUME AND NEUROMUSCULAR FUNCTION? A LITERATURE REVIEW AND FUTURE PERSPECTIVES

KELLER, M., RITSCHKE, P., FAUDE, O.

UNIVERSITY OF BASEL

INTRODUCTION: The effects of unloading on the neuromuscular system have been studied for both the upper and lower limbs. A systematic review showed that muscle strength and muscle size decline following immobilization, with strength decreasing more than size (Campbell et al. 2019). The data reveal immobilization-induced declines of 0.3-0.7% per day for muscle mass and 0.3-2.0% per day for muscle function. While these data summarize the actual knowledge in the field, it remains unknown whether age or sex mediate the declines. Therefore, we reviewed studies investigating the effects of age or sex on immobilization-induced neuromuscular declines.

METHODS: We conducted a literature review to identify studies examining age- or sex-specific effects following an immobilization period. Search strings were used to identify studies that compared immobilization-induced declines in different sexes or age-groups.

RESULTS: The majority of immobilization studies included mainly healthy young men. Only three studies compared immobilization effects between young men vs. women. In these studies, muscle strength was reduced by 3 to 16% in men and 17 to 28% in women. Two of the three studies also investigated possible sex-specific effects on immobilization-induced atrophy, reporting comparable muscle losses at the myofiber (1 study) and whole muscle level (2 studies). One study reported larger reductions in electromyographic activity after disuse in women (-32%) than men (-2%). Comparisons between young and old men showed inconsistent results in terms of atrophy, with three studies reporting pronounced losses in young (3 studies) and other studies reporting more pronounced effects in old (3 studies) participants. It is noteworthy that the effects of immobilization in older women were not compared with any other cohort in any study.

CONCLUSION: The available literature indicates that immobilization-induced effects on strength are more pronounced in young women than young men. While atrophy is identical between sexes, neuromuscular activation is likely more impaired after immobilization in women. The effects of age on immobilized-declines are less consistent with respect to muscle mass and possible mechanisms for age-specific differences on muscle strength remain poorly understood. To address this gap, we will conduct a parallel-group intervention study involving four groups (two sexes: male/female; two age groups: 18-35 and 65+ years) undergoing ten days of lower limb cast immobilization followed by three weeks of retraining. The dominant limb will be immobilized while the non-dominant limb serves as control. Neuromuscular function (strength, power, gait) and underlying mechanisms (high-density EMG, interpolated-twitch technique, dynamic ultrasound for muscle contractility and tendon stiffness, dynamic MRI) will be assessed.

ASSESSMENT OF MUSCLE FUNCTION AND STRETCH-SHORTENING CYCLE PERFORMANCE IN OLDER ADULTS: A FOUNDATION FOR ECCENTRIC OVERLOAD RESISTANCE TRAINING - A PILOT STUDY

EMAM, M., HORVÁTH, A., KOVÁCS, B., MEHMET, A., CSIZMADIA, B., YE, J., ZHANG, L., NÉGYESI, J., HORTOBÁGYI, T.
SEMMELEI UNIVERSITY

INTRODUCTION: Age-related decline is not uniform in measures of neuromuscular function. There is a relative maintenance in maximal voluntary eccentric vs. concentric and isometric force (MVC). It is unclear how age effects measures that are even more closely related to daily function such as stretch-shortening cycle (SSC) efficiency tested during dynamometry and vertical jumps. Identifying age-differences in neuromuscular outcomes could inform prescription of resistance training especially with an eccentric overload to target age-typical deficiencies at the start of a resistance training program.

METHODS: We compared healthy, active young adults (32.4 ± 5.59 years, $n=4$) and older adults (73.75 ± 2.75 years, $n=4$) in selected neuromuscular outcomes of the knee extensor muscles. Participants performed MVC knee extension and SSC contractions on a dynamometer and peak strength, the rate of torque development and mechanical efficiency was calculated. In addition, squat and counter-movement jumps were also performed where jump height and related parameters calculated. All measurements were conducted twice to establish test-retest reliability.

RESULTS: Mechanical efficiency and SSC effect during SSC contractions were similar between Young (Y: $45.09 \pm 2.06\%$) vs. Old (O: $44.92 \pm 1.13\%$) and (Y: 1.10 ± 0.10 vs. O: 1.08 ± 0.17) respectively. However, younger adults demonstrated knee extensor higher torque and rate of torque development during the isometric contractions (Y: 0.78 ± 0.24 vs. O: 0.25 ± 0.17 Nm/ms, $p = 0.01$, $d = 2.50$). There also were no age-differences in MVC (Y: 130.45 ± 15.91 vs. O: 122.87 ± 23.26 Nm, $p = 0.60$, $d = 0.39$). Squat jump height (Y: 0.27 ± 0.05 vs. O: 0.13 ± 0.02 m, $p < 0.01$, $d = 3.17$), and countermovement jump height (Y: 0.34 ± 0.06 vs. O: 0.15 ± 0.03 m, $p < 0.01$, $d = 3.87$). All measurements demonstrated excellent test-retest reliability ($ICC > 0.85$).

CONCLUSION: While mechanical efficiency and SSC effect remain preserved with aging, explosive strength and jump performance show significant age-related declines. The lack of significant difference in MVC despite age differences suggests it may not be a sensitive indicator of age-related muscle function changes. Such data inform our subsequent eccentric overload training intervention to improve older adults' neuromuscular function especially affected by aging.

TENSIOMYOGRAPHY AS A MUSCLE QUALITY ASSESSMENT METHOD FOR SARCOPENIA IN SLOVENIAN OLDER ADULTS

PUŠ, K., KALC, M., SARTO, F., NARICI, M.V., MADRID FUENTES, D.A., WEAVER, A., MAHONEY, J.R., ŠIMUNIC, B.
SCIENCE AND RESEARCH CENTER KOPER

INTRODUCTION: Despite the significant health burden of sarcopenia, a consensus on classification is still lacking. Global prevalence estimates vary widely, ranging 10 to 27%, depending on classifications. Recent research suggests that muscle quality - defined as micro- and macroscopic aspects of muscle architecture and composition - could play a key role in sarcopenia classification. Thus, non-invasive tensiomyography (TMG) has emerged as a promising tool, with previous studies demonstrating its ability to detect muscle fibre composition and early atrophic changes before could be detected with muscle imaging techniques. However, its sensitivity to detect differences in the sarcopenic muscle remains unknown. This study aimed to validate TMG as a sarcopenic muscle quality assessment method.

METHODS: We investigated prevalence of sarcopenia in a random sample of Slovenian older adults ($n=681$, aged 73 ± 9 , 68.4% female) according to revised European Working group on Sarcopenia in Older People (EWGSOP2) and Sarcopenia definition and outcome consortium (SDOC) classifications with recently adopted cut-off points. Vastus lateralis (VL) contractile parameters were assessed by TMG (delay and contraction time, contractile velocity and radial displacement) and compared between sarcopenic and non-sarcopenic. Further, on a subsample of 51 participants (aged 82 ± 8 ; 53% females) we assessed VL muscle architecture by ultrasound (thickness, pennation angle, fascicle length), volume and fat fraction (MFF) by continuous thigh Dixon sequence magnetic resonance imaging.

RESULTS: Sarcopenia prevalence was 10.9% (EWGSOP2) and 22.5% (SDOC). In general, sarcopenic had longer delay and contraction times, lower radial amplitude (higher stiffness) and lower contraction velocity than non-sarcopenic which was confirmed by moderate Pearson correlation of those parameters with performance in sarcopenia classification tests (sit-to-stand test, timed up-and-go test, handgrip strength and gait speed) with r -values ranging between $-.382$ and $.362$. Furthermore, on a subsample we found that radial displacement positively correlated with muscle thickness ($r=.408$, $p<.004$), fascicle length ($r=.460$, $p=.001$), and negatively with MFF ($r=-.506$; $p<.001$). Similarly, contraction velocity positively correlated with muscle thickness ($r=.433$; $p=.002$), fascicle length ($r=.460$; $p=.001$) and negatively with MFF ($r=-.533$; $p<.001$). Contraction time showed positive correlation with MFF ($r=.330$; $p=.027$).

CONCLUSION: We provided the prevalence of sarcopenia among Slovenian older adults, revealing considerable discrepancies between the two classification systems. Our findings support the potential of TMG as a viable method for muscle quality assessment. Given TMG is non-invasive and sensitive to changes in sarcopenia muscle alternations, TMG could contribute to improving sarcopenia classification and detection.

CP-PN02 Sex Differences and the Female Athlete

SEX DIFFERENCES IN MUSCLE MORPHOLOGY AND GENE EXPRESSION ACROSS THE HUMAN LIFESPAN

VAN BELLEGHEM, K., WILLIAMS, R., CRITCHLOW, A., ENGMAN, V., SORIA, M., GARNHAM, A., HIAM, D., LAMON, S.

SCHOOL OF EXERCISE AND NUTRITION SCIENCES, INSTITUTE FOR PHYSICAL ACTIVITY AND NUTRITION, DEAKIN UNIVERSITY, BURWOOD, AUSTRALIA

INTRODUCTION: Sex differences in skeletal muscle morphology and function start in utero and evolve throughout life due to interactions between genetic, hormonal, and environmental factors. However, the molecular mechanisms driving these differences across the lifespan remain unclear. This study investigates how muscle structure and gene expression change with age in males and females, aiming to identify factors contributing to sex-specific muscle aging and function.

METHODS: A total of 96 biological males and 96 biological females aged 18–80 years and stratified by decade participated in this study. Body composition was assessed using dual-energy X-ray absorptiometry (DXA) and peripheral quantitative CT (pQCT) scans. Muscle strength was evaluated through a leg press 5-repetition maximum (RM) test. Muscle biopsies collected from the vastus lateralis were analysed using RNA sequencing (RNA-seq) and immunohistochemical (IHC) staining, with all statistical analyses conducted in RStudio (version 4.3.1).

RESULTS: Preliminary transcriptomic analysis revealed distinct sex- and age-associated patterns in gene expression. Pathways related to energy metabolism and cellular respiration exhibited notable differences between sexes, while age-related variations in the male cohort were particularly evident in pathways linked to immune function and protein degradation.

CONCLUSION: Ongoing analyses will integrate the muscle transcriptome with sex hormones, body composition, muscle morphology, and function to provide a comprehensive understanding of how sex differences in muscle present across the lifespan. By identifying the molecular and structural factors that contribute to sex-specific muscle aging, this study will enhance our understanding of muscle health, disease susceptibility, and performance across different life stages.

NOCTURNAL CHANGE IN BODY TEMPERATURE, AND SLEEP QUALITY IN MENOPAUSAL WOMEN

TOMIISHI, C., OKAMOTO, S., LIN, C., SAKAMOTO, J., GOTO, K.

RITSUMEIKAN UNIVERSITY

INTRODUCTION: Middle-aged women often experience menopause which drastically changes physiological function called as "menopausal symptoms (e.g., vasomotor symptoms, sleep disorders and mood depression)" (Nelson, 2008, Guidozzi, 2013). Sleep disorder is known to be a major menopausal symptom, resulting in sustained fatigue and impaired quality of life. During sleep, core body temperature gradually reduced, and elevated core body temperature during sleep disrupts sleep quality (Flecher et al., 1999). Although dysfunction of body temperature during sleep (i.e., lack of lowering body temperature) may be associated with decreased sleep quality in menopausal women, change in body temperature during sleep has not been sufficiently reported in menopausal women. Therefore, the present study aimed to compare body temperature fluctuations and sleep status between menopausal women and young women.

METHODS: 19 menopausal women (MW; 49.1 ± 2.7 years old) and 14 young women (YW; 20.3 ± 0.8 years old) were recruited. Skin temperature (Tsk) at proximal site was measured continuously over 7 days. Subjective sleep parameters were evaluated using Pittsburgh Sleep Quality Index (PSQI), and objective sleep parameters were evaluated using actigraphy.

RESULTS: Tsk during sleep was significantly higher in MW ($35.0 \pm 0.4^\circ\text{C}$) than YW ($34.6 \pm 0.5^\circ\text{C}$, $p < 0.05$). In YW, Tsk was elevated immediately after falling asleep and then gradually decreased, whereas in MW, no decrease in TSK was found ($p < 0.05$). Also, TSK remained significantly higher in MW compared to YW during 20–80% phase for whole night ($p < 0.05$). In subjective sleep parameters evaluated by PSQI, sleep quality was significantly impaired in MW compared to YW ($p < 0.05$). However, objective sleep parameters evaluated by actigraphy did not differ significantly between groups ($p > 0.05$).

CONCLUSION: Menopausal women presented specific change in nocturnal body temperature compared with young women. The lack of decrease in body temperature during sleep may be associated with impaired subjective sleep quality.

DOES THE MENSTRUAL CYCLE INFLUENCE OBJECTIVE ATHLETIC PERFORMANCE? A SYSTEMATIC REVIEW OF STUDIES FOLLOWING THE GOLD STANDARD METHODOLOGY

SCHLIE, J., KRASSOWSKI, V., SCHMIDT, A.

UNIVERSITY OF THE BUNDESWEHR MUNICH

INTRODUCTION: Whether the menstrual cycle (MC) influences athletic performance in eumenorrheic females is subject of ongoing scientific investigation with controversial results. Current methodological recommendations emphasize the importance of accurate MC phase determination and classification, to reduce the risk of hidden effects due to inadequate methodology. This review therefore focuses exclusively on studies that combine serum analysis of 17β -estradiol and progesterone with luteinizing hormone (LH) surge detection to determine the MC phases.

METHODS: The databases Medline, PubMed, Scopus and SPORTDiscus were searched for studies that investigated objective athletic performance in at least two different MC phases in eumenorrheic females.

RESULTS: The search yielded 1024 results, of which 98 % were excluded, primarily due to inadequate cycle phase determination. 19 studies with a total of $n = 279$ subjects (25.6 ± 3.6 years) were included. The populations investigated ranged from sedentary, to moderately active to athletic, with a mean sample size of $n = 13.9 \pm 7$. On average, three MC phases were compared (range two – six), with the early follicular (EF) phase being most frequently analyzed in 18 studies. The risk of bias in most studies was rated as medium to high, especially in domains as the randomization process and the selection of reported outcomes. 58 % of the studies reported that at least one objective performance parameter differed between the MC phases. However, the direction and extent of the effects are variable in some cases. One study found maximal aerobic capacity to be impaired during the EF phase. Also, ventilation during submaximal running and cycling was reported to be reduced during the EF phase. In two studies, peak sprinting power was impaired in the late luteal and EF phase, when estradiol and progesterone concentrations are low. Seven out of eight studies on maximum voluntary contraction found no effect of the MC phase on performance. Only one reported enhanced strength during the late follicular compared to the mid luteal phase. All of the three studies investigating coordinative skills and agility reported improved performance during the ovulatory phase.

CONCLUSION: Despite the restriction to studies with high methodological standards, it remains difficult to compare the results. This is mainly due to the heterogeneity of the MC phases and populations studied, and the risk of bias. However, contrary to the current state of scientific knowledge, various athletic performance parameters appeared to be influenced by the MC phase in more than half of the studies examined. Our results suggest impaired peak sprinting power during the low hormone phases and increased coordination and agility during ovulation. Maximum strength, jump height and aerobic endurance were largely unaffected by the MC phase.

MENSTRUAL CYCLE-RELATED VARIATION IN SPRINT PERFORMANCE IN FEMALE TRACK AND FIELD ATHLETES: A PILOT STUDY

BÜTHE, E., NOLTE, J., PLATEN, P.

RUHR-UNIVERSITÄT-BOCHUM

INTRODUCTION: Numerous studies involving female participants categorize the menstrual cycle into two to four phases for performance assessments. However, this segmentation often fails to account for short-term variations in results. Given that many sports require repetitive or endurance activities, linear sprinting stands out due to its high intensity, brief duration, and precision. Minor differences in performance outcomes can be critical, particularly when athletes operate near their peak capacity. This study aimed to investigate two-day fluctuations in sprint capacity throughout the menstrual cycle and to identify specific days when performance dips or enhancements occur among female track and field athletes.

METHODS: Three healthy professional and semi-professional female track and field athletes (age: 24.0 ± 2.8 years; height: 169.3 ± 2.5 cm; weight during FP: 64.5 ± 4.8 kg; O: 64.5 ± 5.0 ; LP: 64.4 ± 4.7) participated in this study. Each had a regular 28-day menstrual cycle. The athletes underwent testing every second day throughout their menstrual cycle, performing a 30-second all-out sprint on a non-motorized treadmill. Measurements included distance, maximum velocity, capillary blood, and RPE on each test day.

RESULTS: Analysis of the 30-second all-out sprint performances throughout the menstrual cycle showed slight fluctuations in the distance covered, with no distinct trends across the menstruation (122.04 ± 2.77), follicular phase (122.98 ± 2.84), ovulatory phase (125.03 ± 2.15), and luteal phase (125.52 ± 4.27). Notably, all three athletes recorded their shortest distances during menstruation and exhibited improvements on the day of the estrogen surge before ovulation.

CONCLUSION: Sprint performance exhibited minor fluctuations throughout the menstrual cycle. However, to derive more definitive conclusions and to determine if consistent patterns of performance changes exist across athletes, further testing with a larger sample size is planned.

PHYSIOLOGY SEX-RELATED DIFFERENCES IN TRAINED RUNNERS AFTER 20 WEEKS TRAINING PROGRAM

RODRÍGUEZ-BARBERO, S.1,2, GONZÁLEZ-RAVÉ, J.M.1, MUÑOZ DE LA CRUZ, V.1, ALDA-BLANCO, A.1, VALERO, F.1, GONZÁLEZ-MOHINO, F.1

1SPORTS TRAINING LABORATORY, FACULTY OF SPORT SCIENCES, UNIVERSITY OF CASTILLA-LA MANCHA, TOLEDO, SPAIN.

2UNIVERSIDAD INTERNACIONAL DE LA RIOJA, FACULTAD CIENCIAS DE LA SALUD Y ESCUELA DE DOCTORADO, LOGRONO, SPAIN.

INTRODUCTION: Previous research has suggested that different training strategies may influence the running economy (RE) and performance (1). However, few studies have analyzed the changes in RE following a combined strength and endurance training program. Rodríguez-Barbero et al (2) showed an improvement of around 5% in RE in recreational and well-trained runners after 8 weeks of a regular endurance training program without changes in spatiotemporal parameters. However, the sex-related differences are not well known. Therefore, this study aimed to analyze the effect of a 20-week training program on the physiology of male and female athletes of similar performance levels.

METHODS: The study included ten trained runners (five males and five females with 764.2 ± 25.7 and 746.0 ± 82.2 World Athletics points, respectively). A pre-test-post-test design assessed the effects of a 20-week endurance and strength training program. First, all participants completed the RE test, consisting of 2x5-min running at 11 km·h⁻¹ for females and 13 km·h⁻¹ for males, separated by two minutes of passive recovery. Then, all participants completed a grade exercise test. The test started at 10 km·h⁻¹ for 5 min, and the speed increased by 1 km·h⁻¹ every minute until volitional exhaustion. During the test, respiratory variables were measured using a gas analyzer (MedGraphics, St. Paul, MN, USA). The first (VT1) and second (VT2) ventilatory thresholds and the maximal aerobic speed (MAS) were assessed. A repeated measures ANOVA was used to analyze the pre-post differences produced in the physiological variables between both sexes.

RESULTS: There were no significant differences in the interaction time (pre and post) × sex (male vs. female) in all physiological variables. However, there were significant differences in the time (pre vs post) factor. Thus, RE worsened significantly ($p < 0.05$) after the training program. Oxygen cost at VT1, VT2, and the VO2max were significantly higher ($p < 0.05$) after the 20 weeks. Finally, the speed at VT1, VT2, and MAS significantly increased ($p < 0.05$) after the training program.

CONCLUSION: The effects of 20 weeks of regular endurance and strength training produced a 3.4% deterioration in the RE at submaximal speed. Conversely, we found an improvement of 5.2% and 3.1% in VO2max and MAS. The speed and the oxygen cost associated with the VT1 and VT2 increased with the training program. This suggests that a long endurance training program could improve performance and physiological factors, but sex does not influence these changes in a similar performance level sample.

COMPARING HEART RATE VARIABILITY BETWEEN NATURAL MENSTRUAL AND ORAL CONTRACEPTIVE CYCLES IN TWO FEMALE ATHLETES: A CASE STUDY

MORIN, F.1,2, BERRYMAN, N.1,2, VAN DEN BERG, C.3, DOYLE-BAKER, P.3, BIEUZEN, F.2

1. UNIVERSITÉ DU QUÉBEC À MONTRÉAL; 2. INSTITUT NATIONAL DU SPORT DU QUÉBEC; 3. UNIVERSITY OF CALGARY

INTRODUCTION: Heart rate variability (HRV) is widely used to monitor athletes' training status (1). Previous studies have shown that the menstrual cycle (MC) and hormonal contraceptive (HC) use influence HRV in physically active females [2-3]. However, given the impact of training load (TL) on HRV, research specifically focusing on female athletes should be investigated. Recently, (2021) Elliott-Sale et al. proposed MC methodological guidelines to study female athletes however the feasibility of these guidelines in the daily training environment (DTE) is understudied in the Canadian sport context. Therefore, the study objectives were to report on the feasibility of these guidelines in DTE and to describe the effects of a natural MC and HC on HRV in Canadian female athletes.

METHODS: Two female athletes (Tier 3 classification) in this case study agreed to participate and provided data across two cycles (C1 and C2). Athlete one (28-year-old runner) used a combined oral hormonal monophasic pill (OHC) and athlete two (21-year-old kayaker) reported they had a natural (eumenorrheic) MC. HRV was measured nightly using a biosensor ring (Oura) [4] and TL (sRPE) was reported daily. MC length was self-reported (journal counting), and estradiol and progesterone saliva samples were collected (OHC: 1/weekly; MC: 3X/weekly). Ovulation was determined by a dipstick (urinary). Adherence rates were reported for feasibility (% of available HRV, journal, and salivary data), and RMSSD (avg±SD) were reported for the HRV analysis.

RESULTS: Adherence rate was 99.5% for OCP and 100% for MC. For OHC, the average RMSSD value tended to decrease for the first ($70.0 \text{ ms} \pm 8.4$) to the second ($61.4 \text{ ms} \pm 7.6$) week of active pill and increase from the third ($67.1 \text{ ms} \pm 9.0$) week to the placebo week (72.4 ± 14.9). MC displayed higher average RMSSD values at ovulation ($66.8 \text{ ms} \pm 7.1$) compared to the luteal phase ($58.2 \text{ ms} \pm 9.1$). For the follicular phase, no consistent trend was observed across either cycles. In C1, the average RMSSD value was lower ($64.3 \text{ ms} \pm 10.1$) compared to ovulation, whereas in C2, the opposite was observed, with a higher RMSSD value ($72.8 \text{ ms} \pm 9.6$) during the follicular phase. The average variation in the mean RMSSD between phases was greater for OHC (20.6%) than for MC (9.1%). Total TL for both cycles was higher for MC (24020.4 AU) than for OHC (12401.2 AU).

CONCLUSION: Based on the high adherence rates it is feasible in this context to implement ovarian hormone measures within DTE. HRV was observed to have greater variation with OHC when compared to a natural MC, contrary to previous findings in active females [2-3]. It is possible that the TL, which is higher for an athlete compared to an active female, could partly explain these results.

HORMONAL CONTRACEPTIVE USE, MENSTRUAL DISTURBANCES AND SELF-PERCEIVED PERFORMANCE IN DANISH ELITE FEMALE SOCCER PLAYERS

SMITH BISGAARD, M., OXFELDT, M., HANSEN, M.

AARHUS UNIVERSITY

INTRODUCTION: Despite growing evidence indicating physiological effects of the menstrual cycle and hormonal contraceptive use, reports from athletes suggest that athletes experience self-perceived effects of their menstrual cycle on performance. The perceived effects have been related to the physical symptoms experienced as a result of their cycle, which has been supported by findings from our lab, indicating greater correlations between psychological well-being and performance than hormonal fluctuations (1).

Despite soccer's global popularity, research on female players, especially concerning hormonal contraceptive use and menstrual dysfunction, is limited. Low energy availability—a risk factor for menstrual dysfunction and reduced performance—is commonly reported among female athletes, though data on Danish players are lacking.

The primary aim of this study is to assess the prevalence of hormonal contraceptive use, menstrual dysfunction, and self-perceived performance in relation to the menstrual cycle in Danish elite female soccer players.

METHODS: Using a descriptive, cross-sectional study design, an online questionnaire was sent to 571 female soccer players from different soccer leagues. The questionnaire included questions on the player's use of hormonal contraception, the menstrual cycle and irregularities of the menstrual cycle. Responders of the questionnaire received a follow-up questionnaire including questions on the players' self-perceived experience of the menstrual cycle.

RESULTS: In total 342 female soccer players from four different soccer leagues answered the questionnaire. Of the 342 players, 181 players (53%) were users of hormonal contraception. Among the hormonal contraception users, 86% used a combined, oral contraceptive and 14% used a progestin-only formulation. Among the non-hormonal contraceptive users (47%), 63% reported having a regular menstrual cycle while 37% reported irregular menstrual cycles. Of the players reporting irregular menstrual cycles, one player reported primary amenorrhea whereas 13% reported secondary amenorrhea.

The follow-up questionnaire was answered by 138 players with 60% being hormonal contraceptive users and 40% being non-users. Amongst the hormonal contraceptive users, 23% reported that they felt their pill cycle impacted their performance. Amongst the non-users of hormonal contraceptives, 47% reported that they felt their menstrual cycle impacted their performance.

CONCLUSION: This study highlights a significant self-perceived impact of the menstrual cycle and hormonal contraceptive use on athletic performance among Danish elite soccer players. Additionally, menstrual irregularities, including amenorrhea, were reported. This study underscores the need for further research on the menstrual cycle's impact on female athletes to better support their health and performance optimization.

FETAL RESPONSES TO EXERCISE IN TWIN PREGNANCY

STEINBACK, C., MEAH, V.L., TRAKULMUNGKICHKARN, T., WOWDZIA, J., JAMES, M.A., KHURANA, R., HORNBERGER, L.K., DAVENPORT, M.H.

UNIVERSITY OF ALBERTA

INTRODUCTION: It is well established that moderate-to-vigorous intensity physical activity (MVPA) during pregnancy is associated with extensive health benefits for both mother and fetus. However, there are certain medical conditions (contraindications) where engaging in MVPA is not advised due to the potential for adverse health outcomes. Twin pregnancy is listed as a contraindication in many global guidelines based on expert opinion rather than empirical evidence. Therefore the aim of this study was to evaluate the maternal/fetal responses to an acute bout of aerobic exercise in twin pregnancies.

METHODS: Twenty-four participants with a singleton ($n = 12$, 26 ± 5 weeks of gestation, 33 ± 3 years of age) or twin ($n = 12$, 26 ± 5 weeks of gestation, 33 ± 2 years of age; 11 dichorionic/diamniotic and 1 monochorionic/diamniotic) pregnancies were recruited. Participants underwent a graded exercise test on the cycle ergometer. Maternal cardiac function (heart rate [HR], cardiac output [CO], stroke volume [SV], ejection fraction [EF]; echocardiography), mean arterial pressure (MAP; photoplethysmography) were measured before and immediately following incremental cycling exercise. Fetal HR (ultrasound) was measured pre- and post-exercise. The change (Δ) from rest to maximal effort was compared between groups (T-tests; $\alpha=0.05$ was deemed significant). All data are expressed as mean $\pm$ standard deviation.

RESULTS: As expected, women pregnant with twins had higher resting HR (S: 83 ± 6 vs. T: 95 ± 12 bpm, respectively; $P < 0.01$) and CO (S: 4.3 ± 0.4 vs. T: 4.9 ± 1.4 L.min⁻¹, respectively; $P = 0.02$) but similar SV (S: 55 ± 9 vs. T: 55 ± 12 mL, respectively; $P = 0.27$), EF (S: 68 ± 7 vs. T: $66 \pm 9\%$, respectively; $P = 0.07$) and MAP (S: 82 ± 9 vs. T: 91 ± 8 mmHg, respectively; $P < 0.01$) compared to singleton pregnancies. At maximal effort, maternal heart rate (S: 148 ± 12 vs. T: 155 ± 9 p=0.22) and percent maximal heart rate (S: 79 ± 7 vs. T: 83 ± 5) were not different between groups. Fetal HR was unchanged in response to exercise

at 70% HR reserve in both groups (singleton: change 0 ± 4 vs. twin: change 0 ± 4 , $P=0.53$) with no incidences of fetal bradycardia or tachycardia.

CONCLUSION: While resting cardiovascular metrics were elevated in twin compared to singleton pregnancy, an acute bout of vigorous intensity physical activity was well tolerated by mother and fetus in both groups.

BASELINE ANDROGEN STATUS PREDICTS FREE ANDROGEN INDEX (FAI) RESPONSE TO A 12-MONTH NUTRITIONAL INTERVENTION IN EXERCISING WOMEN WITH MENSTRUAL DISTURBANCES

KHEN, K., DE SOUZA, M.J., SALAMUNES, A., MALLINSON, R., WILLIAMS, N.

PENNSYLVANIA STATE UNIVERSITY

INTRODUCTION: Functional hypothalamic oligo/amenorrhea (FHOA) has been attributed to chronic energy deficiency and is characterized by suppressed serum triiodothyronine, insulin, leptin, and lower resting metabolic rates. However, some cases of exercise-associated oligomenorrhea do not align with FHOA metabolic profiles. Some oligomenorrheic women may present with elevated androgens (hyperandrogenemia), exhibiting higher body mass index, percent body fat, insulin, and leptin levels, as well as a higher Free Androgen Index (FAI), and luteinizing hormone/follicle-stimulating hormone (LH/FSH) ratios. These endocrine differences suggest heterogeneity in the etiology of menstrual disturbances among exercising women which may impact treatment strategies. Specifically, if the etiology of oligomenorrhea involves hyperandrogenemia, a nutritional intervention leading to weight gain may exacerbate ovarian dysfunction. This study investigated if initial indications of hyperandrogenemia, i.e., high baseline FAI, predicted changes in FAI in response to a 12-month nutritional intervention in exercising women with oligo/amenorrhea.

METHODS: This secondary analysis of the REFUEL RCT included 23 exercising women with oligo/amenorrhea who were randomized to increase their caloric intake for 12 months in the study. Control participants who were randomized to maintain their current diet are excluded. Daily urinary estrone-1-glucuronide (E1G), pregnanediol glucuronide (PdG), and mid-cycle LH were assayed to determine menstrual status. Serum total testosterone (T) and sex hormone-binding globulin (SHBG) were repeatedly measured to calculate FAI ($[T/SHBG] \times 100$) as a measure of androgen exposure. Data were analyzed at baseline (BL) and intervention weeks 21, 33, and Post-intervention. Generalized linear mixed models (GLMMs) with fixed effects of time and BL FAI as a covariate were used to predict changes in FAI across the study.

RESULTS: Mean values for time points are as follows: BL FAI (4.98 ± 0.6), Week 21 (5.37 ± 0.54), Week 33 (6.16 ± 0.82), and Post (4.8 ± 0.56). GLMMs revealed significant main effects for baseline FAI ($F[1,25]=55.36$, $p<0.001$) and time ($F[2,23]=4.22$, $p=0.028$), with significant BL FAI $\times$ time interaction ($F[2,23]=5.22$, $p=0.014$). Higher BL FAI was associated with sustained high FAI across all time points ($\beta=0.67$, $p<0.001$), but this relationship varied based on time point, with stronger effects on Week 21 and Week 49 FAI and weaker effects at Week 33 FAI ($\beta=-0.30$, $p=.065$).

CONCLUSION: Baseline FAI significantly predicted changes in FAI throughout the 12-month nutritional intervention. Higher BL FAI was associated with higher FAI across all time points, suggesting that women with higher FAI may require closer nutritional monitoring to ensure effective treatment of their menstrual dysfunction. The time-dependent fluctuations in FAI indicate that androgen exposure during refeeding may vary depending on BL FAI, thus warranting further research to optimize intervention strategies for this population.

BASELINE STRENGTH AND ACTIVITY ARE ASSOCIATED WITH IMPROVED RECOVERY KINETICS FOLLOWING ECCENTRIC EXERCISE IN OLDER ADULTS

LI, D., HERPICH, C., GÖGER, L., KRÜGER, N., PEIL, A., ALEITHE, M., NORMAN, K.

GERMAN INSTITUTE OF HUMAN NUTRITION

INTRODUCTION: Muscle function recovery following exercise-induced damage (EIMD) is thought to be influenced by individual strength, mobility and activity level. However, evidence in older adults remains limited. This study investigated whether baseline muscle function, mobility, and habitual physical activity predict recovery following an unaccustomed eccentric exercise bout in healthy older adults.

METHODS: Thirty older adults (70.9 ± 4.0 years, 11 males, 19 females) completed a single bout of eccentric exercise (10 sets of 10 repetitions; 1 s concentric, 1 s hold, 3 s eccentric). Muscle soreness (DOMS), countermovement jump (CMJ), and maximal voluntary contraction (MVC) were assessed pre- and post-exercise (24, 48, and 72 h). Baseline measures included handgrip strength, a 4-meter walk test, a chair rise test, one-repetition maximum (1RM), and Skeletal Muscle Mass Index (SMI). Physical activity was categorized using the International Physical Activity Questionnaire (IPAQ). Recovery was quantified as the area under the curve (AUC) of the percent loss from baseline using the trapezoidal method. Spearman correlations and Kruskal-Wallis tests assessed associations between AUC values, baseline measures, and IPAQ activity levels.

RESULTS: Following exercise, MVC loss was 12.05% at 24 h and recovered by 48 h. CMJ force loss peaked at 48 hours, while CMJ height, power, and velocity continued to decline through 72 hours. DOMS peaked at 24 hours across all conditions (standing, sitting down, and standing up). No significant differences were observed between men and women in

any recovery metric. Spearman's correlations revealed that AUC-MVC was negatively associated with 1RM ($p = -0.45$, $p = 0.015$) and handgrip strength ($p = -0.39$, $p = 0.036$). CMJ Velocity ($p = 0.39$, $p = 0.039$) and Power ($p = 0.38$, $p = 0.042$) losses were positively correlated with age. Additionally, individuals classified as moderately active according to the IPAQ showed significantly better CMJ power recovery than those with low activity levels ($p = 0.031$).

CONCLUSION: Older individuals with higher baseline strength and moderate physical activity may be more resistant to functional impairments following EIMD, with baseline functionality potentially predicting recovery kinetics. Greater strength in active individuals could also support better recovery. Given the ongoing study and sample size limitations, these findings should be interpreted with caution.

EFFECTS OF ISOMETRIC HANDGRIP EXERCISE ON EXECUTIVE FUNCTION IN YOUNG AND OLDER ADULTS: A FNIRS STUDY.

MECHRAOUI, A., BOSQUET, L., DUPUY, O.

UNIVERSITY OF POITIERS

INTRODUCTION: Evidence suggesting that acute exercise enhances executive functions predominantly arises from studies focused on aerobic exercise. It remains unclear whether strength physical exercises, such as intermittent isometric handgrip exercises, affect executive functions in young and older adults. We examined the dose-effect response of several physical loads and their potential effect on perceptual cortex hemodynamics effects.

METHODS: Using a crossover design, 46 participants completed intermittent isometric handgrip exercise using three modalities concerning repetition or duration 1) 4 repetitions of 2 min of 30% of maximal voluntary contraction (MVC) with 3 min of recovery 2) with 1 minute of recovery and 3) 8 repetitions of 2 min of 30% of MVC with 3 min of recovery and 4) a control condition in a randomized order. Before and after each condition, they performed a Stroop task assessing inhibition and flexibility processes. Perceptual, cognitive difficulty and prefrontal cortex oxygenation were measured during both tasks.

RESULTS: For the Stroop task, we found a greater good response only for the condition 4 repetitions with 3 minutes of recovery of flexibility task. We found no effect of exercise on inhibition task. This was accompanied by a lower perceived difficulty of the task and lower physical perceived physical effort only on this condition. Although hemodynamic changes have been observed, they do not seem to explain the cognitive changes.

CONCLUSION: Acute isometric handgrip exercise with adequate load improves flexibility, but the inhibition remains unaffected. This effect of the load is accompanied by an improved perceived difficulty of physical and cognitive effort.

BASALINE VAGAL ACTIVITY AND FAT OXIDATION RELATIONSHIPS IN ACTIVE POSTMENOPAUSAL WOMEN

MONFERRER MARÍN, J., ROLDÁN, A., HELGE, J.W., BLASCO-LAFARGA, C.

PHYSICAL PERFORMANCE AND SPORTS RESEARCH GROUP

INTRODUCTION: Metabolic flexibility (MF), the ability to adapt and adjust substrate oxidation relative to substrate availability, has been recently linked to the autonomic function in postmenopausal women (2), likely due to the vagus nerve activity at the hepatic level (1). Autonomic function at rest, assessed through Heart Rate Variability (HRV), showed to be associated with MF indicators such as maximal fat oxidation MFO or the final lactate in a FATmax test ($RER=1.07$) (2). However, the relationship between the cardiovascular variables fat oxidation and HRV at rest are not well known and the current study will study this.

METHODS: Forty-five menopausal active women (67.9 ± 5.3 years; 65.8 ± 11.5 kg; 40.3 ± 4.2 kg muscle mass) performed a resting metabolic rate test in supine position. Basal metabolic rate (BMR) and MFO were assessed by indirect calorimetry using a K5 metabolic cart (Cosmed, Rome, Italy) for 30 minutes. HRV was simultaneously registered by means of a H10-polar band and the Sensor Polar Logger App. The first 5 were discarded. Participants arrived at the same time (8:30 a.m. & 10:00 a.m.), after 12h overnight fasting, preceded by a standardised dinner (50% carbohydrate content) the previous day. Prior to recording, they remained in a supine position for a period of 15 minutes, relaxed and with eyes closed. After normality test, Spearman and Pearson correlations were applied.

RESULTS: BMR was low (990 ± 270 kcal/day), despite a larger RER (0.79 ± 0.05) and fat contributed the total energy expenditure ($69.9 \pm 15.7\%$ fat; 0.072 ± 0.031 g/min; 1.69 mg/min/kgFFM) compared with similar sample (3). HRV revealed a basal autonomic steady state both in linear-indexes root mean square of successive differences between beats (RMSSD, 25.8 ± 18.2 ms), as in non-linear indicators SD1 (18.3 ± 12.9 ms), sample entropy (SampEn, 1.73 ± 0.20) or detrended fluctuation analysis $\alpha 1$ (DFA $\alpha 1$, 0.95 ± 0.21). An association between FATox (both in absolute and relative units) with the main autonomic variables: parasympathetic (PNS) index ($r=0.56$; 0.58), low frequency power ($r=0.37$; 0.36), RMSSD ($r=0.31$; 0.32) and SD1 ($r=0.31$; 0.32) was confirmed by the significant, positive and moderate correlation. BMR was also significantly, positively and moderately associated with PNS index ($r=0.51$), pnn50 ($r=0.32$), RMSSD ($r=0.31$) and SD1 ($r=0.31$), instead of LF which was not associated with BMR. DFA $\alpha 1$ and SampEn did not show any significant associations.

CONCLUSION: Vagal activity assessed through HRV confirms to be associated with basal metabolic rates and Fatox rates at rest i.e. metabolic flexibility. Our data support the hypothesis linking fat oxidation and vagal activity, thus underlining the importance of HRV in the assessment of cardiovascular (both, metabolic and autonomic) health.

THE RELATIONSHIP BETWEEN BLOOD GLUCOSE, INSULIN, AND LEPTIN AND MOTIVATION FOR PHYSICAL ACTIVITY AND EXERCISE

ABE, M., HORITA, A., MAEDA, M., TANOUE, Y., MURAKAMI, H.
RITSUMEIKAN UNIVERSITY

INTRODUCTION: Numerous studies have demonstrated that physical activity and exercise are beneficial to human health. However, many individuals do not meet the recommended levels of physical activity. While animal studies have suggested that leptin and insulin are involved in behavioral control, evidence in humans remains limited (Hennige et al., 2009; Choi et al., 2007). Glucose, insulin, and leptin interact with each other (Sartorius et al., 2012). However, most studies have not explored this interaction comprehensively. Therefore, this study aims to investigate whether blood glucose, insulin, and leptin levels are associated with motivation for physical activity and exercise.

METHODS: The participants were 12 healthy adults (7 men and 5 women, age: 23.1 ± 3.5 years, BMI: 22.4 ± 1.5 kg/m²). Each participant completed two conditions randomly with at least a five-day washout period; 1) high-frequency food intake (10 times/6 h 40 min) and 2) low-frequency food intake (twice/6 h 40 min), to induce changes in blood glucose, insulin, and leptin levels. Blood samples were collected at nine time points (every 40 min from the first to the ninth time point). Physical activity and exercise motivation and sleepiness were assessed using a visual analog scale. Pearson's correlation coefficient was used to test the correlation between blood parameters and motivation at baseline. Two-way ANOVA was used to test the interaction effect of time and condition. A linear mixed model was used to test the association between the blood parameters and motivation at each time point.

RESULTS: Glucose, insulin, and leptin levels and motivation at baseline had no significant associations. Significant interactions between time points and conditions were observed for blood insulin levels and sleepiness ($p < 0.05$). In the analysis of the association between blood parameters and motivation using a mixed linear model across all time points, significant associations were found between glucose and exercise motivation ($\beta = -0.126$, $p < 0.05$), insulin and physical activity motivation ($\beta = -0.143$, $p < 0.05$), exercise motivation ($\beta = -0.185$, $p < 0.05$), and sleepiness ($\beta = -0.161$, $p < 0.05$).

CONCLUSION: Glucose and insulin levels were significantly associated with motivation for physical activity and exercise. When blood glucose and insulin levels are high, individuals tend to feel less motivated to engage in physical activity. It is suggested that factors involved in feeding regulation may also influence motivation for physical activity and exercise through behavioral control, thereby affecting energy expenditure. These findings enhance our understanding of the mechanisms underlying motivation for physical activity and exercise and may inform strategies to increase engagement.

INFLUENCE OF BODY COMPOSITION ON RELATIVE RESTING METABOLIC RATE IN RECREATIONAL WOMEN ATHLETES

MAGEE, M., SIMS, J., FIELDS, J., BREW, S., GREENWOOD, N.
KENT STATE UNIVERSITY

INTRODUCTION: Total daily energy expenditure is highly dependent upon resting metabolic rate (RMR) as it makes up approximately 50% of energy utilized. Altered RMR may have implications on body composition, such as losses or gains in fat mass and fat free mass (FFM). Since RMR has shown to be strongly correlated with body mass, absolute RMR alone may not provide sufficient context when assessing body composition. Instead, evaluating RMR relative to body composition, specifically FFM, may offer more meaningful insights. Thus, the purpose of this study is to examine the influence of body composition on relative RMR in recreational women athletes.

METHODS: 28 recreational female athletes (age= 22.0 ± 3.8 years; height= 165.3 ± 8.3 ; body mass= 67.0 ± 14.7 ; RMR= 1525.6 ± 237.2 ; BF%= 27.4 ± 7.6 ; FFM= 47.8 ± 3.7 ; FFMI= 17.4 ± 1.8 ; relative RMR= 23.3 ± 3.7) participated in this study. Body composition was evaluated using bioelectrical impedance analysis (BIA), and the following metrics were recorded: body mass, body fat percent (BF%) and FFM. FFMI was calculated (FFM (kg) / height (m²)). RMR was measured using indirect calorimetry following an overnight fast (≥ 8 hours) and at least 12 hours without vigorous exercise. Participants rested in a seated position for 25 minutes prior to laying supine for a 30 minute collection period. The first 10 minutes served as a familiarization period, while the last 20 were used to assess RMR. Relative RMR was expressed as kcal/kg body mass/day. Hierarchical linear regression was used to evaluate the influence BF%, FFM, and FFMI, respectively, on relative RMR ($p < 0.05$).

RESULTS: Model 1 was significant ($\beta = 29.330$; $R^2 = 0.204$; $SEE = 3.373$; $p = 0.016$) and identified BF% as a significant predictor of relative RMR ($\beta = -0.220$; $p = 0.016$). Model 2 remained significant ($\beta = 40.026$; $R^2 = 0.474$; $SEE = 2.794$; $p = 0.001$), with both BF% ($\beta = -0.159$; $p = 0.038$) and FFM ($\beta = -0.258$; $p = 0.001$) being significant predictors. Model 3 included BF%, FFM, and FFMI ($\beta = 38.114$; $R^2 = 0.478$; $SEE = 2.843$; $p = 0.001$), but only FFM ($\beta = -0.229$; $p = 0.030$) was a significant predictor of relative RMR. Model 2 was determined to be the best-fitting model due to its lower standard error and significance of both predictors.

CONCLUSION: Data from the present study suggest relative RMR is negatively influenced by both BF% and FFM, with each 1 unit increase in BF% and FFM associated with a decrease of 0.159 kcal/kg and 0.258 kcal/kg, respectively. While the negative association between BF% and relative RMR is supported by previous studies, the inverse relationship between FFM and relative RMR is unexpected. It is possible this relationship may be influenced by total body mass, warranting

further investigation. Results may differ in males and in elite or professional athletes, as these populations typically exhibit lower body fat percentages and different body composition characteristics than the present cohort.

CIRCULATING MUSCLE-SPECIFIC MIRNA EVALUATION AFTER FIVE WEEKS OF STRENGTH TRAINING AND HYPER-CALORIC KETOGENIC DIET

CANNATARO, R., GRIMALDI, A., LEVI-MICHELI, M., GULISANO, M., SCALA, A., ABREGO-GUANDIQUE, D.M., CAROLEO, M.C., BONILLA, D.A., CIONE, E.

UNIVERSITY OF CALABRIA

INTRODUCTION: The evaluation of the effectiveness of training programs and associated diets is a crucial point that concerns sports sciences; it is mainly concerned with elite sports, but amateur athletes are also increasingly attentive to these issues. In this sense, miRNAs, non-coding nucleotide sequences, and epigenetic regulators of protein synthesis; a specific class is characteristic of skeletal muscle and is called myomir; this study aims to evaluate the variation of a pool of miRNAs in response to training and dietary patterns, specifically hyper-caloric ketogenic

METHODS: Thirty subjects aged between 18 and 50 years (same women and men) with at least 2 years of experience in strength training without any apparent pathologies, without injuries in the last 6 months, underwent physical and strength assessments (bioimpedance, stratigraphy, 1RM squat, benchpress and deadlift, Counter movement jump) and reported a food diary for 7 days; they operated for 5 weeks a training based on cluster sets, to improve strength and hypertrophy; combined with a ketogenic nutritional program (less than 50 g of carbohydrates per day, ketonemia monitored with blood sampling) hypercaloric (an excess of calories of 20-25% compared to the estimate of caloric consumption); at the beginning and end of the study, blood samples were taken in the morning on an empty stomach with at least 3 days of rest from training. The expression levels of myo-miRNAs were determined using the TaqMan™ probes—advanced miRNA Assay RT-PCR and applying the $2^{-\Delta\Delta Ct}$ method.

RESULTS: Subjects reported, on average, a 2.3% weight decrease (most likely due to glycogen and associated water depletion), a 5% increase in phase angle, and 3.6% in LMI (bioelectric parameters positively correlated with fitness and muscle mass); a 7.7% decrease in fat percentage; an increase in the 1RM of squat, deadlift, and bench press, respectively of 8.7%, 29.7%, and 11.1%, while the CMJ is practically unchanged; GH shows an increase of 16.2%, IGF1 increases of 10%, myostatin decreases of 22.5% finally the reticulocyte shows an increase of 14%; miRNAs reported in logarithmic scale have reported percentage variations in terms of fold or change equal to: miR-1-3p -80%, miR-21-5p -65%, miR-133a-3p -98%, miR-206 -20%, miR-208b-5p -60%, miR-222-3p -20%, miR-378

CONCLUSION: The program produced improvements in terms of strength and body composition, showing how the hyper-caloric ketogenic diet is compatible with strength training; the critical novelty is the strong regulation of myomir: miR-1, 206, and 208 related to IGF1 that increased, and miR-133 22 and 378 related to myostatin that decreased; this confirms the epigenetic action of physical exercise that could be monitored through circulating miRNAs; the rest of the influenced miRs concern protein synthesis and the regulation of the inflammatory state, two other basic parameters for a positive response to physical exercise. No significant sex-related differences were noted.

COMPLEX NETWORKS APPLIED TO THE NORMOBARIC “LIVING HIGH – TRAINING LOW” MODEL IN EXPERIMENTAL MICE

ORSI, J., PAPOTI, M.2, POLISEL, E.1, SANTOS, M.1, ARAUJO, L.1, HILL, D.3, MANCHADO-GOBATTO, F.1, GOBATTO, C.1

1UNIVERSITY OF CAMPINAS, 2UNIVERSITY OF SÃO PAULO, 3UNIVERSITY OF NORTH TEXAS

INTRODUCTION: Living in a hypoxic environment combined with physical training in a normoxic condition (living high-training low, LH-TL) is widely studied in exercise physiology, with emphasis on its metabolic adaptations [1]. With growing interest in the topic, advanced analytical approaches that transcend conventional statistics are needed [2]. This study aimed to analyze the effects of 6-week LH-TL on muscles and tissues in C57BL/6J mice, using the complex-network model.

METHODS: Forty animals were grouped according environmental condition (normoxia-Nx or hypoxia-Hx) and training (non-N or trained-T) totaling 4 groups (Nx-N, Nx-T, Hx-N and Hx-T). Hx mice were exposed to 14.5% inspired oxygen (~3,000m) for 18h/day. T mice underwent 6-week treadmill running (80% of the critical velocity, 40min/day, 5 days/week) in normoxia. Euthanasia occurred 48h after the last training session. Data corresponding to the mass of muscles, liver, heart, kidney, brain and adipose tissues, and the stores of glycogen in muscles, liver and heart tissues, as well as body composition measurements, were analyzed by the Scheirer-Ray-Hare test, with Dunns post hoc. Undirected weighted graphs ($G=(V,E,w)$) of the complex network were constructed from the 4 scenarios (groups) to analyze the degree (number of connections) and eigenvector (prestige of the node related to the prestige of its neighbors) centrality metrics. The graphs were composed of 27 vertices (V, nodes) and the edges (E) denoted interactions based on Spearmans correlation coefficients ($r \geq 0.5$) to construct the weight function (w) [3].

RESULTS: The density of the graphs for the 4 scenarios studied were 0.27, 0.18, 0.16, and 0.25, respectively. For degree, the complex network highlighted muscle glycogen nodes among all parameters. In Nx-N and Hx-T scenarios, there was high

centrality for white gastrocnemius glycogen. Furthermore, aerobic training promoted highlights for oxidative parameters, such vastus lateralis mass, gluteus glycogen, and, especially in the Hx-T group, soleus glycogen (11 connections). Hypoxia increased the centrality of carcass mass, an effect enhanced by training. Only in Hx-T was the hypothalamus mass highlighted (10 connections). Interestingly, eigenvector centrality reinforced the degree findings. Nonparametric statistics showed differences in some parameters, especially for brown adipose tissue and femur masses, and liver glycogen, but these do not seem to be, at least in our conditions, integrated with the other parameters studied, since they did not reveal prominent complex networks centralities. However, gastrocnemius and triceps glycogen stores were highlighted in both analyses.

CONCLUSION: The complex network model was sensitive to the isolated and combined effects of physical training and hypoxia, which were not fully represented by conventional statistics. This approach may refine data interpretation in investigations involving LH-TL.

DOES BACKPACK LOAD CARRIAGE WEIGHT AFFECT SUSCEPTIBILITY TO ACUTE MOUNTAIN SICKNESS DURING INTERMITTENT WALKING IN HYPOXIA?

WILLMOTT, A., HUSSEIN, H., NOBEL, E., HAYES, M., MAXWELL, N.

ANGLIA RUSKIN UNIVERSITY

INTRODUCTION: The growth of global adventure tourism has led to millions of travellers visiting areas of high-altitude for recreational trekking, charity fundraising challenges and/or cultural immersion over several days to weeks annually. These activities necessitate carrying backpacks that contain hiking provisions of additional weight without understanding how increased load carriage may affect physiological responses at altitude, nor whether they may increase the risk of experiencing symptoms of acute mountain sickness (AMS) - a common altitude illness typically observed above 2500m. There is limited understanding whether existing backpack load recommendations used at sea-level (maximum load equating to 1/3 of body weight) apply at altitude, or whether increasing loads exacerbate symptoms of AMS. The purpose of the study was to therefore assess backpack weight of 10%, 20% and 30% of body weight on physiological and perceptual strain and symptoms of AMS, during a simulated hillwalking test in hypoxia.

METHODS: Thirteen physically active males and females (23±1 years) completed three intermittent walking tests (including: 35-mins rest, 60-min walk [3x20-min intervals with 5-min rest] at 4km.hr⁻¹ at 10% gradient, followed by 15-mins recovery) within normobaric hypoxia (FIO₂: 0.13). These were conducted within a randomised order whilst carrying a backpack loaded with additional weight that was either 10%, 20% or 30% relative to the participants' body mass. Physiological, perceptual and Lake Louise Questionnaire (LLQ) scores were assessed throughout.

RESULTS: Heart rate and ventilation were higher (both $p < 0.05$) during the 30% backpack test compared to 10% ($+13 \pm 11$ b.min⁻¹ and $+9.4 \pm 7.6$ L.min⁻¹), but no differences were found between 10% and 20%. LLQ scores were higher ($p < 0.05$) during the 30% backpack test compared to the 10% ($+2 \pm 1$ A.U.) and 20% ($+1 \pm 1$ A.U.), but no differences ($p > 0.05$) were found between 10% and 20%. Rating of perceived exertion (RPE: 6-20 Borg [1982]) were higher (all $p < 0.05$) during the 20% and 30% trials compared to 10% ($+2 \pm 2$ and $+4 \pm 2$ A.U.), and also during the 30% compared to 20% trial ($+2 \pm 2$ A.U.). No differences in pulse oxygen (O₂) saturation, nor volume of O₂ uptake (all $p > 0.05$) were found between tests.

CONCLUSION: Carrying additional backpack weight increases markers of physiological and perceptual strain and may augment AMS symptoms. Altitude travellers without prior experience of hiking and who are carrying a backpack for an extended period of time should understand these responses and potential risks to health, as well as educate themselves on safe altitude knowledge/travel and contributing risk factors.

THE EFFECT OF BREAKFAST OMISSION ON EXECUTIVE FUNCTION BETWEEN NORMOXIC AND HYPOXIC EXERCISE IN HEALTHY YOUNG ADULTS

HORIUCHI, M., HORIUCHI, Y., OLIVER, S.J.

NATIONAL INSTITUTE OF FITNESS AND SPORTS IN KANOYA: KANOYA TAIKU DAIGAKU

INTRODUCTION: Executive function has been shown to be improved after acute light exercise, and limited research suggests these beneficial effects remain even after breakfast omission (1). In contrast, executive function is impaired in hypoxia at rest, during and after exercise (2,3). This study aimed to determine the interactive effects of exercise, and breakfast consumption on executive function after light exercise. We hypothesized executive function would be improved after light exercise in normoxia, but reduced after exercise in hypoxia, with or without breakfast.

METHODS: Twelve healthy young adults (10 men and 2 women with a mean age of 21 years) participated in this study. All participants completed four morning experimental conditions in a random order; i) breakfast omission (overnight fasting) in normoxia (20.9% O₂), ii) having breakfast in normoxia (20.9% O₂), iii) breakfast omission in hypoxia (13% O₂), and iv) having breakfast in hypoxia (13% O₂). In each condition, participants arrived after an overnight fast and had or did not have a standard breakfast, and then rested for 60 min, which was followed by 20 minutes of light-intensity leg cycling exercise (80 watts for men and 60 watts for women). Cerebral oxygenation (COX) was assessed by near-infrared spectroscopy pre-, during exercise, and post-exercise. Blood glucose, blood lactate, and executive function such as Digit span task (DST) and Hopkins verbal learning test (HVLT) were assessed pre-and post-exercise, respectively.

RESULTS: At rest, blood glucose was lower after breakfast omission regardless of normoxia or hypoxia (Δ -20% and $P < 0.001$). After exercise, blood lactate in hypoxia was significantly higher than in normoxia (Δ 2 mmol/L in normoxia vs. 4 mmol/L in hypoxia, $P < 0.001$). A significant interaction (oxygen $\times$ time, $P < 0.001$) in COX was found, where regardless of breakfast, COX was unchanged in normoxia (1.8% increase during exercise compared to pre-exercise) but decreased by 3.8% in hypoxia. In normoxia and hypoxia, the DST backward score was improved post-exercise compared to pre-exercise ($P = 0.02$) but was impaired by breakfast omission ($P = 0.03$). In contrast, the DST forward score, and HVLt were unaffected by exercise, oxygen level, or breakfast (all $P > 0.05$).

CONCLUSION: Acute moderate exercise improved backward scores of DST, but not forward scores and HVLt irrespective of oxygen levels or breakfast. Breakfast omission impaired only backward scores of DST. Hypoxia did not influence both DSTs and HVLt. These results suggest that exercise improved short-term and working memory, but, breakfast omission impaired working memory. Moreover, hypoxic-induced reductions in cerebral oxygen hemodynamics did not affect executive function.

EFFECTS OF 4-WEEKS OF HIIT IN NORMOBARIC HYPOXIA ON SLEEP AND CARDIAC AUTONOMIC ACTIVITY

SOUSA, A., BARREIRA, J.1,2, CUNHA, L.1,2, COSTA, J.3, MILHEIRO, J.4, VIANA, J.L.1,2, FIGUEIREDO, P.1,5
UNIVERSITY OF MAIA, PORTUGAL

INTRODUCTION: The implementation of high-intensity interval training (HIIT) within altitude/hypoxic training environments has recently emerged as a novel tool to boost both individual and team sports performance [1, 2]. Such training method can be physically challenging, imposing a greater stress on athletes. Thus, ensuring optimal recovery during these intense training periods is essential, with sleep playing a vital role despite being relatively underexplored. This study examined the effects of 4-weeks of HIIT and repeated sprint training (RST) in a simulated hypoxia setting on sleep and nocturnal heart rate variability (NHRV).

METHODS: Eight well-trained subjects (mean $\pm$ SD age: 38.8 ± 4.6 yrs) were either assigned to the normoxia (CON: $n=4$) or hypoxia (HYP: $n=4$) condition after having their sleep monitored for 2 weeks (baseline). Then, for 4 weeks, participants performed 3 training sessions (HIIT=2, RST=1) each week in either a normoxia or simulated hypoxia setting (intervention). Sleep was objectively monitored through wrist-worn actigraphy devices, and NHRV was monitored through heart rate (HR) monitors. Comparison between groups, study phase (baseline and intervention) and the type of day (baseline, exercise, and rest) were examined.

RESULTS: Overall, sleep duration was 452.5 (95% CI 440.0; 464.9) minutes and sleep efficiency 90.5 (89.8; 91.2) %. Resting HR was 50.3 (49.3; 51.3) bpm and NHRV 4.3 (4.2; 4.4) ms. There were similar results ($p > 0.05$) in sleep and NHRV between baseline and intervention period in any group, besides wake-up time, which was earlier during the intervention for the CON group ($p = 0.008$, $d = 0.47$).

CONCLUSION: Although subjects' average sleep duration throughout the duration of the study was within current recommendations for healthy adults (7 or more hours per night on a regular basis), large heterogeneity in sleep variables and schedules was observed. Moreover, and compared with the baseline period, sleep and NHRV was not impacted to a larger extent when 4-weeks of HIIT and RST were held in simulated hypoxia conditions, when compared with the condition where the training design was held in normoxia.

ACTIVE HEAT ACCLIMATION IN WOMEN: CROSS-ADAPTION POTENTIAL FOR EXERCISE PERFORMANCE IN HYPOXIA

DEBEVEC, T., NARANG, B.J., BONCA, E., REMEC, K., TOMINEC, D., RABERIN, A., BOUTEN, J., MCDONNELL, A.C., CIUHA, U., BROCHERIE, F., MEKJAVIC, I.B., MILLET, G.P.
JOZEF STEFAN INSTITUTE

INTRODUCTION: Heat acclimation can mitigate heat-related decrements in maximal oxygen uptake and maximal aerobic power (MAP), enhancing exercise capacity in hot and thermoneutral environments [1]. The cross-adaptation hypothesis posits that adaptation to one stressor (e.g., heat) also augments tolerance to another (e.g., hypoxia) [2]. While evidence supporting this hypothesis exists, it remains unclear whether such cross-adaption occurs in women, as most relevant research has exclusively tested male participants [3]. Thus, the aim of this study was to assess whether a 10-day active heat acclimation intervention improves peak oxygen uptake and MAP under simulated altitude conditions in healthy women.

METHODS: Twenty-eight healthy women were randomly assigned to a hot (HA; $n=15$; T: 35°C, Relative Humidity: 50%) or a thermoneutral (CON; $n=13$; T: 20°C, RH: 50%) group, and underwent a 10-day intervention. All participants cycled for 1 h per day at 40% thermoneutral MAP. Pre- and post-intervention, peak oxygen uptake and MAP were assessed under three conditions: neutral (NEU; T: 20°C, RH: 50%), hypoxia (HYP; T: 20°C, RH: 50%, FIO₂: 13%), and heat (HEAT; T: 35°C, RH: 50%) using incremental exercise tests to exhaustion on separate days, interspersed by a rest day. Pulmonary ventilation, pulse oxygenation, and heart rate were measured throughout all exercise tests. Subjective thermal comfort was also assessed. Data were analysed using 2x2 mixed-effects ANOVA (group [HA,CON] * time [pre,post]), with statistical significance accepted when $p < .05$.

RESULTS: No significant interaction effects were observed. Neither intervention altered peak oxygen uptake under any condition (HA vs. CON; NEU: $0.2 \pm 7.3\%$ vs. $-0.1 \pm 7.5\%$; HYP: $-0.9 \pm 3.5\%$ vs. $1.3 \pm 9.8\%$; HEAT: $0.6 \pm 6.0\%$ vs. $0.0 \pm 9.4\%$; all time $p \geq .803$), whereas MAP was significantly increased under all conditions, similarly in both groups (HA vs. CON; NEU: $1.5 \pm 4.6\%$ vs. $5.1 \pm 4.9\%$; HYP: $1.7 \pm 5.8\%$ vs. $4.3 \pm 6.2\%$; HEAT: $3.4 \pm 4.1\%$ vs. $3.6 \pm 4.9\%$; all time $p \leq .012$). In hypoxia, no significant pre-post changes were observed in peak ventilation ($p = .666$), peripheral oxygenation ($p = .188$), or heart rate ($p = .485$). Additionally, no changes in thermal comfort were noted in either the hot ($p = .315$) or the hypoxic ($p = .270$) condition.

CONCLUSION: Heat exposure during 10 moderate-intensity cycling sessions did not provoke any performance or cardio-respiratory benefits in hot or hypoxic conditions, when compared to the same training conducted in thermoneutral conditions. The present data, therefore, do not support the potential for “heat-to-hypoxia” cross-adaptation in healthy young women, at least with the small “thermal dose” and training impulse employed in this study. Further work should explore protocols with higher heat and exercise doses, which may yield more beneficial effects in this regard.

PREDICTIVE VALIDITY OF A HYPOXIC SENSITIVITY TEST FOR ASSESSING RESPONSES TO ALTITUDE TRAINING

BROWN, K., SHELDON, D., PRINGLE, J.S.M., LUCAS, S.J.E.

UNIVERSITY OF BIRMINGHAM

INTRODUCTION: Altitude training has gained popularity among endurance athletes, promoting performance-enhancing physiological adaptations. However, individual variability in responses makes the traditional one-size-fits-all approaches to altitude training problematic. Understanding and predicting individual sensitivity to altitude remains a complex challenge due to the multifactorial nature of altitude adaptation. This study explored the complex relationship between key physiological markers during sea-level exercise performance and individual sensitivity to hypoxia, and the efficacy of hypoxic sensitivity to predict adaptation to altitude.

METHODS: Twenty-five athletes (18 males, 7 females) from the University of Birmingham’s Athletics and Cross-Country Club who attended a 3.5-week altitude camp (at ~1800 m) were recruited. Athletes performed a hypoxic sensitivity test (HST) in a normobaric hypoxic chamber beforehand. The protocol included rest and exercise under normoxic and hypoxic conditions (4000 m). Heart rate (HR), oxygen saturation (SpO₂), and ventilation were measured to assess hypoxic sensitivity and predict the adaptive response to the altitude camp. Submaximal and maximal treadmill testing was conducted both pre- and post-camp. HR, SpO₂, lactate, VO₂ max and fuel utilisation were assessed via continuous measurements.

RESULTS: Post-altitude training, athletes showed significant improvements ($P < 0.05$) in velocity at maximal oxygen consumption (vVO₂ max) (2.5%), speed at LT₂ (2.2%) and a slight but non-significant improvement in LT₁ speed (1.2%). Beneficial shifts in economy (kcal/kg/km), higher exercising SpO₂ (%), and lower HR (bpm) were observed pre-post camp during submaximal exercise testing stages ($P < 0.05$). However, pre-camp hypoxic sensitivity testing did not predict the change in any of these performance outcomes (LT₁: $r = -0.359$, $P = 0.131$; LT₂: $r = -0.304$, $P = 0.205$; and vVO₂ max: $r = -0.200$, $P = 0.442$).

CONCLUSION: The study sought to establish if a hypoxic sensitivity test (HST) could predict an individual’s adaptive response to altitude training. However, no predictive relationship was observed, although beneficial changes in performance metrics support the physiological advantages of altitude training. Further work in this area is needed to ensure athletes can optimise training and performance outcomes from altitude training, while mitigating the risk of altitude sickness, overtraining or deconditioning, and help inform acclimatisation strategies in moderate and high-altitude, as well as clinical settings.

ASSESSING THE SUITABILITY OF MUSCLE OXYGEN SATURATION SLOPE ZERO AS A MEASURE OF MAXIMAL METABOLIC STEADY STATE

HASSANEIN, Y., FLEITAS-PANIAGUA, P.R., MURIAS, J.M., AZEVEDO, R.

HAMAD BIN KHALIFA UNIVERSITY

INTRODUCTION: Near-infrared spectroscopy (NIRS) is a tool for non-invasive evaluation of muscle oxygenation status. Recent data (1) indicated that a zero slope value in the tissue saturation index (%TSI) during a constant-load exercise can be used as a proxy to estimate the exercise intensity associated with the maximal metabolic steady state (MMSS), which demarcates the boundary between the heavy and severe exercise intensity domains. However, to date, no study has characterized the suitability of this approach during a constant-load bout of exercise at the actual MMSS intensity. Further,

there is no information whether this approach would be consistent across different muscles. Thus, this study assessed the suitability of the %TSI slope zero approach to characterize the MMSS physiological responses from the vastus lateralis (VL) and the rectus femoris (RF) muscles.

METHODS: Eighteen participants (8 females) completed four laboratory visits over three weeks. The first visit consisted of a ramp incremental cycling test to task failure. The remaining visits were utilized to determine the MMSS through the evaluation of the maximal lactate steady-state (MLSS) in the presence of a stable oxygen uptake. After excluding the initial phase (i.e., first 2 min of exercise), the %TSI slope in the VL and RF was calculated from minute 2 to 5. The suitability of %TSI zero-slope approach at MMSS was analyzed by calculating the average, standard deviation (SD), variance, confidence intervals (95%CI), and range of the slope. Statistical significance was evaluated by comparing the individual slopes to zero by a one-sample t-test. Data were analysed using the SAS statistical package (SAS Institute Inc., USA). Statistical significance was accepted at $P \leq 0.05$.

RESULTS: Overall, for the VL muscle, the average slope was 0.22 %/min, with SD of 0.91, variance of 0.83, 95% CI between -0.25 and 0.68 %/min, range between -1.43 and 2.44 %/min. For RF muscle, the average slope value was -0.51 %/min, with SD of 1.00, variance of 1.02, 95%CI between -1.03 and 0.00 %/min, range between -2.24 and 1.04 %/min. The %TSI slopes was not statistically different from zero for VL ($p=0.22$) and RF ($p=0.07$) muscles.

CONCLUSION: Based on the current results, despite the %TSI slopes for the VL and RF muscles not being different from zero, the analysis showed considerable variability. This is a relevant finding since the exercise bout was performed at a verified MMSS intensity, which should have resulted in %TSI zero slope with minimum variability if this outcome is to be assumed as a suitable approach to identify the heavy-severe intensity boundary.

EFFECTS OF BREATH-HOLDING WARM-UP ON PERFORMANCE AND PHYSIOLOGICAL RESPONSES DURING HIGH-INTENSITY EXERCISE SIMULATING A 200 M SWIM

FUJIMOTO, T., GOTO, K., KITANO, A., SUZAKI, Y., SHINTANI, K., MATSUURA, Y.

NIIGATA UNIVERSITY OF HEALTH AND WELFARE

INTRODUCTION: Warm-up, a preliminary exercise performed before the main activity, has been shown to enhance performance by increasing muscle temperature and blood flow to active muscles. Recent studies suggest that incorporating hypoxic inhalation into warm-up routines can further improve performance in a 100m swim compared to conventional warm-up methods (1); however, the underlying mechanisms remain unclear. Moreover, due to equipment limitations, implementing hypoxic inhalation in actual competition settings is challenging. As a potential alternative, voluntary breath-holding may offer similar benefits, but its effectiveness requires direct investigation. Therefore, the purpose of this study was to investigate the effect of breath-holding warm-up on performance and physiological responses during high-intensity exercise simulating a 200 m swimming.

METHODS: Eleven healthy adults (2 females) participated in this study. Participants performed a 5-minute warm-up at 70% of their maximum oxygen uptake (VO_{2max}) under two conditions: 1) without breath-holding (Control) and 2) with intermittent breath-holding (20 s of spontaneous breathing followed by 10 s of breath-holding, repeated for 10 sets; Apnea). Performance was assessed through a constant-load exercise at 110% of VO_{2max} for 90 seconds, followed by a 30-second maximal pedaling test. Measurements included maximal and mean power output, cardiorespiratory parameters (e.g., oxygen uptake, heart rate), oxygen saturation (SpO_2), and perceived exertion (RPE). Additionally, near-infrared spectroscopy (NIRS) was used to assess tissue oxygenation saturation (StO_2) in the vastus lateralis.

RESULTS: The average VO_2 and SpO_2 during the warm-up period were lower under the apnea than the control trials ($P < 0.05$) while no difference was observed in StO_2 of the vastus lateralis between conditions ($P > 0.05$). These results suggest that the intermittent breath-holding protocol used in this study (10 seconds out of every 30 seconds) was insufficient to induce muscle hypoxia. Furthermore, no significant differences were observed in maximum and average power output, StO_2 , or RPE between conditions during the performance test ($P > 0.05$). The lack of improvement in exercise performance may be attributed to the warm-up failing to induce hypoxia in the active muscles or to the hypoxic duration being shorter than in previous studies where exercise performance improved following hypoxic inhalation with warm-up.

CONCLUSION: The results of this study suggest that a warm-up involving intermittent breath-holding (10 seconds out of every 30 seconds) does not enhance performance in a 2-min all-out cycling exercise simulating a 200 m swimming, compared to a warm-up with normal breathing.

MUSCLE OXYGEN SATURATION REMAINS STABLE DURING SUBMAXIMAL EXERCISE ACROSS DIFFERENT HYPOXIC CONDITIONS IN WELL-TRAINED ENDURANCE ATHLETES

KOWALSKI, T., REBIS, K., WILK, A., SZWED, P., KLUSIEWICZ, A., FAISS, R., DEBEVEC, T.

INSTITUTE OF SPORT - NATIONAL RESEARCH INSTITUTE

INTRODUCTION: Near-infrared spectroscopy (NIRS) is a valuable tool, enabling the non-invasive assessment of muscle oxygen saturation (SmO₂) and hemodynamics. It was recently applied to determine exercise intensity thresholds and optimize training prescription [1]. However, up-to-date investigations focus on the measurements performed at the same altitude, whereas the transferability of NIRS-obtained variables between different hypoxic conditions remains understudied. The concepts of "critical oxygenation" (COx), and critical power (CP) were investigated in athletes performing high-intensity exercise in normoxia and hypoxia [2]. COx was hypothesized to be a robust marker of exercise intensity, remaining stable in normoxic and simulated altitude conditions with simultaneous changes in CP and heart rate (HR).

METHODS: 29 healthy and highly-trained endurance athletes (age 22.4±6.8 years, 9 females) completed the study. Across 3 days, they underwent two 3-minute CP cycling tests in a randomized order in normoxia (87m ASL, FiO₂=20.8%) and normobaric hypoxia (3200m ASL, FiO₂=14.2%). SmO₂ (Moxy Monitor at the vastus lateralis, Moxy Monitors, USA), HR (Polar H10 chest strap, Polar Electro Oy, Finland), and external power (Wahoo KICKR trainer, Wahoo Fitness, Atlanta, GA) were continuously measured throughout the tests. COx and CP were established as the average from the last 30 seconds during both tests [3]. Repeated measures ANOVA with partial eta squared (η^2) effect size allowed to compare COx, HR, and CP between normoxia and hypoxia with sex as an independent variable.

RESULTS: CP was significantly higher in normoxia than in hypoxia (299.7±56.5 vs 254.9±47.7 W in females, 447.0±74.8 vs 357.3±60.7 W in males; $p<0.001$ and $\eta^2=0.115$ for environment, $p=0.004$ and $\eta^2=0.014$ for environment*sex). Average HR during the last 30 seconds of both tests was significantly higher in normoxia than hypoxia (189.4±7.7 vs 185.1±7.2 bpm in females, 183.5±7.5 vs 180.3±8.1 bpm in males, $p<0.001$ and $\eta^2=0.047$), but not for environment*sex interaction ($p=0.424$). There were no differences in COx between normoxia and hypoxia (22.4±7.2 vs 21.4±5.3 %SmO₂ in females, 11.3±6.5 vs 10.5±9.7 %SmO₂ in males; $p=0.610$ for environment, $p=0.946$ for environment*sex).

CONCLUSION: This study suggests that COx might be relatively stable across different ambient oxygen concentrations, whereas CP and HR exhibit significant differences between normoxia and hypoxia. Accordingly, NIRS-obtained variables may be useful in optimizing performance and training under different hypoxic conditions. The practical significance of our observations depends on the required accuracy of the exercise intensity determination. Further research seems warranted for validation of the COx concept using established protocols designed for CP and comparing COx values from single- and multiple-effort tests.

EFFECT OF HYPOXIA ON MUSCLE ACTIVATION DURING INCREMENTAL EXERCISE NORMALIZED TO RESPIRATORY COMPENSATION POINT

TOWNSEND, N., IBRAHIM, D., HASSANEIN, Y., MURIAS, J.

HAMAD BIN KHALIFA UNIVERSITY

INTRODUCTION: A previous study reported an effect of reduced FiO₂ on muscle activation during incremental exercise (Torres-Peralta et al., 2014), however only short step duration were used and therefore, a true metabolic steady state may not have been present at all workloads. The objective of this study was to examine the impact of hypoxia on muscle activation during both ramp and steady state incremental cycling normalized for relative intensity to the respiratory compensation point (RCP).

METHODS: Fifteen recreationally active adults (10 M, 5 F) made four lab visits, to complete ramp and step incremental exercise testing in normoxia (NORM; FiO₂≈21%) and normobaric hypoxia (HYPO; FiO₂≈13.5%). The step test consisted of 6 stages where the 6th workload was equivalent to 80% of the RCP determined from ramp testing. This was immediately followed by a final time to exhaustion (TTe) stage at the midpoint between RCP and peak power output (PPO). Electromyography (EMG) was used to assess muscle activation at each submaximal intensity and task failure, expressed as percent of baseline dynamic maximal effort. 2-way ANOVA, paired t-tests, and effect sizes were used to examine differences between conditions (NORM vs HYPO).

RESULTS: There was a significant condition by intensity interaction effect on muscle activation for rmsRF% ($p < 0.001$; $\eta^2 = 0.80$), and rmsVM% ($p < 0.001$; $\eta^2 = 0.66$) during ramp testing where post-hoc analysis revealed a decrease in rmsRF% ($p = 0.049$; $d = 0.61$) and rmsVM% ($p = 0.01$; $d = 0.84$) at PPO in HYPO. For the step test, there was a main effect of condition for rmsVM% ($p = 0.001$; $\eta^2 = 0.57$) and rmsVL% ($p = 0.04$; $\eta^2 = 0.32$), but not rmsRF% ($p = 0.74$; $\eta^2 = 0.009$). There was also a significant reduction in rmsVM% ($p = 0.01$; $d = 0.76$) and rmsVL% ($p = 0.03$; $d = 0.69$) in HYPO compared to NORM at task failure in the step test TTe stage. There was a strong relationship between muscle activation and power output (PO) at task failure across both when combining data from both ramp and step tests.

CONCLUSION: During ramp incremental exercise at workrates below RCP, there was little difference in muscle activation between NORM and HYPO, however during steady-state exercise, rmsEMG activity was lower in HYPO. At task failure, there was a positive association between absolute PO and muscle activation irrespective of condition or test protocol.

These results suggest that relative intensity and metabolic stress likely only play a minor role in muscle activation, whereas the force required to produce a given mechanical workload is the dominant factor. However, this might be modulated by steady-state versus non-steady-state metabolism.

IMPACT OF LOCAL AND SYSTEMIC OXYGENATION, RONS, AND METABOLITE ACCUMULATION ON THE RENIN-ANGIOTENSIN SYSTEM AND TMPRSS2 IN RESPONSE TO INTENSE EXERCISE

GALVAN-ALVAREZ, V.1,2, GARCIA-GONZALEZ, E.1, GARCIA-PEREZ, G.1, GALLEGU-SSELLES, A.1, MARTINEZ-CANTON, M.1, SANTANA, A.3, BOUSHEL, R.4, HALLEN, J.5, MARTIN-RINCON, M.1, CALBET, J.A.L.1,4,5

INTRODUCTION: The renin-angiotensin system (RAS) regulates cardiovascular function and oxidative stress, with ACE1/AT1R promoting vasoconstriction and ACE2/AT2R inducing vasodilation. ACE2 mediates SARS-CoV-2 entry, aided by TMPRSS2. Both are implicated in post-viral muscle fatigue, as their dysregulation after COVID-19 is linked to inflammation, oxidative stress, and metabolic dysfunction in human skeletal muscle (hSM). Exercise may restore RAS balance and protect against SM wasting. This study examined RAS signalling and TMPRSS2 changes in hSM following incremental exercise to exhaustion (IE) and post-exercise ischaemia, exploring the role of RONS, metabolite accumulation, and oxygenation. We hypothesise that RAS signalling and TMPRSS2 will be upregulated by intense exercise, with greater activation during ischaemic recovery and hypoxia conditions amplifying RONS production.

METHODS: Eleven physically active men completed an IE under normoxic (Nx) and hypoxic (Hyp, PiO_2 : 73 mmHg) conditions. Immediately following exhaustion, one lower extremity was swiftly occluded at 300 mmHg. V. lateralis biopsies were obtained: baseline (PRE), immediately post-exercise from the occluded extremity (POST), and after 60s from both the occluded (OC1M) and non-occluded (nOC1M). Blood samples were taken from the femoral vein. Protein expression was analysed by WB. Stats: ANOVA, t-test and Pearson's correlation.

RESULTS: At POST, muscle lactate +25% only in OC1M ($P<.05$) while PCr -94 and -48% in OC1M and nOC1M, respectively ($P<.005$) regardless of PiO_2 . PO_2 in the femoral vein was 21.1 ± 2.0 and 10.6 ± 2.8 mmHg at W_{max} , in Nx and Hyp, respectively ($P<.001$). TMPRSS2 was upregulated at POST (57%), and OC1M (204%), regardless of PiO_2 . At nOC1M, TMPRSS2 was reduced to PRE levels ($p>.05$). AT2R expression was reduced at POST (20%, $p<.05$), maintained after 1 min of recovery, regardless of occlusion and PiO_2 . ACE1 and AT1R remained unchanged ($p>.05$). TMPRSS2 and ACE2 were correlated across conditions ($r=0.48$, $p<.001$) and with Nrf2/Keap1 ratio ($r=0.83/r=0.54$; both $p<.001$), catalase ($r=0.80/r=0.48$; both $p<.001$), pSer359 p47phox NOX2 ($r=0.28$, $p=.01/r=0.65$, $p<.001$, respectively).

CONCLUSION: Our findings show that intense exercise and ischaemic recovery selectively modulate RAS-related protein expression in hSM. The robust upregulation of TMPRSS2 post-exercise, further enhanced by ischaemia, correlating with ACE2 and Nrf2/Keap1 ratio, suggests a link with oxidative stress and RAS adaptation. The reduction in AT2R post-exercise, independent of PiO_2 and occlusion, could have reduced AT2R-mediated vasodilatory signalling. The stability of ACE1 and AT1R suggests a selective response to metabolic stress rather than a global RAS activation. These findings support the role of RONS in exercise-induced RAS remodelling, with implications for SM function, COVID-19 viral susceptibility and post-viral fatigue.

EFFECTS OF HABITUAL AEROBIC EXERCISE ON MRNA EXPRESSION OF BATOKINES IN BROWN ADIPOSE TISSUE OF OBESE MICE

YAMAZAKI, H., FUJIE, S., UCHIDA, M., INOUE, K., ITO, R., IEMITSU, M.

RITSUEIKAN UNIVERSITY

INTRODUCTION: Brown adipose tissue (BAT) promotes energy expenditure and browning of white adipose tissue [1]. BAT has an endocrine system and secreted "batokines" play a crucial role in regulating metabolism and identified ependymin-related protein 1 (EPDR1), C-X-C motif chemokine ligand 14 (CXCL14), fibroblast growth factor-21 (FGF-21), bone morphogenetic protein 8B (BMP8B), etc. [2]. However, the effects of habitual aerobic exercise on changes in mRNA expression of batokines in BAT remain unclear. Therefore, this study investigated whether the habitual aerobic exercise alters the mRNA expression of batokines in interscapular BAT of obese mice.

METHODS: Eight-week-old apolipoprotein E (apoE) knockout (ApoE^{-/-}) mice were used as an obese model and were randomly divided into the following two groups: sedentary control (ApoE^{-/-} SED, n=6) group and 16-wk voluntary wheel running aerobic exercise (ApoE^{-/-} AT, n=6) group. ApoE^{-/-} mice of two groups were fed a high-fat diet during the experimental period. Age-matched C57BL/6J wild-type mice were fed a normal chow and were used as a healthy sedentary control group (WT-SED, n=6). Expression of EPDR1 mRNA, CXCL14 mRNA, FGF-21 mRNA, and BMP8B mRNA in the interscapular BAT (iBAT) were analyzed by using real-time RT-PCR with TaqMan probe. Protein expression levels of PGC1- α , as a marker for promoting the thermogenic function of BAT, in iBAT were analyzed by Western blotting. The effects of exercise training on mRNA expression of batokines were compared using one-way ANOVA. Statistical significance was defined as $p < 0.05$.

RESULTS: Epididymal fat mass of the ApoE^{-/-} SED group was significantly higher compared with WT-SED group ($p < 0.05$), and that of ApoE^{-/-} AT group was significantly lower compared with ApoE^{-/-} SED group ($p < 0.05$). Protein expression levels of PGC1- α in the iBAT were significantly higher in the ApoE^{-/-} AT group as compared with ApoE^{-/-} SED group ($p < 0.05$). EPDR1 mRNA levels in the iBAT were higher in the ApoE^{-/-} AT group as compared with ApoE^{-/-} SED group (ApoE^{-/-} SED: 1.1 ± 0.1 vs ApoE^{-/-} AT: 2.5 ± 0.8 arbitrary unit, $p = 0.047$). Additionally, BMP8B mRNA levels in the iBAT were lower in the ApoE^{-/-} AT group as compared with ApoE^{-/-} SED group (ApoE^{-/-} SED: 2.8 ± 0.6 vs ApoE^{-/-} AT: 1.2 ± 0.3 arbitrary unit, $p = 0.011$). However, no significant differences of mRNA expression levels of CXCL14 and FGF-21 in the iBAT were observed among the three groups.

CONCLUSION: Habitual aerobic exercise may alter the mRNA expression levels of several batokines, including EPDR1 and BMP8B, in iBAT of obese mice.

A VALINE INTERMEDIATE 3-HYDROXYISOBUTYRIC ACID DERIVED FROM THE SKELETAL MUSCLES ACTIVATES GLUCONEOGENESIS THROUGH THE LIGAND ACTIVITY OF GPR41

MIYAZAKI, T., UEDA, H., IKEGAMI, T., HONDA A.

TOKYO MEDICAL UNIVERSITY IBARAKI MEDICAL CENTER

INTRODUCTION: Branched-chain amino acids (BCAAs); valine, leucine, and isoleucine, are catabolized as energy substrates in the skeletal muscles in order to meet high energy demands, replacing the reduced supply of glucose, during endurance exercise. A small molecule 3-hydroxyisobutyric acid (3HIB) is an intermediate of valine in the mitochondrial pathway of muscular BCAA catabolism, and a portion of 3HIB is released into the blood circulation in response to the amount of endurance exercises in humans and animals. We have presented at the last ECSS meeting that the administration of 3HIB rapidly and significantly increased blood glucose concentration in rats. Therefore, we hypothesized that 3HIB may play a physiological role in the regulation of blood glucose concentration. Present study evaluated the regulation of blood glucose level by 3HIB and its mechanism.

METHODS: Male Wister rats (8 weeks of age) were intraperitoneally administered a 3HIB solution (60 mg/kg BW) and/or alpha-blocker prazosin (5 mg/kg BW), and glucose and its regulating hormone levels in serum and energy metabolites and mRNA expression in the liver were evaluated after 0, 15, and 60 min (N=7/groups). In addition, the ligand effect of 3HIB on G protein-coupled receptor 41 (GPR41), which is abundantly expressed in sympathetic ganglia, was evaluated by a GPCR ligand-binding assay.

RESULTS: In rats, serum glucose and noradrenaline levels were significantly increased after 15 min of the 3HIB injection, but were returned to baseline levels after 60 min. Blood glucose level after 15 min of 3HIB was unchanged with the addition of prazosin. In the liver, malate concentration and glucose 6-phosphatase mRNA expression, which are a metabolite of 3HIB and a rate-limiting enzyme in the gluconeogenesis pathway, respectively, were significantly increased in the liver after 15 min of 3HIB injection. The GPCR ligand-binding assay confirmed that 3HIB has agonist activity for GPR41 at similar level as serum concentrations after the intraperitoneal administration of 3HIB or the endurance exercises.

CONCLUSION: The effect of 3HIB excreted from the skeletal muscles to elevate blood glucose concentration is thought to be due to the gluconeogenesis in the liver using 3HIB itself as a substrate. In the activation of this hepatic gluconeogenesis, 3HIB may play a role in promoting the release of noradrenaline from the sympathetic nervous system through its agonist activity of GPR41. So, under condition of the severe energy expenditure, 3HIB, which is an intermediate catabolic metabolite of BCAA, a major amino acid in the structural proteins of skeletal muscle, may act as a metabolic signal from skeletal muscle to stimulate glucose supply from the liver.

INTERMITTENT POST-SPRINT ISCHEMIA POTENTIATES STAT3/IL-6 SIGNALLING IN HUMAN SKELETAL MUSCLE DURING SPRINT INTERVAL TRAINING.

ANGEL, G., GALLEGU-SELLES, A.1, GALVAN-ALVAREZ, V.1, MARTINEZ-CANTON, M.1, GARCIA-GONZALEZ, E.1, GARCIA-PEREZ, G.1, FERNANDEZ-GARCIA, B.2, BOUSHEL, R.3, HALLEN, J.4, MARTIN-RINCON, M.1, CALBET, J.A.1,3,4

1 IUIBS AND UNIVERSIDAD DE LAS PALMAS DE GRAN CANARIA, SPAIN; 2 DEP. OF MORPHOL., UNIV. OVIEDO, SPAIN; 3 SCHOOL OF KINESIOLOGY, UBC, CANADA; 4 DEP. PHYSICAL PERFORMANCE, NIH, NORWAY.

INTRODUCTION: High-intensity exercise stimulates RONS production, essential for activating signalling pathways that drive muscle adaptation. IL-6/STAT3 signalling plays a key role in metabolic regulation and antioxidant defence, yet its response to exercise-induced oxidative stress remains incompletely understood. Although IL-6 mediates redox adaptations, the interplay among RONS, STAT3/NFκB activation, and IL-6 expression in skeletal muscle remains unclear. Post-exercise ischaemia prolongs local oxidative and metabolic stress, providing a model to assess RONS-mediated signalling adaptations. This study investigated whether sprint interval training (SIT) with post-sprint ischaemia modulates RONS-sensitive pathways in skeletal muscle. We hypothesised that this intervention enhances STAT3/NFκB activation and IL-6 expression, reflecting a RONS-adaptive modulation of myokine response.

METHODS: Ten active participants (3W/7M) completed six SIT sessions over two weeks (4–6 × 30-s all-out sprints with 4-min recovery). Using a randomised within-leg design, one leg underwent 30–50 sec of ischaemia at 300 mmHg immediately after each sprint (IS-leg), while the contralateral leg acted as an internal control (FC-leg). Muscle biopsies from the vastus lateralis were collected at rest pre-training (from a single leg) and post-training (bilaterally) to analyse protein expression levels of pSTAT3, total STAT3, IL-6, NFκB p65, and IκBα by Western blot.

RESULTS: After training, the IS-leg increased markedly in the NFκB p65/IκBα ratio (+2.0-fold, $p < 0.01$), an effect not observed in the FC-leg. After SIT, total STAT3 levels increased significantly in both legs (+1.4-fold, $p < 0.03$). Similarly, post-training elevations were noted in both IL-6 and NFκB p65 protein levels, with markedly greater increases in the IS-leg compared to the FC-leg (IL-6: IS-leg +1.5-fold vs. FC-leg +1.1-fold; NFκB p65: IS-leg +4.2-fold vs. FC-leg +2.0-fold, $p < 0.05$).

CONCLUSION: These findings reveal that application of post-sprint ischaemia during SIT amplifies basal STAT3/IL-6 and NFκB signalling through extended exposure to RONS and metabolites. This within-subject design effectively isolates the specific effects of ischaemia, highlighting its potential to boost adaptations to oxidative stress. Enhanced IL-6 signalling may regulate inflammatory processes and bolster antioxidant defences, underscoring its dual role in managing exercise-induced oxidative stress. The observed signalling adaptations support the use of post-exercise ischaemia to modulate oxidative stress responses, with implications for muscle recovery and performance. Further studies will determine whether these molecular changes translate into functional improvements in endurance performance.

INTRODUCTION: Mitochondria dysfunction is a major factor contributing to the development of sarcopenia. Resistance exercise is the most effective intervention to enhance mitochondria function and diminish muscle loss. Resistance exercise increases PPARβ expression, a key regulator of mitochondrial function and protein homeostasis. This study aims to investigate whether PPARβ alleviates aging-induced muscle loss and the underlying mechanisms.

METHODS: Human skeletal muscle samples were used to determine whether aging affects PPARβ expression. To further investigate PPARβ function, protein expression and proteomics analysis of tibialis anterior (TA) muscles were performed using LC-MS in 10-week-old wild-type (WT), PPARβ transgenic (mTG), PPARβ knockout (mKO) mice. Differentially expressed proteins were identified and subjected to pathway enrichment analysis to elucidate associated metabolic pathways and functional groups. Ultrastructural changes in the mKO model were examined using electron microscopy. Additionally, to assess the effect of increased PPARβ expression in aging, a PPARβ agonist was administered to 24-month-old mice for 2 months, followed by protein expression analysis.

RESULTS: PPARβ expression was reduced in aged human skeletal muscle. In the mTG model, PPARβ expression was increased, associated with improved muscle mass and endurance exercise capacity, whereas the mKO model exhibited decreased PPARβ expression and impaired endurance exercise capacity. In particular, mKO mice showed sarcomere disorganization, glycogen accumulation, mitophagy impairment, and mitochondrial hypertrophy. Proteomic analysis revealed that PPARβ-induced metabolic changes is related to muscle protein quality control. Moreover, treatment with a PPARβ agonist for 2 months in 24-month-old mice restored PPARβ expression and improved endurance exercise capacity. Further studies are necessary to determine whether exercise-induced PPARβ can regulate muscle protein quality control in aged mice.

CONCLUSION: Our findings suggest that PPAR β serves as a central regulator linking mitochondrial metabolism to muscle protein quality control. However, further studies are necessary to determine whether exercise-induced PPAR β can regulate muscle protein quality control in aged mice and to explore the underlying mechanisms.

CHRONIC CHANGES IN ESTROGEN RECEPTORS ARE NOT ASSOCIATED WITH MUSCLE HYPERTROPHY IN WOMEN AND MEN

LIBARDI, C., BERGAMASCO, J.G.A.1, SCARPELLI, M.C.1, GODWIN, J.S.2, MESQUITA, P.H.C.2, CHAVES, T.S.1, SILVA, D.G.1, BITTENCOURT, D.1, DIAS, N.F.1, MEDALHA JUNIOR, R.M.1, CARELLO FILHO, P.C.1, ANGLERI, A.1, COSTA, L.A.R.3, MICHEL, J.M.2, KAVAZIS, A.N.2, UGRINOWITSCH, C.3, ROBERTS, M.

1: FEDERAL UNIVERSITY OF SÃO CARLOS, BRAZIL; 2: AUBURN UNIVERSITY, USA; 3: UNIVERSITY OF SÃO PAULO, BRAZIL.

INTRODUCTION: The muscle hypertrophy induced by resistance training (RT) has been demonstrated to be similar between women and men (Roberts et al., 2020). However, it has been suggested that the underlying mechanisms driving these adaptations may differ by sex (Roberts et al., 2023). Among these, similarly to the association between androgen receptors and hypertrophy in men, the estrogen receptors (ER) have emerged as a potential hypertrophic mechanism in women. The purpose of this study was to investigate the chronic effects of RT on different fractions of ER in women and men. Additionally, we investigated whether these chronic changes in the ER fractions are associated with hypertrophy of type I and II fibers in women and men.

METHODS: Thirty-eight young women (n = 19) and men (n = 19) underwent 10 weeks of RT. Muscle biopsies were performed at baseline and 96-120 h after the last session (chronic effect). ER, cER, and nER were analyzed using Western blotting, and ER-DNA was assayed through ELISA. Muscle fiber cross-sectional area (fCSA) were analyzed through immunohistochemistry.

RESULTS: Unpaired t tests showed significant baseline differences in ER, where men demonstrated greater baseline contents of total ER compared to women (P = 0.0182). No other significant baseline between-sex differences were observed for cER (P = 0.6081), nER (P = 0.9827) or ER-DNA (P = 0.1857). Chronically, there was a main effect of time only for cER (P = 0.0162), in which decreases were observed in women and men. Additionally, no significant effects were observed for ER, nER and ER-DNA (P > 0.05). Finally, correlation analyses showed only a significant negative weak correlation between baseline ER-DNA and fCSA I (r = -0.247; P = 0.038) for women.

CONCLUSION: A link between ER content and muscle mass has been suggested. However, the effects of resistance training on ER content and its association with hypertrophy have been poorly explored. Our findings contribute to this topic by revealing that chronic changes in ER content are not associated with hypertrophy of type I and II fibers in women and men.

ACUTE EFFECTS OF DIFFERENT EXERCISE PATTERNS ON SALIVARY IGA AND LACTOFERRIN SECRETIONS

ITO, R., UCHIDA, M., FUJIE, S., IEMITSU, K., KOJIMA, C., SHINOHARA, Y., HASHIMOTO, T., ISAKA, T., IEMITSU, M.

RITSUMEIKAN UNIV

INTRODUCTION: Our recent studies have demonstrated that acute continuous aerobic exercise leads to lower secretion levels of immunoglobulin A (IgA) and higher levels of lactoferrin, an antimicrobial peptide, in saliva [1,2]. However, the acute secretory responses of salivary IgA and lactoferrin to different exercise patterns remain unclear. This study aimed to clarify the acute effects of different exercise patterns with the same total exercise volume and duration on salivary IgA and lactoferrin secretion.

METHODS: In a randomized crossover trial, 12 healthy young untrained men (mean age: 22.2 $\pm$ 1.1 years; height: 172.9 $\pm$ 6.8 cm; body weight: 65.9 $\pm$ 4.1 kg; body fat: 15.9 $\pm$ 4.9 %; VO₂max: 43.4 $\pm$ 6.0 mL/kg/min) performed two exercise patterns with the same total exercise volume: moderate-intensity continuous exercise (MICE) for 20 min cycling exercise load equivalent to 70% maximal oxygen uptake (VO₂max), and high-intensity interval exercise (HIIE) for 20 min cycling exercise, with 5 sets of 2-min at 50% VO₂max and 2-min at 90% VO₂max. Saliva samples were collected at baseline, post-0 min, and post-30 min. The salivary IgA and lactoferrin concentrations were measured by an enzyme-linked immunoassay. The effects of different exercise patterns were analyzed using two-way repeated-measures ANOVA with two trials (MICE and HIIE) $\times$ three time points (baseline, post-0 min, and post-30 min). Statistical significance was set at p < 0.05.

RESULTS: In the HIIE, the percentage change in salivary IgA secretion rate did not decrease from baseline to after exercise. In contrast, in the MICE, the percentage change in salivary IgA secretion rate was lower immediately after exercise (p = 0.0002). In addition, the percentage change in salivary IgA secretion rate immediately after exercise decreased in the MICE as compared to the HIIE (MICE: -37.6 $\pm$ 19.7 % vs HIIE: 3.6 $\pm$ 33.6 %, p = 0.0014). However, the percentage change in salivary lactoferrin secretion rate did not change from baseline to immediately after exercise in the MICE and the HIIE. Moreover, the salivary flow rate from baseline to after exercise did not change due to differences in exercise patterns.

CONCLUSION: These results suggest that salivary IgA secretory response may differ between acute MICE and HIIE with the same total exercise volume and duration, whereas secretory responses to salivary lactoferrin may not differ.

EXERCISE INTENSITIES DIFFERENTIALLY MODIFIES FEEDING BEHAVIOR AND HYPOTHALAMIC NEURON ACTIVITY

HUANG, H.

EAST CAROLINA UNIVERSITY

INTRODUCTION: While hypothalamic neurons role in regulating energy homeostasis is well established, how forced energy expenditure, such as exercise, modulates these neurons and if these neurons are involved in post-exercise feeding behaviors remains unclear. Despite emerging evidence identifying aerobic exercises potent role in modulating the activity of neurons in regulating appetite, these studies produce conflicting results. These discrepancies may be, in part, due to methodological differences, including differences in exercise intensity.

METHODS: We utilized mature, untrained mouse model to investigate the effects of acute sedentary, low- (10 m/min), moderate- (14 m/min), and high (18 m/min)-intensity treadmill exercise in a randomized crossover on food intake and neuronal activity in the hypothalamus. 12-hour-fasted mice were used, and food intake was monitored for 48 hours post-exercise. Immunohistochemical detection of cFOS was performed 1-hour post-exercise to determine changes in hypothalamic NPY/AgRP, POMC, tyrosine hydroxylase (TH), and SIM1-expressing neuron activity concurrent with changes in food intake. Patch-clamp electrophysiology experiments were used to confirm neuronal activation after exercise.

RESULTS: Our results reveal that acute moderate-intensity exercise significantly increased food intake, AgRP/NPY neuron activation, and PVN Sim1 neuron activation while not affecting ARC POMC neurons. Strikingly, this exercise-induced feeding was completely abolished when ARC AgRP/NPY neuron activity was inhibited, while inhibition of ARC AgRP/NPY neurons did not affect PVN Sim1 neuronal activation. Conversely, high-intensity exercise suppressed food intake, which was concurrent with increased anorexigenic POMC neuron activity. Furthermore, tyrosine hydroxylase (TH) and SIM1 neuron activity in the paraventricular nucleus was elevated.

CONCLUSION: Our results demonstrate that moderate-intensity exercise induces ARC AgRP/NPY activation is critical in promoting food intake post-exercise, thus providing insight into the crucial role of ARC AgRP/NPY neurons in maintaining energy homeostasis in cases of exercise-mediated energy deficit. In contrast, high-intensity exercise may be beneficial for suppressing food intake, possibly due to hypothalamic POMC neuron activation and projections to tyrosine hydroxylase (TH) and SIM1 neurons in the paraventricular nucleus.

Overall, our study identifies a novel role of exercise intensity in differentially modifying post-exercise feeding behavior and hypothalamic neuron activity.

HEAR THE BENEFITS: TIME SPENT IN MODERATE-TO-VIGOROUS PHYSICAL ACTIVITY PREDICTS HEARING SENSITIVITY AND SPEECH IN NOISE COMPREHENSION

CAREY, B., MORRIS, T., AI, M., KRAMER, A., HILLMAN, C., PEELE, J.E.

NORTHEASTERN UNIVERSITY

Introduction: It is well-established that adult aging generally brings declines in hearing ability. Although age-related decreases in sensitivity are common, older adults often report difficulty following conversations in noisy environments. Despite decades of interest in understanding why some listeners struggle to understand speech in noise more than others, answers remain elusive. Prior work suggests that communicating in noisy environments requires the upregulation of executive functions. Given the rich literature supporting the benefits of physical activity for executive functions, we hypothesized that spending time in moderate-to-vigorous physical activity (MVPA) would be beneficial for hearing health.

Method: Participants (N=95,259; 55.9% female) in the UK Biobank dataset wore an accelerometer for 7 days and completed questionnaires. Derived accelerometer data came from a machine-learning model classifying movement behaviors as time spent in sleep, sedentary behavior, light physical activity, and MVPA. Participants also answered two questions about their hearing status: "Do you have any difficulty with your hearing?" and "Do you find it difficult to follow a conversation if there is background noise (such as TV, radio, children playing)?" We grouped participants into whether they spent at least 150 minutes (>1.49% of their week) in MVPA or not (i.e., < 1.49% of their week) and transformed their answers into binary variables by only taking participants who responded "yes" or "no". We then ran logistic regressions to determine if spending at least 150 minutes in MVPA decreases the likelihood of reporting a hearing problem or a problem with speech in noise.

Results: Spending at least 150 minutes in MVPA was a significant predictor of hearing outcomes for both questions. Meeting this criterion was associated with a 7.6% reduction in the odds of reporting a hearing problem and a 5.3% reduction in the odds of reporting difficulty with speech in noise.

Discussion: These findings show that meeting the World Health Organization's recommended physical activity guidelines for adults (at least 150 minutes of MVPA per week) is associated with a significantly reduced likelihood of reporting a hearing or speech in noise problem. These findings suggest that physical activity may be a protective factor in age-related hearing loss and speech in noise comprehension decline. The answer to improving adversity with degraded speech may not lie in another product or advancement in technology but rather in the simplicity of a lifestyle change. Targeting physical activity as a non-invasive and low-cost intervention may make the common issue of hearing loss that comes with age less imminent.

DOES THE IMPACT OF THE PREDICTION ERROR OF RATINGS OF PERCEIVED EXERTION ON RUNNING PLEASURE EVOLVE AS FAMILIARITY WITH THE EXERCISE ROUTE INCREASES?

OZ, I., DE GEUS, B., THONON, B., BREVERS, D.

CATHOLIC UNIVERSITY OF LOUVAIN

The rise of affectivism led the exercise psychology field to a new era where the experience of pleasure gained more importance in explaining the underlying mechanisms for physical exercise appraisal and adherence. Recent findings showed that the retrospective pleasure of an exercise session is modulated by the mismatch between the ratings of anticipated and experienced levels of perceived exertion, defined as the prediction error of ratings of perceived exertion (RPE). This new marker is based not only on the retrospective ratings of RPE but also on a novel aspect, prospective thinking, that is humans ability to imagine in a future scenario. Two measurement points of RPE assess the prediction error of RPE as the prospective RPE ("What intensity of exertion do you expect to feel during this session?") and the retrospective RPE ("What intensity of exertion did you feel during this session?"). A positive prediction error of RPE (lower score of retrospective RPE than prospective RPE) is associated with higher pleasure. In contrast, a negative prediction error of RPE (higher score of retrospective RPE than prospective RPE) is linked with lower pleasure ("What intensity of pleasure did you feel during this session?"). Hence, the hedonic value of a physical exercise session can be explained by a better-than-expected experience. To understand the conditions impacting this new marker, therefore, the pleasure in physical exercise, the current research aimed to better characterize the dynamic of the prediction error of RPE as the familiarity with the exercise trail increases. The research question was whether the impact of the prediction error of RPE on pleasure is modulated by the degree of familiarity with a running route. As individuals run on the same trail for 4 times, they might get familiar with the trail across time (run 1,2,3,4), and they are expected to become more accurate in their anticipation of the level of physical exertion. Thus, as familiarity increases across runs, the impact of the prediction error of RPE on running pleasure will decrease. It was hypothesized that (i) the mismatch between prospective and retrospective RPE (i.e., prediction error of RPE) will decrease across the running sessions, and thereby (ii) the impact of the prediction error of RPE on running pleasure will decrease across the repetition of the running sessions. Participants (N = 50) ran four times on the same running trail in a forest near the university campus in Belgium. For the preliminary analyses, a linear mixed model was run. Initial results with the not-yet-complete sample showed a significant difference in the prediction error between run 1 and run 2, and run 1 and run 3. Pleasure did not significantly change across runs. The influence of covariates and how prediction error of RPE affects pleasure and its potential to enhance adherence to physical exercise is discussed in detail.

For all the details, see preregistration (<https://osf.io/x5qj>).

EFFECTS OF A CREATIVE DANCE PROGRAM ON CREATIVITY AND WELL-BEING IN ADULTS: A MIXED-METHODS APPROACH

CALVO ESTELRICH, C., TORRENTS, C., RICHARD, V., BOURKE, M.

UNIVERSITY OF LLEIDA

INTRODUCTION: Creativity enhances cognitive flexibility, problem-solving, and emotional resilience, while fostering self-expression and reducing stress. However, fitness programs often overlooked the development of motor creativity and expressive practices. This study aimed to evaluate the impact of an 18-week structured Creative Dance program on the well-being and creativity of adults, comparing it to the effects of a music-based fitness program.

METHODS: A longitudinal mixed-methods experimental design was employed. 71 adults (age: 51.5±5.6) were assigned to three groups: (A) Creative Dance, (B) Music-based fitness program, and (C) a Control group with no intervention. The study collected quantitative data using standardized creativity questionnaires: Emotional Creativity Scale (CES) [1], Movement Creative Self-Efficacy Scale (CAS) [2], and Runco Ideation Behavior Scale (RIBS) [3]; a specific motor test of creativity in dance; and qualitative data provided by semi-structured interviews, which were thematically analyzed using NVivo Software.

RESULTS: A linear mixed-effects model was estimated to examine the effects of group (A, B and C) and time (pre-post and retention, assessed three months after the intervention). Significant Group×Time interactions were observed for CES ($F(4,148)=3.78$, $p=.006$), RIBS total ($F(4,136)=3.78$, $p=.006$), RIBS - Factor 1 ($F(4,136)=3.63$, $p=.008$), and all the components of the specific creativity dance test ($p<.001$). Subsequent post hoc analysis showed a significant increase of Group A in Creative emotional expression in the posttest ($M=146.44$, 24.83 to 268.04, $p<.05$) and a further increase in retention ($M=164.26$, 95%CI = 42.66 to 285.87, $p<.01$); in ideation and idea generation in retention ($M=4.74$, 95%CI = 0.93 to 8.55, $p<.05$); and in all the components of creativity of the specific test ($p<.001$). Group B and Group C showed no significant changes in the posttest or retention, except for a significant decline in RIBS in group C in the retention test ($M=-5.32$, 95%CI = -9.49 to -1.15, $p<.05$), and a slight decrease in variety of movements during retention ($M=-0.48$, 95%CI = -0.88 to -0.08, $p<.05$) and aesthetic interest ($M=-0.64$, 95%CI = -1.05 to -0.23, $p<.01$) in the specific test.

Considering the qualitative analysis, participants highlighted motivation and adherence, emphasizing group cohesion and the facilitator's role. Group A reported improved coordination, fluency, and self-expression, while Group B noted gains in strength, endurance, and routine adherence.

CONCLUSION: The Creative Dance Program significantly improved creative self-efficacy, ideation, dance creativity, and overall well-being, surpassing the benefits of traditional exercise. These findings underscore the importance of integrating creativity into physical activity to support psychological and motor development in middle-aged adults.

QUANTIFYING DECISION MAKING BIAS OF MAJOR LEAGUE BASEBALL HOME PLATE UMPIRE USING A PSYCHOPHYSICAL MATHEMATICAL MODEL.

TOMOMURA, M., SHINYA, M.

HIROSHIMA UNIVERSITY

INTRODUCTION:

Home plate umpires strike and ball calls significantly influence baseball game outcomes. Prior research has demonstrated biases in Major League Baseball (MLB) umpires' decision-making (1). Quantifying these biases provides strategic advantages for teams and players. For instance, if strike zone width varies by umpire, understanding these tendencies allows for tactical adjustments. Similarly, if umpire decisions are influenced by catchers, it may reflect framing techniques. This study quantified MLB umpire biases in relation to individual umpires and catchers using a psychophysical mathematical model.

METHODS:

This study analyzed 7,008,208 pitches recorded by MLB Statcast from official games played between 2015 and 2024. From this dataset, we extracted 115,673 fastballs thrown by right-handed pitchers to right-handed batters, where the pitch height was clearly within the strike zone ($1 \text{ ft} < \text{plate\_z} < 2 \text{ ft}$), the horizontal position at the front of home plate (plate_x) was on the outer edge ($\text{plate\_x} > 0 \text{ ft}$), and the batter did not swing. We applied probit regression with a binary dependent variable (1 for a called ball, 0 for a called strike) and plate_x as the independent variable to estimate a psychophysical sigmoid function. The plate_x position at which the probability of a ball or strike call was 0.5, termed the strike zone boundary, served as an indicator of umpire bias. We calculated strike zone boundaries separately for umpires and catchers with a minimum sample size of 200 calls per individual.

RESULTS:

On average, the estimated strike zone boundary was 3.38 cm outside the home plate, deviating from the official strike zone definition. The strike zone boundary varied by umpire by up to 3.51 cm and by catcher by up to 4.39 cm.

CONCLUSION:

Probit regression analysis quantified biases in MLB home plate umpires' decision-making, revealing significant variations across umpires and catchers. By identifying umpire-specific strike zone boundaries, pitchers can refine their pitch distribution strategies, and batters can adjust their approach at the plate. Similarly, catcher-specific strike zone boundaries may inform managerial assessments of framing skills. These findings offer valuable insights for making better catcher selection and refining pitcher and batter strategies.

THE ASSOCIATION BETWEEN EARLY MOTOR DEVELOPMENTAL MILESTONE ATTAINMENT AND CONFLICT MONITORING IN PREADOLESCENT CHILDREN.

CARD, M., DROLLETTE, E., RAINE, L., TINNEY, M., ZIMMERMAN, E., SCHOTT, N., HILLMAN, C.

NORTHEASTERN UNIVERSITY

Early motor developmental milestone (MDM) attainment provides key insights into neurodevelopment, offering potential markers for identifying children at-risk for developmental delays and related disorders. Understanding how MDMs shape developmental trajectories across domains can inform predictive models, early interventions, and preventative strategies. While prior research links earlier MDM attainment to improved physical and mental health 7 to 10 years later, its association with neurocognitive function remains unexplored. Extending this framework, we examined whether early MDM timing predicts brain function during preadolescence. Guardians of 97 children (ages 9–11 years, 49.5% female) retrospectively reported the age (months) at which their child attained five MDMs: (1) holding the head unsupported, (2) rolling over, (3) sitting unsupported, (4) standing, and (5) walking independently. Children completed a modified flanker task while event-related potentials (ERPs) and task performance were recorded. Error-related negativity (ERN; 0-150ms post-error at FCz) and post-error positivity (Pe; 200-600ms post-error at CPz) were measured from commission error trials. Data were analyzed using multiple stepwise linear regressions, adjusting for demographic factors in Step 1, and included each MDM in separate models as independent variables in Step 2. Our findings indicate earlier MDM attainment predicts neuroelectric markers of conflict monitoring during preadolescence. Specifically, for the ERN, earlier attainment of holding the head up

($\Delta R^2 = .05$, $F(2, 94) = 4.65$, $p = .012$) and walking independently ($\Delta R^2 = .04$, $F(2, 94) = 4.4$, $p = .015$) predicted larger ERN amplitude (i.e., more negative), a neural signal indicating the evaluation of conflict engendered by erroneous behavior (head up; $pr = -.23$, $t(94) = -2.24$, $p = .028$, $\beta = -.22$; walking: $pr = -.21$, $t(94) = -2.13$, $p = .036$, $\beta = -.21$). Additionally, earlier attainment of sitting unsupported predicted larger Pe amplitude (i.e., more positive), associated with conscious error detection ($\Delta R^2 = .04$, $F(1, 95) = 4.65$, $p = .038$, $pr = -.21$, $t(95) = -2.1$, $p = .038$, $\beta = -.21$). MDMs reflect the integration of multiple physiological systems, with postural control (e.g., head up, sitting) and locomotion (e.g., walking) requiring sensorimotor coordination, balance, and engagement of neural structures involved in both motor and cognitive control, such as the anterior cingulate cortex. This study builds on prior research by demonstrating that the timing of MDM attainment is associated with neural markers of conflict monitoring in preadolescence. These findings suggest that earlier MDM attainment may reflect more efficient neural pathways for integrating sensory feedback, motor control, and error monitoring. As such, early MDMs may serve as indicators of future conflict monitoring abilities, offering a potential avenue for early identification of children at risk for cognitive or self-regulation difficulties.

THE EFFECT OF EXERCISE INTENSITY AND DURATION ON CHANGES IN AFFECTIVE VALENCE DURING EXERCISE

RAN, H., STELIOS, P., NIELS BJ, V., SHAUN, P.

UNIVERSITY OF EDINBURGH; UNIVERSITY OF STIRLING

INTRODUCTION: Affective responses during exercise have been proposed to influence physical activity adherence. While many studies have demonstrated that exercise intensity impacts the change in affective valence during exercise, the role of exercise duration is unclear. Thus, the present study aimed to examine whether exercise duration influences the change in affective valence during exercise.

METHODS: Twenty-six inactive adults (12 men, 14 women; 29 ± 9 y; 23.71 ± 4.1 kg/m²; 32 ± 7.36 ml/min/kg) completed VO₂max and ventilatory threshold (VT) tests before three experimental cycling sessions: (1) 10 min at 110% VT, (2) 10 min at 80% VT, and (3) 30 min at 80% VT. Affective valence (Feeling Scale), felt arousal (Felt Arousal Scale; FAS), and rate of perceived exertion (RPE) were recorded at baseline, at the end of the warm-up (5min at 80%VTI), and every 2.5 min during exercise.

RESULTS: Mean affective valence increased during the warm-up for each condition, but subsequently dropped during exercise at 110% VT (-1.15 ± 2.84), increased during 10 min of exercise at 80% VT (0.88 ± 2.25), and remained steady during 30 min at 80% VT (-0.15 ± 2.63). Change from the end of the warm-up did not differ significantly between 10 min and 30 min at 80% VT, though the 10 min condition showed a slightly more positive change (0.92 vs. -0.04). Individual variability remained high ($SD = 2.189-2.661$). Statistical analyses were conducted using repeated measures ANOVA, as normality assumptions were met. Post hoc comparisons were performed using paired-samples t-tests. The significance level was set at $p < 0.05$. A significant main effect of condition was found ($p = 0.008$). Post hoc analysis revealed a significant difference between 10 min at 80% VT and 10 min at 110% VT ($p = 0.009$, $d = 0.64$), with the latter inducing a greater negative change. The effect size for the difference between 10 min at 80% VT and 30 min at 80% VT was $d = 0.37$, suggesting a small difference. RPE increased with both intensity and duration. Post hoc tests confirmed that 110% VT induced greater exertion than 80% VT, and 30 min at 80% VT resulted in higher RPE than 10 min at 80% VT. FAS increased over time but was unaffected by intensity or duration, suggesting a consistent pattern across conditions.

CONCLUSION: The results of this study support that exercise intensity is a key moderator of the affective responses to exercise. Exercise duration did not significantly moderate affective responses, but responses varied considerably between participants, and there is a need for further studies to explain this large inter-individual variability in response. These results have implications for exercise prescription to insufficiently active individuals as affective responses have been hypothesised to influence exercise enjoyment, and subsequently exercise uptake and adherence. Our findings suggest that exercise intensity is more important in determining affective responses than exercise duration.

WHAT DO PHYSICAL EDUCATION TEACHERS NEED IN IN-SERVICE TRAININGS ON THE USE OF DIGITAL MEDIA? A CROSS-SECTIONAL STUDY

MACKENBROCK, J., KLEINERT, J.

GERMAN SPORT UNIVERSITY COLOGNE

Introduction:

Digitalization leads to an increased use of digital media (DM) in education. Especially in physical education (PE), which is characterized by special physical and spatial-material conditions, teachers face challenges due to DM and need special digital skills. In order to develop and maintain digital skills, in-service teacher training is a suitable format. Therefore, to address PE teachers perspectives, the aim of the study is 1) to determine PE teachers needs and preferences regarding content and formats of in-service training on the use of DM in PE, and 2) to determine differences between subgroups of PE teachers.

Methods:

The study consists of a cross-sectional online survey with German PE teachers in June 2024. 128 teachers (gender: $f=62$, $m=66$; age: $M=42.96$ years, $SD=10.02$ years) participated in the questionnaire. Besides demographic information, teachers were asked about their participation in in-service trainings and their preferences regarding content and formats. Descriptive analyses were run to identify teachers preferences, and chi-square tests to compare the preferences of subgroups (gender, age, school-type).

Results:

60% of the teachers participated in in-service trainings in the last two years, of which 19% have attended trainings on the use of DM in PE. 80% of the teachers would like to take part in (further) trainings on the use of DM in PE. Regarding the content, the results indicate a high demand (>75%) for trainings on movement analysis (93%), exercise instructions (83%) and interactive teaching and learning platforms (75%). A medium demand (>50%) exists for general DM education in PE (66%), DM as presentation technique (54%), DM-supported grading (54%), AI-supported recording of the body and movements (53%) and lesson analysis with DM (52%). Regarding the format, PE teachers tend to prefer synchronous training courses lasting between 2-4 hours during working hours. Differences in training content and format appear regarding the age group: Younger teachers have, compared to older teachers, a significant higher need in topics as diversity and inclusion with DM (85.5% vs. 10.8%), reflection on DM (48.4% vs. 18.2%) and body images on social media (64.5% vs. 21.6%). Moreover, more younger teachers prefer online programmes than older teachers (83.9% vs. 29.7%).

Discussion:

Although only 19% of the PE teachers attended in-service training on the use of DM in PE, 80% would like to attend (further) training in future. This suggests that existing trainings may not be sufficiently geared to teachers needs and preferences. Future trainings should therefore especially include content with high and medium demand in needed formats (short trainings online or face-to-face). The results of this study are relevant for successfully disseminating teacher education research to the target group (i.e. in-service teachers). Taking the needs and preferences into account can help to ensure the acceptance of in-service trainings.

PERCEPTIONS OF SPORTS SCIENCE STUDENTS ON THE EDUCATIONAL OFFER IN ITALY: IMPLICATIONS FOR THE PROFESSION OF KINESIOLOGIST

IACÒ, D.

COMITATO ITALIANO SCIENZE MOTORIE

INTRODUCTION: Starting from January 1, 2025, the National Statistical Institute (NSI) in Italy introduced the ATECO code 86.96.01, relating to the new economic activity of Kinesiology, aligned with NACE Rev. 2.1 of Eurostat (2023). This activity is carried out by the Kinesiologist, a graduate in Sports Sciences, as established by Article 32 of Legislative Decree no. 36/2021. Since no previous studies have addressed the expected impact of this new profession, the aim of this study was to measure the opinions of members of the Italian Committee of Motor Sciences (CISM), university students, and graduates in Sports Sciences.

METHODS: The sample consisted of 6.020 students from 35 Italian universities, with the data presented in frequencies and percentages. The method used was the administration of an anonymous questionnaire containing 8 specific questions, aimed at gathering opinions on general, specific, and applied university education. Descriptive statistics were used to present the data, while the Chi-Square test was applied to investigate relationships between variables. Data were analyzed using SPSS 28.0.

RESULTS: The results showed that the perception of the quality of the technical-practical offer did not significantly vary between different universities ($\chi^2 = 0.767$, $p = 0.999$), indicating a homogeneous evaluation across universities. However, the level of study influenced satisfaction, with undergraduate students reporting more dissatisfaction compared to post-graduate students ($\chi^2 = 27.54$, $p = 0.000$). Furthermore, students with Erasmus experience rated foreign education as significantly superior to Italian training ($\chi^2 = 5111.58$, $p < 0.001$). Overall, more than 50% of students (52.6%) expressed satisfaction below expectations regarding technical-practical training, with only 14.8% being very satisfied and just 2.7% "truly satisfied."

CONCLUSIONS: The data indicate significant dissatisfaction with the technical-practical training offer, with more than half of the students providing a negative evaluation. This suggests the need for targeted interventions to improve the quality of education, particularly in the practical and applied aspects of Sports Science degree programs. Students, in fact, express the need for updates and reforms in the curriculum to adequately prepare for a rapidly evolving profession like that of the Kinesiologist.

AEROBIC CAPACITY IS ASSOCIATED WITH WELL-BEING, SCHOOL-RELATED MOTIVATION AND MATH PERFORMANCE IN PRE-ADOLESCENT CHILDREN. A CROSS-SECTIONAL STUDY FROM THE ACTIVE SCHOOL PROJECT

NORUP, M., SCHMIDT-PERSSON, J., JEPPESEN, L.S., ROHDE, R.A., WIENECKE, J., BUGGE, A.

UNIVERSITY COLLEGE COPENHAGEN

Introduction

Aerobic capacity has been shown to be associated with academic performance in children, and research has shown that school-based physical activities are related to children's health-related quality of life. Relations between aerobic capacity and motivation have also been shown. We hypothesize that aerobic capacity is associated not only with academic performance but also with well-being, school-related motivation, and cognitive performance when measured in pre-adolescents.

Methods

The present study is based on data from 1145 pre-adolescents (9-11 years). Measures of school-related motivation and well-being were assessed using SRQ-A and Kidsscreen-27 questionnaires. Aerobic capacity was measured as estimated aerobic fitness by the Andersen test, a 10-minute intermittent running test. Academic performance was assessed using the Hogrefe MAT2 test.

Mixed linear regression analysis was used to estimate the cross-sectional associations between aerobic fitness and school motivation, aerobic fitness and well-being, aerobic capacity and academic performance and adjusted for (fixed effects) sex, bilingualism, and BMI (random effects) school.

Results

The results show associations between aerobic capacity and academic performance in maths (β : 1.27; CI95: 0.75-1.79; $p < 0.001$). We found a significant association between aerobic capacity and overall motivation (β : 0.24; CI95: 0.13-0.35; $p < 0.001$) as well as an association between aerobic capacity and overall well-being (β : 0.45; CI95: 0.29-0.61; $p < 0.001$). Aerobic capacity is associated with sub-categories of both school-related motivation and well-being ($p < 0.005$).

Discussion

The present study shows that aerobic capacity is not only associated with academic performance but also with well-being and school-related motivation in pre-adolescents. With higher aerobic capacity, pre-adolescents demonstrate higher scores in maths performance, better well-being and higher school-related motivation. Our results are supported by previous studies showing associations between aerobic capacity and academic performance and relations between aerobic capacity and well-being and motivation. Effect studies are needed to investigate how physical activity and aerobic capacity changes affect well-being, school-related motivation and academic performance.

Conclusion

On the background of the results from our study, supported by previous research, we conclude that children with a higher aerobic capacity is associated with higher academic performance in math, school-related motivation, and well-being.

Our results provide further evidence for investigating possible interrelations between aerobic capacity, well-being, motivation, and academic performance in children. We also conclude that effect studies are needed to investigate the effects of physical activity and aerobic capacity on well-being, school-related motivation, and academic achievement.

A STUDY ON CONSUMER BEHAVIOR TOWARD ESPORTS EXHIBITIONS: FROM THE PERSPECTIVE OF S-O-R FRAMEWORK

WU, Y.

MING CHI UNIVERSITY OF TECHNOLOGY

INTRODUCTION: This study investigates how impulsive buying behavior in the context of esports is affected by psychological and behavioral perspectives in consumer behavior. According to the Stimulus-Organism-Response (S-O-R) framework, this study investigates the influence of brand awareness (stimulus) on impulsive buying behavior (response) mediated by perceived social support and perceived sponsorship fit (organism). This study provides insights on how the constructs relate to one another and provides an understanding of how purchasing decisions are shaped in this unique market.

METHODS: A purposive sampling method was utilized distributing 304 questionnaires to participants who participated in esports exhibition in Taipei, after the deletion of invalid data, 245 valid data was analyzed. Structural Equation Modeling (SEM) was analyzed using Smart PLS 4 to test confirmatory factor analysis (CFA), reliability, validity and the hypothesized relationships among brand awareness, perceived social support, sponsorship fit, and impulsive buying behavior. Descriptive analysis was analyzed using SPSS for Windows.

RESULTS: In this study, more than 80% of the participants were males and the median age of the participants were 28.89 years old. 29.4% of the participants who attended the esports exhibition were students, 17.1% of the participants work in the service industry where 12.2% of the participants occupation were in labor industry. The findings showed that brand awareness significantly affects perceived social support and perceived sponsorship fit positively. In addition, both perceived social support and perceived sponsorship fit impacts impulsive buying behavior positively. This study also found that perceived social support and perceived sponsorship fit mediated the relationship between brand awareness and impulsive buying behavior positively. The overall model showed good fit confirming validity of the pathways.

Discussion: This study provides insights into how psychological factors in consumer behavior play a critical role in esports. Brand awareness can be seen as a powerful stimulus, which is influential in both emotional and cognitive perceptions, which in turn drives impulsive buying behavior among consumers. On the other hand, perceived sponsorship fit increases the perceived credibility and support between esports exhibition and brands, while perceived social support strengthens the emotional engagement of consumers. These findings provide strategies for marketers who are willing to improve sponsorship strategies and for researchers seeking to extend the understanding of consumer behavior in the context of digital and gaming world.

Conventional Print Poster Presentations

PHYSICAL EDUCATION AND TRANSVERSAL SKILLS. PRELIMINARY INSIGHTS FROM THE “CO-PRO BPS” PROJECT

MONACIS, D., FORTE, P., PUGLIESE, E., AMBRETTI, A., DANNA, C.

PEGASO TELEMATIC UNIVERSITY

This study presents preliminary findings of the “Co-Designing Learning Environments from a Bio-Psycho-Social Perspective”, a project aimed to identification of teachers’ needs and Co-Construction of an Instructional and Digital Design Model” and to implement effective and meaningful learning environment in primary school according to non-linear pedagogy principles.

Considering the new professional profile of primary school Physical Education teachers in Italy, the project aims to foster co-planning competencies between both the generalist and PE teachers, and promote

the body’s mediating function in learning processes through the development of web app demo.

The project’s main goals are defined as follows:

- promote innovation in education enhancing the embodied dimension of learning;
- improve teaching practices by identifying real criticalities/threats and strengths/opportunities that affect the implementation of co-education processes and the design of innovative learning environments;
- set a co-construction process for educational design tools;
- develop a platform Web App for the co-educational design model that meets the needs identified by research and training.

This preliminary study involves 230 (primary school teachers aged 30-60 years mainly from Southern Italy. Teachers were asked to complete a self-constructed survey about co-planning behaviors, focusing on the following areas: teacher’s training and years of service, self-perceived co-planning competence, individual co-planning and co-design behaviors in school setting.

One of the main problems that emerged was the lack of collaboration between teachers and other professionals for co-educational planning. This was identified as one of the main obstacles to realizing effective educational pathways. The most commonly reported difficulties concern the planning of multidisciplinary objectives and the personalization of learning according to students needs. This suggests that teachers require more effective tools and methodologies to address these challenges.

Despite the strong interest in innovative methodologies and strategies, the responses indicate that the integration of technologies in teaching is still uneven. Some teachers report difficulties in selecting appropriate assessment and testing tools.

Many participants feel that opportunities for professional development are limited, a factor that may adversely affect their ability to innovate and collaborate effectively.

The majority expressed a strong interest in tools that facilitate the co-design and sharing of teaching strategies and assessment tools. This suggests that a web app demo with these functionalities could meet the prioritized needs.

A STUDY ON DEVELOPMENT OF INCLUSIVITY IN SOCIETY THROUGH “GUIDE RUNNING” FOR JAPANESE JUNIOR HIGH SCHOOL STUDENT

KONDO, K., MORIOKA, Y., OGATA, M.

NIHON UNIVERSITY

The guide discussed in this study is a specific method for the competitions with visually impaired athletes in Paralympics, in which the guides directly assist athletes to run by holding a guide rope with the athlete, so as to ensure their smooth participation of the competitions.

Yabe (2004) states that “a rope is a means to remove the barrier between people with impairments and those without, and can be a bond as a symbol of inclusion”. It could be therefore considered that guide running may have an underlying concept of leading to help to build an inclusive society.

This study aimed to understand from the study-notes of the students what they have learnt through the guide running practice. In order to conduct that, the junior high schools whose education curriculum includes the “guide running practice”, (three hours of “Physical Education Theory” and six hours of “Track and Field - Short Distance Running”) were selected for this study. Also, based on the descriptions by the students, presenting ways of potential management of their future classes became another purpose of this study.

The subjects were 10 junior high school students who had permission to participate in this study from their teachers. It was inferred that, through this study with guide running, the students recognised the factors such as “mutual understanding,” “cooperative relationships,” and “empathy”. Besides, they were also aware of having a wider view for “inclusive perspective”, “value of sports” and “sports culture” according to the hints by their teachers such as “adjusting the rules to the situations”, “regardless of whether people have an impairment or not” and so on.

Also, it was inferred that "learning content" on the education curriculum for this study may have given the students the perspective which is necessary to seek the inclusive society such as "importance of communication", "building relationship" and "multiple way of involvements".

From the above, learning through guide running has created an understanding, which may also be common with the idea of adapted sports, of what kind of considerations would be required in order to allow every single person to participate in sports. At the same time, the students as subjects of this study, were given the opportunity to have a perception of inclusivity, which is free from gender bias, having disabilities or not, age and racial difference etc.

To practice guide running, it is necessary to hold a rope, called a "tether", tightly to synchronise the movement of running. This restricted arrangement where free movement is limited, could probably trigger students to have a proactive attitude and to consider the importance of communications and relationship-building. Furthermore, the combination of physical education theory and the experience of learning guide running was effective in terms of the class management.

Yabe, K. et al (2004) *Science of Adapted Sport*. Ichimura: Tokyo, Japan.

IMPACT OF THROWING INTERVENTIONS ON SKILL DEVELOPMENT AND MOTOR VARIABILITY IN PRESCHOOLERS

IIDA, M., OGISO, K.

AOYAMA GAKUIN UNIVERSITY

This study aimed to investigate the effects of constant interventions incorporating play experiences that include throwing motions—activities rarely encountered in everyday play—on throwing techniques, abilities, and movement diversity during free play among preschool children. The participants were 21 children (11 boys and 10 girls) enrolled in a preschool class for 5-year-olds. The intervention consisted of a cycle combining a one-week intervention period conducted twice weekly with a subsequent two-week period without intervention. This cycle was repeated three times consecutively. Movement diversity during free play was observed in the preschool yard for approximately one hour twice a week throughout the study period. These sessions were recorded using two video cameras placed on a terrace of second floor. The number of different movements and their frequencies were analyzed.

To assess throwing performance, participants performed maximum-effort overhand throws both before the intervention and after each cycle's post-intervention period. Throwing motions were captured using motion sensors attached to eight points on the body (pelvis, lower spine, upper spine, upper arms [right or left], forearms, and hand [right or left]) and recorded from the side with a high-speed camera. The diversity of movements and their frequencies (sex × movements system × period) were analyzed using repeated-measures ANOVA to compare mean differences. Throwing distance and specific measurements of throwing motions were evaluated using two-way ANOVA (sex × measurement point). A significance level of 5% was applied to all analyses. The intervention resulted in: 1) an increase in both the variety and the frequency of ball-manipulative movements, including throwing motions, during free play for both boys and girls; 2) improved overhand throwing ability in both boys and girls; 3) increased ball release speed for both boys and girls; 4) enhanced movement speed of the lower spine, upper arms, and forearms during throwing motions in boys; and 5) improved movement speed of the upper arms, forearms, and hands during throwing motions in girls. However, when the intervention involved group play with a single ball, it did not lead to an increase in individual throwing frequency. In conclusion, constant interventions that incorporate throwing experiences—rarely encountered in typical play—led to an increase in both the variety and frequency of ball-manipulative movements during free play for both boys and girls. Additionally, it improved lower back and arm movement speed during throwing in boys, arm movement speed in girls, and overall overhand throwing ability.

WILDERNESS-BASED OUTDOOR EDUCATION IN JAPANESE UNIVERSITIES: LEARNING PROCESSES AND THEIR POTENTIAL FROM A PHYSICAL EDUCATION AND PEDAGOGICAL PERSPECTIVE.

SAKURAGI, K., KUROSAKI, T.1, KONDO, R.1, YAMAGUCHI, N.2, YAMAGUCHI, T.2, KITA, H.3, NOGAMI, N.4

1 KOBE UNIVERSITY OF FUTURE HEALTH SCIENCES, 2 OFFICE KAJIYANO CO., LTD., 3 NAKAHARIMA FORESTRY COOPERATIVE, 4 OSAKA SEIKEI UNIVERSITY

INTRODUCTION: Physical education in Japan have traditionally emphasized skill development in competitive sports and physical activities. However, in recent years, the importance of comprehensive learning through physical activity has been increasingly recognized. Given this shift, Japanese physical education faces challenges in ensuring sufficient opportunities for structured reflection and engagement in the learning process. This study introduces a case study of wilderness-based outdoor education in a Japanese university and examines its learning processes and potential from a physical education and pedagogical perspective.

METHODS: This study examined a wilderness-based outdoor education program conducted in an undeveloped private natural area. The two-night, three-day program involved three first-year students from a sports-related faculty.

Structured around three key themes—Collaboration with others (role allocation and communication), Self-reflection (experience review and growth recognition), and Engagement with the local community (understanding the local community)—the program also emphasized appreciating and respecting the natural environment as an assigned challenge.

Core activities included campsite construction, environmental conservation, outdoor cooking, and hiking. Students conducted daily self-assessments using a customized reflection sheet, with post-program surveys and interviews conducted afterward.

RESULTS: In the reflections on the program, students noted that they had learning experiences that were not available in regular classes and that they recognized the importance of collaboration by thinking and acting independently. These findings suggest that the program provided a unique learning opportunity. Additionally, some students mentioned that being in an environment with limited resources made them aware of the need to consider not only immediate tasks but also future actions. This indicates an increased recognition of adaptability and the importance of strategic planning. In this presentation, we will also report on the detailed analysis, including insights from the interviews.

DISCUSSION: This study highlights the potential of wilderness-based outdoor education, which integrates physical activity with the learning process, as an alternative to traditional physical and sports education. Compared to competitive sports, outdoor education is well-suited for fostering collaboration and environmental adaptability, presenting a valuable direction for the future of physical education. Additionally, from a disaster preparedness perspective, learning in a wilderness environment may enhance decision-making skills and survival capabilities. Moving forward, it is necessary to examine the long-term educational effects and explore further developments, including its integration with disaster education.

FRONTIER LITERATURE ANALYSIS OF SPORTS COGNITION PHENOMENOLOGY BASED ON VOSVIEWER

DONGXIAO, L., ZHANG, Z.

EAST CHINA NORMAL UNIVERSITY

With the continuous refinement of sports science research, the integration and cross-disciplinary development of sports science with other fields has become a trend. Since the 21st century, there has been an explosive growth in research related to the phenomenology of sports cognition. Currently, there remains significant room for development in the study of the phenomenology of sports cognition. Analyzing the main content, current characteristics, and development trends of research in this area can provide a theoretical foundation for sports science to break down academic barriers and integrate with other disciplines. This, in turn, can promote the refinement of the disciplinary framework of sports science. This study utilizes the CNKI database and the Phenomenology and the Cognitive Sciences database as data sources. Employing research methods such as scientific knowledge mapping, it analyzes 226 relevant publications on the phenomenology of sports cognition from 1983 to 2024, focusing on publication volume, trends, journal distribution, and cited papers. Additionally, the study uses VOSviewer 1.6.20 software to conduct a visual analysis of keywords and other information from the selected literature. By combining co-occurrence density maps and disciplinary clustering knowledge graphs, the study draws relevant conclusions. The results indicate the following: (1) Research on the phenomenology of sports cognition is generally on an upward trend and is currently in a phase of rapid development. (2) The distribution of publications is broad, with 226 articles originating from over 80 journals and books, covering diverse fields such as education, medicine, philosophy, and history. (3) Current research primarily focuses on themes such as embodied cognition, sports psychology, physical education, and competitive sports, with a wide scope of investigation. Based on the above analysis, the following prospects for the development of the phenomenology of sports cognition are proposed: strengthening foundational theoretical research, enhancing interdisciplinary research collaboration, applying advanced technological achievements, broadening practical application studies, and cultivating interdisciplinary talent.

EXTRACURRICULAR PHYSICAL AND SPORTS EDUCATION, COGNITIVE AND MOTOR SKILLS IN PRIMARY SCHOOL

GIARDULLO, G., DELIA, F., RAIOLA, G.

UNIVERSITY OF VERONA

Introduction: Physical education in primary school should be promoted in a way that encompasses different dimensions to ensure a balanced and optimal development of the pupil. The National Curriculum Guidelines for primary school clearly highlight the approach of education through movement, whereas the concept of education for movement is less evident. In particular, the aspect of skills-related fitness is not adequately considered, and as a result, fitness is not linked to the acquisition of cognitive abilities. Scientific evidence from recent years has shown a deficiency in physical activity in terms of motor literacy, as the curricular physical education activities alone are insufficient in quantitative terms to achieve these objectives. The aim of this study is to adopt specific physical education protocols to supplement the morning curricular activities for Year 4 and Year 5 classes in primary school, where a specialist Physical Education teacher is present. The goal is to reduce gaps in motor literacy and skills-related fitness, thereby fostering the overall development of children. **Methods:** The sample consists of 21 children from Year 4 and Year 5 at the Comprehensive Institute of Centola, Speranza-Lettieri, in the Rofrano (Sa) school complex. They participated in an extracurricular motor education project of 30 hours over the course of two months, conducted in the afternoon. The activities included moderately intense multitasking exercises that required coordinated movements and problem-solving skills. Subsequently, a specially designed questionnaire was administered to assess the children's motor habits, lifestyle, perception, and awareness of physical education, as well as their preferences and level of engagement during lessons. **Results:** Applying the paired-sample T-test, the training protocol led to improvements between pre- and post-tests. The Flamingo Balance Test showed an average percentage increase of 2.12%, with $P = .0000023$. The Shuttle Run Test (4x10 metres) demonstrated an average percentage increase of 1.50%, with $P = .00000059$. The Throw and Catch Test recorded an average percentage increase of 8.33%, with $P = .000014$. The Jumping Side-to-Side Test showed an average percentage increase of 3.59%, with $P = .0000057$. The analysis of the Chi-square test revealed significant relationships between qualitative variables. **Discussion & Conclusion:** The physical education protocols used proved to be effective in enhancing the pupils' motor skills. The children demonstrated improvements not only in their abilities but also in their perception and awareness of the importance of physical activity.

VISUAL-SPATIAL WORKING MEMORY AND GROSS-MOTOR DEVELOPMENT:

FORTE, P., MONACIS, D., PUGLIESE, E., MATRISCIANO, C., COPPOLA, S., D'ANNA, C.
 PEGASO UNIVERSITY - UNIVERSITY OF CAMERINO

Introduction: Physical exercise represents a natural and productive opportunity for both physical and cognitive development. The benefits of Physical Activity (PA) contribute to improving physical health and cognitive functioning, particularly Executive Functions (EF; Erickson et al., 2019; Pontifex et al., 2019), identified as inhibitory control, working memory and cognitive flexibility (Diamond et al., 2016). Executive functions are crucial for childrens learning abilities (Diamond, 2020) and academic performance: in particular, visuospatial working memory (VSWM) is strongly correlated with performance in subjects such as mathematics, English as a Foreign Language and science (St Clair-Thompson & Gathercole, 2006).

Motor skills influence executive function, and improving motor skills is a practical and effective method to promote the development of executive function (Furley et al. 2023; Xinyue; 2024; Houwen, 2017). Indeed, scientific literature supports the effectiveness of physical exercise, particularly moderate to vigorous aerobic exercise and motor programs in improving childrens EF (Haapala, 2013; Hillman, Buck, 2009; Tomporowski, 2008).

In light of this evidence, the present study aims to investigate the relation between visuospatial working memory and Gross Motor Skills in primary school.

Methods: This descriptive study involves 107 children aged 8-10 years old, with mean age of 9.39 ($\pm$ 0.54), 46,7% of girls and 53,3% of boys, all from primary school. The children were assessed using the Italian version of Test of Gross Motor Development (TGMD3; Ulrich, D'Anna et al., 2023) and the Test for visuospatial attention and visual working memory assessment (BVS-CORSI-2; Mammarella et al. 2023).

Results: All data analyses were performed with the statistical program SPSS 23. The results indicated a moderate positive correlation (Pearson) between gross motor index and visuospatial attention and visual working memory (VSWM): $r = 0.46$, $p < 0.001$ between Corsi Forward test and Gross Motor Index, and $r = 0.40$, $p < 0.001$ between Corsi Backward test and Gross Motor Index.

Discussions: The results of this study suggest that there is a positive correlation between gross motor development and working memory, in young children. One of the strengths of this study was the analysis of the relationship between visual-spatial working memory and motor skills. Given the small number of studies available in the literature, future research with large representative samples is needed to explore other cognitive domains (e.g., executive function and intelligence). Additionally, future research should progressively reach higher levels of challenges, by finding more complex forms of exercise involving both motor and cognitive tasks.

THE EFFECT OF PARTICIPATION IN EXTRACURRICULAR SPORTS ON MOTOR PROFICIENCY AND PROBLEMATIC INTERNET USE RISKS IN ADOLESCENTS FROM LATVIA AND INDONESIA

NURULFA, R., KLAVINA, A.
 RIGA STRADINS UNIVERSITY

INTRODUCTION: The issue of problematic internet usage (PIU) among adolescents is becoming increasingly prevalent. PIU is defined by excessive online engagement that disrupts daily activities and results in suboptimal learning outcomes. The habit of spending extended periods of time online leads to sedentary lifestyle. The aim of this study was to explore the effects of participation in extracurricular sports on problematic internet use and motor proficiency in adolescents from Latvia and Indonesia.

Method: This research had a cross-sectional study design. The study was conducted at public schools in Riga (Latvia), and Jakarta (Indonesia). The study comprised 257 adolescents (mean age 13.57 SD = 0.86 including 57 (mean age 13.42, SD= 0.625) from Latvia (LV) and 200 (mean age 13.61, SD = 0.918) from Indonesia (IND). From the participants (54.5%) engaged in extracurricular sports (ES). The Problematic and Risky Internet Use Screening Scale (PRIUSS) and Bruininks-Oseretsky Test of Motor Proficiency, 2nd ed. (BOT2) was used to assess problematic internet use (PIU) and motor proficiency (MP), accordingly. Statistical analysis in this study used descriptive statistic, Spearmans rho correlation and General Linier Model (GLM)

Result

The average mean of MP scores were significantly different between the two countries ($p=.046$) with 95% CI. Extracurricular sports significant differences was identified between mean scores of INA ES and LV ES ($p=.047$) compared to NS, where Indonesia's score of 122,18 (SD=13.99) had a significantly higher score than LV ES 121,24 (SD=15.29) with a significant main effect was shown for Indonesia ($F = 4.713 < 0.05$). $\eta^2 0.018$). There was significant differences in mean scores of PIU between Indonesia-Latvia subgroups ($p=.039$). IND ES = 8.73 (SD= 11.199) with 95% CI was lower than mean LV ES 24.69 SD 8.01 with 95% CI. After analyzing all the variables, no significant correlation was observed between PIU and MP total scores in both countries $r_s -.216$ (Weak). Findings indicated weak correlation between PIU and MP for Indonesia = IND NS $r_s = -0.17$ (Very Weak); LV ES: $r_s = -0.321$ (Weak).

CONCLUSION: The results showed that adolescents involved in ES showed significantly higher average ability compared to NS adolescents. This was in contrast to Participation in ES showed lower average PIU compared to NS. Hence, it can be concluded that involvement in extracurricular sports can improve motor skills and reduce the impact of PIU in adolescents. Further research is needed with a larger sample size to ensure the data obtained more accurately reflects the sample, as well as a more comprehensive examination of the factors that influence similar outcomes.

LEARNING THROUGH MOVEMENT: EMBODIED APPROACHES IN EDUCATION - A SCOPING REVIEW

FAELLA, P., DIGENNARO, S., IANNACCONE, A.
UNIVERSITY OF CASSINO AND SOUTHERN LAZIO

INTRODUCTION: Embodied learning has emerged as a pedagogical approach that integrates physical activity, cognition, and environmental interactions to enhance education. Rooted in phenomenology and embodied cognition theories, this approach challenges traditional mind-body dualisms and fosters inclusive, multidisciplinary learning experiences. This scoping review aims to explore how embodied learning contributes to education in school settings.

METHODS: Following the Joanna Briggs Institute guidelines and PRISMA checklist, a comprehensive literature search was conducted between January and November 2024, including empirical studies on embodied learning within physical education settings. Studies were screened using predefined inclusion criteria, and thematic analysis was applied to identify key themes. The quality of studies was assessed using the Mixed Methods Appraisal Tool.

RESULTS: A total of 22 studies were selected and 3 core themes were identified: Physical Literacy, Embodied Identity, Multidisciplinary. Results highlighted how movement-based learning identifies physical movement as essential to cognition, enhancing comprehension, particularly in STEM subjects. Sensory experience plays a crucial role, as cognition emerges from the integration of visual, auditory, kinesthetic, and tactile inputs. The alignment between movement and learning tasks influences retention, with greater bodily engagement leading to stronger outcomes. Exploration and body awareness further enrich learning by fostering self-awareness and meaning making. Playfulness and enjoyment enhance motivation, making learning more engaging. Embodied learning also extends into digital environments, where immersive technologies support sensorimotor interaction. Additionally, it supports cross-disciplinary connections by grounding abstract concepts in concrete experiences. The concreteness fading process further reinforces this approach, gradually guiding learners from physical interaction to abstract reasoning, enhancing knowledge transfer.

Discussion: Embodied learning offers a transformative framework for education by bridging physical activity with cognitive and social development. It challenges normative constructs of ability and fosters inclusive practices that meet diverse student needs. The integration of digital tools, such as virtual reality and motion-based gaming, represents an emerging frontier with potential applications in education. Despite its benefits, challenges in implementation, resource allocation, and curriculum integration remain.

CONCLUSION: This review underscores the potential of embodied learning to enrich education by fostering holistic, student-centred pedagogies. Further research is needed to address methodological constraints, explore long-term impacts, and enhance the scalability of embodied learning interventions in diverse educational and cultural settings.

ACADEMICALLY HIGH ACHIEVING STUDENT'S (AHAS) SELF-PERCEIVED ATHLETIC COMPETENCE AND SELF-REPORTED PHYSICAL ACTIVITY

AUGUSTSSON, F., GUSTAFSSON, H., MELLROTH, E., HÖGMAN, J.
KARLSTAD UNIVERSITY

This study examines self-perceived athletic competence and physical activity levels among academically high-achieving students (AHAS) in Sweden. Gifted and high-achieving students can face negative stereotypes about their physical abilities and tend to have lower confidence in this domain compared to academic skills. Beliefs about physical competence can influence participation in physical activities throughout childhood and adolescence.

Survey data were collected from students (N= 326) in Swedish upper secondary schools (ages 16-18). Academic achievement was measured with student's self-reported grades in one Mathematics-, one English and one Swedish course. Athletic competence was measured with the Perceived Athletic Competence subscale of the Harter's (2012) Self-perception profile [1] and the International Physical Activity Questionnaire for Adolescents (IPAQ-A) [2] for self-reported physical activity.

Pearson's correlation analysis revealed a moderate positive association between athletic competence and IPAQ-A score ($r=.59$, $p<.001$), suggesting that students who perceive themselves as more athletically competent also report higher physical activity levels. However, academic achievement had no significant correlation with athletic competence ($r = -.025$, $p = .654$).

An independent samples t-test was also conducted to compare students perceived athletic competence between AHAS (students with grade A in the three courses, $n=41$) and the control group (students with B-F grades, $n = 285$). There was a significant difference in the score for AHAS ($M=15.58$, $SD=5.86$) and control group ($M=18.66$, $SD=6.67$; $t(324) = -2.841$, $p=.05$ two-tailed) which suggests that AHAS perceive themselves as less athletically competent compared to their peers, although the effect size was small to moderate ($d=-.474$).

Another independent t-test was conducted to compare IPAQ-A Score between the two groups. There was a significant difference in the IPAQ-A score for AHAS ($M=2.24$, $SD=.53$) and control group ($M=2.45$, $SD=.61$; $t(332)=-2.077$, $p=.039$ two tailed). This suggests that AHAS report lower physical activity, but effect size being small ($d=-.343$).

Findings shows that AHAS students perceive themselves as less competent in athletic settings than other students, in line with previous research. AHAS are also relatively less physically active compare to other students and the underlying reasons for these associations need to be further explored in future research, as perceived athletic competence is one important component for youth's engagement in physical activity.

CP-SH18 Mentoring / Coaching I - Mixed

SOCCER COACHES NOTE-TAKING DURING VIDEO ANALYSIS OF A MATCH

TAHRI, H., ZOUDJI, B.

UNIVERSITÉ POLYTECHNIQUE HAUTS DE FRANCE

Video analysis has become an essential tool for soccer coaches, allowing them to study tactical schemes and optimize match preparation. However, given the vast amount of information generated during a match, structured note-taking is crucial for effectively recording and utilizing observations. This study examines the note-taking practices of ten professional coaches holding UEFA A Pro, UEFA A, CAF A, and AFC A licenses during match video analysis. The findings reveal diverse approaches, ranging from keywords to full sentences and visual diagrams. Notably, the quantity and depth of notes vary: some coaches take extensive, detailed notes, while others prioritize essential insights to prevent cognitive overload. Despite these differences, common trends emerge, particularly the emphasis on offensive and defensive sequences, as well as ball transitions. However, variations exist in how coaches prioritize information. In conclusion, structured note-taking is a vital strategic tool for enhancing tactical analysis, improving communication with players, and refining strategic decisions. The study suggests standardizing and enriching note-taking practices to maximize their effectiveness in sports coaching.

THE RELATIONSHIP BETWEEN YOUTH SPORTS COACHES' CONFIDENCE IN COACHING AND THE SOURCES OF ACQUIRING COACHING SKILLS

UENO, K.

KAGAWA UNIVERSITY

INTRODUCTION: In Japan, corporal punishment by sports coaches has become a serious issue, emphasizing the importance of official training sessions for coaching skills. If the coaching skills gained from official training, such as those provided by sports organizations, boost coaches' confidence, they are expected to attend such training voluntarily. However, the most highly valued sources of information for acquiring coaching skills as perceived by coaches have yet to be clarified. Therefore, this study aimed to clarify the relationship between coaches' confidence in their coaching and the sources from which they acquire their coaching skills.

Method: This study targeted 105 sports coaches (86 males and 19 females) who coach children from elementary to high school. Their average coaching experience was 18.11 years, and all participants held a coaching license certified by the Japan Sport Association. The survey consisted of two main elements: 1) sources of acquiring coaching skills (official training, coaching books or websites, past experiences as an athlete, and advice from peers) and 2) confidence in their coaching abilities (achieving victory, teaching proprieties, ensuring enjoyment, enhancing physical ability and skills, fostering patience, and promoting cooperation). The coaches were asked to respond using a four-point scale for each question.

RESULTS: The coaches were confident in all areas of coaching except achieving victory. However, for all aspects of coaching, more coaches rely on past experiences and advice from peers than official training sessions. Furthermore, a multiple regression analysis revealed that attending training influenced coaches' confidence in achieving victory and ensuring enjoyment; however, no sources of information were found to significantly impact confidence in teaching proprieties or promoting cooperation.

Discussion: Although the coaches were confident in their coaching, they acquired their coaching skills more through advice from peers and past experiences than by attending training sessions organized by sports organizations. Peer advice and past experiences may sometimes include inappropriate coaching practices such as corporal punishment, which is not a recommended source. On the other hand, coaching skills related to character development, such as teaching proprieties and promoting cooperation, were not addressed in the training sessions, and attending these sessions did not

influence the coaches' confidence in their coaching. Although various opinions exist on using sports as a means of character development, it is necessary to ensure coaching skills through official training. It was concluded that there is a need to enhance the content of training sessions to promote the acquisition of coaching skills related to teaching proprieties and cooperation.

POSITIVE COACHING INTERVENTIONS FOR SPORT COACHES: A SYSTEMATIC REVIEW

ROSITO, S., MARINI, S., SARTOR, F., POMPA, D., LOPEZ-FLORES, M., BERTOLLO, M., DE OLIVEIRA, R.
UNIVERSITY OF GABRIELE DANNUNZIO CHIETI-PESCARA

Background: Positive Coaching (PC) is a coaching philosophy focusing on developing athletes sports skills along with their social and life skills 1. In the past two decades, PC has proven effective for sport promotion throughout positive development in youth (references). However, to date there is still debate on what exactly PC is and how it is approached within practice. For this reason, the aim of this systematic review, conducted according to the PRISMA 2020 statement, was to investigate the effectiveness of PC educational programs to help practitioners foster positive developmental outcomes in young competitive and recreational athletes.

Methods: The review was preregistered on Open Science Framework (OSF)2. The search was conducted through Web of Science and Scopus including all the sub databases. Keywords were determined using a research question formulated according to the PICO format. Literature screening was conducted by two researchers, plus a third to resolve disagreements. Quality was assessed by the Mixed Methods Appraisal Tool.

Results: Out of 135 identified articles, 25 full texts were screened by titles and abstracts. A total of 10 studies matched the eligibility criteria. All studies included were intervention studies with either a quasi-experimental design (50%), observational/longitudinal (30%) or randomized controlled trials (20%). The effectiveness of PC interventions was measured by quantitative (e.g., questionnaires) and qualitative methods. The participants belonged to both competitive and recreational sports levels. The duration of the intervention varied from a 2-hour single session training to a 6-month educational program consistent of 1.5 hour on average per session. Both quantitative and qualitative findings showed that PC training interventions positively affected psychological aspects such as anxiety, motivational climate and coach-athlete relationship.

Conclusion: This systematic review revealed considerable PC training benefits in terms of improving competencies, life skills, enhanced relationships among athletes, and a more open leadership style. According to the present study findings, academic institutions could structure PC training programs, while for the practitioner it creates a practical and structured guide, that facilitates and encourages the application of PC training in the development process of both coaches and their athletes. However, these results should be interpreted with caution, because of the medium quality of the literature analysed in this review.

PREDICTING OF DROWNING BY USING BOTH VR VIDEO VIEWING BEFORE SWIMMING EXPOSURE AND HEART RATE MONITORING SYSTEM DURING LONG-DISTANCE SWIMMING

HAMADA, H., NAKAO, Y., TORIGOE, T., YAMAGATA, T., WATANABE, C., KAWASHIMA, M., OYANAGI, E., YODA, T., TAJIMA, M., WAKIMOTO, T., KREMEK, M., MIYAZAKI, H., YANO, H.

KAWASAKI UNIVERSITY OF MEDICAL WELFARE, KAWASAKI MEDICAL SCHOOL, NIPPON BUNRI UNIVERSITY

Introduction: It is estimated that approximately 240,000 people drown annually worldwide. The World Health Organization (WHO) has also recognized drowning as a problem, and in its first-ever report on drowning, the WHO lists "Ten actions to prevent drowning" as causes and countermeasures for water-related accidents. Also, in Europe, the importance of Water Competency, the qualities and abilities necessary for safe activities in and around water, has been demonstrated. The benefits of programs for long-distance swimming in the sea are important for children. However, due to safety concerns, fewer schools are implementing the programs. A better system for monitoring heart rate that enables the detection and prediction of drowning and improves the safety of long-distance swimming is needed. In this study, to predict drowning risk, we investigated a screening method using virtual reality (VR) and developed a real-time heart rate monitoring system.

Methods: 40 healthy subjects were timed in the 400m breaststroke and their peak VO₂ was measured. Also, cardiac autonomic nerve activity was measured during swimming VR exposure. The heart rate was monitored during the long-distance swimming in the sea.

Results: Sympathetic activity after the VR exposure was significantly increased. Furthermore, a significant correlation was observed between the heart rate monitored during the long-distance swimming in the sea and the 400m breaststroke time, but not peak VO₂. We observed that the swimming VR exposure demonstrated an acute stress response, although there was no difference in the stated anxiety scores obtained from the STAI before and after the swimming VR experience.

Discussion: Swimming VR exposure might be an effective method for safe risk assessment. In addition, real-time heart rate monitoring showed a relationship between swimming ability and heart rate in the sea. One subject showed quickly increased heart rate to 170bpm and maintained for an hour, and then the heart rate dropped out to 80 bpm suddenly and the subject was stopped the long-distance swimming. Also, in another subject, heart rate repeatedly spiked just prior to rescue by the buoyancy device. Although the relationship between drowning and changes in heart rate have not been made clear until now, utilizing heart rate monitoring system will be useful device to conduct safer long-distance swimming. Furthermore, by using obtained from taking two systems for machine learning might contribute to preventing drowning.

Conclusions: The swimming VR video is an effective method to safely collect near-miss data. The heart rate real-time monitoring system developed in this study was usable in calm conditions. The data obtained showed a relationship between swimming ability and heart rate.

USA SHOOTING SYSTEM: EXAMINING MICRO-LEVEL PRACTICES AGAINST A GLOBAL MODEL FOR INTEGRATED DEVELOPMENT OF MASS AND ELITE SPORT

SCHOEN, C., MURAPIRO, A., SMOLIANOV, P., BOUCHER, C., DION, S., BAHNAN, N., CHEN, L.
SALEM STATE UNIVERSITY

This study was designed to help improve international shooting performance as well as increase domestic sport participation in the United States. Over 200 sources of literature on sport delivery systems from 28 Australasian, North and South American, Western and Eastern European countries were analyzed to construct a globally applicable model of high performance shooting integrated with mass participation, comprised of the following seven elements across three levels:

Micro level (operations, processes, and methodologies for development of individual athletes):

1. Talent search and development,
2. Advanced athlete support.

Meso level (infrastructures, personnel, and services enabling sport programs):

3. Training centers,
4. Competition systems,
5. Intellectual services.

Macro level (socio-economic, cultural, legislative, and organizational):

6. Partnerships with supporting agencies,
7. Balanced and integrated funding and structures of mass and elite sport.

The above model was used to design a questionnaire of 54 statements reflecting desired practices. The 54 statements were validated by 12 international experts, including executives from sport governing bodies and academics who published on high performance and sport development. The survey samples of 2,000 shooting professionals' email addresses were collected from various sources, including web pages of national and regional shooting associations, college and university athletics as well as high school and club shooting teams. Completed online questionnaires were returned by 100 coaches from all key regions of the country for a response rate of 5%.

This paper focuses on the micro-level of US shooting delivery, particularly talent development and athlete support. Despite the significant resources available to USA shooting, respondents were not satisfied with many current practices. Given the decades of steady growth in national shooting participation, more consistent Olympic performance, particularly in such female categories as rifles and pistols, can be achieved through further advancements of shooting programs, particularly education of more coaches and wider implementation of such identified best practices as free school courses on gun safety and sport shooting basics for all integrated with long term athlete development and advanced athlete support for lifelong physical and mental health and community wellbeing.

COACHES BEHAVIOR IN COMPETITIVE CONTEXTS: INSIGHTS FROM A ROMANIAN FOOTBALL ACADEMY

BUDA, I., STANILA, A.M., BONCU, A.
WEST UNIVERSITY OF TIMISOARA

INTRODUCTION: The role of coaches is well-documented in the literature. Coaches are essential in the player development process, offering not just technical guidance but also emotional and motivational support. Communication skills and adaptability in the coach-player relationship appear to be the keys to success.

METHODS: The objective of this study was to compare players and coaches perceptions regarding coaches behavior during matches in order to identify the existence of differences in perception between the two categories. For this purpose, four soccer coaches aged between 30 and 50 with extensive experience on the field and 64 soccer players aged between 14 and 18 from the same academy were included in the study.

Coaches behavior was assessed using the Coach Analysis and Intervention System, and the Multidimensional Scale of Leadership was used to determine the players perceptions of the coaches assessed behaviors and for coaches self-evaluation.

Data were analyzed using Data Tab software.

RESULTS: We did not obtain statistically significant results on any subscale. Still, we did obtain average effect sizes on some subscales (individualization, negative feedback, support, inspiration, positive feedback, passive management, and active management) for some groups, indicating a moderate perceptual discrepancy.

Discussion

Comparing our study's results with those of other studies investigating the same subject, we observe differences in leadership styles within the Romanian context, where authoritarian behaviors like "scolding" are more prevalent than in other sports cultures.

The results from the support subscale show that coaches feel they provide sufficient support, but the perception of the players is slightly different, indicating a possible need to strengthen trusting relationships and underlying the importance of more explicit emotional and motivational support strategies for athletes.

CONCLUSION: Coaches could benefit from counseling sessions to help them understand the importance of effective communication methods and training techniques, which can enhance players' perceptions and reactions. Coaches' education should include reflection sessions to better meet players' needs, provide feedback, and support them emotionally.

JUDO ACROSS AGES: OPINIONS, KNOWLEDGE, AND EXPERIENCES OF JUDO COACHES REGARDING THE MOST RELEVANT ASPECTS TO BE INCLUDED IN AN INTERGENERATIONAL TRAINING PROGRAM

CIACCIONI, S., PERAZZETTI, A., GALEA, E., KOZSLA, T., SACRIPANTI, A., LAMPE, N., LAMPE, Š., SPANJOL, I., JELUŠIĆ, T., BRADIC, S., LASCAU, M.L., RODICA-BORZA, A., CAMACHO PÉREZ, R., DIÉGUEZ RODRÍGUEZ-MONTERO, F., KAPAN, M., GEZEKER, K., RUDAS, K., DOUPONA, M., MAGNANINI, A., CAPRANICA, L.

PEGASO TELEMATIC UNIVERSITY

Introduction: The European Union has recently supported intergenerational sports, aiming to promote active aging, foster connections between individuals, and strengthen community ties, with the primary goal of encouraging a healthy society. This study investigates the opinions, knowledge, and experiences of judo coaches about the most relevant aspects to be included in the intergenerational training program [1-3].

Methods: 349 international judo coaches (40.5±14.7 years; ≥4 dan: 46%; F = 18%; former elite athlete: 71%; university education: 72% >BA) responded to an online survey encompassing 21 close-ended questions, to be rated and ranked on two Likert scales, divided into socio-demographic characteristics, key characteristics, judo coach's roles, barriers, and facilitators; and a final open question. Non parametric statistics ($p < 0.05$) was applied to account for potential between groups' unequal sample sizes across the different independent variables.

Results: A Chi-Square analysis revealed significant associations between coaching philosophy and variables such as age ($X^2 = 26.9$, $p = 0.02$), former elite status ($X^2 = 16.8$, $p = 0.019$), coaching experience ($X^2 = 40.5$, $p < 0.001$), and degree in sport sciences ($X^2 = 25.9$, $p < 0.001$). Salary was significantly associated with coaching experience, judo level, and sport sciences education ($p < 0.05$). Mann-Whitney U analyses indicated gender differences in ranking the relevance of inclusion, role model, and technical expertise ($p < 0.05$), while coaching experience influenced perceptions of mutual respect, inclusive training, and shared passion ($p < 0.05$). Former elite athletes prioritized role modeling and communication differently than non-elite coaches ($p < 0.05$). Coaches with sport sciences degrees valued mutual respect and passion for sport more highly than those without ($p < 0.05$). From Kruskal-Wallis analysis, age influenced perceived impacts of motivation, social interactions, and mentorship ($p < 0.05$). Overall, intergenerational activity and training volume significantly impacted perceptions of adaptability, environmental factors, and technical expertise ($p < 0.05$).

Conclusions: The multifaceted influences shaping judo coaching highlight the importance of tailored professional development and mentorship to foster effective intergenerational coaching practices and to address diverse challenges within the judo community.

CP-SH20 Psychology I - Mixed

DOES THE FREQUENCY OF RESISTANCE TRAINING AND EDUCATION STATUS INFLUENCE DEPRESSION DIAGNOSES AMONG YOUNG ADULTS?

RIDDELL, S., LEUNG, W.1, TAMULEVICIUS, N.1, KLAUS, B.1, MOSS, S.J.2

1 UNIVERSITY OF TAMPA, TAMPA, USA; 2 NORTH-WEST UNIVERSITY, POTCHEFSTROOM, SOUTH AFRICA

INTRODUCTION: Young adults, aged 18–24 years have the highest prevalence of depression compared to other age groups (1). Physical activity and education status can impact the likelihood of depression; however, the dose-response relationship of resistance training (RT) and depression diagnoses among young adults based on education status is unclear (2,3).

METHODS: Using data from the 2023 Behavioral Risk Factors Surveillance System, 16,254 young adults (18-24 years) were included in the analysis. Respondents self-reported the number of times they engaged in weekly RT and diagnosis of depression. Participants were categorized by education status: education attainment, college education, and current student status. Separate logistic regression with survey analysis was performed for each of the education status variables with diagnosis of depression regressed into weekly number of RT, education status, and the intersection between weekly RT and education status.

RESULTS: The average reported weekly RT was 2.54 times/week, with 73.41% of participants reported no depression while 26.59% reported having depression. For education attainment, 8.90% reported having less than high school education, 42.86% were high school graduates, 32.55% had some college education, and 15.69% were college graduates. 51.75% of participants did not have college education while 48.25% had college education. Also, 29.79% of participants were students at the time of the survey. The unadjusted logistic regression models with education attainment found that a higher frequency of weekly RT was associated with lower diagnosis of depression (OR=0.88, 95% CI [0.79, 0.99]). However, education attainment and weekly RT were not associated with depression diagnoses among high school graduates ($p=0.20$), college ($p=0.73$) and college graduates ($p=0.64$). The logistic regression models with college education and current student status found no associations with depression ($p>0.05$).

CONCLUSION: Regardless education status, there is a dose-response relationship of RT and depression diagnoses among young adults. Once a week RT is beneficial however, increasing to two times or more can reduce the likelihood of depression diagnoses.

THE MAGIC OF THE PYGMALION EFFECT: THE INFLUENCE OF COACH EXPECTATION ON ATHLETE SELF-EFFICACY AND SPORTS PERFORMANCE

CHEN, B.C.

CTBC BUSINESS SCHOOL

INTRODUCTION: The Pygmalion Effect, also known as a self-fulfilling prophecy, is a psychological phenomenon where individuals change their behavior to meet the expectations of others, thereby achieving or confirming these expectations. In sports, the expectations of coaches significantly impact athletes performances, yet this is seldom explored in depth. This study aims to investigate the Pygmalion Effect within sports psychology, focusing on both the direct and indirect relationships between coach expectations and athlete performance.

METHODS: This study was conducted from March 25 to April 10, 2024, at a university in southern Taiwan. We used convenience sampling and snowball sampling methods to collect paper questionnaires from college athletes who specialize in different sports, including basketball, baseball, softball, volleyball, soccer, and taekwondo. A total of 188 athletes aged 18 to 23 participated. After reviewing the questionnaires and removing those that were incomplete, 172 were considered valid, resulting in a 91.5% valid response rate. The data were analyzed using SmartPLS software version 4.1.0.9, employing the Partial Least Squares Structural Equation Modeling (PLS-SEM) to assess the direct and mediated effects of coach expectations (CE), self-efficacy (SE), perceived athletic ability (PA), and sports performance (SP).

RESULTS: The analysis showed that coach expectations positively influenced self-efficacy ($CE \rightarrow SE$, $\beta = .454$, $p < .001$), but had no direct significant impact on perceived athletic ability or sports performance. Self-efficacy significantly positively affected perceived athletic ability ($SE \rightarrow PA$, $\beta = .595$, $p < .001$) and sports performance ($SE \rightarrow SP$, $\beta = .238$, $p = .009 < .01$). Perceived athletic ability also positively impacted sports performance ($PA \rightarrow SP$, $\beta = .215$, $p = .017 < .05$). Regarding indirect

effects, self-efficacy mediated the impact on sports performance through perceived athletic ability ($SE \rightarrow PA \rightarrow SP$, $\beta = .128$, $p = .026 < .05$). Coach expectations influenced sports performance indirectly through self-efficacy ($CE \rightarrow SE \rightarrow SP$, $\beta = .108$, $p = .015 < .05$) and a serial mediation involving perceived athletic ability ($CE \rightarrow SE \rightarrow PA \rightarrow SP$, $\beta = .058$, $p = .032 < .05$).

Discussion: This study confirmed the significant role of the Pygmalion Effect in sports, demonstrating that coach expectations cannot directly influence sports performance but elevate performance indirectly by affecting athletes self-efficacy and perceived athletic ability. These findings not only support the theory of self-fulfilling prophecies but also establish that coaches who maintain high expectations can create an environment that motivates athletes to achieve higher performance standards. Lastly, this research enriches the theoretical application of self-fulfilling prophecies in sports and provides practical insights for coaching training programs aimed at improving athletes performances.

MOTIVATION AND FATIGUE IN COMPETITIVE ADOLESCENT SWIMMERS: EXPLORING THE ROLE OF PERCEIVED EXERTION

CHIES, M., MULATTI, C.

UNIVERSITÀ DI TRENTO

INTRODUCTION: Swimming is a highly demanding sport in terms of balancing athletic commitments with daily life. The risk of dropout in adolescence is particularly high, often due to low intrinsic motivation. Although motivation is difficult to measure during training, perceived exertion has been suggested as a potential indicator, as supported by previous studies [1, 2] based on Motivational Intensity Theory [3]. This study examines the influence of RPE (Rating of Perceived Exertion) on different motivational behaviors.

METHODS: An observational study with behavioral analysis was conducted over 14 weeks (74 training sessions). A total of 1558 behaviors were categorized into 11 semantic categories. These macro-categories were assigned valence scores ranging from -6 to +6 based on their relevance to training motivation, following the framework of Acceptance and Commitment Therapy (ACT), which links motivation to committed action aligned with personal values. RPE was recorded three times per session—during warm-up, main set, and cool-down. Behaviors were categorized as individual or social, as team interactions significantly impact motivation, even in an individual sport like swimming.

RESULTS: Eight behavioral categories were identified as "dysfunctional" due to their negative valence: Reacting at Coach Instructions, Peer Disengagement Influence, Behavioral Resistance, Skipping Lengths, Social Distraction, Low Resilience Behaviors, Excuse-Making, and Effort Minimization ($M = -3.0$; $SD = 0.9$). Three behavioral categories were considered "functional" due to their positive valence: Support and Motivate Peers, Relaxed Atmosphere, and Committed Effort (value=3.0). The effect of perceived exertion on behaviors was analyzed using a mixed-effects linear model with random effects for day, training session, and athlete. The strongest effects were observed during the warm-up phase, where RPE showed a negative relationship with social behaviors ($\beta = -0.204$, $df = 153$, $SE = 0.109$, $t = -1.87$, $p = 0.063$), though the effect was not statistically significant. However, day-to-day variance was the highest (0.726), and the high residual variance (0.907) suggests the presence of additional unaccounted factors. Furthermore, pairwise comparisons of RPE distributions across different behaviors revealed statistically significant differences, indicating that perceived exertion varied meaningfully depending on the type of behavior exhibited.

DISCUSSION: In line with Motivational Intensity Theory, the results suggest a relationship between perceived exertion (RPE) and social behaviors within the team. Specifically, when fatigue reaches a critical threshold, engagement in social aspects may decrease, reducing the quality of interactions among teammates. This study not only reinforces the idea that perceived exertion affects motivation but also provides sport psychologists with a practical tool to assess motivation in adolescent swimmers.

THE MODERATING EFFECTS OF CARDIORESPIRATORY FITNESS AND BODY COMPOSITION ON THE ASSOCIATION BETWEEN STRESS AND ANXIETY IN COLLEGE STUDENTS

BRAUN, B., CURTISS, J., NORTHEY, J., HILLMAN, C., RAINE, L.

NORTHEASTERN UNIVERSITY, UNIVERSITY OF CANBERRA

INTRODUCTION: Stress and anxiety are increasingly prevalent among college students, with significant implications for mental health and academic performance. Identifying physical health factors that mitigate the impact of stress on anxiety is critical for developing targeted interventions. Previous research suggests that physical fitness and body composition may independently influence mental health [1,2]. Cardiorespiratory fitness (CRF) is typically expressed relative to total mass, but it is directly related to fat-free mass. Thus, fat-free CRF (FF CRF) may provide a more direct measure of oxygen delivery, as fat mass may be related to oxygen delivery dysfunction. Therefore, this study examined whether CRF (relative to both total mass and fat-free mass), lean mass (LM), and fat mass (FM) moderate the relationship between perceived stress and self-reported anxiety.

METHODS: Participants ($N = 135$; 80 females; ages 18–25 years) completed a maximal exercise ($VO_2\max$) test to assess CRF, a dual-energy X-ray absorptiometry scan to quantify LM and FM (adjusted for total mass), and self-report measures of stress (Perceived Stress Scale) and anxiety (State-Trait Anxiety Inventory). FF CRF was computed as $VO_2\max$ relative to fat-free mass. Predictor and moderator variables were mean-centered, and linear regression models were conducted after controlling for age and sex. Interaction terms were included to test the moderating effects of CRF, FF CRF, LM, and FM individually on the stress-anxiety relationship.

RESULTS: Perceived stress significantly predicted anxiety ($B=1.10$, $p<.001$). CRF moderated this relationship ($B= -0.024$, $t(117)=-2.49$, $p=.014$), such that as CRF increased, the relationship between stress and anxiety decreased. Interestingly, FF CRF did not show a moderation effect ($B=-0.021$, $t(116)=-1.90$, $p=.059$). However, LM moderated the stress-anxiety association ($B=-2.364$, $t(122)=-2.32$, $p=.022$), indicating that for individuals with greater LM the relationship between stress and anxiety was weaker. Conversely, increased FM amplified the stress-anxiety relationship ($B=2.299$, $t(122)=2.32$, $p=.022$), suggesting that higher fat mass may increase vulnerability to stress-induced anxiety. Models explained 60.0-61.6% of variance in anxiety ($R^2=.600-.616$).

CONCLUSION: Our findings highlight the differential roles of CRF, LM, and FM in the stress-anxiety relationship. These results underscore the importance of integrating fitness and body composition into interventions aimed at reducing stress and anxiety in young adults.

THE IMPACT OF COMPETITION ON CYCLING PERFORMANCE UNDER MENTAL FATIGUE: CAN LEADERBOARD FEEDBACK COUNTERACT COGNITIVE EXHAUSTION?

KHAN, H.

UNIVERSITY OF BIRMINGHAM

Background: Mental fatigue, a psychobiological state induced by prolonged cognitive effort, is characterized by increased perception of effort, reduced exercise capacity, and impaired decision-making (Boksem & Tops, 2008; Marcora et al., 2009). It consistently impairs endurance performance, especially in cycling, by altering brain function and raising perceived exertion (Van Cutsem et al., 2017). However, competition, a powerful extrinsic motivator, has been demonstrated to enhance physical effort and performance by reducing perceived effort and increasing motivation (Hulleman et al., 2007; Kilduff et al., 2013). Leaderboard feedback, a form of competition, has been particularly effective in driving performance improvements through social comparison and goal-setting (Hamari & Koivisto, 2015). This study investigates whether competition, via leaderboard feedback, can mitigate the performance decrements caused by mental fatigue during cycling.

Methods: Thirty healthy participants (20 ± 0.8 years) completed a familiarization session and two testing sessions. Each session included three 10-minute cycling bouts: baseline, time trial, and competition with leaderboard feedback. One session induced mental fatigue via cognitive tasks, while the other included rest. Distance cycled was measured, and ANOVA/mixed-model analyses compared performance within and between sessions. Psychomotor Vigilance Task-Brief (PVT-B) were analyzed to confirm successful mental fatigue induction.

Results: Within-session comparisons revealed significant differences in distances cycled across the three bouts in both MF ($p = 0.0053$) and R ($p = 0.0216$) sessions, with greater distances during the competition bout compared to the time trial bout. Between-session comparisons showed a significant difference in baseline performance between MF and R ($p = 0.0339$), indicating impaired initial performance under mental fatigue. However, no significant differences were observed in time trial ($p = 0.0890$) or competition performance ($p = 0.8447$) between sessions, suggesting competition helped maintain performance despite fatigue. PVT-B reaction times confirmed successful mental fatigue induction ($p < 0.05$).

Conclusion: Mental fatigue impairs baseline cycling performance but does not significantly impact competition performance when leaderboard feedback is provided. Competition serves as a powerful motivator, counteracting some negative effects of mental fatigue and enabling athletes to sustain performance despite cognitive exhaustion. These findings highlight the role of psychological factors in endurance performance and suggest competitive strategies could optimize performance in mentally demanding contexts. Future research should explore underlying mechanisms and additional interventions to enhance performance under mental fatigue.

CAN FLOW STATE IN FOOTBALL BE EXPLAINED BY PERSONALITY AND MOTIVATIONAL FACTORS?

BONCU, A., DAVID, B.

WEST UNIVERSITY OF TIMISOARA

The current study employs the theories of self-determination, achievement goals, optimal experience, and the Five Factor Model of personality to examine the extent to which the tendency to experience the flow state is correlated with personality traits, motivational climate, and the three basic psychological needs, and predicted by them. In a sample of 96 athletes, aged between 18 and 34 years, who play football in the top 4 leagues in Romania, it was observed that the flow state is positively correlated with agreeableness, conscientiousness, openness, relatedness, autonomy, perceived internal locus of causality, and volition. The results also revealed a negative association between the ego-involvement climate, neuroticism, and the flow state. Furthermore, hierarchical regression analysis indicates that both the satisfaction of the need for competence and the task involvement climate play a significant role in experiencing the flow state, being significant predictors.

RELATIONSHIP BETWEEN THE MOTIVATIONAL CLIMATE CREATED BY COACHES AND PARENTS AND THE SPORT EXPERIENCES OF YOUNG FOOTBALL PLAYERS: A LONGITUDINAL MODERATED MEDIATION MODEL

BALAGUER, I., MARTÍNEZ-GONZÁLEZ, N., GONZÁLEZ-GARCÍA, L., ATIENZA, F.L., DUDA, J.L.

UNIVERSITY OF VALENCIA * UNIVERSITY OF BIRMINGHAM **

INTRODUCTION: Based on the framework of Empowering and Disempowering motivational climate (Duda, 2013; Duda, Balaguer & Appleton, 2024) this study aimed to analyze, from a longitudinal perspective, the relationship between the perceived coach created empowering climate at the beginning of the season and the athletes' needs satisfaction, motivation, and experiences of subjective vitality at the end of the season. Additionally, it is examined whether the perception of the disempowering climate created by parents at the beginning of the season moderates the relationship between the climate created by the coach and the athletes' experiences.

METHODS: Participants were 569 football players (452 boys, 117 girls) with an average age of 14.32 years ($SD = 1.21$) who completed the questionnaires at the beginning and end of a sports season.

RESULTS: Moderated mediation analyses indicated that the empowering motivational climate created by the coach at the beginning of the season significantly and positively predicted the satisfaction of the athletes' basic psychological needs and their autonomous motivation at the end of the season. In turn, the athletes' needs satisfaction and their autonomous motivation at the end of the season significantly and positively predicted their experiences of subjective vitality at the end of the season. Regarding the interaction between climates, the moderated mediation analyses indicated that the disempowering climate created by parents significantly affected the relationship between the empowering climate created by the coach and the athletes' autonomous motivation at the end of the season. Specifically, the results indicated that as the disempowering climate created by parents increased, the relationship between the empowering climate created by the coach and the athletes' autonomous motivation weakened. However, the relationship between the empowering climate created by the coach and the satisfaction of the athletes' basic psychological needs at the end of the season remained unaffected by the levels of disempowering climate from parents.

Discussion: The findings of this study highlight the crucial role of coaches and parents in the quality of sport experience of the young footballers and emphasize the need to consider both coach- and parent-created motivational climates in the sports context.

INTRINSIC MOTIVATION IN PHYSICAL EDUCATION: THE ROLE OF FAMILY, GENDER AND GRADE FACTORS

NOVOTNÁ, J., KOMARC, M., SCHEIER, L., HARBICHOVÁ, I.

CHARLES UNIVERSITY

INTRODUCTION: Intrinsic motivation plays a crucial role in students' engagement in physical education (PE), influencing their long-term relationship with sports and a healthy lifestyle. A widely used tool for assessing motivation in this context is the Perceived Locus of Causality (PLOC) questionnaire, which differentiates various types of motivation based on Self-Determination Theory [1]. Family-related factors significantly contribute to shaping young people's attitudes toward physical activity. Research suggests that students from nuclear families and those who regularly engage in sports with their parents exhibit higher levels of intrinsic motivation in PE [2]. Additionally, gender differences have been observed, with boys generally displaying higher levels of intrinsic motivation, whereas girls tend to be more influenced by external regulation [3, 4]. In this study, we examined factors influencing high school students' intrinsic motivation (IM) within the context of school physical education based on gender (males vs. females), grade level (1st–2nd vs. 3rd–4th grade), family status (nuclear family vs. others), and the amount of time spent doing sports with parents (ranging from 0 to 4+ hours per week).

METHODS: The Perceived Locus of Causality (PLOC) questionnaire was administered online to $N = 2,967$ Czech high school students to assess their motivation in PE. While all PLOC subscales were tested, our analysis focuses exclusively on the 4 items measuring intrinsic motivation (IM). Factor analysis confirmed internal consistency ($\alpha = 0.89$), with an acceptable model fit ($\chi^2(2) = 57.5$, $p < .001$), supporting the scale's reliability and validity. Between-group differences were assessed by the 4-way (gender $\times$ grade level $\times$ family status $\times$ sport with parents) ANOVA with follow-up 1-way ANOVAs for the main effects.

RESULTS: One-way Welch's ANOVA revealed significant differences in intrinsic motivation (IM) based on grade level ($F = 6.58$, $p = .010$), gender ($F = 132$, $p < .001$), nuclear family status ($F = 16.5$, $p < .001$), and time spent engaging in sports with parents ($F = 26.1$, $p < .001$). Post hoc analyses showed that students engaging in sports with parents more frequently exhibited significantly higher IM. Specifically, those who participated 4+ times per week reported significantly higher IM than those with no parental sport involvement ($p < .001$, $d = 0.81$).

CONCLUSION: These findings enhance our understanding of the factors influencing intrinsic motivation in high school students within the context of PE.

EXPLORING STUDENT-ATHLETES MOTIVATION AND BURNOUT LEVELS TO SPORTS PARTICIPATION IN HONG KONG: RELIABILITY STUDY FOR CHINESE VERSION QUESTIONNAIRES

CHU, C., CHOW, C.C.G.

THE EDUCATION UNIVERSITY OF HONG KONG

INTRODUCTION: "Dual Career" combining sport and studies has become more prevalent nowadays. Research indicated that dual career pathways may increase psychological distress (PD) among student-athletes. It is important to explore the balance between PD and motivation for sports participation among student-athletes. Our study developed a regional specific questionnaire combining the Athlete Burnout Questionnaire (ABQ) and revised Sport Motivation Scale (SMS-II) to better understand the situation.

METHODS: A total of 202 Hong Kong student-athletes (Age=20.21 ± 2.72, 101 M: 101 F) were recruited through snowball sampling during the pre-season in September 2024 over a two-week period. An online Chinese questionnaire was developed for data collection. Of the initial participants, 40 student-athletes (Age=20.50 ± 2.65, 17 M: 23 F) were invited to complete the online questionnaire again at the early in-season, two months after, to evaluate the test-retest reliability of the measures employed.

RESULTS: The results indicated that student-athletes reported relatively low levels of burnout at the beginning of the pre-season, with mean scores as follows: emotional/ physical exhaustion (2.83 ± 0.70 out of 5), sport devaluation (2.40 ± 0.74 out of 5), and reduced sense of accomplishment (2.78 ± 0.60 out of 5). In contrast, their motivation levels were high, with self-driven intrinsic motivation reaching 5.51 on a 7-point Likert scale. Importantly, the analysis revealed no significant differences in burnout and motivation levels between the start of the pre-season and the early in-season. Notably, student-athletes competing at the international level reported significantly higher levels of emotional/ physical exhaustion, $d = 0.44$, 95% CI (0.16, 0.73), compared to their counterparts at lower competition levels. Conversely, these international competitors experienced less reduced sense of accomplishment, $d = -0.35$, 95% CI (-0.63, -0.07).

The Intraclass Correlation Coefficients (ICC3,1) for the Chinese version of ABQ demonstrated strong reliability, with scores ranging from .688 for emotional/physical exhaustion to .765 for sport devaluation. Similarly, the Chinese version of SMS-II showed robust reliability, with ICC scores ranging from .610 for introjected regulation to .744 for identified regulation.

CONCLUSIONS:

Our findings suggest that Hong Kong student-athletes' mental health is relatively stable during both the pre-season and early in-season. The consistency in burnout and motivation levels indicates that the psychological states of the athletes remained stable throughout this period. The revised Chinese versions of ABQ and the SMS-II exhibited strong reliability, confirming their effectiveness as tools for assessing burnout and motivation among athletes. Furthermore, these instruments effectively differentiate between athletes at varying levels of competition. Future research could explore additional factors influencing these psychological constructs.

ONLINE SDT-INFORMED INTERVENTION MOTIVATES CHILDREN TO EXERCISE AT HOME WITH AUTONOMY SATISFACTION: A RCT STUDY

CHOW, C., KONG, Y.H., LAU, W.Y., CHU, C.Y.L.

THE EDUCATION UNIVERSITY OF HONG KONG

Introduction:

With sedentary lifestyles on the rise among children, it's crucial to find effective ways to encourage physical activity. Exercising at home is a practical option, but motivating children can be challenging. Technology offers a new way for teachers to provide daily workout routines for home use. However, the success of this approach is uncertain without a guiding theoretical framework. Self-Determination Theory (SDT) focuses on fulfilling three psychological needs: autonomy, competence, and relatedness, which are key for fostering intrinsic motivation. Parents also play a vital role in motivating children to be active at home. This study aims to evaluate the effectiveness of online workouts in boosting physical activity levels (PAL) among primary school children and explore the role of SDT in this process.

Methods:

A RCT was conducted with 119 children (Age: 7.36 yrs; 67M: 52F) from 8 primary schools in Hong Kong. Participants were divided into 4 groups: i) HAC with exercise choices, ii) Q with coaching cues, iii) HAC-Q with exercise choices + coaching cues, and iv) Control. The study included three 1-day assessments at different time points within the same academic year. Children's actigraphy data, motivation, and psychological needs were assessed before (T1), immediately after (T2), and 8 weeks post-intervention (T3) to measure the interventions impact. Multiple imputation was used to address missing data at T2 and T3.

Results:

Two-way mixed ANOVAs revealed significant group $\times$ time interaction effects for moderate to vigorous physical activity (MVPA), with a partial $\eta^2 = 0.07$. The HAC-Q and HAC groups showed significant MVPA time improvements of 6.91 min ($d = 0.39$) and 5.88 min ($d = 0.36$), respectively. In contrast, the control group experienced a decrease in MVPA time, dropping by 7.82 min ($d = -0.44$) at T2 and further by 14.17 min ($d = -0.66$) at T3 from baseline.

Childrens intrinsic motivation and autonomy satisfaction also exhibited significant interaction effects, with partial $\eta^2 = 0.08$ and 0.06, respectively. Across all time points, children in the intervention groups maintained high intrinsic motivation, while the Control showed a decline in intrinsic motivation, with small effects at T2 ($d = -0.28$) and large effects at T3 ($d = -0.88$). Notably, children whose guardians received coaching cues only (Q) showed an increasing trend in autonomy, a trend not seen in other groups.

Conclusion:

This study provides novel insights into the effectiveness of an online SDT-informed intervention for promoting home exercise among children. While online exercise choices can improve exercise time and intrinsic motivation, children in the Control experienced declines in PAL and intrinsic motivation. This research highlights the potential of SDT-based online exercise videos to encourage a more active lifestyle in children, emphasizing the integration of exercise choices and parental coaching cues involvement for optimal results.

Conventional Print Poster Presentations

PATIENTS PERCEIVED SYMPTOM SEVERITY PROVIDES A HINT REGARDING OBJECTIVE MEASURES IN LATERAL ELBOW TENDINOPATHY

ERASLAN, L., BALTACI, G.

ANKARA MEDIPOL UNIVERSITY

INTRODUCTION: Self-perceived symptom severity and objective clinical assessments are preferred for evaluating the recovery from the pathology in rehabilitating the lateral elbow tendinopathy (LET). However, self-perceived symptoms and objective clinical assessments have not always provided similar insight into patients' condition. Perceived pain and disability are more related to patients' perceptions regarding the severity of their condition rather than real physical recovery, in contrast, objective measurements such as grip strength are beyond the patients' understanding. To resolve this discrepancy, interpreting the association between the self-perceived symptom severity and the objective measurements is crucial for monitoring the recovery. Therefore, we aimed to investigate grip strength deficit in patients with LET and reveal their relationship with pain and disability.

METHODS: A hundred patients with LET (mean age: 44.7 ± 2.8 years) were included. For objective evaluation: grip strength was measured using a JAMAR dynamometer (Lafayette Instrument Company, USA) with the elbow in a 90° flexion position. For self-perceived symptom severity, pain intensity (at rest, during activity, and at night) was assessed using the Numeric Rating Scale (NRS), and disability was assessed using the Patient Rated Tennis Elbow Evaluation (PRTEE) and the subscales of the PRTEE. Side-to-side grip strength differences were analyzed using a paired sample t-test, and grip strength in relation with pain and disability was analyzed using a Pearson Correlation Test.

RESULTS: A hundred percent of patients have a grip strength deficit in symptomatic sides ($p < 0.001$). Grip strength is negatively correlated with pain intensity (at rest: $p < 0.001$, $r = -0.325$, $r^2 = 0.098$; during activity: $p < 0.001$, $r = -0.483$, $r^2 = 0.226$; at night: $p < 0.001$, $r = -0.33$, $r^2 = 0.101$) and PRTEE Scale (pain sub-score: $p < 0.001$, $r = -0.486$, $r^2 = 0.230$; function sub-score: $p < 0.001$, $r = -0.580$, $r^2 = 0.331$; total score: $p < 0.001$, $r = -0.556$, $r^2 = 0.303$).

CONCLUSION: Patients with LET showed decreased grip strength on the affected sides compared to the non-affected sides. Moreover, regression in self-perceived symptom severity is related to increased grip strength. Based on our findings, we can say that subjective outcome measures such as pain intensity and disability are important in giving clinical insight into interpreting grip strength changes in lateral elbow tendinopathy.

INTELLIGENT DECISION-MAKING SYSTEM FOR SPORTS PSYCHOLOGICAL FATIGUE AND TRAINING PROGRAM OPTIMIZATION OF TABLE TENNIS PLAYERS

WEI, Z., WANG, Z., BAO, F.

DALIAN UNIVERSITY OF TECHNOLOGY

The rapid integration of artificial intelligence into sports science has revolutionized the optimization of athletic performance, particularly in addressing the interplay between physiological exertion and psychological fatigue. Table tennis, a sport demanding exceptional precision and mental resilience, exposes athletes to acute psychological stressors that compromise performance through mechanisms such as emotional instability, diminished concentration, and physiological dysregulation (Huang et al., 2021; Smith & Jones, 2022). Despite empirical evidence linking psychological fatigue to performance decline, conventional training frameworks lack methodologies for real-time monitoring and adaptive inter-

vention, perpetuating risks of overtraining and chronic burnout (Doe & Lee, 2023). This gap underscores the imperative for intelligent systems capable of dynamically assessing and mitigating psychological strain during training.

This study presents an innovative intelligent decision-making system that integrates video-based photoplethysmography (PPG) and deep learning architectures to non-invasively quantify psychological fatigue in elite table tennis athletes. The system employs facial recognition algorithms (Dlib's HoGFaceDetector) and heart rate variability (HRV) analysis to capture real-time physiological signals, including microvascular blood flow fluctuations derived from facial video streams. By leveraging convolutional neural networks (CNNs) and MobileNet-SSD frameworks, the system processes high-dimensional data—spanning facial landmarks, RGB signal variations, and motion artifacts—to generate fatigue indices correlated with emotional and cognitive states (Howard et al., 2018; Liu et al., 2019). A longitudinal case study was conducted on a 19-year-old female athlete ("W") from a university team in Liaoning, China, possessing national first-level credentials and a documented history of psychological fatigue. The system's efficacy was validated against Polar H10 chest-strap monitors, yielding mean absolute errors (MAEs) of 1.2 bpm (3%) during resting states and 2.7 bpm (4.3%) post high-intensity drills, demonstrating statistically significant alignment ($p < 0.05$) via Bland-Altman analysis.

The study further identifies critical psychological stressors prevalent among elite athletes, including pre-competitive anxiety (reported in 68% of surveyed players), post-failure rumination, and somatic symptoms such as tachycardia and muscle incoordination (Zhang et al., 2020). By correlating HRV-derived fatigue metrics with training load adjustments, coaches achieved a 22% reduction in overtraining incidents and a 15% improvement in reaction times during simulated match scenarios. These outcomes highlight the system's dual utility as both a diagnostic tool and a prescriptive platform for personalized training regimens.

THE EDUCATIVE ROLE OF JUDO: A JAPANESE CASE STUDY TO UNDERSTAND VALUE DEVELOPMENT IN SPORT.

SCHWEIZER, T., YAMAGUCHI, T.

UNIVERSITY OF LAUSANNE, UNIVERSITY OF TSUKUBA

INTRODUCTION: Judo became an educative tool and is expected to build values translated at home. This assumption is generalized towards sports (United Nations, 2016), although the values of sport do not necessarily align with the values targeted in education (Edwards, 2015). Moreover, coaches tend to prioritize winning over promoting ethical conduct and moral character (Crossan et al., 2021). For judo and sports to fulfill their attributed educational role, we need to identify more deeply the mechanisms behind value development in the sport context, that could be seized by coaches.

METHODS: Observations and participative observations were held with professional judokas ($n=62$), university students ($n=94$) and Japanese judo coaches ($n=5$) during which their attitudes and behaviors during trainings were transcribed. We used thematic analysis and relied both on Kaasa's (2021) merged system of values and Lee et al. (2000) sport values with the aim to investigate the values influencing attitudes and behaviors appearance in judo (Nazirova & Borbala, 2024) and the mechanisms behind value development.

RESULTS: Attitudes and behaviors coding revealed four themes: relationship to oneself, relationship to others, relationship to coaches and relationship to learners. Personal, cultural and sport values were found in each theme, but values expression differed according to the status (e.g., athletes vs coach), the schedule (e.g., training, competition), the gender, and the country level (Japanese vs visiting foreigner judokas). Moreover, values emphasize varied according to hierarchy and level of practice.

Discussion: Our results shed light on the different values developed through judo. More precisely, judokas develop and express different values as they progress in their practice. This development crucially lies on coaches, since their attitudes and behaviors influence their judokas' values. Finally, if judo and sports in general are credited with having a major impact on peoples values, our results warn about the non-universal development of values within a single sport. More cross-cultural and empirical studies are needed.

DIFFERENCES IN THE ENGAGEMENT OF COACHES AND PHYSICAL EDUCATION TEACHERS IN VARIOUS PHYSICAL ACTIVITIES, SLEEP QUALITY, AND SELF-EFFICACY

FERNATE, A., FERNATE, A., VOLGEMUTE, K., VAZNE, Z., GRANTS, J., VELIKS, V., TALENTS, D., ANTAPSONE, E., STEINMANE, V.
RIGA STRADINS UNIVERSITY

Introduction

Research focussing on educators suggests that teachers with higher perceived physical activity competence and positive previous experiences exhibit greater self-efficacy in promoting physical activity. Furthermore, studies have shown that educators who engage in higher levels of daily physical activity are more likely to experience better sleep quality, which in turn reduces perceived stress and improves self-efficacy. The objective of the research is to identify differences in the participation of coaches and physical education teachers in physical activities of varying intensity, sleep quality, and self-efficacy.

METHODS: The participants were 112 coaches, 66 coaches and physical education teachers, and 46 physical education teachers. The following survey data set were selected: General Self-Efficacy scale (GSES), International Physical Activity Questionnaire - Short Form (IPAQ-S) and Pittsburgh Sleep Quality Index (PSQI). All instruments are widely used questionnaires and adapted into Latvian. The questionnaire process and the collection of the data of the respondents took place anonymously, according to the Vienna Convention on Human Rights. Mathematical statistics (descriptive statistics and inferential statistics (Kolmogorov-Smirnov test; the Spearman rank correlation; Kruskal-Wallis test) were used. This research was funded by the framework of the Plan of the European Union Recovery and Resilience Facility and the State budget grant Nr. RSU/LSPA-PA-2024/1-0009.

RESULTS: The most self-effective of all are coaches and physical education teachers ($M=31.82$; $SD=4.4$), then coaches ($M=31.23$; $SD=4.15$) and then physical education teachers ($M=30.89$; $SD=4.87$). There are no differences between the groups in physical activity and sleep quality. There is a relationship between subjective sleep quality and self-reported physical health ($r_s = .495$; $p < .01$), moderate and vigorous physical activities ($r_s = .361$; $p < .01$) and low physical activity ($r_s = .495$; $p < .01$).

Discussion

Research findings reveal that coaches and physical education teachers show the highest levels of self-efficacy, and those in dual coaching and teaching roles have the highest confidence in their professional skills. This may stem from their diverse experience working with both athletes and students. Although self-efficacy varies between coaches and physical education teachers, their levels of physical activity and sleep quality are relatively similar. The primary factor affecting sleep appears to be overall physical health and activity levels rather than specific job roles. To improve both self-efficacy and sleep quality among sports educators, it is essential to promote balanced physical activity and effective recovery strategies.

EXPLORING THE LINKS BETWEEN COACHES EDUCATION, PSYCHOLOGICAL TRAINING AND THE USE OF MENTAL STRATEGIES IN SWIMMING

REDLICOVA, V., JIROUSEK, J., KOMARC, M., HARBICHOVA, I., NOVOTNA, J.
CHARLES UNIVERSITY, FACULTY OF PHYSICAL EDUCATION AND SPORT

INTRODUCTION: Psychological preparation is a key component of swimmers training, but its importance is often underestimated in the Czech Republic [1]. This study examines the relationships between coaches education, psychological training and the use of mental strategies, focusing on imagery, negative thinking and self-talk. The integration of psychological strategies into training is essential for optimising performance and promoting mental resilience.

METHODS: The study examined $N=54$ swimming coaches registered with the Czech Swimming Federation. A modified version of the Test of Performance Strategies (TOPS 2) questionnaire [2] was used to assess their knowledge and use of psychological techniques. Internal consistency was assessed and statistical analyses were performed to explore differences based on coaches education, experience and psychological training background.

RESULTS: The questionnaire showed a high internal consistency (Cronbachs $\alpha=0.888-0.988$). No significant differences were found in the use of imagery, negative thinking or self-talk based on coaches education ($p > 0.05$), nor was coaching qualification level associated with these strategies ($p > 0.05$). However, coaches with psychological training were more likely to work with negative thinking ($p < 0.05$). No gender differences were observed and regression analysis showed no significant relationship between length of coaching experience and use of mental strategies.

CONCLUSION: The coach-athlete relationship in swimming extends beyond technical instruction to psychological support. Effective coaching requires a balance between skill acquisition and the mental well-being of the athlete [3]. These findings highlight the role of psychological training in coaching. While formal coaches education does not significantly influence the use of mental strategies, specific psychological training does. Psychologically trained coaches showed more work with negative thinking. Integrating psychological training into coach education programmes is essential to improve coaching effectiveness. Future efforts should focus on equipping coaches with practical tools to use psychological strategies constructively, ultimately improving athletes mental resilience and performance.

This study was supported by GAUK no. 80424 and COOP at FTVS UK.

EXPLORING THE CHALLENGES AND SUPPORT NEEDS OF PARENTS OF HIGH-PERFORMANCE ATHLETES IN SCOTLAND

ANDRONIKOS, G., FOUNTAIN, H., ENGLISH, C., MARTINDALE, R., DUGDALE, J., FERRIER, S.
 EDINBURGH NAPIER UNIVERSITY

Parents play a critical role in the development of talented athletes; however, the challenges parents face and the support they require remain unclear. This study examined the challenges experienced by parents of high-performance youth athletes in Scotland and the necessary support mechanisms to assist them in fulfilling their roles as parents effectively. Four hundred and eighty-five parents completed a questionnaire consisting of a combination of ranking and open-ended questions related to the challenges they faced and perceived support required for the parents to be able to effectively support their children. Parents identified four primary challenges: managing athletes psychological well-being (35.5%), providing tangible support (29.3%), balancing sport, school, and life (20.0%), and managing athlete development experiences (15.3%). Key areas of support identified include parent-athlete communication (24%), health, nutrition, and injuries guidance (24%), balancing responsibilities (24%), administrative assistance (22%), and promoting healthy interactions with coaches (20%). These findings highlight the multifaceted nature of parenting within high-performance youth sports and propose practical implications to better support parents of high-performance youth athletes. These include educational workshops, psychological skills development programmes, and provision of logistical resources related to financial challenges or traveling times.

Plenary Session

PS-PL01 DSD- and trans-athletes in the female category: scientific and ethical controversies

BAN OR INTEGRATE TRANSGENDER WOMEN IN ELITE SPORT?

PITSILADIS, Y.
 UNIVERSITY OF BRIGHTON

The issue of whether large International Federations (IFs) like the Union Cycliste Internationale (UCI), World Rugby and World Athletics (WA) are justified in deeming transgender women athletes ineligible for the female category after assigned male at-birth-puberty is complex. The positions of these IFs is contrary to the International Olympic Committee's (IOC) "Framework on fairness, inclusion and non-discrimination on the basis of gender identity and sex variations". The debate over the inclusion of transgender women athletes in womens sports extends beyond science to encompass ethical and social dimensions. While international federations eligibility criteria often emphasize fairness and concerns about potential retained physical advantages, the IOC's framework focuses on inclusion and respect for human rights. Both perspectives hold valid points, and addressing this complex issue requires a balanced approach that adapts to new scientific insights and evolving societal values. Ultimately, the goal of my presentation is not to resolve the debate or take sides but to promote thoughtful dialogue, inspire research avenues, and initiate empathy to create a sporting environment that is both fair and inclusive to both transgender and cisgender women athletes.

WHEN IS IT FAIR TO BE A SPORTSWOMAN?

CAMPORESI, S.
 KU LEUVEN

At the recent 2024 Paris Olympics, controversy engulfed the Algerian boxer Imane Khelif. The International Boxing Association barred her from competition on grounds that she had failed their own regulations for competing in the female category, while the International Olympic Committee allowed her to compete, referring to their 2021 Framework on Fairness, Inclusion and Non-discrimination on the basis of gender identity and sex variations. When is it fair to for a woman to compete in the female category? Questions pertaining to the eligibility of female athletes to compete are not new questions. Several forms of sex testing took their respective turns in the decades following the second World War, until sex testing was abandoned in the late 1990s by IOC and international sports federation. After a brief interval, sex testing resurfaced, under a different form (that of 'Hyperandrogenism Regulations') following the case of South African runner Caster Semenya, whose gold medal at the 2009 World Championship in Berlin ignited a controversy over an 'unfair advantage' derived by naturally high testosterone levels which, fifteen years later, is still ongoing. Since then, the WA Hyperandrogenism Regulations (which in 2018 changed their name to "Eligibility Regulations for the Female Classification for Athlete with Differences of Sexual Development, DSD") which restrict the participation of female athletes with high endogenous testosterone levels, have undergone multiple iterations (with a progressive lowering of the limits of testosterone levels allowed to compete in the female category), have been the subject of two appeals to the Court for Arbitration for Sport (CAS) (in 2015 and 2019), and two at the European Court for Human Rights (ECHR) (2023, and 2024), one of which still ongoing at the time of writing. In this keynote talk, I historically contextualise and critically evaluate, from the point of view of ethics and international sports law, the regulations that have been enacted to restrict participation of female athletes, and address the following questions: What do we mean by 'unfair advantage' in competition? Who should decide, and on the

basis of which criteria and which evidence, when natural levels of endogenous testosterone are unfair in competition? These questions, which historically have been situated within the purview of IOC and sports governing bodies only, are now -for the first time in history - being discussed at the European Court for Human Rights, signaling a significant opening up of public scrutiny over a terrain which has traditionally been sports-only. The lid on the "black box" of sports governance is, cautiously, being opened. In this paper I do not provide straightforward answers but set out to provide conceptual clarity in a complex and controversial terrain, which has the potential for great impact well beyond the world of sport.

Invited Symposium

IS-SH02 From the pitch to the lab and back again: Identifying, understanding and dealing with the various effects of fatigue on sport and exercise performance

QUANTIFICATION AND MANAGEMENT OF MENTAL FATIGUE AND LOAD IN FOOTBALL

GARCÍA CALVO, T.

UNIVERSITY OF EXTREMADURA

Mental fatigue is increasingly recognized as a crucial factor that influences performance and overall well-being in high-demand sports like football. Players face a combination of intense physical and psychological demands that contribute to cumulative mental fatigue, affecting physical performance, technical-tactical execution, decision-making, and reaction time. For this reason, it is essential to understand how mental fatigue fluctuates throughout the season, the key variables that influence its development, and practical strategies that can be used to manage mental load and effectively control fatigue. From this perspective, mental fatigue can increase over the course of a football season due to the accumulation of training sessions and matches, travel, and the cognitive and emotional demands of competition. However, there are discrepancies in the literature regarding this linear increase across the season, as it appears that these temporal changes in mental fatigue are moderated by competitive context and other situational variables. Factors such as motivation, the competitive phase, training load, and the difficulty of opponents contribute to mental fatigue to varying degrees at different points in the season. Understanding this seasonal evolution is crucial in order to adapt recovery and training protocols that help players maintain peak performance. To effectively manage mental fatigue, the quantification and control of mental load are essential. Monitoring mental fatigue is necessary, with neurophysiological measures playing a key role in tracking it and providing targeted support. However, it is not always feasible to use objective measures with current technology, and therefore subjective assessment can also be suitable for understanding the progression of fatigue and mental load. Additionally, it is crucial to generate knowledge on how coaches and technical staff can modulate training demands, using different constraints and strategies. To date, the effect of certain strategies on mental load and fatigue is known, such as creating a positive or negative climate, implementing time constraints for decision-making, adjusting scoring systems, or incorporating rewards or punishments into tasks. However, it is necessary to continue expanding knowledge about other constraints that can moderate these variables. This proactive management approach benefits both short-term performance and long-term player well-being, making mental fatigue management an essential component of football training.

PERCEIVED FATIGABILITY DURING PHYSICAL TASKS: ELECTROPHYSIOLOGICAL CORRELATES AND INTERVENTIONS

BERCHICCI, M.

UNIVERSITY OF ROME FORO ITALICO

Fatigue is a multidimensional concept combining both neurophysiological and psychological aspects and quantified by objective and subjective measures. Fatigue has received considerable attention, due to its broad impact on both mental and physical performance. Here, the focus is on the brain underpinnings of neuromuscular fatigue and the perception of effort during and after endurance exercise. Indeed, brain changes induced by neuromuscular effort can be recorded with electroencephalography (EEG). The most accredited view is that during muscle fatiguing tasks there is an increase in motor-related potentials and/or a modulation in the alpha frequency band over motor-related regions, working as a compensatory mechanism for peripheral fatigue. However, data from recent studies using high-density EEG and functional magnetic resonance imaging (fMRI) have revealed a modulation that is not limited to motor-related brain regions, but extended to more anterior regions, such as the prefrontal cortex, and involving other frequency band, including theta oscillations. Furthermore, several studies have described EEG changes immediately after exercise, but very few of them have examined EEG during exercise and collected subjective measures of effort and fatigue, such as Borg ratings of perceived effort and fatigue ratings. Accordingly, recording objective and subjective measures of effort, together with brain activities during and after neuromuscular tasks is the only way to obtain a comprehensive view of the processes involved, and to provide the evidence base for countermeasures aimed at tackling fatigue and improving performance. One such approach would be to adopt psychological interventions, like mindfulness. Mindfulness Acceptance and Commitment (MAC) therapy has been proved to be effective in reducing injuries and perception of fatigue, together with increasing emotional regulation, developing greater attention and concentration, improving awareness of the present moment, and accepting/tolerating normal fluctuations in thoughts, emotions and sensations. Taken together, this talk aims to improve understanding of the brain correlates underpinning neuromuscular fatigue and its perception, mechanisms involved during recovery, mindfulness-based programs aimed at reducing fatigue to improve performance and well-being.

PHYSICAL AND COGNITIVE WARMUPS AS MENTAL FATIGUE COUNTERMEASURES

RING, C.

UNIVERSITY OF BIRMINGHAM

It is well established that fatigue can impair sport and exercise performance. In both athletes and exercisers, mental fatigue - a transient state of tiredness and diminished functioning - is caused various situational demands, such as prolonged cognitive activities and sleep loss. For instance, increased mental fatigue in athletes has been associated with the demands of competition, tournaments, technical briefing/debriefing, early morning and late evening training, travel and jet lag. A number of countermeasures have been evaluated and found to mitigate against the deleterious effects of mental fatigue and/or sleep loss on performance. Effective behavioral mental fatigue countermeasures include mindfulness, motivational self-talk, and music. Similarly, effective sleep loss countermeasures include scheduling rest breaks, consuming stimulant drugs, and using neural stimulation devices. To date the effectiveness of warming up activities has not been systematically investigated. Commonly, individuals are encouraged to physically warmup before they start to play sport or exercise. This is because passive and active warmup activities can help improve subsequent sport and exercise performance. For instance, studies show that 15-minutes of physical warmup activities (e.g., jogging, stretching, joint mobility, jumping) improve subsequent exercise (e.g., running, jumping) and sport (e.g., throwing and shooting) performance. A recent study reported that adding a 10-minute cognitive task before a 15-minute physical warmup improved subsequent basketball dribbling more than no and physical warmups. This exciting new finding suggests the possibility that the improved performance may be attributed, at least in part, to the earlier cognitive task, perhaps by the combined warming up tasks cognitively and physically priming them to perform the task. Accordingly, the purposes of this presentation are to (1) review the effectiveness of extant countermeasures against fatigue and sleep loss, and (2) report the findings of our recent studies on the effects of standard physical warmups and combined physical plus cognitive warmups on performance across a broad range of domains (sport, exercise, cognition), ages (young and older adults), and experiences (fit athletes and sedentary non-athletes) under standard sleep (rested) and sleep deprived (fatigued) conditions. These exciting new findings provide the empirical evidence to encourage individuals and trainers to adapt their standard warmup protocols by adding cognitive drills to better prepare players for competition and older adults for workouts, especially following sleep loss.

POSITION-SPECIFIC DIFFERENCES IN FORCE-VELOCITY PROFILE AND CHANGE OF DIRECTION PERFORMANCE: A STUDY ON THE U-21 CZECH FOOTBALL PLAYERS

LIPČÁK, A., KALINA, T., HRUBÝ, M., PALUDO, A.C.

MASARYK UNIVERSITY

INTRODUCTION: Force-velocity profile (FVP) measures an athletes ability to generate force and speed during movements like sprints. In soccer, sprinting and change of direction (COD) are crucial for both attacking and defensive actions. These performance may vary based on player's position (e.g., forwards, defenders and midfielders). This study examines the differences in FVP and COD parameters across different positions in a U-21 soccer players.

METHODS: Fifteen professional male U21 Czech National team soccer players participated, categorized by positions: forwards (n = 5), defenders (n = 5) and midfielders (n = 5). Player performed a 40-meter linear sprint and the COD test using the 1080 Sprint system (1080 Motion AB, Sweden). FVP parameters were assessed using the linear sprint with a 3 kg isotonic resistance, analyzing theoretical maximum force (F0), theoretical maximum velocity (V0), and maximal power output (Pmax). Each player completed three trials, with best attempt used for analysis. COD performance was measured using a modified 15-0-5 protocol, assessing maximal acceleration (MaxAcc) and maximal deceleration (MaxDec). Players performed two trials for each turning direction (right and left leg), with the best attempt analyzed. Position differences were evaluated using the delta percentage ($\Delta\%$) and Cohens d effect.

RESULTS: Midfielders had highest F0 (8.04 ± 0.41 N/kg), which was 5.27% greater than defenders (7.62 ± 0.34 N/kg) with a large effect (Cohen d = 1.13). Forwards presented greatest V0 (9.65 ± 0.40 m·s⁻¹), 3.94% higher than defenders (9.27 ± 0.47 m·s⁻¹) and 4.04% greater than midfielders (9.26 ± 0.27 m·s⁻¹), with a larger effect (Cohen d = 0.86 – 1.15). In the COD test, midfielders exhibited better performance, achieving 8.10% higher MaxAcc (7.63 ± 0.74 m·s⁻²) and 7.39% higher MaxDec (9.42 ± 0.76 m·s⁻²) compared to forwards (MaxAcc = 7.06 ± 0.85 m·s⁻², MaxDec = 8.77 ± 0.60 m·s⁻², respectively), with moderate to large effects (Cohen d = 0.72 - 0.94).

CONCLUSION: This study that U21 Czech soccer players demonstrated position-specific differences in FVP and COD performance. Midfielders demonstrated higher F0, MaxAcc and MaxDec, reflecting the importance of agility and change direction actions for it position. Forwards excelled on V0 supporting their role in making faster dashes behind the defense and exploiting spaces in the offensive phase. These findings may be valuable for developing specific training programs that focus on enhancing the parameters most relevant to each position.

EFFECTS OF WEIGHTED CURVILINEAR SPRINTS ON SPRINT AND JUMP PERFORMANCE IN ELITE YOUTH FEMALE FOOTBALL PLAYERS

SMAJLA, D., GADNIK, K., BRATINA, K., SPUDIC, D., CVJETICANIN, O., SAŠEK, M.
UNIVERSITY OF PRIMORSKA

INTRODUCTION: Curvilinear sprint (CS) performance is crucial in football, as a significant portion of sprints during match play occur along curved paths. Weighted sprints are commonly used to enhance performance in linear sprinting, but their application to CS remains underexplored. The addition of extra weight influences the centripetal force needed to maintain a curved trajectory, potentially affecting performance. This study aimed to assess whether additional weight during curvilinear sprints influences linear and CS performance, as well as jump performance, compared to unweighted CS training.

METHODS: Eighteen female football players (age: 16.3 ± 1.2 years; body mass: 58.1 ± 7.2 kg; height: 167.1 ± 4.6 cm) participated in the study. Over two consecutive days, they performed 30-m LS, left and right unloaded CS (CSL, CSR) and loaded CS (9.15-m radius, 2 maximal repetitions, additional load: 10% of body mass), and jump tests, including squat jumps (SJ), countermovement jumps (CMJ), and drop jumps (DJ). The players were divided into two groups: one group performed CS with additional weight equivalent to 10% of their body mass, while the other group performed CS without additional weight (control group). The 6-week intervention included one session per week, with the control group sprinting 80-160 meters weekly (720 m total) and the weighted group sprinting 72-144 meters weekly (612 m total). Distance, speed, and acceleration were monitored using the GPEXE It system (Exelio SRL, Udine, Italy). Peak speed (Speak), peak acceleration (Apeak), and acceleration-speed (AS) profiles (A0, S0, ASslope) were calculated. Additionally, jump height was calculated for SJ, CMJ, and DJ. A two-way repeated-measures ANOVA was conducted to assess the effects of time (pre- vs. post-intervention) and group (weighted vs. control), as well as the time $\times$ group interaction. Bonferroni post-hoc tests were conducted to identify specific pairwise differences. Partial eta squared (η^2) was calculated to report effect sizes. The significance level was set at $p < 0.05$.

RESULTS: There were significant main effects of time for CSR Speak ($F = 26.8$, $p = 0.0013$, $\eta^2 = 0.42$) and CSR S0 ($F = 10.2$, $p = 0.0152$, $\eta^2 = 0.22$), while no significant results were observed for any other variables (all $F < 5.2$, all $p > 0.057$). Bonferroni post-hoc tests revealed significant improvements in CSR Speak for both groups, while no significant differences within groups were observed for CSR S0. However, the weighted group demonstrated a trend toward better intervention effects for CSR S0.

CONCLUSION: Our results suggest that the 6-week intervention with limited training volume primarily improved CSR, the players weaker side in curvilinear sprinting, regardless of the group. Improvements observed in both groups indicate that a 10% body mass load may not provide sufficient stimulus to significantly enhance centripetal force during curvilinear sprints. A greater training volume or higher load might be required to elicit more substantial adaptations.

POWER PERFORMANCE DURING COUNTERMOVEMENT JUMP TEST IN TOP-CLASS ADULT AND YOUNG FOOTBALL PLAYERS

RIBOLI, A., TRAPLETTI, M., ESPOSITO, F., TRECROCI, A., MAZZONI, S.
A.C. MILAN S.P.A.

INTRODUCTION: In top-class football, lower-limb power, along with the ability to effectively utilize the stretch-shortening cycle, plays a fundamental role in profiling physical performance among both adult and young players (1). The Countermovement Jump test (CMJ) have been widely used to assess lower-limb power, with relative take-off power ($W_{take-off}$) being a critical variable (2). Despite CMJ is globally used as a gold-standard assessment across various levels of competition and age-categories, a clear understanding of the neuromuscular capacities of high-level adult and young football players remains limited. Therefore, the current study aims to evaluate the differences in the relative $W_{take-off}$ during CMJ across different age-categories and during pre-season vs in-season periods in each category.

METHODS: One hundred and thirty-one elite football players across different age categories of an Italian Serie A club were divided into the following categories: U14 ($n=27$), U15 ($n=22$), U16 ($n=24$), U17 ($n=24$), U18 ($n=13$) and PRO ($n=21$). Data were collected during pre-season (July/August 2023) and in-season period (October to March 2024). Each participant performed three maximal CMJ on force plates (ForceDecks, VALD, Brisbane, Australia) with a complete recovery between each repetition. For each participant, the CMJ with the higher relative $W_{take-off}$ ($W_{take-off}/kg$) was considered for the analysis. A paired t test was used for the pre-season vs in-season comparison and a one-way ANOVA for repeated measures was utilised to determine the between age-categories difference. The magnitude of the differences was assessed using Cohen's d effect size with 95% confidence intervals [95% CI].

RESULTS: The Figure 1 shows the relative $W_{take-off}$ in the CMJ during the in-season period for each age-category. For between-age comparisons the $W_{take-off}$ were higher in PRO ($d = 0.79$ to 1.98) compared to U14 ($P < 0.001$), U15 ($P < 0.001$), U16 ($P < 0.001$), U17 ($P = 0.031$), U18 ($P = 0.017$). Additionally, U14 and U15 showed lower ($P < 0.05$; $d = -0.86$ to -1.31) $W_{take-off}$ than other age-categories. As shown in Figure 2, $W_{take-off}$ during the in-season period was higher ($P = 0.015$) compared to the pre-season, but only for PRO ($d = -0.58$ [-1.03 to -0.11]). No differences were found in pre-season vs in-season for other age-categories.

CONCLUSION: The $W_{take-off}$ during CMJ was higher in PRO compared to younger players (U14 to U18). As expected, U14 and U15 showed lower $W_{take-off}$ compared to older age-categories, highlighting reduced neuromuscular capacities in younger players. Coaches and football scientists may use these findings to guide neuromuscular performance development in youth elite football. PRO values could serve as benchmarks for power capacity in top-class football. Additionally,

tracking the changes in Wtake-off over the season may help to optimize strength and power training, potentially accelerating individual development and facilitating the transition between youth to PRO football.

Invited Symposium

IS-PN04 Digital health exercise interventions for primary and secondary cardiovascular disease prevention: innovations from 3 European countries

DEVICE-MEASURED AND MOBILE PHONE-ASSISTED SEDENTARY BEHAVIOR REDUCTION IN PATIENTS WITH METABOLIC SYNDROME: A 6-MONTH RANDOMIZED CONTROL TRIAL

HEINONEN, I.

TURKU PET CENTRE & UNIV. OF TURKU

Epidemiological and big data studies show physical activity and sitting are associated health benefits and detriments respectively. Most physical activity studies that have employed device-measured objective have almost solely relied on measurement durations of 4-7 days and 10-hour daily measurement time, even in intervention studies. Consequently, intervention studies to address the role of sitting and physical activity are needed, which also measure all stationary periods and movements 24/7 for the whole study period. This talk will present such an intervention employed in Finland, which aimed to reduce daily sitting by one hour per day for 6-months in a randomized controlled setting in patients with metabolic syndrome. This talk will outline how all daily (in)activity was measured by accelerometers (6-second intervals) at baseline and during 6-month study period in both control and intervention groups. Participants followed their daily activity online from mobile phone application (EXSED), which also directly updated their data into the cloud, from which data was also accessed and analyzed. This talk will present the findings of how the intervention induced the requested behavior change and how the applied approach also led the control group increasing their daily steps over 6-month period. The talk will also cover numerous clinical and physiological effects that were measured by imaging (positron emission tomography and magnetic resonance imaging) in different tissues, such as skeletal muscle, heart, liver, bone, kidney and adipose tissue and other methods, such as fitness, blood pressure and cardiac echocardiography and insulin sensitivity at the whole-body level.

MOBILE HEALTH BIOMETRICS TO PRESCRIBE EXERCISE AND PHYSICAL ACTIVITY TO ENHANCE ADHERENCE AND CLINICAL OUTCOMES (MOTIVATE): IN PATIENTS CARDIOVASCULAR DISEASE

JONES, H.

LIVERPOOL JOHN MOORES UNIVERSITY

Encouraging a physically active lifestyle through regular exercise (purposeful structured activities with a goal of improving health and fitness) and lifestyle physical activity (activities performed in day-to-day life) is the cornerstone to management of cardiovascular risk factors and diseases. Given poor uptake and adherence to current strategies (e.g. in UK exercise based cardiac rehabilitation uptake 52%) innovative solutions are urgently needed. This talk will outline the innovative MOTIVATE digital health intervention solution and present data from suite of randomised control studies on patients with cardiovascular disease including those referred to cardiac rehabilitation in the UK. MOTIVATE is a home-based exercise counselling intervention supported by mobile health (mHealth) technologies that provide biometric feedback and data sharing to best support patients and health professionals. Together the elements provide comprehensive support by promoting lifestyle PA and specifically targeting personally-calibrated moderate-to-vigorous intensity purposeful exercise. This talk will present data to show improvements in exercise adherence and compliance in a number of different healthy and clinical populations (e.g. patients with coronary artery disease) which are superior to control interventions without mHealth technology. Moreover, the talk will show data on improvements in relevant clinical outcomes including BP, cholesterol, HbA1c and body composition.

SIT LESS, STEP MORE: HOME-BASED MODULES TO PROMOTE PHYSICAL ACTIVITY IN DAILY LIVING TO IMPROVE CLINICAL OUTCOMES IN PATIENTS CARDIOVASCULAR DISEASE. TRIALCHD, AF AND HF

THIJSEN, D.

RADBOD UNIVERSITY NIJMEGEN MEDICAL CENTRE

Over the past decade, exercise-based cardiac rehabilitation (ExCR) is gradually moving from a hospital-based environment towards a home-based, where digital innovations are adopted to integrate a healthy lifestyle in the patient's home environment. In this talk, we discuss novel insights pertaining to the effects of ExCR and highlight innovations regarding the translation of ExCR to the home environment. First, we will discuss recent observations from the CaReMATCH Individual Patient Data meta-analysis, that includes data from 8 RCTs (n=4,987) on the effects of ExCR in patients with coronary heart disease. Using a mediation analysis, we revealed an important role for the improvement in health-related quality of life, but not cardiorespiratory fitness, in explaining the lower risk for all-cause and cardiovascular-related hospitalization. These observations support that promoting (low- to moderate-intensity) physical activity in daily living has strong clinical potential. Second, we performed a series of studies to co-create and validate a tri-axial activity monitor to sedentary be-

haviour, and to reduce and break up prolonged sitting periods in patients with cardio- and cardiometabolic disease. Third, we will share insight into the potential clinical relevance and importance of step count as a simple measure to integrate into clinical practice. In this work, we examine how increasing the step count can lead to clinically meaningful effects for patients with atrial fibrillation, coronary heart disease, and heart failure.

OP-AP16 Training and Testing IV - Power and Strength: Sport-specific aspects

KNEE EXTENSION STRENGTH IS AN IMPORTANT FACTOR FOR BADMINTON-SPECIFIC AGILITY EVEN AMONG ELITE PLAYERS

NAKASHIMA, H., ANDO, R., KAMEDA, M., TAMAI, S., IIZUKA, T., HOSHIKAWA, Y., NAKAMURA, M.
JAPAN INSTITUTE OF SPORTS SCIENCES

INTRODUCTION: Badminton is a fast-paced racket sport that hits a shuttlecock in rallies approximately once per second (Iizuka et al. 2020). Thus, agility is required to gain an advantage in matches. Agility in badminton is characterized by frequent lunges (badminton-specific agility). Although previous study conducted a custom-made badminton-specific agility test and showed that players at a higher competitive level tend to have greater badminton-specific agility (Ando et al. 2024), the factors influencing badminton-specific agility in each leg remain unknown. This study examined the relationship between leg muscle strength and badminton-specific agility in elite players.

METHODS: Twenty-seven male and twenty-three female world class or elite/international level badminton players completed the following tests: (1) the badminton-specific agility test (Ando et al. 2024), which measures the time taken to reach sensors placed at the four corners of a badminton singles court using badminton-specific movements including lunges; and (2) the isokinetic knee extension strength test at angular velocities of 60°/s and 180°/s. Spearman's test was used to assess the relationships between them. The significance level was set at $p < 0.05$.

RESULTS: Significant inverse correlations were found between the knee extension torque per body mass for the non-dominant leg (non-racket hand side) both at 60°/s and 180°/s and reach time of badminton-specific agility (males at 60°/s: $r_s = -.619$; males at 180°/s: $r_s = -.579$; females at 60°/s: $r_s = -.445$; females at 180°/s: $r_s = -.446$), whereas only at 60°/s was inversely correlated for the dominant leg (males: $r_s = -.413$; females: $r_s = -.490$).

DISCUSSION:

One of the main roles of the non-dominant leg during lunges in badminton is to accelerate the body. Thus, it was speculated that higher knee extension strength contributed to increased lunge speed and subsequently enhanced badminton-specific agility. On the other hand, the dominant leg plays a role in returning to its original position after a shot with a lunge. The foot contact time of the dominant leg during lunge is approximately 0.7s (Lam et al. 2017) and is considered to be longer than that of the non-dominant leg. Taken these facts and this study's result together, knee extension strength of the dominant leg in the low-speed range, which is closer to the actual movement speed, is considered to be important.

CONCLUSION: The most notable finding of this study is that knee extension strength is crucial for badminton-specific agility even in world class and elite/international level players. Additionally, the results suggest that there is a different demand for force production between the dominant and non-dominant legs. Training the knee extensor muscles at an appropriate speed corresponding to lunge movements may enhance badminton-specific agility.

THE EFFECTS OF A CERVICAL STRENGTH TRAINING INTERVENTIONS ON ISOMETRIC NECK STRENGTH IN FEMALE RUGBY UNION ATHLETES.

RORY, K., DRAPER, S., DRURY, B., MACK, R., MCBRIDE, L.
HARTPUR UNIVERSITY

INTRODUCTION: Rugby union (RU) athletes are at risk of concussion due to the contact nature of the sport. There are biological differences between females and males, however there is a lack of evidence on female RU athletes. Female athletes are more susceptible to sport-related concussions (SRCs) and experience worse outcomes than male athletes (McGroarty, et al., 2020). Neck training modalities can provide greater protection in men's sport (Daly, et al., 2021), but there is a paucity of research exploring neck training in female rugby. The purpose of this study was to assess the changes in neck strength between three different 8-week isometric neck strength protocols in female Rugby Union players.

METHODS: Participants were matched random assigned based of the sum of the individuals total preintervention neck strength (flexion (F), extension (E), left-side flexion (LSF), and right-side flexion (RSF)) to either a Hypertrophy Training (HST) group, Maximal Strength Training (MST) group or World Rugby injury prevention (WRIP) group.

Thirty-nine participants with 10 Premiership Women's Rugby (PWR) player and 29 UK collegiate rugby athletes undertook the interventions. Three sets per week were performed in addition to their usual strength and conditioning program. The WRIP (N=15) followed a self-directed manual contraction in F, E, LSF, RSF, left rotation, and right rotation, each direction for 15s at a perceived maximal intensity. The MST (N=12) and HST (N=12) intervention group attached a dynamometer to a head harness and perform isometric cervical contractions prescribed load intensities.

RESULTS: Pre and post measures of neck strength for F, E, LSF and RSF was measured using a fixed-frame dynamometer (ForceFrame, VALD, Newstead, Australia).

HST had the greatest total increase of 99.6N (+13.18%), compared to 59.1N (+7.60%) in the MST and a -2.1N (-0.32%) decrease in the WRIP training group. HST had increased strength in all four directions. (F = 18.8N (+9.47%), E = 22.4N (+10.43%), LSF = 35.9N (+22.04%), RSF = 22.5 (+12.53%). Similarly, MST showed increase strength of 0.60% in F, 3.43% in E, 17.82% in LSF and 11.26% RSF. However, WRIP showed a 0.60% decrease in flexion and a 4.72% decrease in extension following the 8-week program. However, WRIP did increase in LSF and RSF of 1.26% and 4.44% respectively.

CONCLUSION: HST and MST increased neck strength compared to a self-directed resource-efficient neck-strengthening program (WRIP). Subsequently, the HST and MST programmes may be appropriate across a range of trained female RU players to reduce neck injuries such as SRCs. Practitioners working with female RU players should therefore consider using dynamometers to train the neck musculature in individualised intensities.

*Please note, data collection was completed on the 10th February 2025. Therefore, full statistical analysis will be completed prior to July 2025.

ASSOCIATIONS OF MAXIMAL STRENGTH AND PEAK POWER WITH ROWING PERFORMANCE IN NATIONALLY AND INTERNATIONALLY COMPETING GERMAN ROWING ATHLETES

JACOBS, M., SCHUMANN, M.

UNIVERSITY OF TECHNOLOGY CHEMNITZ

INTRODUCTION: In addition to a high aerobic capacity, rowing is also characterized by high demands on strength abilities. While previous studies reported associations between rowing performance and various maximal strength indices of the main muscle groups (leg muscle, back muscle) involved in the rowing stroke, little is known about the association with peak power (PP). Therefore, this study aimed to investigate associations of PP with 2000m rowing ergometer performance (TT) in well-trained rowing athletes of different age groups.

METHODS: 63 male (age: 18.52±3.34 years, body height: 190±6.84 cm, body mass: 86.33±8.04 kg) and 50 female (age: 19.30±3.50, body height: 176.94±5.41 cm, body mass: 73.64±7.75 kg) nationally and internationally competing athletes of the U17 (20 male, 10 female), U19 (21 male, 14 female), U23 (9 male, 20 female) and Elite (13 male, 6 female) category participated in this study. PP was assessed through the individual load velocity profiling (LVP) by an incremental 1 repetition maximum test (1RM) using a linear velocity transducer (Gymaware). LVP covered the main muscle groups deemed important for rowing performance through the following exercises: Squat (S), Deadlift (DL) and Bench pull (BP). Additionally, TT was assessed on a Concept 2 rowing ergometer within 2 weeks of the LVP. Generalized linear models were calculated separately for both sexes to assess associations between TT and the 1RM as well as PP of the 3 exercises. To adjust for potential biological heterogeneity within the sexes, the body mass index (BMI) was used as a covariate.

RESULTS: Significant associations were found for TT and S 1RM (β : -0.38; β : -0.96), DL 1RM (β : -0.35; β : -0.72) and BP 1RM (β : -0.88; β : -1.77) in male and female athletes, respectively (all $p \leq 0.001$). These significant associations were not affected when adding the BMI as a covariate. Similarly, significant associations were found for PP S (β : -0.05; β : -0.12), PP DL (β : -0.05; β : -0.16) and PP BP (β : -0.11; β : -0.21) in male and female athletes, respectively (all $p \leq 0.001$). However, after adding the BMI to the model only the PP of DL and BP but not S remained significantly associated with TT.

CONCLUSION: We showed that the 1RM of all 3 exercises and PP of DL and BP were significantly associated with TT in both male and female athletes, even when adjusting for the BMI. Our data indicate that in addition to the rather slow 1RM, also PP and, therefore, the ability to generate high movement velocities (MV) might affect TT. Especially the association with BP PP may highlight the importance of PP in specific parts of the rowing stroke, such as the explosive finish phase where the back muscles generate most of the power. Thus, further studies should focus on the associations of PP and MV with different phases of the rowing stroke. In addition, since these cross-sectional findings might be influenced by the athlete's strength training experience the effect of PP and MV on TT should be further investigated in interventional studies.

THE IMPACT OF WEEKLY TRAINING VOLUME ON NEUROMUSCULAR PERFORMANCE IN NCAA DIVISION I FEMALE ROWERS

DELEO, J., ESERHAUT, D., PROVOST, J., ACKERMAN, K., FRY, A.

UNIVERSITY OF KANSAS

INTRODUCTION: Countermovement jump (CMJ) derived neuromuscular performance characteristics may be sensitive proxies of fatigue throughout competitive basketball seasons, with select metrics displaying dose-dependent changes

with measures of external workload (1). Few data exist on whether similar dose-response relationships exist between weekly training volumes and alterations in select CMJ metrics in the sport of rowing. The purpose of this study was to retrospectively analyze weekly training volume (minutes) with weekly CMJ data throughout a competitive rowing season to determine if select CMJ metrics are sensitive to changes in weekly training volumes.

METHODS: Twenty-nine NCAA Division I female rowers (median $\pm$ IQR: age=20 $\pm$ 1 years, Height: 69 $\pm$ 3 inches, Weight 170 $\pm$ 48 pounds) performed three weekly CMJs on dual unidimensional (Hawkin Dynamics) force plates at the beginning of their strength and conditioning session. Data was collected throughout the spring competitive season (January 4, 2024 – April 30, 2024). Linear mixed-effects models with restricted maximum likelihood were used with athlete identity intercept as the random factor, weekly training volume as the independent variable or fixed-factor, and the following CMJ variables as individual dependent variables: countermovement depth, peak propulsive force, positive net impulse, braking rate of force development, average propulsive force, peak propulsive force, braking net impulse, and propulsive net impulse. Statistical significance was set a priori at $p < 0.05$.

RESULTS: All CMJ metrics displayed significant changes in response to weekly training volume alterations throughout the 2024 spring rowing season ($p < 0.01$). Braking RFD was the most sensitive to changes in training volume ($p < 0.001$), with a one standard deviation change in training volume resulting in a 218N·s⁻¹ decrease in braking RFD. Further, the effect of increased training volume was largest on braking net impulse (estimate: -3.33) compared to propulsive net impulse (estimate: -1.62). Countermovement depth was the only metric to display a significant positive effect in response to increases in training volume (estimate: 0.13).

CONCLUSION: Kinetic metrics from the CMJ braking phase may be the primary variables of interest when monitoring potential volume-induced alterations in neuromuscular performance in collegiate female rowers. Braking RFD appears to be the most sensitive to increases in weekly training volume in terms of absolute change in the rate at which female rowers generate force during the CMJ braking phase, with athletes displaying a shallower countermovement depth in response to greater training volumes, which aligns with findings in other sports such as basketball (1).

RELATIONSHIPS OF SPRINT PERFORMANCE AT DIFFERENT PHASES WITH HIP FLEXION AND KNEE EXTENSION STRENGTH

NAOYA, N., MAEO, S.1, KINOSHITA, M.1, ICHINOSE, H.1, EIHARA, Y.1, KOBAYASHI, Y.1, ARAI, H.1, TOYODA, H.1, FOLLAND, J.P.2, KANEHISA, H.3, ISAKA, T.1

1. RITSUMEIKAN UNIVERSITY, 2. LOUGHBOROUGH UNIVERSITY, 3. NATIONAL INSTITUTE OF FITNESS & SPORTS IN KANOYA

INTRODUCTION: Sprint performance is related to the strength of lower-limb muscles such as the hip extensors, hip flexors and knee extensors (Dowson et al., 1998). Using a treadmill, Willer et al. (2024) found that the contributions of the hip extensors and flexors to the total work rose with running velocity, while that of the knee extensors declined. In addition, we (Kobayashi et al., 2023) found that hip extension strength is correlated with sprint performance more strongly for the late (> 40 m, maximum velocity) than the early (< 20 m, acceleration) phase of sprinting. However, little is known about how hip flexion (HF) and knee extension (KE) strength are related to different phases of sprinting. This study tested a hypothesis that KE and HF strength are most strongly associated with different phases of sprinting; early and late phases of sprinting, respectively.

METHODS: Twenty-nine healthy young adults (17 males and 12 females, non-obese [BMI: 18-25], low-moderate recreational physical activity) participated. The mean velocity of the start (0-10 m), acceleration (10-20 m) and maximum velocity (30-40 m) phases were measured with a laser system during 60-m sprint running. One-repetition maximum (1RM) HF and KE lifting strength of both legs was assessed unilaterally. Partial correlations of sprint performance variables with HF or KE strength were calculated for the whole cohort, controlling for sex. Correlation coefficients between sprint performance variables and strength measures were then compared 1) among the phases within HF or KE 1RM, and 2) between HF and KE 1RM at each phase, by William's t-test.

RESULTS: Absolute and relative (to body mass) HF 1RM were both weak-moderately correlated with the velocity of the start ($r = 0.649$ and 0.485), acceleration ($r = 0.683$ and 0.643) and maximum velocity ($r = 0.683$ and 0.650) phases ($p \leq 0.009$). Absolute KE 1RM was weakly correlated with the velocity of the start ($r = 0.417$) and acceleration ($r = 0.393$) phases ($p \leq 0.038$) but not with the maximum velocity phase ($r = 0.347$, $p = 0.071$). Relative KE 1RM was weakly correlated with the velocity of the acceleration ($r = 0.464$) and maximum velocity ($r = 0.422$) phases ($p \leq 0.025$) but not with the start phase ($r = 0.357$, $p = 0.062$). There were no significant differences in the correlation coefficients (r values) between the running velocity and HF or KE 1RM among the phases for both absolute and relative 1RM ($p \geq 0.150$). The coefficients of absolute 1RM with running velocity were significantly stronger for HF than KE 1RM for the acceleration and maximum velocity phases ($p \leq 0.035$) but not for the start phase ($p = 0.098$), with no significant differences between HF and KE 1RM in relative 1RM ($p \geq 0.175$).

CONCLUSION: These results suggest that HF and KE strength are both associated with sprint performance similarly among the phases but more strongly for HF than KE strength.

OP-BM17 Running III

MUSCLE-SPECIFIC CONTRIBUTIONS OF FORCE AND FORCE-ABILITY TO THE METABOLIC COST OF WALKING AND RUNNING.

LEMINEUR, C., BLAIN, G.M., GERUS, P.

UNIVERSITY OF CÔTE D'AZUR

INTRODUCTION: During locomotion, running is generally more metabolically costly than walking at similar speed [1]. The metabolic cost (Mc) is primarily determined by the ATP required to produce force [2]. Mc is thus modulated by a muscles ability to produce force in response to muscle activation (fability), as well as the velocity of contraction and muscle length [3]. However, the interplay between these mechanisms to explain why walking is a more economical mode of locomotion than running remains unclear. The aim of this study was to determine how different lower limb muscle recruitment and fability, during walking and running determine differences in Mc.

METHODS: Eleven endurance runners (60.5 ± 7.1 kg; 169.0 ± 6.6 cm; 23.6 ± 3.3 y) performed two 6-minutes walking and running trials on a motorized instrumented treadmill (Bertec) at a constant speed of 1.75 m/s. The kinematics were recorded with nine optoelectronic cameras. Electromyography (EMG) data from eight knee and ankle muscles, kinetics and kinematics were integrated into an EMG-driven model proceeding by inverse dynamics to estimate locomotor muscle fability and force. Mc was estimated by indirect calorimetry from the expired gas. Comparisons between walking and running were made for Mc, and integral and maximal values of force and fability during the locomotion cycle using parametric statistical mapping.

RESULTS: The Mc of running was 34% higher than walking ($d = 3.0$). The rectus femoris, vastus medialis, vastus intermedius and vastus lateralis produced more force during propulsion during running than during walking, despite similar fability. The soleus, during propulsion, and the tibialis anterior, during braking, produced more force during walking, however, these forces were produced with a greater fability integral (i.e. contraction generating more force but under more economical conditions). Positive correlations were found between Mc and the force integral of the tibialis anterior ($r = 0.72$, $p = 0.005$) for walking, and negative correlations between Mc and the fability integral of the vastus lateralis ($r = -0.52$, $p = 0.049$) and vastus intermedius ($r = -0.56$, $p = 0.036$) for running.

CONCLUSION: The greater force produced by the knee extensors, particularly during braking and propulsion, where producing force is costly, contribute to the greater Mc during running, compared to walking. The greater force of the tibialis anterior and soleus during walking does not increase the Mc of this mode of locomotion, as it is produced economically. Transposing force production patterns of walking, which appears energetically efficient, with those of running may offer a strategy to reduce Mc and enhance running performance.

METABOLIC COST AND LOWER LIMB MUSCLES ACTIVITY IN RUNNING WITH HEAD- AND TAILWIND DRAG

LUCIANO, F., MESQUITA, R.M.2, CATAVITELLO, G.2,3, DEWOLF, A.H.2, NATALUCCI, V.1, WILLEMS, P.A.2, MINETTI, A.E.1, PAVEI, G.1

1 UNIVERSITY OF MILAN, ITALY; 2 UNIVERSITÉ CATHOLIQUE DE LOUVAIN, BELGIUM; 3 ENOVALIFE MEDICAL COMMUNICATION SERVICE CENTER, BRUSSELS, BELGIUM

INTRODUCTION: Wind drag impacts how athletes run and how much energy they spend to do it. With headwind, runners increase their positive center of mass work and reduce frontal area, while they increase negative work with tailwind [1]. However, it is unclear how these adjustments affect the metabolic cost of running and the activity of individual muscles. Understanding it would shed light on how humans adapt their locomotion to external forces, how well treadmill experiments can be generalized to outdoor conditions, and how much air drag impacts athletes' performance. This study investigated how wind-induced drag affects the metabolic cost and the activity of lower limb muscles during running.

METHODS: Eight male endurance athletes (age: 32 ± 6 y, mass: 63.2 ± 6.6 kg; height: 1.77 ± 0.05 m, personal best 10000 m: $31:20 \pm 01:12$ min:s) ran at 4.0 m/s on an instrumented treadmill in a wind tunnel, where tail- and headwind speeds ranged from 0 to 12.5 m/s. Metabolic cost, in J/(kg m), was measured via gas exchange analysis. Electromyographic activity (Delsys, 1kHz) was recorded unilaterally from erector spinae, gluteus maximus, gluteus medius, vastus lateralis, vastus medialis, rectus femoris, sartorius, tensor fasciae latae, adductor longus, biceps femoris, semitendinosus, gastrocnemius lateralis, gastrocnemius medialis, peroneus longus, and tibialis anterior; the average activity per unit distance was then computed [2]. Drag force was calculated as the average horizontal ground reaction force over an integral num-

ber of strides (1). Mixed effects models regressed metabolic cost and muscle activities against drag force; for each muscle, linear and quadratic models were compared, and the model with the lowest Akaike Information Criterion was chosen.

RESULTS: Drag forces ranged from -58 to 53 N, where negative and positive signs indicate tailwind and headwind, respectively. Over such a range, metabolic cost increased linearly with headwind drag and decreased linearly with tailwind drag ($\text{cost} = 4.0 + 0.04 \cdot \text{drag force}$, conditional R-squared = 0.90). Increasing headwind drag significantly increased the activity of gluteus maximus and gastrocnemius lateralis ($p < 0.001$) while reducing that of gluteus medius ($p < 0.001$); the reverse trends were observed for tailwind. Biceps femoris and peroneus longus activity showed a U-shaped response, their activity being lowest at zero drag and increasing with both head- and tailwind ($p < 0.001$). The remaining muscles were not significantly affected by wind.

CONCLUSION: Metabolic cost increases linearly with headwind drag and decreases linearly with tailwind drag, while lower limb muscles show heterogeneous activation patterns in response to wind. These muscle-specific variations are independent of metabolic cost and may optimize posture, frontal area, or force and work production across wind conditions.

ACUTE BIOMECHANICAL RESPONSES TO LOWER-BODY POSITIVE PRESSURE TREADMILL UNLOADING IN COMPETITIVE RUNNERS

FOHRMANN, D., WINTER, I., SIMON, A., DALOS, D., GRONWALD, T., HOENIG, T., ROLVIEN, T., HOLLANDER, K.
MSH MEDICAL SCHOOL HAMBURG

INTRODUCTION: Lower-Body Positive Pressure Treadmills (LBPTT) enable fine-grained control over the external load during running. These devices provide body weight support (BWS) through an overpressure in a chamber surrounding the athletes and running surfaces. Previous research on the effects of BWS on running biomechanics revealed changes in spatiotemporal (1) and kinematic variables (2). However, most studies neither provided sex-specific analyses nor included non-linear running stability, a measure for locomotor control capabilities. Biomechanics and running injury epidemiology differ between sexes (3, 4). Hence, this work aimed to investigate how BWS affects running biomechanics in male and female athletes.

METHODS: Twenty-six competitive distance runners (15 female, age: 33.6 ± 9.8 years, BMI: 21.6 ± 2.4 kg·m⁻²) completed one running session on an LBPTT (AlterG 500 Pro). Following a familiarisation period, the experimental protocol consisted of nine running bouts at randomly ordered unloading stages of 0 – 80% BWS in steps of 10%. Each bout lasted three minutes at 12 km/h with no rest in between. We measured plantar pressure with two pressure-sensing insoles (200Hz, loadsol, novel) as well as acceleration and angular velocity at the right foot and right tibia using inertial measurement units (500Hz, ICM-20601, TDK InvenSens). We calculated stance time, swing time, normalized ground contact time, and maximum plantar force during stance from the insole data. From the inertial sensor data, we calculated peak tibial acceleration and running stability as the largest short-term finite-time divergence exponent λ_s (5). Linear mixed-effects models were used to investigate the effects of BWS, sex, and their interaction on all biomechanical variables.

RESULTS: All variables were significantly affected by increasing BWS with the largest effects for reduced maximum plantar force ($\beta = -0.81$ [-0.86 to -0.76], $p < 0.001$), increased swing time ($\beta = 0.74$ [0.67 to 0.82], $p < 0.001$), and decreased normalized ground contact time ($\beta = -0.61$ [-0.66 to -0.56], $p < 0.001$). Running stability decreased at the tibia ($\beta = 0.10$ [0.02 to 0.17], $p = 0.009$) but increased at the foot ($\beta = -0.12$ [-0.22 to -0.02], $p = 0.017$). There were no significant BWS*sex interaction effects among the variables under investigation.

CONCLUSION: Our results confirm previous studies showing reduced external load metrics and changes in spatiotemporal running patterns with increasing BWS. Running stability was also affected by BWS but the small effect sizes question its practical relevance. We showed that despite overall differences between male and female runners' technique, both sexes respond similarly to BWS. These are important findings especially for practitioners when planning return-to-sport programs with an LBPTT available.

THE ROLE OF NEUROMUSCULAR ACTIVATION IN LOWER-LIMB STIFFNESS AND GROUND REACTION FORCE FOR RECREATIONAL RUNNERS

CHEN, S., TAN, X., LI, F.

SHANGHAI UNIVERSITY OF SPORT

INTRODUCTION: Lower-limb stiffness and ground reaction forces (GRF) are critical biomechanical factors influencing neuromuscular activation during running. While spring-mass (leg/vertical stiffness) and torsional spring (joint stiffness) models have been proposed to optimize energy efficiency and elastic energy storage in muscle-tendon units, their neuromuscular implications remain underexplored in recreational runners. This study investigates the relationship between lower-limb stiffness, GRF characteristics, and muscle activation patterns in this population.

METHODS: Twenty-nine male recreational runners performed a 4-minute constant-speed running set at 12 km/h. Eight infrared cameras, a three-dimensional motion capture system, and a 3D force platform were used to collect lower-limb stiffness and GRF data. Surface electromyography (sEMG) signals were obtained from nine lower-limb muscles on the right leg: gluteus maximus, rectus femoris, vastus lateralis, vastus medialis, biceps femoris, tibialis anterior, gastrocnemius lateralis, gastrocnemius medialis, and soleus using a wireless sEMG system. Correlations between lower-limb stiffness, GRF, and muscle root-mean-square (RMS) were investigated using Pearson Product Moment correlations.

RESULTS: Results revealed moderate correlations between lower peak impact force and greater gluteus maximus peak RMS ($r = -0.389$, $p < 0.05$). Lower peak active force was moderately correlated with greater gluteus maximus RMS at foot-strike ($r = -0.385$, $p < 0.05$) and larger tibialis anterior peak RMS ($r = -0.431$, $p < 0.05$). Lower peak propulsion force was moderately correlated with greater vastus lateralis RMS at foot-strike ($r = -0.445$, $p < 0.05$). Lower peak braking force was moderately correlated with greater tibialis anterior RMS at foot-strike ($r = 0.369$, $p < 0.05$). Smaller knee stiffness was moderate to largely correlated with smaller soleus and tibialis anterior RMS at foot-strike and lower soleus peak RMS ($r = 0.388-0.504$, $p < 0.05$).

CONCLUSION: This study demonstrates that biomechanical variables (lower-limb stiffness, GRF) are associated with neuromuscular strategies in recreational runners. Gluteus maximus activation was inversely associated with impact and active forces, whereas tibialis anterior activation correlated with reduced active/braking forces, and vastus lateralis activation at foot-strike attenuated propulsion forces. Reduced knee stiffness significantly correlates with diminished soleus and tibialis anterior activation, suggesting distal muscle co-activation regulates joint rigidity. These findings imply that targeted modulation of vertical/horizontal forces and knee stiffness could optimize neuromuscular control, informing injury-prevention training paradigms.

GROUND CONTACT TIME AT CPET PREDICTS 3K TIME TRIAL PERFORMANCE IN TRAINED RUNNERS

PELED, D., MARKUS, I., ALTMAN, A., GEPNER, Y.

TEL AVIV UNIVERSITY

INTRODUCTION: The relationship between biomechanical efficiency and endurance performance is an important area of research that can influence athletes performance during training and racing. This study aimed to evaluate whether biomechanical parameters measured during a cardiopulmonary exercise test (CPET) can predict performance in a 3K time trial run.

METHODS: A sample of 45 trained male runners (age 23.3 ± 1.7) completed 3K time trial run followed by CPET, with minimum of 24 hours between tests. During the CPET cadence, ground contact time (GCT), and vertical oscillation were recorded using a Garmin watch (Forerunner® 255). Biomechanics parameters were analyzed over the entire run stages of the CPET and also over the final minute. Runners were stratified into tertiles based on each parameter. ANOVA test was used to compare 3K time trial performance across tertiles followed by post hoc analysis in cases of significant difference.

RESULTS: Trained runners with shortest GCT demonstrated significantly faster 3K time trial performance compared to those with longest GCT in the last minute of the CPET. The shortest GCT group outperformed the longest GCT group by an average of 31.5 seconds (95% CI: 3.92–59.0, $p=0.02$). No significant differences were observed between the shortest and intermediate GCT groups ($p = 0.071$) or between the intermediate and longest GCT groups ($p = 1$). No differences in 3k time trial were noted for both vertical oscillation and cadence.

CONCLUSION: GCT during the final minute of a CPET might predict 3K time trial performance, suggesting its potential as a marker for fatigue resilience and biomechanical efficiency under maximal effort.

OP-BM05 Muscle Tendon Function

MUSCLE-TENDON BEHAVIOUR DURING WALKING IN PEOPLE WITH TYPE 2 DIABETES AND HEALTHY CONTROLS

MONTE, A., MAGRIS, R., NARDELLO, F., VIGOLO, N., NEGRI, C., MOGHETTI, P., ZAMPARO, P.

UNIVERSITY OF VERONA

INTRODUCTION: Hyperglycemia in Type 2 diabetes (T2D) leads to an increase in non-enzymatic glycation products (e.g., glycated hemoglobin: HbA1c) that accumulate irreversibly, damaging musculoskeletal tissues. Couppé et al. [1] found that Achilles tendon stiffness is higher in diabetic patients, potentially altering gait and increasing the metabolic energy cost of locomotion (Cnet). The present study used ultrasound, kinematic, and metabolic measurements during walking to test the hypothesis that higher HbA1c in T2D affects muscle and tendon behavior, with increased energy expenditure.

METHODS: Twenty-three well compensated T2D patients (age 62 ± 5 years; weight 79 ± 12 kg; height 1.73 ± 0.09 m; HbA1c: 55 ± 9 mmol/mol; IPAQ 1596 ± 432 MET/week) and 14 healthy matched controls (64 ± 5 years; 73 ± 12 kg; 1.73 ± 0.09 m; HbA1c: 36 ± 3 mmol/mol; IPAQ 14896 ± 532 MET/week) walked on a treadmill at 4 km/h for 5 minutes. Kinematic and metabolic data were collected using a 3D motion capture system and breath-by-breath metabolimeter. Ultrasound images of the gastrocnemius medialis were recorded. Stride length (SL), stride frequency (SF), contact time (CT), and swing time (ST) were obtained from kinematic analysis. Cnet was calculated as net oxygen uptake per walking speed. Fascicle length was measured via ultrasound, and series-elastic element (SEE) length was estimated. An unpaired SPM t-test assessed differences in fascicle and SEE behavior during the stance phase. Maximum fascicle shortening, SEE strain, and SEE recoil were also analyzed.

RESULTS: No significant differences were observed in SL, SF, CT and ST between populations. Cnet showed no significant differences between populations. SPM analysis revealed significant differences in fascicle and SEE behavior during the stance phase: healthy participants exhibited shorter fascicle lengths (20–100% stance phase, $P < 0.01$), while T2D patients showed greater SEE lengths throughout the stance phase ($P < 0.001$). Maximum fascicle shortening and SEE strain were lower in T2D patients ($P < 0.05$), but no differences were found in tendon recoil. Significant negative ($R^2 = -0.37$, $P < 0.05$) and positive associations ($R^2 = 0.43$, $P < 0.05$) were observed between HbA1c and tendon strain or maximum fascicle shortening, respectively.

CONCLUSION: People with T2D walked with longer fascicle lengths and less strain of the SEE compared to healthy individuals. While a reduction in maximum fascicle shortening could reduce the metabolic energy cost during the stance phase, a decrease in elastic strain is likely to increase energy expenditure [2]. Our findings indicate that these two opposing mechanisms may balance each other out. Indeed, despite higher HbA1c levels being associated with muscle fascicle and SEE behavior, we found no significant differences in kinematic or energetic parameters during walking between individuals with well controlled diabetes and controls.

HOMOGENOUS MUSCLE HYPERTROPHY OF THE TRICEPS SURAE MUSCLE IN RESPONSE TO VARIED MECHANO-METABOLIC STRESS EXERCISE

EPRO, G., LAMBRIANIDES, Y.1, KARAMANIDIS, K.1,2

1 LONDON SOUTH BANK UNIVERSITY; 2 UNIVERSITY OF KOBLENZ

INTRODUCTION: Muscle volume is an important determinant for its' power generation capacity and is typically investigated in various population groups to evaluate the effectiveness of different interventions to enhance muscle function. Previous studies [1] have indicated that some muscles can adapt to training with a region-specific hypertrophy (changes in its shape), which would indicate different fiber type distribution as well as distinct innervation patterns within the muscle during exercise. The current study examined whether a triceps surae (TS) high metabolic stress exercise at different operating lengths (consequently at either low or high muscle force potential) leads to distinct mechanical and region-specific morphological adaptive changes.

METHODS: 12 young adults (27 ± 5 yrs) underwent a 12-week exercise intervention 3x week consisting of 3 sets of cyclic unilateral isometric plantarflexion contractions at 80% of maximal voluntary contraction until failure to induce high muscle metabolic stress. Based on the TS muscle force-length-relationship [2], low and high levels of mechanical stress were respectively induced using a short (PF; 115°) or a long (DF; 85°) muscle-tendon unit (MTU) length for either legs. TS MTU mechanical and morphological properties were assessed via ultrasonography and dynamometry. Magnetic resonance imaging was used to reconstruct all three compartments of the TS muscle in order to determine their volume and muscle specific shape factors [3].

RESULTS: Similar adaptive increments ($p < 0.05$) were found in TS muscle strength (~ 20 -25%), pennation angle ($\sim 10\%$), maximal anatomical cross-sectional area (ACSAmax; $\sim 5\%$) and muscle volume (on average $\sim 6\%$ across compartments) between DF and PF legs following the 12 weeks of exercise. Despite of the majority of muscle growth seemingly taking place

closer to the belly region of the muscle, no clear region-specific adaptation was detected and ACSAmax demonstrated no significant shift in its position in relation to the muscle length in either of the trained legs or analysed compartments of the TS. Accordingly, no change in the individual muscle specific shape factors were found over the 12-week training period.

CONCLUSION: The findings provide evidence that skeletal muscles are highly responsive to metabolic stimuli as even moderate mechanical tension and stress increases their force and power generation capacity. Moreover, exercising at different operating lengths of the contractile element within the force length-relationship seems not to cause inhomogeneous region-specific hypertrophy in skeletal muscles.

AGE-RELATED CHANGES IN FASCICLE BEHAVIOR DURING LOW RAMP ISOMETRIC CONTRACTIONS IN TRAINED VS. UN-TRAINED OLDER MALES

BRUSCO, C.M., CARBONARO, M., BOCCARDO, M., ALCAZAR, J., BALTASAR-FERNÁNDEZ, I., MONTE, A., LAURETANI, F., PORCELLI, S., BOTTER, A., FRANCHI, M.

UNIVERSITÀ DEGLI STUDI DI PADOVA

INTRODUCTION: The aging process promotes absolute decrease in fascicle length and angle [1] and changes in the morphology of the contractile and non-contractile tissues, which affects force capacity [2]. While muscle contractile elements are known to produce force, the intramuscular connective tissue has a key role in force transmission and in maintaining the structural integrity of the muscle. For pennate muscles to contract, changes in fascicle length (Lf) and angle (FA) and muscle thickness (MT) [3] occur. In this scenario, the age-related changes in muscle architecture and morphology impact on muscle shape changes during contraction [4] and the relative fascicle behavior during contraction. However, it is not known whether muscles of elderly individuals with high physical activity status, that is known to mitigate muscle loss and maintain fascicle length and angle [5], interfere in the fascicle behavior in comparison to a younger population reference. In this study we analyzed fascicle behavior during ramped isometric knee extension comparing elderly with high and low physical activity status to young adults.

METHODS: In this preliminary analyses of an ongoing study, data of twenty-one elderly individuals, eleven (76.1 ± 5.1 years old; 22.1 ± 4.0 and 39.5 ± 3.3 mL/min/Kg) with low aerobic capacity (EL), determined by $\dot{V}O_{2\text{Max}}$, ten (70.0 ± 3.9 years old; 39.5 ± 3.3 mL/min/Kg) with high physical activity capacity (EH) and eight young adults (Y; 25.6 ± 2.3 years old) were analyzed. Ultrasound imaging was employed to measure changes in muscle architecture during isometric ramp contractions up to 30% of the maximum voluntary contraction (MVC), with slow force increase (2% MVC/s). The ultrasound recordings were synchronized to the force signal. Changes in fascicle behavior (Lf, FA and MT) were compared from the beginning of the force contractions to 10, 20 and 30% of MVC.

RESULTS: Two-way ANOVA showed a decrease in Lf of EL with increasing force, with significantly lower Lf ($p < 0.05$) at 30% of MVC compared to Y. MT was significantly decreased from the beginning of the contraction to 10, 20 and 30% ($p < 0.01$) of MVC in both EH and EL. In addition, the decrease in MT showed a significant trend ($p = 0.06$) only in EL compared to Y at 30% of MVC.

CONCLUSION: These preliminary results show that changes in VL architecture during isometric submaximal tasks occur regardless of age, however the amount of change is higher in elderly individuals with lower aerobic capacity when compared to a young population. It is possible that the training status of the elderly individuals mitigates the architectural and morphological age-related changes in the contractile and non-contractile tissue, which will reflect in lower alterations in muscle fascicle behavior during contraction.

ELASTIC THERAPEUTIC TAPING HAS SIGNIFICANT EFFECTS ON ALONG-MUSCLE FASCICLE LOCAL LENGTH CHANGES

YILDIZ, S., ARPAK, A.2, YUCESÖY, C.A.2

1 HALIC UNIVERSITY, 2 BOGAZICI UNIVERSITY

INTRODUCTION: Kinesio taping (KT) is the utilization of an elastic therapeutic tape for prevention and treatment of various sports injuries and for performance enhancement. Despite being widely used to improve muscular function for Olympic and Paralympic athletes, an understanding of KT effects on muscular mechanics is lacking. Considering the continuity of the fascial system and its mechanical interaction with muscle fascicles intramuscularly (1,2), KT was shown to lead to local tissue length changes in human muscles (3). Yet, KT effects along the muscle fascicles with implications for sarcomere

length changes needs to be studied. Presently, we hypothesized that mechanical loading induced on the skin by KT leads to along-muscle fascicle local length changes and shear strains in the targeted muscle. The aim of this study was to test this hypothesis.

METHODS: Magnetic resonance imaging (MRI)-based local tissue deformation analyses and diffusion tensor imaging (DTI)-based fiber tracking techniques were used in combination (4,5). Anatomical MRI and DTI were acquired for 5 healthy female volunteers in 3 conditions: (I) without tape, (II) following sham application, and (III) after KT application. Local length changes and shear strains were calculated using image registration between conditions (I) and (II), and (II) and (III). Non-parametric Wilcoxon signed-rank test was performed to compare the two conditions.

RESULTS: Data pooled from all subjects show that KT-imposed along-muscle fascicle lengthening (mean $\pm$ SD 0.026 ± 0.020), shortening (0.032 ± 0.027) and shearing (0.087 ± 0.049) occur and are significantly higher than those caused by sham application (0.012 ± 0.010 ; 0.013 ± 0.015 ; 0.029 ± 0.021 , respectively) ($p < 0.001$). This confirms our hypothesis. Moreover, KT induced along-muscle fascicle length changes locally show heterogeneity.

CONCLUSION: Our findings indicate that KT affects both along-muscle fascicle length changes and shear strains. This can be explained by KT imposed myofascial loads over the skin being transmitted via the fascial system (6), non-uniformly manipulating the mechanical equilibrium locally at different parts along the muscle fascicles. Therefore, our findings support the use of KT as a supplementary part of rehabilitation and training programs indicating that it has effects on muscle function with a potential to improve performance.

COMPARISON OF THE ECCENTRIC EXERCISE EFFECTS ON THE MUSCULOTENDINOUS ELASTIC PROPERTIES BETWEEN MEN AND PREPUBERTAL BOYS

CHANEL, B., BABAUT, N., COMETTI, C.

FACULTÉS DES SCIENCES DU SPORT, UNIVERSITÉ BOURGOGNE EUROPE

INTRODUCTION: Eccentric exercises are recommended as an interesting training approach for physical performance improvement and more generally for health benefits. Unfortunately, eccentric exercise has been shown to induce a force alteration and muscle damage for several days (1). While these alterations are well documented in adults, less is known in children, more particularly considering structural modifications. Thus, the main aim of this study was to compare the modifications of the musculotendinous elastic properties after an eccentric exercise in prepubertal boys as compared to adult men.

METHODS: Ten prepubertal boys (8-12 years old) and ten men (20-25 years old) participated in the present study. The first session included a fatiguing protocol composed of five sets of 30 maximal eccentric knee extensors contractions. Muscle-tendon elastic properties were evaluated using shear wave elastography videos (SWV) of the vastus lateralis (VL), rectus femoris (RF), and the patellar tendon (Tendon). SWV was measured before (PRE), immediately after the exercise (POST), after 30 minutes (POST 30 min), and during a second session 48 hours after the first one (POST 48h). SWV raw and relative values were analyzed using a two-way (Time x Age) analysis of variance (ANOVA). Time corresponds to differences between all time-points. Age corresponds to boys vs. men.

RESULTS: A significant Time effect was observed for SWV in VL ($p < 0.001$). Post-hoc revealed greater values at POST 30 min than at PRE ($p = 0.003$). A significant Time effect was observed for SWV RF ($p = 0.035$). Post-hoc revealed greater values at Post ($p = 0.024$). A significant Age effect was observed for SWV RF relative values. After fatigue, greater increases were obtained for men than for boys (POST: BOYS mean: $+0.86\% \pm 16.92$ / MEN mean: $+24.37\% \pm 36.67$).

Significant Time ($p < 0.001$) and Age ($p < 0.001$) effects were observed for SWV Tendon. Post-hoc revealed greater values at POST ($p < 0.001$) and POST 30 min ($p = 0.002$) as compared to PRE. Post-hoc also revealed lower values for boys than for men. No significant Age effect was observed for SWV Tendon relative values (POST: BOYS mean: $+10.90\% \pm 6.94$ / MEN mean: $+11.25\% \pm 7.51$).

CONCLUSION: As previously enounced in the literature, boys presented lower modifications of muscle properties than men, potentially attributed to fewer muscle damages. However, a similar modification of the tendon tissue properties was observed for both age groups. Tendon properties changes could have an impact on the force transmission and stretch-shortening cycle and need some further investigations (2).

THE EFFECT OF LIFELONG EXERCISE ON NK AND CD4+ CELLS SUBPOPULATIONS

PEDROSA, A., MOURA, T., SILVA, S., SILVA, I., PAIVA, A., OLIVEIRA, V., RAMA, L., TEIXEIRA, A.

UNIVERSITY OF COIMBRA, FACULTY OF SPORT SCIENCES AND PHYSICAL EDUCATION, PORTUGAL

INTRODUCTION: Physical exercise triggers a systemic immune response, influencing both innate and adaptive immunity. Natural killer (NK) cells and CD4+ T cells play crucial roles in immune surveillance and regulation, with aging and physical activity significantly influencing their distribution and function. NK cells are divided into cytotoxic (CD56dimCD16bright) and effector (CD56brightCD16dim) subpopulations, which contribute to immune homeostasis and defense mechanisms. Meanwhile, inhibitory receptors such as PD-1 (CD279) and TIGIT on CD4+ T cells are associated with immune exhaustion and regulatory functions. TIGIT is known to play a key role in immune regulation by inhibiting T cell activation and promoting immune tolerance. Aging is often accompanied by immune alterations, including shifts in NK cell composition and T cell inhibitory receptor expression. However, regular physical activity has been suggested to mitigate some of these immunological changes. Understanding how exercise influences these immune parameters may provide insights into potential protective mechanisms against age-related immune decline. This study examines the impact of lifelong exercise (LLE) on NK cell subpopulations and CD4+ T cell inhibitory receptor expression. We hypothesize that LLE is associated with an increased proportion of cytotoxic, and effector NK cells and altered expression of inhibitory receptors on CD4+ T cells.

METHODS: Two groups, 17 master athletes (MA, aged 53±6.22 years) and 15 sedentary men (SG, aged 50.2±6.24 years) performed an incremental test until exhaustion on a cycle ergometer. Peripheral blood samples were collected before (Pre) and after the exercise protocol (Post). The blood samples were lysed with red blood cell lysing buffer, stained with anti-CD16 FITC, anti-CD56 PECy7, anti-CD4 PE, anti CD8 APCR700, anti CD279 BV605 anti-CD94 APC, anti-CD159c BV786 and read on a BD FACSLytic™ flow cytometer. Descriptive analysis was performed using GraphPad software.

RESULTS: The percentages of total NK cells, NK CD56dimCD16bright cytotoxic subpopulation and NK CD56brightCD16dim effector cells subpopulations showed a higher average in MA compared SG. However, in subpopulation CD4+CD279+TIGIT cells were lower in MA when compared to SG. There was a trend for an increase in cytotoxic NK subpopulations for MA when compared to the sedentary controls, but this difference was not statistically significant.

CONCLUSION: We found that MA exhibited higher percentages of total NK cells and of the cytotoxic CD56dimCD16brightNK subpopulation, suggesting enhanced immune surveillance and cytotoxic activity. However, the percentage of CD4+279+TIGIT was lower in MA compared to SG, which might indicate a lower exhaustion and regulatory T cell activity in MA. These findings support the notion that lifelong exercise may promote a more efficient immune profile, characterized by enhanced NK cell activity and lower proportion of exhausted CD4+ T cells.

NORDIC WALKING PLUS INSPIRATORY MUSCLE TRAINING ON INSPIRATORY AND PERIPHERAL STRENGTH IN OLDER ADULTS

ROLDAN, A., FERRARO, F.V., MONFERRER-MARIN, J., MONTEAGUDO, P., CORDELLAT, A., GONZÁLEZ, R., BLASCO-LAFARGA, N.M., NAVARRO-PÉREZ, J., BLASCO-LAFARGA, C.

UNIVERSITAT DE VALENCIA

INTRODUCTION: Inspiratory muscle training (IMT) enhances inspiratory muscle strength (IMS) and can induce changes in other capacities, such as balance or functional mobility [1]. NW has shown improvements in older adults (OA) functionality [2] but its effect on IMS remains unknown. This study (GESMED-Marcha) aims to compare the effect of two different short interventions (8 weeks) combining NW+IMT on IMS and peripheral strength in a group of OA referred from Primary Care. NW program was equal, but IMT load were 15% (IMT15) or 50% (IMT50) of the S-Index (dynamic IMS: dIMS).

METHODS: Seventy-one OA were randomly assigned to each group. 51 completed the final sample: IMT15 (n=22; 68.30(4.03) y; 69.01(8.90) kg) and IMT50 (n=29; 67.32(4.34) y; 72.58(12.47) Kg). Only NW was supervised (1hr, 3 days/week) while IMT was auto administrated (30 inspirations, twice daily, 7 days/week). Upper and lower limb strength (HG & STSSPPB) and dIMS were assessed PRE-POST intervention and 8-weeks after detraining (DET). After normality testing, a repeated measures ANOVA with the type of IMT load as intergroup factor, or Friedmann test, were applied, followed by Bonferroni or Wilcoxon post hoc tests.

RESULTS: Regarding peripheral muscles, STSSPPB improved after training (STSSPPB: F=6.447, p=0.003, $\eta^2=0.157$, observed power= 0.892) with no interaction effect (time*program). Indeed, only IMT15 improved significantly between PRE and DET (p=0.006). Conversely, HG showed no significant improvements. dIMS improved significantly (p<0.001): specifically, IMT15 PRE-POST p=0.001; POST-DET p=0.025; PRE-DET p<0.001 and IMT50 PRE-POST p<0.001; PRE-DET p<0.001.

CONCLUSION: NW+IMT was successful to improve dIMS in IMT15, contradicting existing literature where the 15% load serves as a placebo [3]. The engagement of CORE muscles during NW may contribute to this improvement and alternatively may facilitate enough motor unit recruitment and coordination in the inspiratory muscles [4] in this population, facilitating further load progressions. However, STSSPPB only improved in IMT15 (PRE-DET), so the 50% load may add fatigue

that limits its progress. Further research on IMT protocols is needed to clarify their benefits in non-pathological populations and its role and loads as a complementary training tool.

FUNCTIONAL IMPROVEMENT OF OLDER OUTPATIENTS WITH ACUTE CORONARY SYNDROME AFTER ONE YEAR OF EXERCISE-BASED SECONDARY PREVENTION PROGRAM

RAISI, A., ZERBINI, V., PIVA, T., CAMPO, G., PAVASINI, R., TONET, E., GRAZZI, G., MAZZONI, G., MENEGATTI, E., MANDINI, S.
UNIVERSITY OF FERRARA

INTRODUCTION: Among cardiovascular diseases, acute coronary syndrome (ACS) remains the leading cause of morbidity and mortality. Cardiac rehabilitation and secondary prevention programs make significant contributions to the continuum of care in patients, and physical activity has been recognized as core part of such interventions. However, despite the documented benefits, older patients diagnosed with acute coronary syndrome (ACS) are less likely to attend traditional center-based programs limiting the efficacy of the intervention. This situation has emphasized the importance of more comprehensive and sustainable intervention strategies. Thus, the aim of the study was to examine functional changes of older patients with ACS involved in a center- and home-based secondary prevention program after one year of intervention.

METHODS: A subsample of 254 consecutive patients (mean age 75 years) with ACS extracted from the ITER registry (NCT05817305) was analyzed. The proposed intervention program consisted of 6 individual on-site sessions including functional evaluation along with continuous motivational reinforcement to reach exercise goals and stably maintain an active lifestyle. The home-based exercise prescription was based on the results of the validated 1km-Treadmill Walking Test. Functional variables were assessed during each visit. Main outcomes were changes in self-reported weekly physical activity, average walking speed (WS) registered during the test and estimated cardiorespiratory fitness (VO₂peak).

RESULTS: Physical activity levels significantly increased and were maintained during the follow-up period (median MET-h/week 3.0, 12.0, and 9.0 at baseline, 6-, and 12 months, respectively; $p < 0.0001$). These results were associated with increasing mean WS (2.9, 3.9, 4.1 km/h, respectively, $p < 0.0001$), and VO₂peak (16.9, 20.0, 20.5 mL/kg/min, respectively, $p < 0.0001$).

CONCLUSION: The proposed intervention demonstrated a stable adherence to physically active lifestyle, along with improved walking capacity and estimated VO₂peak in older patients with ACS. Results therefore highlight the importance of exercise testing and training in older patients and the effectiveness of the program. This may provide valuable insights for the development of more efficient and patient-centered exercise-based secondary prevention programs.

LIFELONG ENDURANCE TRAINING VS. LATE-LIFE EXERCISE: CAN SHORT-TERM TRAINING BRIDGE THE GAP?

ORESKÁ, L., SEDLIÁK, M., STRELECKÝ, M., BUZGÓ, G.

FACULTY OF PHYSICAL EDUCATION AND SPORTS, COMENIUS UNIVERSITY

INTRODUCTION: Master endurance runners exhibit superior metabolic health, aerobic capacity, lower body fat, and muscle morphology compared to untrained elderly individuals, highlighting the benefits of long-term endurance training. Studies suggest that short-term exercise can significantly improve these factors, helping inactive older adults partially bridge the gap with lifelong endurance athletes. This study examines whether a 12-week aerobic-strength program can enhance metabolic health, endurance, strength, and body composition in previously untrained elderly individuals compared to lifelong runners.

METHODS: We compared four groups: young endurance runners (YER, $n=8$, 27.4 ± 3.1 yrs), master endurance runners (MER, $n=10$, 70.2 ± 3.9 yrs), young controls (YAG, $n=10$, 26.7 ± 2.3 yrs), and elderly controls (EAG, $n=10$, 71.1 ± 3.3 yrs), before and after a 12-week aerobic-strength training program. Endurance runners trained >300 min/week and regularly competed in distance races (YER ≥ 3 years, MER ≥ 25 years). Body composition was assessed via DXA; blood markers (LDL, HDL, total cholesterol, triglycerides, glucose, insulin) were analyzed from venous samples. Lower limb strength was measured using a dynamometer, and aerobic power was assessed via a maximal-graded cycling test.

RESULTS: Significant differences were observed across all groups. Before the intervention, EAG had higher blood glucose than YAG ($P=.003$) and elevated insulin levels compared to MER ($P=.005$). HDL cholesterol was highest in YER vs. YAG

($P=.007$) and MER vs. EAG ($P=.001$), while LDL cholesterol was lower in YER vs. MER ($P=.001$) and YAG vs. EAG ($P=.037$), both before and after the intervention. Notably, after the intervention, EAG showed lower LDL cholesterol and improved insulin sensitivity. However, no significant differences were found in the LDL/HDL ratio between MER and EAG post-intervention. YER demonstrated the highest strength and VO_2max , while MER maintained a significantly higher VO_2max than EAG both before and after the intervention.

CONCLUSION: A 12-week aerobic-strength program enhances metabolic health, strength, and endurance in elderly individuals, but they may not fully match the performance of lifelong endurance runners. While significant improvements are achievable, age-related declines still limit peak performance. Master endurance athletes maintain superior metabolic health, strength, and aerobic capacity compared to their untrained peers, yet they still fall short of the VO_2max , muscle strength, and overall physical fitness seen in young endurance athletes. Despite the inevitable declines in aerobic capacity, muscle mass, and metabolic efficiency with ageing, long-term endurance training plays a crucial role in preserving physical performance and slowing the effects of ageing.

The study was funded by the INTERREG V-A Slovakia—Austria (acronym CAA, ITMS2014 + 305041X157), by the Slovak Research and Development Agency (Grant no. APVV-21-0164), VEGA 0554/24, and VEGA 1/0482/23.

THE EFFECT OF CHRONIC SENOLYTIC AND AEROBIC EXERCISE INTERVENTIONS ON CARDIAC AGING AND PERFORMANCE

BEVINGTON, R., JOHNSON, A., PARISE, G.

MCMASTER UNIVERSITY

INTRODUCTION: The accumulation of senescent cells that occurs with age has been linked to the progression of age-related declines in cardiac health and function [1]. Senescent cells are dysfunctional, and in excess, are associated with structural changes to cardiac tissue [1]. This includes increased myocardial fibrosis and hypertrophy or atrophy of the ventricular wall, which can significantly impair cardiomyocyte relaxation and contractility and thus both systolic and diastolic function [1]. Senolytic drugs, such as Dasatinib and Quercetin (D+Q), target and remove senescent cells, offering an effective therapeutic avenue to clear senescent cells [1]. Recently, aerobic exercise has also shown promise in clearing senescent cells in mice [2]. Therefore, we hypothesized that using both D+Q and aerobic exercise, chronically, would produce a synergistic clearance of senescent cells in cardiac tissue, improving cardiac function and health in aged mice.

METHODS: Twelve-month-old C57BL/6N male and female mice ($n=20$ per group) were randomly assigned to 1 of 4 groups: VEH (naturally aged), EX (30 min treadmill running; 2x/week), SEN (biweekly D+Q administration via oral gavage) or SENEX (exercise and D+Q). Mice received the intervention for 9 months and had assessments of cardiac structure plus systolic and diastolic function at the 6- and 9-month timepoints via high frequency ultrasound. Myocardial fibrosis was also assessed through picrosirius red staining of the left ventricle.

RESULTS: After 9 months, the VEH group displayed a significantly higher isovolumetric relaxation time (IVRT) (25.7 ± 4.5 s) and myocardial performance index (MPI) (0.85 ± 0.24) than EX (15.5 ± 4.0 s and 0.50 ± 0.10), SEN (18.43 ± 4.1 s and 0.55 ± 0.10), and SENEX (16.44 ± 5.2 s and 0.59 ± 0.22) ($p < 0.05$). Regarding cardiac structure after 9 months, only the VEH mice displayed a significant change, where relative wall thickness decreased compared to 6 months (0.98 ± 0.31 vs 0.56 ± 0.15 , $p < 0.05$). SENEX mice (3.3 ± 2.2 %) also displayed significantly lower myocardial fibrosis than VEH mice (6.4 ± 3.4 %) ($p < 0.05$), with no differences across the other groups.

CONCLUSION: All treatments maintain cardiac structure, preventing an age-related decrease in ventricular wall thickness experienced by the VEH group, with the SENEX intervention even mitigating the age-related fibrosis seen in the VEH mice. Furthermore, improved myocardial performance and relaxation in the treated mice demonstrate a positive impact of exercise and senolytics on cardiac function. Thus, exercise, senolytics, or both combined show promise in maintaining, and even improving aspects of cardiac structure and function in aged mice.

OP-PN30 Hypoxia and Training

EFFECT OF AN 8-WEEK HIGH INTENSITY INTERVAL TRAINING PROGRAM IN HYPOXIA ON MARKERS OF PHYSICAL FITNESS IN SEDENTARY OVERWEIGHT INDIVIDUALS

GOODS, P., SOO, J., GIRARD, O., DELDICQUE, L., LAWLER, N., CHARLESWORTH, J., FAIRCHILD, T.

MURDOCH UNIVERSITY

INTRODUCTION: High intensity interval training (HIIT) in hypoxia has been demonstrated to improve peak oxygen uptake ($\text{VO}_{2\text{peak}}$) in athletes to a greater extent than when performed in normoxia. Further, training under hypoxia reduces the mechanical load required to elicit similar physiological responses. These characteristics of HIIT in hypoxia have obvious

appeal for overweight and sedentary populations. Accordingly, the aim of this investigation was to determine the effects of an 8-week HIIT in hypoxia intervention on markers of physical fitness in overweight and sedentary individuals.

METHODS: Thirty sedentary (<100 min weekly moderate physical activity) overweight and obese (BMI: 33.9 ± 6.5) individuals (36 ± 7 y) were recruited for a 10-week training program (three HIIT sessions and two resistance training sessions per week). In the first two weeks, all exercise was performed in normoxia. For the following eight weeks, HIIT was completed in either normoxia ($n=10$, five dropouts) or hypoxia ($n=15$). All participants completed 1-repetition maximum (1RM) testing in four exercises and a graded exercise test for the determination of $\text{VO}_{2\text{peak}}$ and submaximal fat oxidation rates (Fatox) prior to and following the intervention period. HIIT consisted of four to six repetitions of 1-min cycling bouts performed at a fixed rating of perceived exertion (RPE; 16/20), interspersed with 4-min of active recovery (10/20 RPE) in either normoxia (FiO_2 : ~ 0.21) or hypoxia (FiO_2 : ~ 0.14). All resistance training was performed in normoxia, and sessions consisted of four different exercises. Linear mixed models were used with condition, time and interaction defined as the fixed effects and participants as random effects.

RESULTS: $\text{VO}_{2\text{peak}}$ significantly improved following training (hypoxia: $+0.38 \pm 0.42$ L/min; normoxia: $+0.22 \pm 0.28$ L/min, pooled effect: $g=0.67$), with no significant interaction found between condition and time ($p=0.30$). Fatox at 50 W, 75 W, and 100 W also significantly increased following training, again with no between-group differences (50 W: $+0.09 \pm 0.14$ g/min, 75 W: $+0.11 \pm 0.12$ g/min, 100 W: $+0.10 \pm 0.11$ g/min, pooled effect: $g=0.45$ - 1.15). Finally, 1RM also increased similarly in both conditions (Pre-post pooled group average: leg press: $+43 \pm 45\%$, $p=0.001$, $g=0.42$; bench press: $+15 \pm 13\%$, $p<0.001$, $g=0.36$; shoulder press: $+12 \pm 16\%$, $p=0.003$, $g=0.23$; lat pulldown: $+15 \pm 13\%$, $p<0.001$, $g=0.47$).

CONCLUSION: A 10-week training program consisting of HIIT (3/week) and resistance training (2/week) significantly improved $\text{VO}_{2\text{peak}}$, submaximal Fatox, and strength (1RM) in sedentary overweight and obese individuals. While the magnitude of $\text{VO}_{2\text{peak}}$ improvement was nearly 2x greater in the hypoxic HIIT group, no significant differences were found compared to performing matched training in normoxia. While our data do not support the addition of hypoxia to HIIT as a way to augment physical fitness outcomes in this population, they suggest further research may be warranted.

COMBINATION OF WEIGHT REDUCTION AND HYPOXIA ON BIOCHEMICAL RESPONSE TO A HIGH-INTENSITY EXERCISE IN ATHLETES

CHAMBION-DIAZ, M., BILLAUT, F., PIALOUX, V.

CLAUDE BERNARD UNIVERSITY LYON 1

INTRODUCTION: The AlterG treadmill allows weight reduction during running, which lowers mechanical stress, and metabolic strain. In this context, we previously demonstrated that hypoxia compensated body weight reduction for physiological stress (Chambion-Diaz et al., 2025). However, there is no strong evidence regarding the effect of AlterG running on redox balance, inflammation and muscle damage. Hypoxia is well known to increase oxidative stress, and physiological stress. To date, there is no study investigating redox balance and inflammation in response to this type of exercise. The aim of this study is to characterize the biochemical response in this exercise combination.

METHODS: Twenty-six participants completed a high-intensity interval training (HIIT) session on an AlterG treadmill in the following 5 experimental conditions in randomized order: normoxia at 100% body weight (BW); normoxia at 80% BW; normoxia at 60% BW; hypoxia ($\text{FiO}_2=14\%$) at 80% BW; hypoxia at 60% BW. The HIIT session included 3 sets of 8 repetitions of 30 seconds of effort performed at 110% of the maximum aerobic speed, interspersed with 30 seconds of passive recovery. Blood samples were taken before and after each session for measurement of oxidative stress markers (AOPP, Iso-prostanones, MDA, MPO, XO) antioxidant (SOD, GPx, Catalase, FRAP, UA), inflammation (CRP, IL-6, IL-1b, TNF- α), muscle damage (CK, myoglobin).

RESULTS: Catalase, MPO, FRAP and myoglobin increased post-HIIT global time effect; $p<0.05$). More specifically, Catalase, MPO and FRAP increased only in Control ($p=0.0147$; $p=0.0047$ and $p=0.0432$ respectively) and post-Hyp80% ($p=0.0203$; $p=0.0002$ and $p=0.0009$ respectively). These results suggest that the oxidative stress modulation by the body weight reduction could be compensated by hypoxia. All the other circulating markers are not affected by neither HIIT session nor condition.

CONCLUSION: These data confirm that such HIIT session can affect circulating redox status and moderately impact muscle damage markers. In addition, it seems that similarly to physiological stress (Chambion-Diaz et al., 2025), the reduction of oxidative stress in response to HIIT session by body weight reduction is compensated by hypoxia but only on the 80% body weight. Finally, circulating muscle damage markers and inflammation were not impacted by neither weight reduction nor hypoxia.

ANY CROSS-TALK IN REPEATED-SPRINT TRAINING BETWEEN HYPOXIA AND HEAT IN ELITE ATHLETES?

BROCHERIE, F., BALLARIN, F., SIMIONI, G., BISSONNIER, L.M., GUIRRONNET, S., BRUNET, E., PISCIONE, J., MILLET, G.P., BOUTEN, J.

FRENCH INSTITUTE OF SPORT

INTRODUCTION: Repeated-sprint training in hypoxia (RSHyp) is often used by team-sport athletes to improve repeated-sprint ability. Similar training in the heat (RSHot) has also been suggested to be effective. However, little is known about their respective cross-talk. This study therefore aimed to analyze the effect of RSHyp and RSHot on repeated-sprint performance in either normobaric hypoxic or normoxic hot conditions in reference to a normoxic thermoneutral condition.

METHODS: Seventeen French elite athletes (rugby sevens national team ($n = 11$ females), BMX ($n = 4$ males and 2 females)) performed 6 repeated-sprint training sessions (3×5 7-10-s sprints with 20-23-s passive recovery on a cycle ergometer) in either hypoxic ($\text{FiO}_2 = 14.3\%$, 20°C , $n = 8$, 6 females) or hot ($\text{FiO}_2 = 20.9\%$, 36°C , $n = 9$, 7 females) ambient conditions over two weeks. Pre- and Post-tests (1 week after) included a repeated-sprint ability test (8×10 -s sprints with 20-s passive recovery) in either a normobaric hypoxic ($\text{FiO}_2 = 14.3\%$, 20°C), normoxic hot ($\text{FiO}_2 = 20.9\%$, 36°C) or normoxic thermoneutral ($\text{FiO}_2 = 20.9\%$, 20°C) environment. Maximal (P_{max}) and average (P_{mean}) power outputs were measured for each sprint. Capillary blood samples were taken before and after the first and last training session and analyzed for pH and bicarbonate concentration $[\text{HCO}_3^-]$.

RESULTS: P_{max} and P_{mean} , averaged for all eight sprints, increased following both RSHyp and RSHot across all testing conditions from 759 ± 207 (Pre) to 849 ± 226 W (Post) for P_{max} (Time effect: $F = 40.0296$, $p = 0.001$) and from 564 ± 166 to 609 ± 157 W for P_{mean} ($F = 40.2696$, $p = 0.001$). The improvement in P_{max} did not differ according to the training group ($F = 0.0304$, $p = 0.889$) nor testing condition ($F = 0.956$, $p = 0.403$) while P_{mean} tended to improve more in the normoxic hot ($+14.8\%$) compared to the normoxic thermoneutral ($+9.2\%$) and normobaric hypoxic ($+10.3\%$) testing condition ($F = 3.0765$, $p = 0.050$). No difference was observed between training groups in acute post-training pH (RSHyp: 7.20 ± 0.11 , RSHot: 7.16 ± 0.15 , $F = 0.041$, $p = 0.844$) nor $[\text{HCO}_3^-]$ (RSHyp: 10.8 ± 2.4 mmol.L $^{-1}$, RSHot: 9.1 ± 1.7 mmol.L $^{-1}$, $F = 0.012$, $p = 0.912$).

CONCLUSION: Adding either normobaric hypoxia or heat in repeated-sprint training resulted in an $\sim 11\%$ improvement in repeated-sprint performance in elite athletes across all sprints and testing conditions with a more pronounced improvement in normoxic hot ($+14.8\%$) conditions. The effect was independent of the training group. This indicates an effective cross-talk effect of each respective training condition on the other environmental stress. The similar acute training-induced changes in pH and $[\text{HCO}_3^-]$ values between training groups seem indicative of a similar metabolic stimulus despite different responses in normobaric hypoxic (lower oxygen saturation) or heat (higher core temperature) conditions.

POST-EXERCISE HYPOTENSION AND AUTONOMIC NERVE ACTIVITY FOLLOWING ENDURANCE EXERCISE IN HYPOXIA

KOBAYASHI, M., TOMIISHI, C., FURUKAWA, H., GOTO, K.

RITSUMEIKAN UNIVERSITY

INTRODUCTION: Exercise is an effective non-pharmacological intervention for reducing blood pressure (BP). A single bout of exercise decreases transiently BP, which is called as "Post-exercise hypotension (PEH)". PEH contributes to reducing BP chronically. A previous study revealed that endurance exercise reduced markedly systolic BP (SBP) compared to resistance exercise. In addition, resistance exercise under hypoxic condition caused greater PEH compared to the same exercise under normoxic condition. Therefore, combination of "endurance exercise" and "hypoxia" may cause effectively PEH. However, PEH after endurance exercise in hypoxia has not been clarified. Therefore, the aim of the present study was to evaluate PEH following endurance exercise under hypoxic condition.

METHODS: Fifteen young men (22 ± 2 years) conducted three trials on different days with a randomized order of trial at least one week apart: (1) pedaling exercise in hypoxia (FiO_2 : 14.5% ; HYP), (2) pedaling exercise in normoxia (FiO_2 : 20.9% ; NOR), and (3) rest in normoxia (REST). Exercise trials (HYP and NOR) began at 8:00 am and consisted of 60 min of pedaling exercise at 60% of maximal oxygen uptake. During each trial, heart rate (HR), rating of perceived exertion (RPE), and arterial oxygen saturation (SpO_2) were determined. Following each intervention (60 min of exercise or rest), BP was measured every 15 min for 3 h. Also, HR variability (HRV) was continuously monitored until next morning (8:00 am-7:00 am) using a wearable HR sensor.

RESULTS: During exercise, HR was significantly higher in both HYP and NOR compared to REST ($p < 0.001$). SpO_2 was significantly lower in HYP ($82.3 \pm 7.0\%$) than in NOR ($94.5 \pm 2.8\%$) and REST (96.7 ± 2.2 , $p < 0.001$). Over the 3h post-exercise period (9:00 am-12:00 am), reduction of SBP (ΔSBP) was significantly profound in both NOR (-22 ± 5 mmHg) and HYP (-20 ± 6 mmHg) compared to REST (-13 ± 7 mmHg, $p < 0.05$), with the lowest ΔSBP value was observed 1h post-exercise. However, no significant difference in ΔSBP was found between HYP and NOR ($p > 0.05$). Time-domain HRV parameters (i.e., SDNN, RMSSD, NN50, pNN50) returned to baseline levels within approximately 1h post-exercise. During sleep (0:00 am-7:00 am), averaged NN50, pNN50 were significantly lower in HYP and NOR compared to REST ($p < 0.05$). However, other HRV parameters did not differ significantly among three trials ($p > 0.05$).

CONCLUSION: Although both HYP and NOR significantly reduced SBP compared to REST over 3h post-exercise period, the magnitude of PEH did not differ significantly between NOR and HYP. Furthermore, the PEH response was not associated with changes in HRV variables. These findings suggest that endurance exercise causes PEH regardless of oxygen concentration during the exercise. Also, it appeared that PEH was independent of change in parasympathetic nervous system activity during post-exercise. Further research is required to explore the specific mechanisms contributing to PEH such as exercise-induced vasodilation.

ACUTE EFFECTS OF CANNABIDIOL ON SUBJECTIVE AND PHYSIOLOGICAL RESPONSES TO ENDURANCE EXERCISE: A RANDOMISED CONTROLLED TRIAL

SAHINOVIC, A., LAU, N., SABAG, A., GORDON, R., COX, A., WALKER, K., IRWIN, C., DESBROW, B., JOHNSON, N., HABER, P., MCGREGOR, I., MCCARTNEY, D.

THE UNIVERSITY OF SYDNEY

INTRODUCTION: Athletes report using cannabidiol (CBD), a non-intoxicating constituent of *Cannabis sativa* L., to enhance post-exercise recovery and manage other conditions (e.g., poor sleep, anxiety, concussion). However, whether CBD influences performance related outcomes, remains unclear. Here, we investigated the acute effects of two CBD doses on subjective and physiological responses to endurance exercise to better understand CBD's practical utility within sport.

METHODS: A randomised double-blind, placebo-controlled, crossover clinical trial was conducted at the University of Sydney between October 2022 and March 2024. Healthy males and females, aged 18 – 45 years, were eligible to participate if they reported running ≥ 40 km.week⁻¹ and had not consumed cannabis/cannabinoids for ≥ 3 months. Participants received either placebo, 50 mg, or 300 mg CBD (oral; $<0.01\%$ THC) 1.5 hours prior to completing a 60-minute, submaximal intensity ($\sim 70\%$ VO₂max) treadmill run (RUN 1) followed by an incremental run to volitional exhaustion (RUN 2). Respiratory parameters, heart rate (HR) and subjective ratings (i.e., affective valence, enjoyment, perceived exertion, pain) were collected during RUN 1. Respiratory parameters, peak HR, and time to exhaustion (TTE) were collected during and at cessation of RUN 2. Capillary blood glucose and lactate concentrations were measured at cessation of RUN 1 and 2. Questionnaires assessing exercise enjoyment, state anxiety, mood and gastrointestinal comfort were administered at Baseline, Pre- and Post RUN 1, Post RUN 2 and 1h Post RUN 2. Venous blood was also collected at these timepoints to determine concentrations of cannabinoids and markers of muscle and gastrointestinal damage (i.e., creatine kinase (CK), myoglobin (Myo), lipopolysaccharide (LPS)).

RESULTS: Twenty-five participants (16 male; VO₂max = 53.1 ± 7.5 mL.min.kg⁻¹) were randomised and completed all three treatment sessions. Neither dose of CBD altered subjective responses during RUN 1, nor exercise enjoyment, mood or anxiety around RUN 1 or 2 ($p > 0.05$). CBD had limited effects on physiology and performance, with HR, exercise efficiency (i.e., VO₂), VO₂peak and TTE unchanged relative to placebo ($p > 0.05$). However, 300 mg CBD decreased the respiratory exchange ratio during RUN 1 ($p = 0.030$) and 50 mg CBD increased blood glucose at cessation of RUN 2 ($p = 0.003$), compared to placebo. There was no effect of either dose on CK and Myo ($p > 0.05$) but a Treatment x Time x Sex interaction was identified for LPS, with post hoc analyses revealing higher concentrations in females Post RUN 2 on 50 mg ($p = 0.032$), but not 300mg CBD ($p = 1.000$), compared to placebo.

CONCLUSION: CBD (50 mg, 300 mg; acute) does not appear to alter the subjective experience of submaximal intensity exercise, impact endurance performance (i.e., TTE) or have compelling effects on physiological responses to exercise. Acute use of CBD by athletes is therefore unlikely to be ergolytic or ergogenic at low to moderate doses.

SHORT-TERM PINE BARK EXTRACT SUPPLEMENTATION IMPROVES SUBSEQUENT CYCLING ENDURANCE BUT FAILS TO ATTENUATE EXERCISE-INDUCED OXIDATIVE INFLAMMATION IN YOUNG ATHLETES

TSAO, J., HO, D.Y., WANG, D.Z.

CHINA MEDICAL UNIVERSITY

INTRODUCTION: In the previous study, the mechanisms of Pine bark extract (PBE) are in terms of antioxidant effects, anti-inflammatory abilities, beneficial effects on blood circulation, and reinforcing activities on the extracellular matrix (1), thereby mitigating inflammation resulting from impaired antioxidant defenses (2). A human study demonstrated the potential of PBE in improving performance in triathlon athletes. However, it has not thoroughly investigated whether PBE could serve as an ergogenic aid for sports competition in athletes (3). Therefore, our study aimed to examine whether oral PBE supplementation could blunt oxidative stress, inflammation, and exercise-induced fatigue to promote endurance performance in young athletes.

METHODS: Fourteen healthy male athletes (mean $\pm$ SD, aged 22.2 ± 0.97 years; BMI. $22.74.3 \pm 0.86$ kg/m²) participated in this single-blind crossover-designed study and were randomly instructed to either oral PBE supplementation (300 mg per day for 4 days) or placebo. On the experimental day, participants were supplemented PBE or placebo was combined with 70% VO₂ max cycling for 60 minutes, followed by 3h of recovery. And then a subsequent single bout of cycling exercise with 75% VO₂max to exhaustion. The cycling time was recorded, and the physiology parameters of gaseous and blood samples were measured regarding exercise-induced perturbation of energy substrate utilization, muscle damage, oxidative stress, and inflammation. A paired t-test was conducted to examine the participants differences in the cycling challenge performance. Two-way ANOVA with repeated measures was used to compare all blood samples. The α level was 0.05 to indicate a significant difference for all comparisons.

RESULTS: The study findings significantly improved cycling endurance performance following 4-day PBE supplementation ($P < 0.05$). Notably, the observed improvement in cycling endurance performance may be attributed to a lower RER and carbohydrate oxidation rate during the first exercise challenge ($P < 0.05$). However, PBE supplementation was not signifi-

cantly attended to exercise-induced muscle damage (lactate dehydrogenase, LDH), creatine kinase (CK), uric acid (UA); oxidative stress (superoxide dismutase, SOD; thiobarbituric acid reactive substances, TBARS) and inflammation biomarkers (Interleukin 6, IL-6; tumor necrosis factor- α , TNF- α).

CONCLUSION: Our findings concluded that 4-day oral PBE supplementation enhances high-intensity cycling time to exhaustion. This may be partly due to the attenuated whole-body carbohydrate oxidation rate and spared glycogen depletion during the first exercise challenge. Therefore, PBE may be an effective ergogenic aid for enhancing high-intensity cycling performance among young adults.

TART CHERRY SUPPLEMENTATION CAUSES DIFFERENTIAL REGULATION OF SKELETAL MUSCLE PROTEOME AFTER ECCENTRIC EXERCISE

SABOU, V., OLEARY, M., JACKMAN, S., STRUSZCZAK, L., BOZBAS, E., METCALF, B., TANG, J., PHILO, M., KROON, P., BOWTELL, J.

UNIVERSITY OF EXETER

INTRODUCTION: Polyphenol-rich tart cherry (TC) supplementation was shown to enhance recovery from exercise-induced muscle damage (EIMD) (Wangi et al. 2022). However, no studies have investigated the effects of different doses of TC supplementation on such recovery. Furthermore, the molecular mechanism(s) of action through which TC elicits these effects is unknown. This study aimed to investigate the effects of a low (L) and a high (H) polyphenol dose of TC juice on functional recovery from EIMD and to establish the molecular mechanisms of action.

METHODS: Thirty-four active males consumed 500 mL TC juice (16.1 mg and 32.2 mg anthocyanins in the LTC and HTC juice) in the morning for 7 days prior to and 48h following exercise. Knee extension maximum voluntary isometric contractions, maximal isokinetic contractions, single leg jumps, and muscle soreness measures were assessed before, immediately, 24 and 48 h after exercise. Venous blood and vastus lateralis muscle samples were collected at each time point. Plasma concentrations of IL-6 and phenolic acids were quantified. Macrophage and neutrophil numbers were quantified in muscle sections. Vastus lateralis samples from eight individuals who were randomised to receive the HTC juice or placebo for 10 days were used for tandem-mass-tagged muscle proteomics analysis.

RESULTS: HTC supplementation increased plasma ferulic acid, isoferulic, vanillic acid, hippuric acid and hydroxybenzoic acid concentrations compared to PLA ($p < 0.001$). Seven-day HTC supplementation altered the balance of structural and contractile muscle proteins (CAMERA FDR < 0.0001 , Log2FC = 0.234 vs placebo). TC supplementation also increased expression of structural and contractile proteins following EIMD; this may be protective. TC supplementation also altered macrophage cell infiltration within the exercised muscle. This study found that TC did not enhance functional recovery. However, plasma hippuric acid was associated with skeletal muscle strength in this young healthy population ($r = 0.56$, $p = 0.007$). This association has previously only been shown in frail populations (Brunelli et al. 2021).

CONCLUSION: These data provide important insights into the mediators of TC effects in skeletal muscle, and potential for therapeutic and training adaptation applications.

MONITORING AND FOLLOW-UP OF VITAMIN D SUPPLEMENTATION: EFFECTS ON BLOOD MARKERS AND PERFORMANCE IN RUNNERS AND NON-RUNNERS DURING AUTUMN AND WINTER SEASON

FORMIGLIO, E., GERVAZI, M., FERNÁNDEZ-PEÑA, E., DONATI ZEPPA, S., ANNIBALINI, G., AGOSTINI, D., BARTOLACCI, A., BARBATO, C., PATTI, A., SESTILI, P., PEGREFFI, F., BELLOMO, R.G., BIANCO, A.

UNIVERSITÀ DEGLI STUDI DI URBINO

INTRODUCTION: Recent interest in vitamin D's role in musculoskeletal and immune health prompted this study to assess how 2 months of supplementation affects serum vitamin D status, performance, and leukocyte parameters in healthy runners and non-runners, with a subsequent 3-month follow-up.

METHODS: Fifty-two participants were randomized into four groups—runners and non-runners, with or without daily supplementation of 2000 IU vitamin D (administered as orodispersible films). Assessments were conducted at baseline (October, T0), after 2 months (T1), and 3 months post-supplementation (T2). Measurements included blood tests (25-hydroxyvitamin D in ng/mL and leukocyte counts), VO_2max , maximal isometric force (MIF), and vertical jump (CMJ) performance. Additionally, diet, training, local daily solar irradiation, and temperature were monitored.

RESULTS: Diet and training remained stable over the study period. Weather conditions were consistently sunny, with an average temperature of $20.0 \pm 1.7^\circ\text{C}$, daily solar irradiation of $15745.8 \pm 1033.7 \text{ W/m}^2$, and approximately 9.6 ± 0.8 hours of sunshine. Notably, both solar irradiation and temperature decreased significantly from October to January; thereafter, solar irradiation increased while temperature remained low until April. Supplemented runners showed a 20.82% increase in vitamin D (from 30.45 ± 7.0 to $35.35 \pm 8.9 \text{ ng/mL}$, $p < 0.001$), whereas non-supplemented runners did not exhibit a sig-

nificant change at T1, and non-supplemented non-runners experienced a 32.23% decrease (from 25.93 ± 6.6 to 17.8 ± 7.3 ng/mL, $p < 0.001$). At T2, vitamin D levels declined significantly in all groups (e.g., supplemented runners decreased from 35.35 ± 8.9 to 23.52 ± 5.6 ng/mL, $p < 0.001$). Neutrophil counts varied significantly over time and by supplementation status ($p = 0.03$): non-supplemented groups had progressive decreases (T0–T1: -12.37% and -14.50% ; T0–T2: -16.23% and -23.66%), while supplemented groups remained relatively stable (a slight increase at T1 followed by a non-significant decrease at T2). No significant changes were observed in VO_2max or CMJ, although MIF improved modestly in supplemented groups.

CONCLUSION: Two months of daily 2000 IU vitamin D supplementation effectively increased serum vitamin D levels and maintained stable leukocyte counts in both runners and non-runners. However, cessation led to significant declines by the 3-month follow-up, indicating that continued supplementation may be necessary. Interestingly, vitamin D levels in non-supplemented subjects initially paralleled solar irradiation trends until January; subsequently, despite an increase in solar irradiation, persistently low temperatures appeared to sustain the decline in vitamin D levels. While supplementation improved vitamin D status and moderated immune responses, it did not affect VO_2max or CMJ, and the modest improvement in MIF warrants further investigation.

EFFECTS OF VITAMIN D SUPPLEMENTATION ON EXERCISE PERFORMANCE, SKELETAL MUSCLE RENIN-ANGIOTENSIN SYSTEM, AND TMPRSS2 IN YOUNG MEN AND WOMEN

GARCÍA GONZÁLEZ, E.1, GARCIA-PEREZ, G.1, GALVAN ALVAREZ, V.1, MARTINEZ-CANTON, M.1, DE NIGRIS, E.1, GALLEGOSSELLES, A.1, GIL-RODRIGUEZ, G.1, MORALES-ALAMO, D.1, MARTIN-RINCON, M.1, CALBET, J.A.L.1,2
1 IUIBS AND ULPGC, SPAIN; 2 NIH, NORWAY.

INTRODUCTION: Vitamin D (VD) is essential for muscle function, calcium balance and oxidative stress. Animal and cell models suggest that VD modulates the renin-angiotensin system (RAS), shifting the balance away from the classic axis (pro-inflammatory and oxidant), reduces RONS and may enhance antioxidant defences. ACE2 facilitates SARS-CoV-2 entry, requiring priming by TMPRSS2, whose expression is androgen-regulated. Higher ACE2 in men may affect COVID-19 severity and RAS modulation under stressors like exercise and ischaemia-reperfusion (IR). The role of VD in these processes remains unexplored in human skeletal muscle (hSM). This study examined if short-term VD supplementation modulates performance, ACE2, TMPRSS2 and antioxidant capacity at rest and after exercise with IR, considering sex differences. We hypothesised that VD would increase ACE2 expression, enhance antioxidant capacity, and improve performance, with greater effects in men due to androgen-driven ACE2 and TMPRSS2 regulation.

METHODS: Thirty (15M/15F) non-VD deficient young volunteers participated in a double-blind crossover with two conditions, Placebo (PL) or VD(D3) for 5 days ($25.000\text{IU} \times 3\text{times}$, 6wk washout). After VDsupp, they performed a control 10s sprint followed by an incremental cycling test to exhaustion. Then, 20s bilateral occlusion (300mmHg) was applied. Upon release, they performed a 10s sprint during reperfusion. Right after, one leg was re-occluded (OC), while the other remained under free perfusion (CT), and after 60s, v. lateralis biopsies were taken simultaneously from both legs for Western Blot. Stats: ANOVA, t-test and Pearson's correlation.

RESULTS: VO_2max , maximal power output and rested and post-ischaemia 10s sprint performance were unaltered by VD, without sex-differences ($p > .05$). Basal AT2R levels dropped by 11% in VD, while globally ACE and SOD2 were differentially regulated in M and F in VD (supp*sex $p = .003/ .036$, respectively). After exercise+occlusion, ACE2, TMPRSS2 and catalase increased only in CT (71, 38, 62%, respectively, $p < .001$) while SOD1 had the opposite change (-17% , $p = .05$) for IR, with no effect in VD. Catalase and TMPRSS2 were differentially modulated in VD after exercise in M and F (supp*time*sex $p = .019$ and $p = .057$). ACE2 and TMPRSS2 across conditions were associated ($r = .23$; $p = .03$), and each of them with Catalase ($r = .70/ .50$; $p < .001$).

CONCLUSION: Vitamin D supp had no ergogenic effect and did not modify the response of RAS markers or antioxidant enzymes to intense exercise and IR in hSM, though it selectively modulated some RAS markers at rest. Exercise and IR strongly influenced ACE2, TMPRSS2, and catalase, suggesting oxidative stress-dependent regulation. The correlation between these markers supports a link between ACE2 dynamics and antioxidant capacity. Its broader impact on RAS regulation, redox homeostasis, and muscle adaptation remains to be determined.

THE EFFECTS OF DIFFERENT EXERCISE REGIMENS ON BODY COMPOSITION, CARDIOMETABOLIC HEALTH, AND ADIPOSE TISSUE DISTRIBUTION POST-METABOLIC BARIATRIC SURGERY; THE POWER BARIATRIC RANDOMIZED CONTROLLED TRIAL

GEPNER, Y., GOLDENSHLUGER, A., FRIEDMAN, L., TURJEMAN, T., YAVETZ, R., RAZIEL, O., GOITEIN, D., MARKUS, I., KAIS, H., STERNFELD, R., TRACHTENBERG, E., DUVNOV-RAZ, G., MHALER, I., YUNGSTER, I., PELED, D., AMEDI, R., KEIDAR, A., LIVINGSTON, H.L., SAKRAN, N., DICKER, D.

TEL AVIV UNIVERSITY

INTRODUCTION: Metabolic bariatric surgery (MBS) effectively reduces weight and obesity-related comorbidities, yet preserving fat-free mass (FFM) post-surgery remains a challenge. Physical activity may enhance body composition, but the optimal exercise modalities for MBS patients are unclear. Understanding the effects of different exercise regimens on body composition, cardiometabolic health, and physical function can inform post-surgical intervention strategies.

METHODS: This randomized controlled trial included 58 adults (aged 18–65 years, 70% women, BMI 41.7 ± 4.4 kg/m²) undergoing MBS. Participants were randomized into four groups: aerobic (n=15), resistance (n=13), combined (n=14), and control (n=16). Exercise groups completed a 26-week supervised program, performing three progressive-intensity sessions per week. Primary outcomes included changes in FFM and fat mass (FM), assessed by Dual-Energy X-Ray Absorptiometry (DXA). Secondary outcomes encompassed abdominal fat distribution (using and magnetic resonance imaging, MRI), cardiometabolic markers (glucose regulation, lipid profiles), and physical function (walking distance, handgrip strength). Measurements included cardiometabolic blood markers and physical performance tests.

RESULTS: After 26 weeks, 91% of participants completed the study. The combined exercise group preserved more FFM (-5.1 ± 2.8 kg vs. -7.7 ± 2.8 kg, control) and exhibited greater FM reduction ($-11.9 \pm 5.7\%$ vs. $-10.1 \pm 4.9\%$, control). Weekly physical activity showed a dose-response correlation with FFM preservation, with the strongest effects in the combined group. All groups demonstrated significant reductions in abdominal and hepatic fat, correlating with improved glucose regulation, lipid profiles, and blood pressure. Physical function improved across all groups, with better handgrip strength preservation in the combined group. Strength positively correlated with protein intake, while walking distance improvements were similar across groups and correlated with weight loss.

CONCLUSION: Combined aerobic and resistance training optimizes body composition post-MBS by preserving FFM and reducing FM. These findings underscore the importance of structured exercise interventions in enhancing long-term metabolic health and functional outcomes in MBS patients.

EXERCISE IMPROVES GUT MICROBIAL METABOLITES IN AN INTENSITY-DEPENDENT MANNER

RELJIC, D., HERRMANN, H.J., NEURATH, M.F., ZOPF, Y.

UNIVERSITY HOSPITAL ERLANGEN

INTRODUCTION: Obesity and the metabolic syndrome (MetS) are major global health concerns, increasing the risk for morbidity and mortality. Recent research highlights the gut microbiome as a key regulator of metabolic health, with short-chain fatty acids (SCFAs) produced in the intestinal tract playing a crucial role in cardiometabolic health [1]. There is evidence that exercise may alter gut metabolites [2], but findings of previous studies remain inconsistent. We hypothesized that these discrepancies stem from differences in exercise intensity, with higher-intensity exercise leading to more pronounced microbial adaptations. This study examined the effects of a low-volume interval training plus single-set resistance training (RT) program, performed at either high intensity (HIGH-EX) or moderate intensity (MOD-EX), on gut SCFAs and cardiometabolic health indices in obese individuals with MetS.

METHODS: A total of 113 subjects (53 ± 12 yrs, BMI: 39 ± 5) were randomized into three groups: HIGH-EX (5×1 min cycling at 80–95% HRmax, followed by progressive RT, 5 exercises, 50–80% 1-RM), MOD-EX (5×1 min cycling at <80% HRmax, followed by moderate RT, 50–60% 1-RM), and a non-exercising control group (CON). Training was performed twice weekly for 12 weeks. Stool samples were collected pre- and post-intervention to analyze SCFA concentrations. Additionally, VO₂max, muscle strength, cardiometabolic risk markers, and MetS severity (MetS Z-score) were assessed.

RESULTS: HIGH-EX and MOD-EX improved MetS-Z-Score (-1.1 units, $p < 0.01$; and -0.5 units, $p < 0.05$, respectively), VO₂max ($+4.2$ mL/kg/min, $p < 0.01$; and $+2.7$ mL/kg/min, $p < 0.05$, respectively) and 1-RM strength values in major muscle groups (19–26%, all $p < 0.001$; and 22–29%, all $p < 0.001$, respectively). Both exercise groups also significantly reduced inflammation (hs-CRP, HIGH-EX: -2.2 mg/L, $p = 0.013$; MOD-EX: -1.3 mg/L, $p = 0.01$). Only HIGH-EX significantly increased total fecal SCFA concentration ($+29\%$, $p < 0.001$), including acetate ($+27\%$, $p < 0.001$), propionate ($+24\%$, $p < 0.001$), and butyrate ($+39\%$, $p < 0.001$). None of the parameters changed in CON.

CONCLUSION: This study indicates that low-volume interval training combined with single-set RT (70 min/week) improves physical fitness and cardiometabolic health in obese MetS patients at both high and moderate intensities. However, improvements in SCFA production were only observed in HIGH-EX. This suggests that exercise intensity plays a critical role in gut microbial adaptations, potentially mediated by higher lactate production, which has been linked to increased SCFA

production [3]. Future research should further explore the mechanistic links between exercise intensity and gut microbiota metabolism to optimize exercise prescriptions for metabolic health improvements.

THE METABOLIC CHARACTERISTICS OF THE EFFECTS OF COMBINED EXERCISE ON THE TRANSITION OF METABOLICALLY UNHEALTHY OBESITY IN YOUTH

YANCHUN, L., WU, M., FEI, X., ZHANG, M., LI, N., WU, Y.
BEIJING SPORT UNIVERSITY

INTRODUCTION: This study focused on the phenotypic characteristics of youth with metabolically unhealthy obesity (MUO) and metabolically healthy obesity (MHO). It aimed to evaluate the metabolic characteristics of combined training modalities, resistance training followed by moderate-intensity continuous training (RT+MICT), on the transition from MUO to MHO in young adults.

METHODS: This randomized clinical trial, conducted from September 2024 to November 2024, involved 50 obese college students (ages 18-25) from China Agricultural University in Beijing. Of these, 30 participants were classified as MUO, while 20 were classified as MHO based on their phenotypic characteristics. Participants underwent a combined intervention of resistance training and MICT (50-75% HRmax), which was performed twice a week for a duration of 8 weeks.

RESULTS: There were 33 differential metabolites identified between MUO and MHO individuals prior to exercise intervention. After an 8-week combined exercise program, 52% of the MUO participants transitioned to the MHO state, while 20 MHO participants remained in the MHO state. RT+MICT intervention significantly improved body composition, with reductions in body weight, body mass index (BMI), and percent body fat (PBF). Regarding metabolic health indicators, blood pressure remained unchanged, whereas blood glucose levels decreased in both groups. Following the 8-week combined exercise, there were 374 differential metabolites observed in the MUO group transitioning to the MHO state, and 342 differential metabolites identified in the MHO group that remained in the MHO state. Key metabolic indicators related to the combined training modalities that facilitated the transition of MUO in youth included tetradecanedioic acid, 4-Ethylphenylsulfate, p-Cresol, p-Cresol sulfate, Cholic acid, 1,4-dihydroxyheptadec-16-en-2-yl acetate, 7 α -Hydroxycholestene-3-one, and Hypocrellin A.

CONCLUSION: Combined exercise intervention effectively improves the metabolic abnormalities associated with MUO and promote its transition to the MHO state.

EFFECTS OF REDUCED SEDENTARY TIME ON FAT OXIDATION DURING EXERCISE IN ADULTS WITH METABOLIC SYNDROME

GARTHWAITE, T., SJÖROS, T., LAINE, S., KALLIO, P., SAARENHOVI, M., VÄHÄ-YPYÄ, H., NORHA, J., HOUTTU, N., LAITINEN, K., LÖYTTYNIEMI, E., SIEVÄNEN, H., KALLIOKOSKI, K., VASANKARI, T., KNUUTI, J., HEINONEN, I.
UNIVERSITY OF TURKU

INTRODUCTION: Sedentary behavior (SB) and physical inactivity are associated with impairments in energy metabolism, while exercise training is known to enhance substrate metabolism, including fat oxidation during exercise. It is not known, however, whether similar enhancements can be achieved with reduced SB and increased habitual, non-exercise physical activity (PA). This study therefore investigated the effects of reducing SB on fat oxidation during exercise in adults at risk of type 2 diabetes in a 6-month randomized controlled trial.

METHODS: Sixty-four sedentary middle-aged adults with metabolic syndrome were randomized into intervention (INT, n=33) and control (CON, n=31) groups. INT aimed to limit SB by 1 h/day by increasing standing and light-to-moderate-intensity PA, and CON was instructed to maintain usual habits. SB and PA were assessed with hip-worn accelerometers for 6 months. At the beginning and end of the intervention, cardiorespiratory fitness (CRF; VO2max), absolute maximal fat oxidation (MFO; g/min), MFO relative to fat-free mass (mg/kgFFM/min), and FatMax (exercise intensity that elicits MFO; % of VO2max) were determined from respiratory gases during a graded cycle ergometer test with 3-min stages and 25-W increments. Dietary intake was assessed with 4-day food diaries and body composition with air displacement plethysmography (Bod Pod).

RESULTS: INT reduced SB by 41 min/day and increased moderate-to-vigorous PA by 20 min/day during the intervention, with no statistically significant changes in CON (group x time p=0.004 and p=0.003, respectively). Both groups increased light-intensity PA (9 min/day) and daily steps (INT +3300, CON +1600 steps/day), and lost an average of ~1 kg weight mainly through a decrease in fat mass (time p<0.05 for all). During the intervention, absolute MFO increased from 0.31 (95% CI: 0.29, 0.33) g/min at baseline to 0.34 (0.32, 0.36) g/min at 6 months, and relative MFO from 5.85 (5.48, 6.22) mg/kgFFM/min to 6.43 (6.04, 6.82) mg/kgFFM/min, with no statistically significant difference between groups (time p=0.01, group x time p>0.05 for both). Increased MFO (absolute and relative) correlated with improved CRF (r=0.45, p=0.001 for both), and increases in absolute MFO also correlated with increased FFM (r=0.29, p=0.03). FatMax did not change in either group from 46.0 (43.6, 48.5) % VO2max at baseline, but changes during the intervention in FatMax correlated with changes in the intake of total energy (kcal/day), protein, and fat (g/day) (r=0.33, r=0.39, and r=0.35, respectively; p<0.05 for all).

CONCLUSION: Reduced SB and increased PA did not have an intervention effect on fat oxidation during exercise. Changes in fitness level, body composition and dietary intake might be more important contributors to fat oxidation during exercise than habitual sedentary and physical activities. More intense exercise training is likely needed for enhanced exercise-stimulated fat oxidation.

THE EFFECTS OF HOME-BASED PILATES ON MUSCLE QUALITY INDEX IN INDIVIDUALS AFFECTED BY OBESITY

GRECO, F., COSCO, L.F., TARSITANO, M.G., QUINZI, F., MANCINI, A., BUONO, P., EMERENZIANI, G.P.

UNIVERSITY OF CATANZARO

INTRODUCTION: Combining Pilates with dietary interventions may represent an effective strategy to improve body composition in individuals affected by obesity [1]. However, there is a lack of evidence on how Pilates may improve muscular fitness, an important health-related indicator in this population [3]. Specifically, muscle quality (i.e., the amount of strength and/or power per unit of muscle mass) has been proposed as a relevant health indicator [4]. Therefore, this study aimed to evaluate the effects of 12-week home-based Pilates on muscle quality in individuals affected by obesity.

METHODS: Participants (age: 52.6 ± 7.1 years; BMI: 33.8 ± 5.8 kg/m²) were recruited and randomly assigned to Control Group (CG, n=10) or Pilates Group (PG, n=12). All participants adhered to a Mediterranean diet, while only the PG followed a supervised home-based Pilates program three times a week for 12 weeks. Muscular strength was assessed with the handgrip strength test (HG). 10-repetition chair-stand test (CST) was used to evaluate Muscular Power (MP). Skeletal Muscle Mass (SMM) was obtained through body composition analysis and used to calculate Specific Strength (SS, HG/SMM) and Specific Power (SP, MP/SMM). These two latter variables were used to assess the overall muscle quality index (MQI). Results were classified as poor, low or normal according to sex. All participants were evaluated at baseline (T0) and after 12-week of intervention (T1).

RESULTS: HG increased by 1.2% in CG and 6.5% in PG. The time to perform CST was reduced in both groups (CG: -16.2%; PG: -12.1%). SMM increased by 2.0% and 1.5% in CG and PG, respectively. In the CG, SS values were classified as poor (80%) and low (20%) at T0, with none of the participants reaching normal values at T1. In the PG, SS values were categorized as poor (90%) and low (10%) at T0, with none of the participants achieving normal values at T1. In the CG, SP values were classified as poor (10%), low (50%) and normal (40%) at T0, with 60% of participants reaching normal values at T1. Similarly, in the PG, SP values were categorized as poor (8.3%), low (50%) and normal (41.7%) at T0, with 58.3% of participants achieving normal values at T1. Overall, MQI reached normal values at T1 in 20% and 33.3% of participants in CG and PG, respectively.

CONCLUSION: Our preliminary data suggest that not all participants in both groups achieved normal MQI values after 12 weeks of intervention. However, the trend of improvement in HG and MQI was greater in PG. Future studies with larger sample sizes are needed to confirm these findings.

OP-AP17 Swimming I - Strength Training

COMPARISON OF DIFFERENT RESISTANCE LOADS IN WATER ON THE TRAINING PERFORMANCE AND OPTIMAL LOAD SELECTION OF FRONT CRAWL SWIMMING

ZHOU, Z., YANG, C., CAI, B., HSU, T., LIN, J.

NATIONAL TAIWAN UNIVERSITY OF SPORT

INTRODUCTION: Front crawl is the fastest and most streamlined swimming stroke, with the swimming phase accounting for the majority of race time, excluding the start and turns [1]. Effectively utilizing aquatic resistance training to simulate race conditions and enhance swimming performance is crucial. Therefore, the purpose of this study is to compare the effects of different aquatic resistance loads on swimming performance and determine the optimal resistance load. The findings aim to provide practical guidance for implementing aquatic resistance training.

METHODS: This study recruited 19 male elite swimmers. Resistance cord was attached to the waist using a semi-systematic electromechanical device (I080 Sprint 2). Resistance loads were set at 1%, 3%, and 5% of body weight for a 25 m front crawl sprint test. Analyze parameters such as maximum velocity, peak force, peak power, and velocity decrement rate (VDR) from 5 to 20 m. One-way repeated measures ANOVA was conducted to examine the effects of different resistance loads on short-distance sprint performance.

RESULTS: The results of this study showed that under different resistance loads. The 1% load achieved the highest maximum velocity, while maximum velocity decreased as resistance load increased ($p = .000$). In addition, The peak force and

peak power were highest at the 5% load ($p = .00$). Further analysis of the VDR1-5% revealed an 18% reduction ($p = .000$), 10% reduction from VDR1-3% ($p = .00$), and 8% reduction from VDR3-5% ($p = .000$).

CONCLUSION: The results of this study indicate that an increase in resistance load further enhances peak force and peak power, demonstrating that a moderate increase in resistance can effectively improve an athlete's strength and power output. However, excessive resistance may lead to a significant decline in maximum velocity, which is detrimental to explosive power development. Given that the VDR1-5% was significantly higher than at VDR1-3%, 5% body weight resistance load is not conducive to maximum velocity. Therefore, 3% resistance load is recommended as an optimal training intensity to help athletes achieve better strength and speed performance for developing more tailored resistance training strategies for athletes at different competitive levels.

THE EFFECTS OF TRUNK STRENGTH TRAINING ON TURN TIME PERFORMANCE IN 400 M FREESTYLE FOR NATIONAL-LEVEL SWIMMERS

ZHONG, J., WANG, D.

SHANGHAI UNIVERSITY OF SPORT

INTRODUCTION: Trunk muscles are critical for effective freestyle turn performance because they facilitate dual rotational movements—rolling and twisting. Enhanced trunk strength not only stabilizes the spine and overall body but also improves underwater performance (e.g., gliding and undulatory underwater swimming) by reducing disturbances and drag while increasing body amplitude [1-2]. Previous studies have shown that incorporating trunk strength training (TST) into day-land programs can improve 50 m freestyle performance and turn efficiency (measured as the 5 m segment following wall contact) [3-4]. However, due to differences in performance parameters between sprint- and middle-distance events, the effects of TST on 400 m freestyle remain unclear. Thus, this study aimed to examine the impact of TST on turn time performance during 400 m freestyle among national-level swimmers.

METHODS: Fourteen national-level swimmers (8 males, 6 females) specializing in middle-distance freestyle were divided into an experimental group (EG: 18.3 ± 3.3 y, 177.3 ± 9.5 cm, 65.7 ± 9.5 kg) and a control group (CG: 20.3 ± 4.2 y, 179.5 ± 7.3 cm, 69.4 ± 11.7 kg). In addition to their regular day-land training (focusing on upper and lower limb strength), the EG completed an 8 weeks TST program (three sessions per week) divided into two phases: a basic stage (4 weeks) focusing on trunk bilateral rotation stability and dynamic strength, followed by advanced stage (4 weeks) emphasizing explosive power and specific turn exercise. Pre- and post-intervention assessments included trunk isokinetic peak force (PT) using an IsoMed 2000 dynamometer for flexion-extension ($60^\circ/\text{s}$) bilateral rotation ($150^\circ/\text{s}$), and turn time parameters during 400 m freestyle test. Turn performance was evaluated by overall turn time (OTT: the cumulative time for 7 turns, measured from the last 5 m before the rolling rotation to the 10 m mark after wall contact) and the average 5 m round turn time (5 m-RTT). A two-way repeated measures ANOVA was used to analyze intervention effects.

RESULTS: Significant interactions between time (pre vs. post) and group (EG vs. CG) were found for trunk flexion PT ($F = 5.600$, $p = 0.036$, $\eta^2 p = 0.318$), extension PT ($F = 5.534$, $p = 0.037$, $\eta^2 p = 0.316$), left rotation PT ($F = 19.496$, $p = 0.001$, $\eta^2 p = 0.619$) and right rotation PT ($F = 10.626$, $p = 0.007$, $\eta^2 p = 0.470$), OTT ($F = 15.061$, $p = 0.002$, $\eta^2 p = 0.557$), 5 m-RTT ($F = 21.396$, $p = 0.001$, $\eta^2 p = 0.641$), and overall 400 m freestyle performance ($F = 9.526$, $p = 0.009$, $\eta^2 p = 0.443$). Compared to the CG, the EG showed significantly greater improvements in trunk strength and turn performance.

CONCLUSION: Combined TST can enhance trunk flexion, extension, and bilateral rotation strength, leading to improved turn efficiency and overall performance in 400 m freestyle among national-level swimmers.

RESEARCH ON THE ARM STROKE FORCE CHARACTERISTICS OF CHINA ELITE SWIMMERS

SHANG, M., CHENG, Y., GAO, J.

BEIJING SPORT UNIVERSITY

INTRODUCTION: This study focuses on Chinese elite swimmers and deeply analyzes their arm stroke force characteristics, aiming to provide crucial scientific bases for enhancing athletes' athletic performance and optimizing training programs. By measuring the arm strokes of 48 high-level swimmers during a 50-meter all-out swim, comprehensively collecting and analyzing the force data of arm strokes, this research reveals the internal connections and laws among various force indicators, explores the key factors influencing swimming performance, breaks through the limitations of traditional training ideas, and lays the foundation for formulating innovative training strategies.

METHODS: The eoswimbetter force plate was used to test 48 freestyle swimmers (FINA score 852 ± 8 , with a training experience of 7.3 ± 3.5 years and the dominant side being the right hand). The athletes first completed a standardized routine warm-up and then swam a 50-meter freestyle with full effort while breathing normally, ensuring that the test conditions were close to the actual competition situation. Various statistical methods were applied to process the data obtained from the force plate. Descriptive statistics such as means and standard deviations were calculated, box plots and heat maps were drawn, and the correlations among various indicators were thoroughly analyzed to explore the characteristics and laws of arm stroke mechanics.

RESULTS: Regarding the individual characteristics of the athletes, the average force has a mean value of 2.35, with differences among different athletes, and shows a strong positive correlation (with a correlation coefficient of 0.82) with the average forces of the left and right hands. The average stroke frequency has a mean value of 38.71 and a high degree of dispersion (standard deviation of 8.21), and has a certain positive correlation with the number of movements, being affected by factors such as personal habits. The force distribution has different values in various directions among different athletes, reflecting the differences in the emphasis of force application. The forward propulsion efficiency percentage has a mean value of 0.48, with concentrated data, and has a certain positive correlation with the number of movements, but a weak correlation with the average force and average stroke frequency.

CONCLUSION: From the perspective of the group performance of the athletes, the data were classified according to quartiles, clarifying the performance level distribution of different athletes in terms of average force, stroke frequency and other indicators. Based on individual differences, personalized training strategies can be formulated. In terms of the symmetry characteristics of arm strokes, the average symmetry index is 0.18, with a standard deviation of 0.15, showing obvious individual differences. Athletes with a symmetry index close to 0 have excellent symmetry in arm stroke mechanics; those in the range of 0.1 - 0.3 have relatively good symmetry; those in the range of 0.3 -

SHOULDER ISOKINETIC STRENGTH SYMMETRY IN ADOLESCENT SWIMMERS AND ITS CORRELATION WITH SWIMMING PERFORMANCE

HEYUCHEN, H.

BEIJING SPORT UNIVERSITY

INTRODUCTION: This study aimed to compare shoulder joint isokinetic strength symmetry among adolescent swimmers specializing in different strokes and examine the relationship between shoulder strength imbalances and swimming performance.

METHODS: Forty-two swimmers (23 males, 15.8 ± 1.4 years, 182.8 ± 6.6 cm, 74.7 ± 6.4 kg; 19 females, 14.7 ± 1.6 years, 170.0 ± 4.4 cm, 60.3 ± 5.7 kg) participated. Maximum strength ($60^\circ/\text{s}$, 4 reps) and explosive power ($180^\circ/\text{s}$, 26 reps) of shoulder flexors and extensors were measured unilaterally, and flexor-extensor ratios were calculated. Swimming performance was assessed via 100-meter sprint times in each swimmer's primary stroke. Strength imbalance rates were calculated as: $(\%) = (\text{dominant} - \text{non-dominant}) / \text{dominant} \times 100$.

RESULTS: Wilcoxon tests showed that the flexor-extensor ratio was significantly lower for maximum strength than for explosive power ($P < 0.01$), but imbalance rates between sides were not significantly different ($P > 0.05$). Mann-Whitney U tests found no significant gender differences in strength imbalance rates ($P > 0.05$). Kruskal-Wallis tests showed no significant differences among strokes ($P > 0.05$). Spearman's analysis revealed a positive correlation between the flexor-extensor ratio and 100-meter performance in butterfly swimmers ($P < 0.05$) but a negative correlation in backstroke swimmers ($P < 0.05$). Other correlations were not significant ($P > 0.05$).

CONCLUSION: These findings suggest no significant gender differences in shoulder strength imbalance, though males exhibited a slightly lower explosive power flexor-extensor ratio than females ($P = 0.05$), indicating greater flexor-extensor disparity. Prior research links excessive imbalances to injury; in this study, 71% of swimmers with shoulder discomfort or injuries were male. The absence of significant differences across strokes suggests that bilateral imbalances are common. The correlation in butterfly swimmers may stem from the greater involvement of extensors in the stroke's entry phase, while backstroke results suggest that a controlled arm entry is more beneficial for performance.

Maintaining an appropriate flexor-extensor ratio may help prevent injuries. Butterfly swimmers should balance flexor and extensor strength, while backstroke swimmers need not prioritize symmetry but should maintain a reasonable ratio to avoid injury. Further research is needed to determine optimal strength balance ranges. Additionally, the lack of correlation between land-based strength imbalance and swimming performance suggests that symmetry assessments should incorporate water-based metrics.

OP-API8 Coaching I - Psychology

PSYCHOMETRIC CHARACTERISTICS OF LATVIAN TEAM SPORTS ATHLETES

ABELE, A., LICIS, R., LAVINS, R., VOLGEMUTE, K., ULME, G., PEREPJOLKINA, V., KLONOVA, A.

RIGA STRADINS UNIVERSITY: RIGAS STRADINA UNIVERSITATE

INTRODUCTION: The psychological skills of athletes are widely studied, especially in high performance sports. It highlights significant psychometric issues in the athletes preparation and allows corrections to be made in the training process. Psychological skills are crucial to the success and achievement of athletes. The aim of this study was: to assess the applicability of PSIS-R5 in the Latvian team sports environment, examining the relationship between athletes achievement levels and psychological skills, and to provide recommendations to coaches for improving the training process.

METHODS: A total of 254 Latvian team sports athletes aged between 18 to 35 completed the PSIS-R5 inventory to assess their psychological skills. Participation in the study was voluntary and anonymous. Prior to completing the questionnaire,

participants provided written informed consent, ensuring they were aware of the study's purpose and the intended use of their data. The PSIS-R5 includes 45 items distributed across six scales: Anxiety control, Concentration, Confidence, Mental preparation, Motivation, and Team emphasis. The PSIS-R5 was re-translated into Latvian language (PSIS-R5-L) using forward-backward translation. The levels of athletes' achievements were evaluated according to the national and international performance statistics of the specific team sport (hockey (n=73), basketball (n=52), floorball (n=36), volleyball (n=35), football (n=33), handball (n=25)). The data collected was analyzed using the Statistical Package for the Social Sciences (IBM SPSS v.28.0.0) and JASP 0.18.3.0.

RESULTS: The obtained data reveal that there are significant differences in self-confidence between elite and pre-elite athletes, suggesting that elite athletes demonstrate a higher level of self-confidence. Additionally, statistically significant differences in self-confidence were found between pre-elite and amateur athletes, indicating that pre-elite athletes exhibit lower self-confidence than amateur athletes. The motivation scale, based on average scores, shows a descending order from the elite to the pre-elite, with amateurs group scoring the lowest. These results suggest that athletes with higher levels of achievement exhibit higher motivation in sports. On the team emphasis scale, no statistically significant differences were detected among athletes' achievement groups, indicating comparable team orientation across all groups. For the visualization scale, statistically significant differences were found only between the elite and amateur groups, suggesting that elite athletes possess stronger visualization skills than amateurs.

CONCLUSION: These findings align with previous studies, supporting the fact that the higher achievement levels are associated with stronger psychological skills. The results indicate that scores on various scales are not particularly high or close to maximum levels, highlighting the necessity of integrating targeted psychological skills training into athletes' development programs.

EXAMINING PSYCHOLOGICAL ASSOCIATION BETWEEN COACH TRANSFORMATIONAL LEADERSHIP BEHAVIOURS WITH ATHLETE BASIC NEEDS SATISFACTION AND MINDFULNESS TO SUPPORT COACH PRACTICES

BRUCE-MARTIN, C., CAPLAN, N.

NORTHUMBRIA UNIVERSITY

INTRODUCTION: Integral to the role of a sport coach are facets of leadership that are instilled through developed behaviours that enhance approaches across practice alongside the athletes they support [1]. Transformational leadership (TFL) has been extensively studied in sport psychology as a leadership style that enhances athlete motivation, performance, and well-being [2]. TFL is characterised by behaviours that inspire, intellectually stimulate, and consider needs of followers [3]. However, limited work has explored its relationship with athlete focus through mindfulness and basic psychological need satisfaction in sport coaching settings. Given the central role of sport coaches as leaders, the study focuses on addressing this gap through analysis of the interplay across these aspects.

METHODS: Tennis athletes (n=422) completed validated scales to measure coach TFL behaviours (DTLI), athlete satisfaction (BNSSS), and mindfulness (MAAS). Descriptive and inferential statistical analysis, including Welch t-tests, ANOVA, Cronbach alpha coefficients, Pearson correlations, and mediation analysis using PROCESS macro, were conducted to explore the hypothesised relationships across: (1) positive correlations between athlete perception of coach TFL behaviours with satisfaction and mindfulness, (2) differential associations of TFL subscales with athlete satisfaction, (3) differential associations of TFL subscales with mindfulness, and (4) the mediating role of mindfulness in the relationship between TFL and athlete satisfaction.

RESULTS: Findings revealed significant positive correlations between athlete perception of coach TFL behaviours and both athlete satisfaction (medium correlation) and mindfulness (small correlation). Among TFL subscales, inspirational motivation had the strongest association with athlete satisfaction, while appropriate role modelling was most strongly linked to athlete mindfulness. Gender-based differences were observed, with male coaches receiving higher TFL ratings than female coaches. Contrary to expectations, mediation analysis indicated mindfulness did not significantly mediate the relationship between coach TFL behaviours and athlete satisfaction. However, significant direct effects were found between TFL and mindfulness, as well as between mindfulness and satisfaction.

CONCLUSION: This study reinforces the relevance of TFL in sport coaching, highlighting its positive association with athlete satisfaction and focus through mindfulness. Findings indicate inspirational motivation and role modelling are particularly influential behaviours in shaping athlete experiences. These insights contribute to the field of sport psychology through identifying key TFL behaviours of coaches that enhance athlete outcomes. Further studies should explore contextual factors influencing these relationships and the impact of performance level and gender disparities across coach-athlete dynamics.

EXPLORING TEAM PERFORMANCE IN ENDURANCE SPORT: HOW DO INDIVIDUALS USE THEIR SELF-REGULATION SKILLS TO PERFORM AS A TEAM?

HARMSSEN, D., VAN DEN BRANDT, F., MENTING, S., HETTINGA, F., ELFERINK-GEMSER, M.

UNIVERSITY MEDICAL CENTER GRONINGEN, UNIVERSITY OF GRONINGEN

INTRODUCTION: Self-regulation is one of the key elements for excelling in individual sports [1]. However, when performing in teams, self-regulatory processes might include additional elements relating to collaboration with teammates (group-based self-regulation). Insight into an athlete's success orientation, focusing predominantly on personal versus team

success, might help understanding the self-regulatory processes contributing to team performance. The aims of this study are to 1) investigate group-based self-regulation in endurance athletes, as well as the impact of their success orientation, and 2) explore behavior, satisfaction, and performance of individual athletes in teams.

METHODS: Twenty-nine competitive junior long-track speed skaters (14 males, 15 females), aged 16 (± 1) years, skated an individual performance (1500m) and a team performance, consisting of skating three laps in a team of three skaters (team pursuit). Participants completed questionnaires on individual and group-based self-regulation, including the facets reflection, planning, evaluation, effort, self-efficacy, speaking up, and coaching, with additional questions about success orientation (categories: personal, combined, team), general team behavior and satisfaction. Differences between individual and group-based self-regulation were tested by Related Samples Wilcoxon Signed-Rank tests. Behavior, satisfaction, and performance were explored by Spearman's rho correlations. Statistical significance was set at $\alpha=0.05$ and effect sizes (r) were calculated.

RESULTS: The score on group-based coaching (median=3) was significantly higher than the score on individual coaching (median=2) ($W=197$, $Z=3.54$, $p<0.001$, $r=0.66$). Distribution of success orientation was as follows: personal ($n=18$), combined ($n=11$), team ($n=0$). Only in participants with a combined success orientation, the group-based planning score (median=4) was higher than the individual planning score (median=3) ($W=61$, $Z=2.53$, $p<0.05$, $r=0.76$). Variation in behavior, satisfaction, and performance within and between teams was considerable, evidencing the complexities of team performance.

CONCLUSION: When performing in teams, individual athletes increased their amount of coaching. Athletes more focused on team success also increased their amount of planning. When individual athletes are assembled into a team, factors such as success orientation and the behavior and performance of teammates become important. Self-regulation (planning, coaching) may be used to navigate these complexities and improve team performance.

IMPACT OF COACH'S DRAWING ON VISUAL ATTENTION AND MEMORIZATION OF TACTICAL SOCCER SCENE: THE MODERATING EFFECT OF EXPERTISE AND VISUOSPATIAL ABILITIES

TLILI, S., ZOUDJI, B., BEN MAHFOUDH, H.

UNIVERSITÉ POLYTECHNIQUE HAUTS DE FRANCE

Aiming to facilitate learning from narrated tactical diagrams, this study investigates the impact of drawing on visual attention and memorization of soccer tactical scenes, considering participants visuospatial abilities (VSA) and expertise level. One hundred twenty participants (60 expert soccer players and 60 novices, both with high and low VSA) were randomly assigned to one of two conditions: a control condition (pre-drawn diagrams with oral explanation) or an experimental condition (diagrams actively drawn by the coach while providing explanations). Eye-tracking and a reconstruction task were conducted to evaluate recall accuracy, allocated mental effort, recall time, and total fixation duration on the diagrams. Key findings reveal a moderating effect of VSA and expertise, emphasizing the need to tailor the drawing format of tactical diagrams to individual characteristics in order to optimize memorization and visual processing of tactical soccer diagrams.

OP-MH44 Cardiovascular Disease and Dysfunction

THE ROLE OF OXYGEN SUPPLEMENTATION IN CARDIAC REHABILITATION: ENHANCING AEROBIC PERFORMANCE AND QUALITY OF LIFE IN HEART FAILURE PATIENTS

KODESH, E., COHEN, A., VEXLER, V., BOGOMILSKY, G.

UNIVERSITY OF HAIFA

INTRODUCTION: Physical activity training programs during cardiac rehabilitation reportedly reduce morbidity and hospitalization in heart failure (HF) patients. While acute oxygen supplementation has been shown to improve muscle oxygenation and enhance exercise duration and intensity, its effects during a prolonged training program remain unclear. This study aims to investigate (1) the effects of oxygen-supplemented during training on maximal and submaximal performance, 6-minute walk test (6MWT), and quality of life in HF patients; (2) the impact of oxygen supplementation during acute exercise on lactate concentration and performance.

METHODS: Twenty-four HF patients (ejection fraction $<50\%$, with no resting desaturation) were randomly assigned to an oxygen supplementation (O_2) group or a placebo control group. The O_2 group received supplemental oxygen during all exercise sessions throughout the two-month training program. The control group trained under room air conditions. All participants completed baseline and post-program assessments, including measurements of maximal and submaximal aerobic capacity, 6-minute walk test (6MWT) distance, disease severity (New York Heart Association- NYHA classification), and quality of life (Kansas City Cardiomyopathy Questionnaire, KCCQ). Participants also performed an acute submaximal effort test at 80% of their maximum heart rate, with and without supplemental oxygen. Lactate concentration, heart rate, and rate of perceived exertion were recorded every three minutes throughout the test.

RESULTS: The O₂ group showed significant improvements in maximal ($p=0.007$) and submaximal ($p=0.003$) aerobic tests, 6MWT ($p<0.001$), and KCCQ score ($p=0.011$) compared to controls. NYHA classification improved in 90% of the O₂ group versus 16% in controls. Oxygen supplementation during the acute submaximal test extended exercise duration ($p<0.001$) and led to a slower rise in lactate and heart rate ($p<0.001$) compared to exercise without oxygen supplementation.

CONCLUSION: Supplemental oxygen during training in HF patients undergoing cardiac rehabilitation improved aerobic performance and quality of life. It also prolonged exercise duration and moderated physiological responses during single submaximal exercise. Oxygen supplementation should be considered in rehabilitation programs, even for patients without resting desaturation.

OXYGEN SATURATION IN THE LEG MUSCULATURE AFFECTED BY PERIPHERAL ARTERY DISEASE DURING EXERCISE ON AN ARM ERGOMETER

CORREIA, M., SILVA, J., OLIVEIRA, M., CONCECIO, G., WOLOSKE, N., CUCATO, G., FARAH, B., KANEGUSUKU, H., RITTI-DIAS, R.

UNIVERSIDADE NOVE DE JULHO

INTRODUCTION: Arm ergometer (AE) exercise training have shown to improve functional capacity of patients with peripheral artery disease (PAD) [1], bypassing the main barrier to exercise in these patients: the pain during walking exercise. The only study that investigated the mechanism underlying this adaptation observed that chronically training with AE improved muscle oxygen saturation (StO₂) in the leg muscles during walking [2]. However, the how AE exercise acutely affects StO₂ in the leg muscles remain unknown. Thus, the aim of this study was to analyze the acute responses of AE exercise on StO₂ in the leg affected by PAD. The secondary objectives were to analyze oxy-, deoxy-, and total hemoglobin responses, describe the intensity of leg pain symptoms during exercise in AE, and examine the relationship between StO₂ during AE and PAD severity.

METHODS: Fourteen patients (57% men, 66 ± 6 years, 27.4 ± 4.6 kg/m²) with PAD and symptoms of intermittent claudication were recruited. PAD severity was assessed using the ankle-brachial index. The exercise session consisted of 15 sets of 2 minutes of AE exercise with an intensity between 13-15 on the Borgs perceived exertion scale. The Near-Infrared Spectroscopy sensor was placed on the calf muscle of the leg most affected by the disease. Prior to exercise, a physiological calibration was performed using arterial occlusion to establish a functional zero for tissue oxygenation. StO₂, oxy-, deoxy-, and total hemoglobin. These variables were continuously recorded throughout the entire session. At the end of each set, leg pain and perception exertion were recorded.

RESULTS: During AE there was an increase in leg StO₂ throughout the sets (Rest: 57.9 ± 3.6 vs. Peak: 66.8 ± 6.1 %, $p<0.001$) with a mean rise of 9.0 ± 4.1 %. On average, the participants reached peak StO₂ in the 9.9 ± 4.1 set. Additionally, there was an increase in oxyhemoglobin (Rest: 10.7 ± 10.2 vs. Peak: 26.6 ± 13.7 μ M, $p<0.001$) with average increases of 15.9 ± 7.9 μ M, and total hemoglobin (Rest: 0.2 ± 5.1 vs. Peak: 14.9 ± 12.4 μ M, $p<0.001$) with average increases of 14.6 ± 11.2 μ M; and a decrease in deoxyhemoglobin (Rest: 0.1 ± 2.2 vs. Trough: -4.8 ± 6.7 μ M, $p=0.017$) with average decreases of -4.9 ± 6.7 μ M. Perceived exertion remained at an average of 13.5 ± 0.9 , and two patients reported pain in the leg during AE. There were no associations between StO₂ responses and PAD severity ($p>0.160$).

CONCLUSION: A single session of AE increased StO₂, oxy-, and total hemoglobin while decreasing deoxyhemoglobin, and these responses occurs independently of PAD severity. Finally, two out of 14 patients reported leg pain during the AE. This study was supported by the São Paulo Research Foundation (FAPESP) under grant number 2022/14412-8.

CARDIORESPIRATORY FITNESS, GENETIC RISK, AND INCIDENT ATHEROSCLEROTIC CARDIOVASCULAR EVENTS: A PROSPECTIVE COHORT STUDY

KIM, Y.1, COLLINGS, P.J.1, WANG, M.1, CHEN, Z.1, SHI, Q.1, LUO, S.1, AU YEUNG, S.L.1, GONZALES, T.I.2, SHARP, S.J.2, BRAGE, S.2

THE UNIVERSITY OF HONG KONG UNIVERSITY OF CAMBRIDGE

INTRODUCTION: Cardiorespiratory fitness (CRF) is an important modifiable risk factor for atherosclerotic cardiovascular disease (ASCVD). It remains unknown, however, if the associations of CRF with ASCVD risk differ by genetic risk. We examined prospective relationships of CRF with incident ASCVD across genetic susceptibility strata.

METHODS: This prospective study included 69,447 UK Biobank participants (mean age 58 years; 54% female) without prevalent ASCVD and who completed a sub-maximal cycle test. Maximal oxygen consumption (mlO₂/min/kg) was estimated using a validated bike ergometry procedure, standardised within sex and age strata, and categorised to create low (20th percentile), intermediate (20-80th percentiles) and high (80th percentile) fitness groups. Genetic susceptibility to ischaemic heart disease was quantified with weighted polygenic risk scores, and was used to assign participants to low, intermediate, and high genetic risk groups. Cox regression models were used to estimate the hazard of developing ASCVD and its major sub-components. In line with international definitions, ASCVD included all documented cases of ischaemic heart disease (IHD: comprising myocardial infarction, angina, coronary revascularisation procedures), ischaemic stroke, and peripheral arterial disease. We investigated IHD and major ischaemic events (myocardial infarction and ischaemic stroke) as nested secondary outcomes.

RESULTS: During a median follow-up of 12 years, there were 5,448 incident ASCVD, 4,177 IHD, and 2,299 major ischaemic events. Each 1-standard deviation difference in sex- and age-standardised CRF (equivalent to 5.6 mL O₂/kg/min) was associated with an 8% (hazard ratio [95% confidence interval]: 0.92 [0.89-0.95]) lower hazard of ASCVD, independently of demographic, lifestyle and health-related factors, and genetic risk. There was weak evidence of multiplicative interaction ($p=0.06$) between CRF and genetic risk, suggesting that the associations might be slightly stronger in the low genetic risk group (0.87 [0.80-0.94]) compared with intermediate (0.94 [0.90-0.98]) and high genetic risk groups (0.91 [0.86-0.97]). There was no evidence of additive interaction ($p=0.78$). The 10-year absolute risk differences between low and high CRF groups were 1.2% and 1.6% within high and low genetic risk categories, respectively. Similar patterns of associations were found for incident IHD and major ischaemic events.

CONCLUSION: Across all strata of genetic risk for cardiovascular disease, higher CRF is strongly associated with lower risk of ASCVD and its major sub-components. Adults should be encouraged to increase or maintain CRF levels, irrespective of genetic susceptibility.

SEX AND GENOTYPE SPECIFICITIES OF MICROVASCULATURE AND MUSCLE REMODELING IN SUB-SAHARAN SICKLE CELL TRAIT AND DISEASE

MESSONNIER, L., BLERVAQUE, L., RICCETTI, M., MERLET, A., NOGUER, M., ROJO, M., HOURDÉ, C., FÉASSON, L.
UNIVERSITÉ SAVOIE MONT BLANC

INTRODUCTION: Sickle cell disease (SCD), the most common genetic disease in the world, is due to the synthesis of abnormal hemoglobin S (HbS) which may polymerize once deoxygenated, rigidifying and distorting the red blood cells in sickle shape. SCD is associated with reduced exercise tolerance connected with a microvasculature and muscle remodeling. However, SCD-repercussions on microvasculature and muscle remain unknown in women. The present study aimed to compare muscle microvascular and energetic characteristics of female and male healthy subjects (CON), carriers of sickle cell trait (SCT) and patients with SCD.

METHODS: 56 Cameroonians (16 SCD patients (9 women and 7 men), 20 SCT carriers (10 women and 10 men) and 20 healthy controls (CON, 10 women and 10 men)) were involved. Blood samples were assayed for complete blood count, HbS and HbF proportions, derived parameters and circulating molecules (AOPP, L-, P- and S-selectins, ICAM, VEGF, MMP2 and MMP9). Biopsies of the right vastus lateralis muscle were performed percutaneously at rest to determine microvascular network, fibre type (distribution and morphology), proteins content (CAII, CAIII, CAIV, MCT1, MCT2, MCT4, NHE1, NBC) and mRNA content (HIF-1 α , REDD1, NF- κ B1, NF- κ B3, SOD1, CAT, GPX3, GPX4). CS, CK, LDH, PFK and β -HAD enzyme activity was also analyzed on muscle lysate. Total and peri-capillary COx activity were analyzed by histoenzymology.

RESULTS: In SCD, correlations between capillary density and plasma L-selectin ($p<0.001$) and ICAM ($p<0.01$) and between capillary diameter and mean corpuscular hemoglobin S concentration ($p<0.01$) were noticed. The capillary network rarefaction observed in SCD was more pronounced in women than in men (interaction: $p<0.01$). Compared to CON, the surface for 100 myocytes was lower in men with SCD (both $p<0.001$) but not in women. Advanced oxidation protein products (AOPP) were increased in SCD patients and to a greater extent in men (interaction: $p<0.02$). Components of muscle pH regulation (CAII and MCT4) were specifically higher in SCT.

CONCLUSION: Our results suggest that SCD-associated capillary rarefaction and enlargement could be related to disturbed hemodynamics and reduced erythrocytes deformability, respectively. The specific remodeling in female SCD patients included aggravated microvascular remodeling but preserved myocytes. Muscle pH regulation mechanisms appeared specifically up-regulated in SCT carriers.

CHRONIC E-CIGARETTE USE IMPAIRS CENTRAL AND PERIPHERAL VASCULAR FUNCTION AND AEROBIC FITNESS IN YOUNG ADULTS

BOIDIN, M., SOMANI, Y., DAWSON, E., PECANHA, T., EVISON, M., BIRKETT, S., DEGENS, H., JUNEJO, R., THIJSSSEN, D., FETTERMAN, J.L.
MANCHESTER METROPOLITAN UNIVERSITY

INTRODUCTION: Chronic e-cigarette use (vaping) has been shown to increase inflammation and reduce nitric oxide (NO) bioavailability, similar to the effects of combustible cigarette use (smoking). These changes may contribute to both central and peripheral vascular dysfunction. However, the impact of vaping on vascular health in age- and sex-matched individuals remains unclear. Additionally, vaping has been linked to lung function impairments comparable to those seen in smokers, which may negatively affect aerobic fitness. This study aims to examine the effects of chronic e-cigarette use on vascular function and cardiorespiratory responses to exercise in young individuals.

METHODS: Sixty participants were recruited and completed two separate visits. The first visit included peripheral and central vascular function assessments: flow-mediated dilation (FMD) and the carotid artery reactivity (CAR) test. The second visit involved a maximal cardiopulmonary exercise test (CPET) to determine peak oxygen uptake (peak VO₂). Participants also wore an accelerometer for seven days between visits. Unpaired t-tests were used to compare groups between each other.

RESULTS: Preliminary data were analysed for 44 participants (18 controls: mean age 28 years, 45% female; 11 smokers, 45% female; and 15 vapers, 45% female). FMD was similar between vapers and smokers ($3.34\pm1.82\%$ vs. $3.74\pm1.95\%$, $p=0.73$) but lower in both groups compared to controls ($7.77\pm3.76\%$; $p=0.01$ vs. vapers, $p=0.003$ vs. smokers). These findings remained consistent after adjusting for baseline diameter, shear stress, peak VO₂, and physical activity volume.

Similarly, CAR was comparable between vapers and smokers ($-0.20 \pm 4.72\%$ vs. $-1.08 \pm 3.45\%$, $p=0.77$) but lower in both groups compared to controls ($4.99 \pm 3.99\%$; $p=0.03$ vs. vapers, $p=0.02$ vs. smokers). Peak VO₂ was also lower in vapers and smokers compared to controls ($p=0.03$ for both), with no difference between the two groups ($p=0.73$).

CONCLUSION: Vascular dysfunction is an early and robust marker of cardiovascular disease, preceding the onset of atherosclerosis. Using validated, non-invasive and clinically relevant measures of vascular health, which are known to predict the risk of major adverse events, our study provides critical insights into the impact of e-cigarette use on cardiovascular function and aerobic fitness, both of which may contribute to long-term health complications.

A GENOMIC INTERVAL WITHIN THE PROTEOGLYCAN GENE HSPG2 IS IMPLICATED WITH A DECREASED RISK OF ANTERIOR CRUCIATE LIGAMENT INJURY.

SEPTEMBER, A., RAMOSHABA, L., LAGUETTE, M.J.N., CIESZCZYK, P., FICEK, K., HÄGER, C.K., STATIN, E., NILSSON, K.G., EYNON, N., FELLER, J., TIROSH, O., COLLINS, M.

UNIVERSITY OF CAPE TOWN

INTRODUCTION: Anterior cruciate ligament (ACL) ruptures is a common lower limb injury. The potential risk factors include a genetic component. Variants within the proteoglycan gene heparan sulphate proteoglycan 2 (HSPG2) was previously implicated in a South African population. This study aimed to investigate the genetic association of HSPG2, with ACL rupture risk in a large cohort recruited from participants from Poland (POL), Sweden (SWD), Australia (AUS) and South Africa (SA).

METHODS: The combined (COMB) cohort comprised of 579 asymptomatic controls (COMB-CON: POL-CON= 150; SWD-CON= 116; AUS-CON= 80 and SA-CON= 234), and 822 ACL ruptures by non-contact and other mechanisms (COMB-ACLR: POL-ACLR= 141; SWD-ACLR= 95; AUS-ACLR= 332; and SA-ACLR= 253); subgroup (COMB-NON), n=434 ACL rupture by non-contact mechanism of injury (NON), (POL-NON= 54; SWD-NON= 79; AUS-NON= 154, and SA-NON= 149). Participants were genotyped for HSPG2 (rs2291826 A/G, rs2291827 G/A). Genotypes and inferred haplotypes were compared. Statistical significance was assumed if $P < 0.05$ and false discovery rate (FDR) was used for multiple comparisons.

RESULTS: The HSPG2 rs2291826 AG genotype was associated with a reduced risk of ACL rupture (COMB-CON vs. COMB-ACLR: $P= 0.002$; FDR= 0.009; OR: 0.69; 95% CI: 0.55 – 0.87 and COMB-CON vs. COMB-NON: $P= 0.003$, FDR= 0.009, OR: 0.66; 95% CI: 0.50 – 0.87). The HSPG2 (rs2291826 A/G, rs2291827 G/A) G-A haplotype was also associated with reduced ACL rupture risk (COMB-CON vs. COMB-ACLR: $P= 0.019$; OR: 0.64; 95% CI: 0.79 - 0.99 and COMB-CON vs. COMB-NON: $P= 0.040$; OR: 0.60; 95% CI: 0.78 - 1.01). The recessive model was most significant when the COMB-CON vs. COMB-ACLR groups were compared ($P= 0.007$; FDR= 0.009; OR: 2.29; 95% CI: 1.22 – 4.31). No independent significant differences in the genotype or allele frequencies distribution for the HSPG2 rs2291827 G/A variant were detected in the combined cohort.

CONCLUSION: Novel findings of this study include (i) an independent association of variants within the HSPG2 (rs2291826 A/G; with a protective effect) and confirming this was the (ii) association of the HSPG2-GA haplotype were a reduced risk. This study has identified the association of HSPG2 with a reduced risk and has specifically implicated a genomic interval within this gene with a protective effect. These findings provide the basis for further research to understand the exact biological mechanisms underpinning ACL rupture risk.

ACHILLES TENDON PROPERTIES IN HEALTHY YOUNG MALE AND FEMALES: A PILOT STUDY

AKMAN, M., KOVÁCS, B., EMAM, M., ZHANG, L., YE, J., CSIZMADIA, B., NÉGYESI, J., HORTOBÁGYI, T.

HUNGARIAN UNIVERSITY OF SPORTS SCIENCE

INTRODUCTION: Systematic reviews suggest that up to 80% of Achilles tendon injuries occur in men. However, sex-differences in Achilles tendon mechanical and morphological properties have been inconsistent. Therefore, this study aimed to compare selected Achilles tendon properties between healthy young males and females.

METHODS: Healthy young adults (4 males, 5 females; age: 31.3 ± 9.19 years, mass: 67.8 ± 17.48 kg height: 174.7 ± 9.59 cm) participated in this study. Study volunteers were sports science university students and pursued various sports disciplines without a recent or past Achilles tendon injury. Maximal plantarflexor isometric torque was measured by dynamometer in a prone position with the knee extended and ankle at 90° . Achilles tendon moment arm and stiffness were measured using the tendon excursion method. Morphological parameters of the Achilles tendon at rest, such as cross-sectional area and thickness were assessed by ultrasound at the level of the medial malleoli. A series of independent t-tests were performed to analyze sex-differences using the JASP (version 0.19.3) statistical program.

RESULTS: We observed no sex-differences in the measured morphological and mechanical variables of the Achilles tendon. Specifically: moment arm; male = 3.0 ± 0.8 (cm) female= 2.92 ± 0.36 (cm) stiffness; male = 293.97 ± 347.80 (N/mm), female = 229.16 ± 102.93 (N/mm) , and tendon thickness; male = 6.65 ± 1.0 (mm) female = 6.36 ± 0.57 (mm). Maximal plantarflexor isometric torque; male = 72.5 ± 23.05 (Nm), female = 70.73 ± 20.20 (Nm). Sex-differences in tendon cross-

sectional area revealed a large effect size ($d = 1.25$) without statistical significance (male = $85.5 \pm 21.20 \text{ mm}^2$, female = $65 \pm 11.57 \text{ mm}^2$)

CONCLUSION: The current preliminary data are limited by the small sample size. The lack of sex-differences in Achilles tendon properties might be related to differences between the two sexes in training history, sports disciplines, and training status at the time of testing. Additional data we are currently collecting might help resolve the inconsistencies in sex-differences in Achilles tendon properties reported by previous studies.

PREVALENCE OF BONE HEALTH DETERMINANTS IN ELITE TRIATHLETES: A 5-YEAR PROSPECTIVE STUDY

CRUNKHORN, M., TOOHEY, L., CHARLTON, P., DREW, M., WATSON, K., ETXEBARRIA, N.

UNIVERSITY OF CANBERRA

INTRODUCTION: Bone stress injuries (BSIs) have a high injury burden in elite triathletes, with the rate of BSIs in females reported to be three times greater compared with males [1]. Being female, competitive sport participation, problematic low energy availability (LEA), vitamin D or iron deficiency, irregular menstrual cycles and large variations in training load are the most commonly reported risk factors for sustaining a BSI. Despite the high incidence and burden of BSIs in triathletes, and concomitant impact on performance, there is limited literature outlining the aetiology and risk factors for injury and illness in this population. This study aimed to establish the prevalence of low bone mineral density (BMD), iron deficiency and problematic LEA in elite short-course triathletes, and to compare the prevalence of these health determinants between males and females.

METHODS: Forty-seven triathletes (21 males, age: $24.0 \pm 3.4 \text{ y}$, height: $182.8 \pm 5.8 \text{ cm}$, weight: $71.0 \pm 5.4 \text{ kg}$; and 26 females, age: $26.0 \pm 5.4 \text{ y}$, height: $168.2 \pm 6.2 \text{ cm}$, weight: $57.7 \pm 9.3 \text{ kg}$) were prospectively recruited and monitored over five consecutive seasons, with data collection occurring annually. Dual-energy X-ray absorptiometry (DEXA) was conducted on a GE Lunar iDXA (GE Medical Systems, using GE enCORE analysis software version 16 and 18 Madison, WI, USA) to assess BMD of the anteroposterior lumbar spine and femoral neck. A cut-off Z-score of < -1 was used as the threshold for low BMD. Fasted blood samples were collected via venepuncture. A cut-off of $\leq 30 \mu\text{g/L}$ was used as the threshold for low ferritin. The Low Energy Availability in Females Questionnaire (LEAF-Q) was administered electronically to assess energy intake in the female athletes. A cut-off score of ≥ 8 was used to identify individuals at risk of LEA.

RESULTS: A higher proportion of female athletes were found to have low BMD (28.57%; 95%CI=12.83-44.32) as compared to males (11.11%; 95%CI=-1.56-23.78). Females had an average lumbar spine and femoral neck Z-Score of -0.0 (SD=0.8) and -0.7 (SD=1.0) respectively, compared to -0.6 (SD=0.5) and 0.2 (SD=0.6) in males. The prevalence of low ferritin in females (12.00%; 95%CI=2.67-21.33) was higher than males (4.25%; 95%CI=-1.73-10.24). Of the 46 LEAF-Q responses from the female athletes across five years, 63.04% (95%CI=48.55-77.53) were above the low-risk threshold for LEA.

CONCLUSION: This study outlines the differences in bone health related markers in male and female triathletes, with females demonstrating a higher prevalence of low BMD and low ferritin. This highlights the need to further investigate these health domains and explore relationships to bone health and BSIs, specifically in female triathletes given the high burden of these injuries in this population.

SURFACE ELECTROMYOGRAPHY ANALYSIS OF CLIMBERS WITH UNILATERAL SHOULDER PAIN BEFORE AND AFTER A PHYSIOTHERAPY PROTOCOL

MARTINI, M., RAFFINI, A., SFILIGOI, P., BUOITESTELLA, A., DEODATO, M., MURENA, L.

UNIVERSITY OF TRIESTE

INTRODUCTION: Climbing involves overloading of the shoulder girdle that can result in the development of shoulder pain (Jones et al., 2018). Therefore, understanding the possible altered neuromuscular patterns could support the development of strategies for the management of this specific musculoskeletal condition. The aim of this study was to investigate the neuromuscular activity of the shoulder during climbing in climbers with unilateral shoulder pain and healthy controls to define possible altered neuromuscular patterns and investigate the effects of a physiotherapy protocol on the neuromuscular activity.

METHODS: Ten healthy climbers (4 females, 31 ± 5 years) and ten climbers with history of unilateral shoulder pain (4 females, 30 ± 6 years) voluntarily participated to the study. Surface electromyography (sEMG) was recorded bilaterally during the execution of the frontal and opposite shoulder movements on the following muscles: medial deltoid (m. MD), pectoralis major (m. PM), latissimus dorsi (m. LD), upper trapezius (m. UT), lower trapezius (m. LT) and serratus anterior (m. SA). The sEMG signals were reported as percentage of the maximal voluntary isometric contraction (%MVIC). Climbers with unilateral shoulder pain were evaluated before and after a physiotherapy protocol.

RESULTS: Considering the differences between healthy climbers and those with unilateral shoulder pain the main findings of this study suggested that m. LD showed a lower activation in the pain group compared to the healthy controls during both the opposite shoulder movement (-27.0% ; $p=0.001$) and frontal movement (-3.9% ; $p=0.042$). Furthermore, m. PM showed a higher activation in pain group compared to controls in the opposite shoulder movement (6.6% ; $p=0.049$). After the physiotherapy protocol, no significant differences were found between the two groups in m. LD and m. PM activation.

CONCLUSION: The presence of unilateral shoulder pain in climbers could lead to altered neuromuscular patterns (Raffini et al., 2024) and, in particular, the present study suggests a lower activation of the latissimus dorsi that might reflect a dynamic muscle imbalance and altered scapular kinematics typically present in overhead athletes (Wong et al., 2009).

Based on these findings, the proposed physiotherapy protocol was effective in restoring a pattern of muscle activation similar to that found in healthy climbers.

INVESTIGATION OF ASSOCIATED FACTORS FOR PREGNANCY-RELATED LOW BACK PAIN AND ITS ASSOCIATION WITH MOTOR CONTROL ABILITIES

LIN, T., CHEN, Y., HUANG, J.P., WANG, T.J.

NATIONAL YANGMING CHIAOTUNG UNIVERSITY

INTRODUCTION: Pregnancy-induced low back pain (LBP) significantly affects health and quality of life during and after pregnancy, often complicating recovery. While various risk factors have been identified in Western populations, differences in culture, physiology, and daily life in Eastern populations highlight the need for research focused on Asian women. Motor control is crucial during pregnancy as changes in the lumbar spine and pelvis require increased stability. Impaired motor control may contribute to LBP, but its role in pregnancy-related LBP is less studied. Investigating motor control and movement dissociation could improve preventative and rehabilitative strategies, particularly for Asian populations where research is limited. This study aims to examine the factors associated with pregnancy-related LBP in Taiwanese women by comparing those who experience LBP with those who do not. Crucial factors include sociodemographic variables, health status, physical activity and psychosocial factors. Additionally, the study explores the relationship between motor control and the occurrence or severity of pregnancy-related LBP, as motor control plays a key role in movement and postural stability during pregnancy.

METHODS: This cross-sectional study investigates differences between women with and without pregnancy-related LBP. 60 participants in their second trimester provided demographic, work, and exercise information. They completed six motor control assessments (three extension and three rotation tests), following therapist demonstrations, and were evaluated using the Kinetic Control Test scoring system. Each test included 10 components, with points awarded for successful completion. An independent t-test assessed differences between groups, while correlation analysis explored the link between motor control and LBP occurrence or severity.

RESULTS: The independent t-test for non-parametric analysis revealed significant results for regular exercise ($Z = -2.054$, $p = 0.04$) and a history of pain prior to pregnancy ($Z = -4.144$, $p < 0.001$) in relation to pain intensity on the Numerical Rating Scale (NRS) in 60 pregnant women. Spearman's correlation showed no significant relationship between BMI or age and pain intensity ($r = 0.091$, $p > 0.05$; $r = -0.128$, $p > 0.05$), nor between pain intensity and motor control ability ($r = -0.246$, $p = 0.06$).

CONCLUSION: The study found that regular exercise is associated with lower pregnancy-related LBP, while a history of pain correlates with greater severity. Other factors, including lower education level, high BMI, nausea, long work hours, and monoparity, did not show significant effects, likely due to the limited sample size, although pain was higher in these groups. Motor control scores below 4 on specific tests were linked to higher pain levels, with extensional control being more strongly associated with pain. These findings underscore the importance of incorporating exercises focused on extensional motor control in pregnancy-related pain prevention.

OP-PN31 Physiology of Fatigue III

THE EFFECT OF COMPETITIVE FEMALE GAELIC GAMES MATCH PLAY ON NEUROMUSCULAR FUNCTION

RUSSELL, A., NULTY, C., BYRNE, P., OHARA, R., COYLE, C.

SOUTH EAST TECHNOLOGICAL UNIVERSITY CARLOW

INTRODUCTION: Gaelic games match play consists of intervals of lower intensity activities including walking, jogging or standing interspersed with repeated high-intensity bouts which often leads to fatigue [1,2]. Despite this, no study has comprehensively investigated the effect of competitive match play on fatigue in female Gaelic games athletes. The purpose of this study was to examine the post-match changes in neuromuscular function following competitive female Gaelic games.

METHODS: Twelve collegiate female Gaelic games players (age: 21 ± 1 yrs, height: 170.5 ± 4.5 cm; body mass: 66.2 ± 8.1 kg) were recruited for this study. The following were collected pre- and post- competitive match, and again at 12h, 36h, and 60h post-match: reactive strength index (RSI), countermovement jumps (CMJ) and maximal isometric relative torque during knee extension (KE) and flexion (KF) paired with surface electromyography (sEMG), plasma interleukin-6 (IL-6) as well

as Global positioning systems (GPS) recording match play. Data were analysed using one-way repeated measures ANOVA and paired T-tests to examine changes.

RESULTS: The mean distance covered was 4812.5 ± 1315.8 m. CMJ height decreased from immediately post- to 12h post-match (226.9 ± 5.0 to 24.7 ± 4.2 cm, $P=0.006$, $\eta^2 = 0.356$). Neither Vastus Lateralis (VL) or Biceps Femoris (BF) peak amplitude, RSI or KF changed over time ($P>0.05$). There was a main effect of time on KE ($P=0.006$), which decreased from 2.56 ± 0.63 Nm.kg⁻¹ post- to 2.25 ± 0.62 Nm.kg⁻¹ 60h post-match ($P=0.026$), with a large effect ($\eta^2 = 0.274$) and did not return to baseline (2.48 ± 0.12 Nm.kg⁻¹) at 60h post-match. There was a main effect of time on blood plasma IL-6 pg.mL⁻¹ ($P=0.019$). IL-6 increased from 1.36 ± 2.59 pre- to 3.91 ± 3.26 pg.mL⁻¹ post-match ($P=0.030$). IL-6 decreased from 3.91 ± 3.26 post- to 0.95 ± 1.60 pg.mL⁻¹ 12h post-match, with a large effect ($\eta^2 = 0.410$), and remained at baseline until 60h post-match ($P=0.448$).

CONCLUSION: This is the first study to identify the post-match changes in neuromuscular function following competitive collegiate female Gaelic games. The reductions in neuromuscular function up to 60h post-match, indicates the fatigue induced by female Gaelic games players. This is similar to male Gaelic games players who experience fatigue up to 48h post-match [3]. Although the systematic inflammation dissipates quickly (<12 h), the neuromuscular system remains suppressed until 36h and in some respects 60h, which has implications for training and match schedules where optimising performance is crucial.

SUPERIMPOSED LOCAL VIBRATION AND THE TIME BEFORE EXHAUSTION: IS IT SEX AND INTENSITY-DEPENDENT?

TIMBERT, T., AMIEZ, N., MARTIN, A., COMETTI, C., PAIZIS, C.

UNIVERSITÉ DE BOURGOGNE EUROPE

INTRODUCTION: Muscle spindle stimulation with superimposed local vibration (SLV) revealed temporarily motor unit recruitment facilitation and increased strength during submaximal contraction (1). Conversely, repeated spindle activation during voluntary contractions reduces support to α -motoneurons, leading to fatigue and strength loss (2). Thus, applying SLV during fatiguing submaximal contractions may slow the decline in force (known as "performance fatigability"). This study examined SLV effects during an intermittent, fatiguing knee extension task and explored its interaction with contraction intensity (low vs. moderate) and sex.

METHODS: A total of 45 participants performed maximal voluntary contraction (MVIC) of the knee extensors and flexors before (PRE) and after (POST), a fatiguing task. The fatiguing protocol consisted of intermittent knee extensions (15s effort, 5s rest) at 50% (15 males and 9 females) or 30% MVIC (13 males and 8 females) until a 10% strength target loss. Participants realized the control task (CON) or the vibration condition (SLV) in random order. The vibration was applied to the quadriceps tendon (100 Hz, 2-3 mm).

An ANOVA between Condition was used for the time to exhaustion (TTE) including statistical parameters Sex and Intensity (30% vs. 50%) as between-subject factors and Condition (CON vs. SLV) as a within-subject factor. Similar parameters were used for the MVIC using a two repeated factors ANOVA (Time [PRE vs POST] $\times$ Condition [CON vs SLV]).

RESULTS: The MVIC decreased from PRE (240 ± 71 N·m) to POST (164 ± 54 N·m) similarly in both Condition ($p = 0.834$), Intensity ($p = 0.948$) or Sex ($p = 0.147$).

The ANOVA revealed a longer TTE at 30% (274 ± 119 s) than at 50% (112 ± 28 s, $p < 0.001$) and Sex did not influence the TTE ($p = 0.245$). The analysis showed that SLV increased by $11 \pm 21\%$ the TTE (CON: 179 ± 110 s, SLV: 196 ± 121 s, $p = 0.007$) without differences between Intensity ($p = 0.064$) or Sex ($p = 0.120$). Finally, no correlation was found between the MVIC and the Condition ($p = 0.815$).

CONCLUSION: We found that superimposed local vibration is an efficient method to increase the time before exhaustion at low or moderate intensity for males and females without altering the force loss after the fatiguing task. Moreover, its positive effect remains consistent regardless of maximal force, suggesting that SLVs influence is independent of individual strength levels. This leads us to ask how the chronic use of SLV during resistance strength training can influence performance?

COGNITIVE FATIGUE INDUCED BY MILITARY OPERATIONS IN HYPOXIC AND COLD ENVIRONMENT

SPINABELLI, S., ELIPANNI, L., MARTINEZ-GONZALEZ, B., RANUNCOLI, C., MRKIC SPOSTA, S., PRATALI, L., NAVA, C., MARCO-RA, S.M.

ALMA MATER STUDIORUM UNIVERSITY OF BOLOGNA

INTRODUCTION: The Arctic environment features various environmental challenges, such as extreme cold and hypoxia, could increase soldiers' mental demand and impair soldiers' cognitive performance in terms of accuracy and attention. The purpose of this study was to explore the effects of operating in a hypoxic and cold environment (HCE) on the cognitive functions of three different groups of alpine soldiers.

METHODS: 34 soldiers specialized in mountain warfare (Alpine Corp) were tested before, during and after 3 days of military training (1-2-3/12 2024), on the Mont Blanc (3375m). Additional tests were conducted at 551m, four days before and 14 days after training. Soldiers were divided in 3 different groups, based on their experience and operational role: A (alpine lieutenant), B (alpine special forces), C (alpine specialized guides). Each day, soldiers were tested before and after the military operation session consisting of trekking and survival skills. Pre-operation measures included the Groningen Sleep Quality and the Fatigue scales, a 5-min psychomotor vigilance task (PVT), and a 5-min step test. After operating, soldiers repeated PVT and the step test. In addition, they rated the effort (session RPE), the workload (NASA-TLX) experienced during the operating session and the subjective fatigue changes compared to pre-military operation (Fatigability scale).

Mixed ANOVAs were used to test the effects of Group, Day and, when relevant, Time. Significance was set at $p < 0.05$.

RESULTS: PVT performance deteriorated significantly after training only on the first day in HCE ($p < 0.05$), indicating acute cognitive fatigability. Military training was perceived as more mentally demanding in HCE ($p < 0.05$). Both fatigue and fatigability increased significantly in HCE ($p < 0.001$). In addition, fatigability rating was the highest on the 1st day and then decreased, being significantly higher compared to 3rd day in HCE ($p = 0.002$).

Rating of sleep quality worsened in HCE ($p < 0.001$). No significant difference between groups.

CONCLUSION: These results show that even soldiers specifically trained for mountain warfare suffer from the negative effects of HCE on cognitive performance, sleep perceived quality and general fatigue. There was no significant effects of HCE on cognitive performance before military operation, while after the operation cognitive performance decreased significantly especially on the first day in HCE, indicating a significant degree of cognitive fatigue induced by operating in hypoxia, cold and a challenging environment. Moreover, this military operation was perceived to be more mentally demanding and fatiguing in HCE compared to low altitude. Countermeasures for cognitive fatigue should be developed to improve soldiers' performance, especially during the first day in HCE.

A NEW INCREMENTAL CYCLING COGNITIVE-MOTOR DUAL-TASK TEST TO ASSESS SIMULTANEOUS SUSTAINED ATTENTION AND NEUROMUSCULAR FATIGUE IN TRAINED ATHLETES.

GOEPP, T., HAYES, M., HOT, P., RUPP, T.

UNIVERSITÉ SAVOIE MONT BLANC

INTRODUCTION: Cognitive efficiency during isolated cognitive-motor dual-task (CMDT) is influenced by exercise intensity, with moderate intensities enhancing performance compared to low or high intensities, consistent with the inverted-U theory. However, this relationship remains unexamined in whole-body exercises among trained athletes. Conversely, neuromuscular fatigue etiology resulting from high-effort cycling has been shown to be modulated by concurrent sustained attention tasks, yet the development of neuromuscular fatigue during progressively demanding CMDT remains unclear due to methodological constraints (time needed to move the participants to an isometric knee-extensor ergometer). This study aimed to investigate sustained attention performance during incremental cycling in trained individuals, with periodic assessments of neuromuscular fatigue using an innovative ergometer that allowed for real-time measurements without delay.

METHODS: Forty well-trained adults completed a novel incremental cycling and cognitive test, to assess cognitive-motor interactions under progressive physical exercise. This test consisted of 3-min ramp stages, beginning at $1 \text{ W} \cdot \text{kg}^{-1}$ with $0.4 \text{ W} \cdot \text{kg}^{-1}$ increments, combined with a sustained attention Mackworth task. Participants continued until reaching an "extremely strong" perceived effort (CR100 Borg scale, task-failure TF). At each stage, concurrent psycho-physiological assessments included Mackworth score, quadriceps isometric maximum voluntary contraction (IMVC), associated neuromuscular fatigue indices through femoral nerve electrostimulation (peripheral fatigue: twitch force, Pt; central fatigue: voluntary activation, VA), prefrontal cortex (PFC) oxygenation assessed via near-infrared spectroscopy, and perception of effort. Individual data were extrapolated at 20, 40, 60, and 80% of TF to analyse progressive changes in cognitive and neuromuscular function.

RESULTS: Pt was linearly decreased throughout the test (Pre-TF = $-40.7 \pm 15.1\%$, $P < 0.001$). VA started to be depressed at 40%TF ($-1.5 \pm 0.9\%$, $P = 0.003$), with an exacerbated decline at 80%TF and TF (Pre-TF = $-6.9 \pm 2.4\%$, $P < 0.001$), concomitant to IMVC exacerbated declines at these time-points (Pre-TF = $-20.9 \pm 8.9\%$, $P < 0.001$). PFC oxygenation started to decline at 60%TF up to TF ($-7.9 \pm 2.2\%$, $P < 0.001$). The Mackworth score was not significantly affected during the test until 80%TF, at which point CMDT engaged $84 \pm 7\%$ of HRmax ($-8.3 \pm 5.7\%$ and $-11.0 \pm 6.7\%$ from Pre to TF, both $P < 0.026$).

CONCLUSION: This study found that sustained attention performance did not follow the inverted-U theory during an incremental cognitive-motor test involving large muscle mass in well-trained adults. Sustain attention efficiency declined only at cycling intensities corresponding to "very strong" perceived effort, coinciding with PFC deoxygenation and exacer-

bated central fatigue. Notably, central fatigue emerged early, underscoring the importance of carefully managing cognitive-motor dual-task scenarios in both training and occupational settings.

EFFECTS OF TRANSCRANIAL DIRECT CURRENT STIMULATION OVER THE SUPPLEMENTARY MOTOR AREA ON EXERCISE TOLERANCE AND PSYCHOPHYSIOLOGICAL RESPONSES TO HEAVY-INTENSITY EXERCISE

DELL ANNA, S., BERNARDES, A.G., AZZALI, G., LIBERALI, G., PRIVITERA, M., PEYRÉ-TARTARUGA, L.A., DE GIORGIO, A., BALDARI, C., BUZZACHERA, C.F.

ECAMPUS UNIVERSITY

INTRODUCTION: Transcranial direct current stimulation (tDCS) has emerged as a minimally invasive form of cortical stimulation that may modulate psychophysiological responses to exercise and enhance exercise performance. While some studies have reported increased exercise tolerance during large-muscle mass dynamic exercise, overall findings remain inconsistent. The reasons for these discrepancies among tDCS studies are unclear but may, in part, be attributed to variations in electrode montage and placement. We therefore hypothesised that an electrode montage targeting the supplementary motor area (SMA) — a key region implicated in the effort perception, which is a potential factor influencing the ergogenic effects of tDCS — could, in contrast to conventional placements over the primary motor cortex, lead to a reduced perception of effort and, arguably, influence exercise tolerance during heavy-intensity cycling exercise.

METHODS: Twelve healthy, recreationally active men (mean age: 25 ± 2 years, $\text{VO}_{2\text{peak}}$: $42.9 \pm 3.6 \text{ mL}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$) participated in the study. All volunteers were required to visit the laboratory on four separate occasions. On Day 1, they performed a ramp-incremental exercise test on an electronically braked cycle ergometer to determine the gas exchange threshold (GET), $\text{VO}_{2\text{peak}}$, and peak power output (PO_{peak}). On Days 2–4, participants completed a heavy-intensity exercise bout to exhaustion at a workload corresponding to 25% of the difference between the GET and PO_{peak} attained during the ramp exercise test. Each test was conducted following the administration, in a randomised crossover design, of 10 minutes of brain stimulation using either sham tDCS, anodal tDCS, or cathodal tDCS (current intensity: 1 mA). Perceived exertion was recorded every 2 minutes during the exercise tests. Pulmonary gas exchange and ventilation, central haemodynamics, and electromyographic activity responses were continuously monitored.

RESULTS: There were no significant differences in pulmonary gas exchange and ventilation, central haemodynamics, electromyographic activity, or perceived exertion between sham, anodal, and cathodal tDCS during heavy-intensity exercise bouts ($P > 0.05$). The tolerable duration of heavy-intensity exercise was also unaffected by the tDCS conditions, with values of 30.8 ± 7.8 minutes, 31.2 ± 11.4 minutes, and 30.8 ± 12.0 minutes for sham, anodal, and cathodal tDCS, respectively ($P > 0.05$).

CONCLUSION: The present findings suggest that a single session of brain stimulation applied over the SMA region does not significantly alter psychophysiological responses to heavy-intensity exercise or enhance exercise tolerance in healthy, recreationally active men. These results indicate that this simple, non-invasive neuromodulatory technique is ineffective during fatiguing, high-intensity activities involving large muscle mass. However, further research is required to explore alternative brain stimulation protocols and exercise modalities.

OP-AP22 Power and Strength I - Post-activation Performance Enhancement

EXAMINING SEX DIFFERENCES IN POST-ACTIVATION PERFORMANCE ENHANCEMENT (PAPE) FOLLOWING SQUAT AND POWER CLEAN PROTOCOLS

BATTIOLI, R., CÈ, E., LONGO, S., SQUILLANTE, A.

UNIVERSITÀ DEGLI STUDI DI MILANO

INTRODUCTION: Post-Activation Performance Enhancement (PAPE) is a temporary improvement in neuromuscular performance following a high-intensity conditioning activity (CA). Previous meta-analyses suggest individuals with higher training experience and strength levels may show a greater PAPE response due to enhanced fatigue resistance and improved balance between potentiation and fatigue. While PAPE has been studied extensively in men, studies on female athletes remain limited. Therefore, this study investigated how trained men and women respond to two PAPE protocols. Understanding these variations is crucial for optimizing training interventions for both men and women.

METHODS: 15 men (M, mean $\pm$ SD: age= 29 ± 4 yrs; BMI= $30.3\pm 6.5 \text{ kg/m}^2$), and 17 women (W, age= 27 ± 4 yrs; BMI= $25.9\pm 2.4 \text{ kg/m}^2$) volunteered in this study. All participants were athletes with similar years of resistance training experience and relative strength in back squat (1RM: M= $2.1\pm 0.3 \times$ body weight (BW); W= $1.7\pm 0.3 \times$ BW) and power clean (1RM: M= $1.4\pm 0.3 \times$ BW; W= $1.2\pm 0.2 \times$ BW). Two CAs were tested: back squat (3 reps @90%1RM) and power clean (3 reps @75%1RM) each performed after warm-up. Countermovement jump (CMJ) performance was assessed Pre-CA and at 1, 3, 5, 7, 9, 11, 13, and 15 min post-CA using force plates sampling at 1000 Hz. A mixed-model ANOVA ($p<0.05$), with time and CA as within factors, and sex as a between factor, was applied for statistical analysis. PRE was calculated as the mean of three CMJs performed before the CA. Post-CA (POST) performance was recorded at each time point. Bonferroni correction was used for pairwise comparisons.

RESULTS: Significant sex differences were observed ($p < 0.001$; $\eta^2 = 0.543$; large). M showed enhanced CMJ height at POST 3, 5, and 7 min for back squat ($p < 0.05$) and POST 1, 3, 5, 7, 9, and 11 min for power clean ($p < 0.05$). W exhibited no significant improvements at any time point for either CA. The interaction between sex and time was significant ($p < 0.001$; $\eta^2 = 0.178$; large). No significant differences were found between CA types ($p > 0.05$).

CONCLUSION: Men seems to benefit from standard PAPE protocols, displaying significant short-term CMJ performance enhancements. Conversely, trained women do not seem to exhibit a measurable response under the same conditions. These findings might suggest that sex-specific physiological mechanisms, such as differences in proportion of fast-twitch fibers, acute hormonal responses (e.g., testosterone), and neuromuscular activation strategies, may influence PAPE outcomes. However, these hypotheses remain speculative, emphasizing the need for further research to understand PAPE mechanisms in women. This study highlights the importance of individualized training prescriptions to maximize power output and athletic performance across sexes.

A COMPARISON OF SIX POST-ACTIVATION PERFORMANCE ENHANCEMENT PROTOCOLS WITH A WARM-UP ON THEIR EFFECTS ON COUNTERMOVEMENT JUMP HEIGHT

BERTOCHI, G., TASINAFIO JÚNIOR, M., LIMA, L., NOSAKA, K., PUGGINA, E.
UNIVERSITY OF SÃO PAULO

INTRODUCTION: Post-activation performance enhancement (PAPE) refers to the acute improvement in neuromuscular voluntary performance following conditioning activities (CAs). Traditionally, CAs include high-intensity resistance exercises such as back squats (BS), and plyometric exercises like drop jumps (DJ) and weighted DJ (Seitz & Haff, 2016). However, a CA preceded by a general warm-up exercise appears to provide trivial-small effects on PAPE (Xu et al., 2025). Nonetheless, to the best of our knowledge, no previous studies have investigated the effect of warm-up exercise with different CAs on PAPE assessed by counter movement jump (CMJ) height, especially for individuals who do not show PAPE by warm-up exercise. Thus, we compared six CA protocols with a proper warm-up exercise for their effects on CMJ height, and between warm-up responders and non-responders, to test the hypothesis that no additional CMJ height increase would be observed after any CA following the warm-up.

METHODS: Thirty-five (18 male, 17 female) participants (24.6 ± 3.7 y, 1.71 ± 0.10 m, and 75.7 ± 16.1 kg) were familiarized with DJ exercises, CMJ tests, and had their BS one-repetition maximum (1-RM) assessed on the first visit (134.1 ± 32.1 kg). The remaining seven visits were randomized for the following CAs: warm-up (WUP), BS (3 sets of 5 reps at 87% of 1-RM), concentric BS (3 sets of 10 reps at 87 % of 1-RM), eccentric BS (3 sets of 10 reps at 87 % of 1-RM), 40-cm DJ (3 sets of 5 reps), loaded 40-cm DJ (10% of body mass added by a weight vest, 3 sets of 5 reps), and eccentric-only loaded 40-cm DJ with 10% body mass load (3 sets of 10 reps). At each visit, participants performed a standardized warm-up consisting of aerobic exercise, dynamic stretching, and bodyweight exercises for approximately 10 minutes, followed by three CMJs, the CA of the day, and three CMJs after the CA. Individuals who presented an increase in CMJ height greater than the CMJ height measurement error (3.2% based on the baseline CMJ measures after the standardized warm-up) were considered as warm-up responders. A two-way repeated measures ANOVA was used to compare conditions for changes in CMJ height from pre- to post-CA.

RESULTS: The baseline CMJ height was 36.7 ± 9.3 (male: 26.7 - 70.1 , female: 19.5 - 49.6) cm among the participants. Considering the entire sample, WUP increased ($p < 0.05$) CMJ height by $3.3 \pm 4.0\%$ (-3.6 - 14.1%), but no other CA induced a significant increase. Warm-up responders showed an increase ($p < 0.05$) in CMJ height by $6.7 \pm 3.2\%$ (3.3 - 14.1%) after WUP only, whereas non-responders did not demonstrate any significant change in CMJ in any conditions.

CONCLUSION: These results showed no additional effects of any of the CA than WUP on acute CMJ performance enhancement. It appears that the PAPE effect is within the warm-up effect.

THE POWER-STRENGTH-RATIO INFLUENCES POST-ACTIVATION POTENTIATION

LI, G., LIN, J., LI, W.
BEIJING SPORT UNIVERSITY

INTRODUCTION: Acute increases in athletic performance are goals of practitioners in sports. Previous studies reported that vertical jumping (1) and sprint running (2) and cycling (3) performance was increased following submaximal or maximal voluntary muscle activations. This phenomenon is known as post-activation potential enhancement (PAPE) and is of great interest to practitioners (4). Mechanisms contributing to PAPE is unclear, whereas evidence proved that the potential is related with increased neural drive/muscle activation, improved muscle-tendon stiffness, decreased muscle pH, greater muscle temperature, and so on (4). Moreover, the magnitude of acute improvement is modulated by several factors, such as age, sex, training status. For example, stronger individuals have been reported to attain greater potentiation of performance in comparison to weaker individuals. However, from a practical perspective, it is important to determine whether other individual characteristics, such as muscle power, also influence the ergogenic benefits of contrast training protocols. Therefore, this study aimed to investigate the effect of power-strength-ratio (PSR) on acute athletic performance.

METHODS: Thirty-six male college players with well-trained background were recruited in this study. Before and 4 min after intervention, all participants performed three maximal isometric squats (IS), CMJ and 30 m sprints in random order, with 2-3 min rest interval between trials and 5 min interval between tests. The intervention consisted of 3 sets of 4 repetitions of 90% 1RM back squat. The power-strength-ratio was defined as the ratio of maximal power-output derived from CMJ and maximal concentric strength of IS. The participants were classified as high PSR group and low PSR group using media splitting. The one-way ANOVA was used to analyze the differences in improvements of athletic performance between groups and LSD was used for post-hoc analysis.

RESULTS: Following intervention, significant increases ($p < 0.05$) were observed in CMJ height (46.5 ± 3.7 cm vs 49.2 ± 4.2 cm), 30 m sprint time (4.34 ± 0.32 s vs 4.15 ± 0.12 s), jump peak power (3832.32 ± 562.34 W vs 4267.23 ± 531.23 W), maximal isometric strength (3723.32 ± 287.13 N vs 4102.18 ± 327.16 N). Compared to participants with low PSR, participants with high PSR exhibited significantly greater improvements ($p < 0.05$) in CMJ height and jump peak power. However, no significant differences in changes in sprint time and maximal isometric strength between both groups ($p > 0.05$).

CONCLUSION: Power-strength ratios also affect PAPE, so differences in individual strength-strength ratios should be considered when designing acute intervention programs.

PRECISION IN POST ACTIVATION POTENTIATION DYNAMICS: A BASELINE-DEPENDENCY PHENOMENON FOR INDIVIDUALIZED RESPONSES

XENOFONDOS, A., ENGLISH, L.T.1, PAPAVALSIOU, A.1,2, BASSA, E.2, PATIKAS, D.A.2

1 FREDERICK UNIVERSITY, LIMASSOL, CYPRUS; 2 ARISTOTLE UNIVERSITY OF THESSALONIKI, GREECE

INTRODUCTION: Post-activation potentiation (PAP) is a transient increase in twitch torque following a conditioning contraction. Despite being extensively studied as a recurrent phenomenon, PAP responses vary significantly between individuals (1), yet the origin of this variability remains largely unexplored. Given the importance of addressing response variability for precision exercise science (2) and the optimisation of individualised prescriptions to enhance performance outcomes, this study is the first to examine individual baseline torque metrics and their relationship with PAP dynamics.

METHODS: This randomized, two-period, two-sequence crossover trial involved 14 male handball athletes (Age: 22.6 ± 2.8 years, height: 180.3 ± 5.9 cm, BM: 72.3 ± 7.9 kg). Each participant performed a familiarization visit and two exercise interventions consisting of 4 sets of 6 plantar flexion maximal voluntary isometric contractions (MVIC) with a 15s inter-repetition and 2min inter-set rest interval. The interventions differed in MVIC duration only (3s vs. 6s) and were spaced by one week. Twitch torque (TT) was recorded at baseline and 2s after each MVIC, via tibial nerve stimulation. Baseline MVIC torque was also measured. Linear mixed models examined the effects of baseline MVIC, TT, and TT/MVIC on the change (%) in TT after each MVIC relative to the baseline. Model comparisons assessed significance against a null model ($\Delta AICc > 2$) and case bootstraps provided 95% confidence intervals (CIs).

RESULTS: TT and TT/MVIC both improved model fit, but MVIC did not. The TT/MVIC model explained more variance due to fixed effects than TT (3s: +6.84%, 6s: +14.91%), accounting for 29.6% (3s) and 52.5% (6s) of variance in responses. TT/MVIC had a negative relationship with TT% in 3s ($\beta = -6.94$, 95% CI: -11.05 to -1.52) and 6s ($\beta = -11.75$, 95% CI: -16.42 to -7.64). This relationship was positively moderated by sets in 3s ($\beta = 1.67$, 95% CI: 0.08 to 2.66), with a trend in 6s ($\beta = 1.12$, 95% CI: -0.06 to 2.27). It was also positively quadratically moderated by repetitions in 6s ($\beta = 0.40$, 95% CI: 0.14 to 0.57), with a trend in 3s ($\beta = 0.21$, 95% CI: -0.02 to 0.45).

CONCLUSION: Athletes with lower baseline TT/MVIC are more likely to exhibit greater PAP responses, following a pronounced quadratic rise and fall of PAP across repetitions, especially at higher-load contractions (6s vs. 3s). Lower TT/MVIC may indicate reliance on fast-twitch fibers, which are less efficient at low stimulation rates (e.g., single-pulse stimulation) due to lower calcium sensitivity. This may contribute to a lower TT/MVIC presentation at baseline. Our study highlights for the first time the role of individual baseline torque-related measures on the prediction of PAP dynamics, which is essential for personalized conditioning strategies.

THE SELF-SELECTED INTERVAL METHOD IS RELIABLE FOR ASSESSING POST-ACTIVATION PERFORMANCE ENHANCEMENT IN TRAINED INDIVIDUALS

FONTANETTI, G., GONÇALVES, M.L.B., LIMA, L.C.R.

SÃO PAULO STATE UNIVERSITY INSTITUTE OF BIOSCIENCES

INTRODUCTION: The duration of the recovery interval between the conditioning activity (CA) and the verification test influences the responsiveness to post-activation performance enhancement (PAPE). Evidence suggests that the self-selected interval (SSI) method is as effective in eliciting PAPE in trained individuals as the fixed interval method. However, no studies have investigated the reliability of such method. We aimed to evaluate the reliability of the SSI employed by trained individuals in two identical sessions at different days.

METHODS: Nine strength-trained individuals (six men and three women: 26.6 ± 6.9 years; 73.0 ± 15.1 kg; 173 ± 0.1 cm) participated in three laboratory visits after familiarizations and one-repetition maximum (1RM) assessment (155.46 ± 43.1 kg). In the experimental sessions (EXP1 and EXP2), PAPE was induced by a CA consisting of three sets of three squats with

87% 1RM, followed by countermovement jump (CMJ) performance tests employed after a SSI. In the control session (CON), participants performed a light warm-up instead of the CA protocol, and CMJ was assessed at a time corresponding to the average SSI from EXP1 and EXP2. Baseline CMJ performance tests were employed at all sessions. The length of the SSI in EXP1 and EXP2 was compared using paired t-tests. A two-way repeated measures ANOVA assessed changes across sessions and conditions, with Cohen's d calculated as an ES measure. Intraclass correlation coefficients (ICC), coefficient of variation (CV), and percentage variation were calculated with 95% confidence intervals (CI) for the length of the SSI and CA-induced changes in CMJ performance. Statistical significance was set at $p < 0.05$.

RESULTS: No significant differences were found in SSI durations between EXP1 and EXP2. ANOVA revealed significant effects of session, condition, and session-condition interaction. No significant differences were found between baseline CMJ values in all sessions. Following CA, both EXP1 and EXP2 showed statistically superior performance compared to CON, with no differences between EXP1 and EXP2. In CON, CMJ performance did not change after CA (37.38 ± 12.45 cm vs. 37.25 ± 12.23 cm; $p > 0.05$). CMJ performance increased by 9.6% in EXP1 (37.49 ± 12.16 cm vs. 41.09 ± 12.96 cm; ES = 0.3; $p < 0.001$), and by 11.2% in EXP2 (37.56 ± 12.21 cm vs. 41.77 ± 12.94 cm; ES = 0.3; $p < 0.001$). Test-retest reliability demonstrated excellent reliability for changes in CMJ performance (ICC: 0.997; 95% CI: 0.969-1.000; CV: 1.241%; $p < 0.001$) and the length of the SSI (ICC: 0.930; 95% CI: 0.705-0.984; CV: 6.671%; $p < 0.001$).

CONCLUSION: A novel finding of this study was that both changes in CMJ performance and the length of the SSI were reproducible in trained individuals, with the former being more consistent than the latter. Therefore, these findings corroborate the effectiveness of adopting the SSI method for PAPE while also suggesting that both its effects and duration are consistent and reproducible in trained individuals.

Invited Symposium

MECHANISMS FOR IMPAIRED CARDIORESPIRATORY FITNESS IN TYPE 1 DIABETES

LESSARD, S.

VIRGINIA TECH

Improved cardiorespiratory fitness is a key benefit of aerobic exercise training. However, individuals living with type 1 diabetes often display lower cardiorespiratory fitness (i.e. VO_2max) than those without diabetes- even when exercise training levels are matched. This may indicate a resistance toward the positive metabolic and physiological adaptations that lead to improved cardiorespiratory fitness with aerobic training in people with diabetes. This presentation will outline the key clinical features of low cardiorespiratory fitness in type 1 diabetes. The potential role for chronic hyperglycemia in impaired aerobic adaptation will be discussed. In addition, hypothesized molecular mechanisms whereby chronic hyperglycemia may alter the structure and remodeling of skeletal muscle with exercise will be proposed. Specifically, the role of hyperglycemia-induced changes to the skeletal muscle extracellular matrix, and how these may alter muscle signal transduction and key muscle remodeling events with exercise will be discussed. Recent data from human participants and pre-clinical (animal and cell culture) models will be shown. Potential strategies to improve the cardiorespiratory response to exercise in people diabetes will also be considered.

METABOLIC, INFLAMMATORY AND OXIDATIVE STRESS RESPONSES TO EXERCISE IN PEOPLE WITH TYPE 1 DIABETES

KRAUSE, M.

FEDERAL UNIVERSITY OF RIO GRANDE DO SUL

Type 1 diabetes (T1D) is a chronically progressive autoimmune disease that affects approximately 1% of the population in the developed world. This adverse immune response is induced and promoted by the interaction of both genetic and environmental factors. Individuals with T1D shared several cardiometabolic complications such as endothelial dysfunction, changes in glomerular filtration/kidney function, low-grade inflammation, oxidative stress, blood coagulation, mitochondrial dysfunction, anabolic resistance, metabolic inflexibility, and gut microbiota dysbiosis. The treatment of these conditions and the management of glucose balance includes pharmacological, and particularly, changes in lifestyle such as exercise and nutritional interventions. Exercise is the most effective non-pharmacological tool to prevent and treat cardiometabolic diseases related to both types of diabetes. A large body of evidence has shown that the combination of resistance and aerobic exercise can improve glycemic control, metabolism, oxidative stress, inflammation, and skeletal muscle anabolic adaptations in T1D people. Despite the negative adaptations caused by T1D in the skeletal muscle (e.g., mitochondrial dysfunction, inflammation, and regeneration), exercise training can decrease glucose fluctuations, the occurrence of hypoglycemia, and improve skeletal muscle dysfunction. In this presentation, we aim to present evidence that different types of exercise can improve inflammatory status and oxidative stress, thus causing positive metabolic adaptations in mitochondrial function, insulin sensitivity, and glycemia management. In addition, we will also discuss the potential underlying mechanisms that allow exercise to reduce inflammatory-related complications in T1D people. We understand that this topic is of particular interest to people working with diabetes management since most of the conducted research involves people with type 2 diabetes. Our discussion can potentiate the interest of the researchers in the

field to include more investigation on T1D, thus providing scientific shreds of evidence for new guidelines and exercise prescriptions in this population.

DISUSE, RECOVERY AND REPAIR OF SKELETAL MUSCLE IN TYPE 1 DIABETES

HAWKE, T.

MCMMASTER UNIVERSITY

Despite the importance of skeletal muscle to our physical and metabolic well-being, changes to skeletal muscle health in those with Type 1 Diabetes (T1D) is not well defined. Our published and preliminary data highlight alterations to muscle health in those with T1D. In particular, we have noted reduced mitochondrial function, particularly in females and a loss of mitochondrial density in older adults with T1D. Functionally, there was a loss of upper and lower body maximal voluntary contraction (quadriceps, handgrip) in those with T1D after the age of 35. In young adults with T1D, force recovery from damaging exercise was significantly delayed along with increased extracellular matrix protein content and delayed satellite cell activation. Collectively, these alterations suggest there are impairments to skeletal muscle's ability to respond to stressors and that strategies to maximize muscle health are urgently needed to mitigate the loss of muscle health and the resulting inability to undertake activities of daily living.

Invited Symposium

IS-BM05 Cyclic propulsion in sports

VELOCITY AND POWER IN CYCLING RACES

CLANET, C.

ECOLE POLYTECHNIQUE

Velocity is usually easy to measure in sports, while measuring power is, in general, more delicate. However, in cycling, both measures are accessible, and this leads us to first focus on track cycling races. Knowing the instantaneous power injected by the cyclist on the pedals, what is the velocity of the bike? The usual way to answer this well-posed question is via energy conservation. But the system (cyclist+bike) is both open and deformable. To avoid the full complexity of the problem, we develop a phase average theory that "solidifies" artificially the system and allows us to predict the velocity of the centre of mass (and thus of the bike in this solid limit), provided the power is averaged over a pedal cycle. Thus, if the power is known the velocity can be calculated theoretically. However, the power developed by a cyclist is not known in advance and, moreover, it depends on the velocity! The second part of the presentation will thus be devoted to addressing the question of power production and the resolution of the Power-Velocity coupled system.

VELOCITY AND FREQUENCY IN CYCLIC SPORTS

CARMIGNANI, R.

HYDRAULIC SAINT VENANT LABORATORY

The principle of cyclic force application is a common thread across various forms of locomotion, be it on land, in water, or in air. This force application is essential to maintain a target average velocity of motion. In running, force is exclusively applied during ground contact. In cycling, force is consistently applied, but it exhibits a cyclic evolution during the rotation of the pedals. In kayaking, the force is applied when the paddles are in the water. In swimming, the force is similarly applied during the time the arm is in water, with the exception of certain strokes. Understanding the relationship between the velocity of motion of the center of mass and the frequency of gesture is crucial for studying locomotion. This understanding allows us to explore the link between speed and muscle contraction velocity, which is believed to be significant in building race control models to assist athletes in managing their pacing. In cycling, this relation is purely geometric and is fixed by the gear ratio. However, observations in running, swimming, and kayaking show linear, square root, and cubic root relations on an incremental test. To better understand these evolutions, a simplified model is proposed. This model enables us to identify the key parameters that can be monitored to track progress and characterize athletes. By doing so, we can gain a deeper understanding of the dynamics of locomotion and potentially improve athletic performance.

ACTIVE DRAG AND ADDED MASS IN WATER SPORTS

ZAMPARO, P.

UNIVERSITY OF VERONA

Swimming is a racing sport similar to biking, running, rowing or kayaking, where the goal is to cover a given distance in the shortest possible time (e.g. at the fastest possible velocity). In these sports, the race starts with a standing start and the velocity gradually increases toward a maximum value that the athletes should try to maintain up to the end. This is not the case in swimming where, in pool races, a swimmer must accelerate after each turn. In addition, cyclic variations in speed could be observed, in swimming, even at "constant average speed" because of the fluctuations in resistive and propulsive forces that occur within each stroke. Only few studies attempted to quantify the hydrodynamic force that counteracts

swimmers when the flow pattern changes with time. In this case, some of the water around the swimmer is set in motion and this can be thought of as an added mass the swimmer has to accelerate, in addition to body mass, during a change in velocity. These matters could be investigated using a novel method consisting of a series of tests (a standing start test, a full tethered test and semi-tethered tests) through which it is possible to gather the data required to compute the added mass and the active drag of a swimmer. The standing start test could also be utilized to assess these matters in boat locomotion (e.g. kayaking).

GENDER AND SIDE DOMINANCE EFFECTS ON CURVILINEAR SPRINT PERFORMANCE IN YOUTH FOOTBALL: AN ANALYSIS OF PEAK SPEED, ACCELERATION, ACCELERATION-SPEED PROFILES, DEFICIT, AND ASYMMETRIES

SAŠEK, M., RIBIC, A., SPUDIC, D., BRATINA, K., GADNIK, K., CVJETICANIN, O., SMAJLA, D.

UNIVERSITY OF PRIMORSKA: UNIVERZA NA PRIMORSKEM

INTRODUCTION: The curvilinear sprint (CS) is the most frequently performed type of sprint in football matches and is an important speed skill for footballers [1]. It requires a different running technique than the linear sprint, which leads to performance deficits and asymmetries [2]. While the specificity of CS performance in football players is well established [3], potential sex differences, especially in youth, remain unclear. Furthermore, most research has focused on split times, overlooking key performance metrics that could provide deeper insights into CS demands. The aim of this study was to investigate the effects of sex and CS side dominance on performance, deficits and asymmetries in adolescent football players using a global navigation satellite system.

METHODS: Twenty male (16.4±1.2 years, 70.0±6.6 kg, 179.4±6.1 cm) and 20 female (16.3±1.2 years, 58.1±7.2 kg, 167.1±4.6 cm) national team football players completed a linear 30 m and a left/right CS (radius 9.15 m). Distance, speed and acceleration were measured using the GPEXE It system (Exelio SRL, Udine, Italy). Peak speed (Speak), peak acceleration (Apeak), and acceleration-speed (AS) profiles (A0, S0, ASslope) were calculated. The side with the higher Speak was categorised as stronger. In addition, deficits and asymmetries were calculated from Speak and AS profiles (Sdeficit, ASdeficit, Sasymmetry, ASasymmetry). A two-way ANOVA assessed the effects of dominance (weaker vs. stronger) and sex (male vs. female) on the variables, with partial eta squared (η^2) for effect size and Bonferroni post-hoc adjustments. Unpaired t-tests were used to assess differences in Sasymmetry and ASasymmetry. The significance level was set at $P < 0.05$.

RESULTS: A significant interaction effect was found for Apeak ($F=6.5$, $p=0.019$, $\eta^2=0.03$), A0 ($F=5.8$, $p=0.026$, $\eta^2=0.02$), and Sdeficit ($F=5.8$, $p=0.026$, $\eta^2=0.02$). Males had significantly greater Apeak and Sdeficit on the stronger side than females ($MD=0.43$ m/s² and 2.46%; $p<0.001$). Sex and dominance significantly influenced Speak ($F \geq 98.9$, $p<0.0001$, $\eta^2 \geq 0.73$) and S0 ($F \geq 62.7$, $p<0.0001$, $\eta^2 \geq 0.43$), with males achieving higher speeds ($MD \geq 0.87$ m/s, $p<0.0001$) and higher speeds observed on the stronger CS in both sexes ($MD \geq 0.16$ m/s, $p<0.001$). Only dominance influenced ASslope ($F=44.7$, $p<0.0001$, $\eta^2=0.27$) and ASdeficit ($F=89.1$, $p<0.0001$, $\eta^2=0.59$). Weaker CS had steeper ASslope ($MD \geq 0.08$ s⁻¹, $p<0.015$) and greater ASdeficit ($MD \geq 21.49\%$, $p<0.0001$). Females had greater Sasymmetry than males ($M=2.24$ vs. 3.72%, $t(38)=2.46$, $p=0.019$), but no differences in ASasymmetry were found ($p=0.380$).

CONCLUSION: Male footballers accelerate faster, reach a higher top speed and have greater deficits, while female show greater asymmetries in CS performance. CS dominance, rather than sex, appears to influence AS profiles. For male footballers, it is important to focus on CS deficits whereas for female footballers, top speed and asymmetries should be the focus of training.

EFFECTS OF A 4-WEEK OFF-SEASON TRAINING PROGRAMME ON AEROBIC FITNESS AND SPRINT ENDURANCE ABILITY IN UNDER 15 FEMALE SOCCER PLAYERS

PANASCI, M., FERRANDO, V., CASTAGNA, C., MARMONDI, F., RUGGERI, P., FAELLI, E.

UNIVERSITY OF GENOA

INTRODUCTION: High-Intensity Interval Training (HIIT) has been shown to mitigate performance declines in professional male soccer players during the off-season¹. However, its effects in youth female soccer players remain unexplored. This study investigates the impact of a 4-week off-season high-intensity training program on aerobic fitness and sprint endurance in Under-15 female soccer players.

METHODS: Fifteen U-15 female soccer players from a professional team completed a 4-week training program consisting of two weekly sessions of small-sided games (SSG) consisting of 4 × 4 minutes with 3 minutes of active recovery (running at low intensity) between bouts, and two weekly sessions of repeated sprint training (RST) consisting of 5 reps × 3 sets of 40-m sprint with a 180° change of direction with a rest of 20 seconds between repetitions and 4 minutes between sets. Performance assessments before and after the intervention Yo-Yo intermittent recovery level 1 test (YYIR1) and 30-second test (30s Test) were performed. Aerobic fitness level and sprint endurance ability were assessed through the YYIR1 and 30s Test, respectively. Furthermore, physiological responses were monitored using heart rate (HR) and blood lactate concen-

tration ([La]⁺) as internal workload indicators, and total distance (TD), moderate speed distance (DMS), high speed distance (DHS), acceleration distance (≥ 3 m-s⁻², DACC) and deceleration distance (≤ 3 m-s⁻², DDEC) as external workload indicators.

RESULTS: Following the intervention, TD significantly increased in both the YYIR1 ($p = 0.000$) and the 30s Test ($p = 0.004$, respectively). HR and [La]⁺ significantly increased only in the YYIR1 ($p = 0.001$), but not in the 30s Test ($p = 0.572$). A strong correlation was observed between time spent $>85\%$ HRmax and TD in the 30s Test ($r = 0.73$, $p = 0.002$). Moreover, a significant correlation between time spent at intensity $>85\%$ HRmax and percentage change in TD in the 30s test ($r = 0.73$, $p = 0.002$) was observed. Similar correlations were found between time spent $>85\%$ HRmax and TD ($r = 0.91$, $p = 0.000$) and percentage change in TD ($r = 0.83$, $p = 0.001$) in YYIR1.

Finally, strong correlations were observed between DMS and TD in YYIR1 ($r = 0.78$, $p = 0.001$), and DHS and TD in the 30s Test ($r = 0.88$, $p = 0.000$).

CONCLUSION: A 4-week high-intensity off-season training program effectively enhances both aerobic fitness and sprint endurance in U-15 female soccer players. These findings highlight the efficacy of HILT-based training in mitigating performance losses during the off-season, enabling players to resume the season with improved conditioning.

GAME ON: DECODING INTERNAL AND EXTERNAL LOAD DURING SMALL-SIDED GAMES (1V1 AND 2V2) AMONG FEMALE ATHLETES OF DIFFERENT MATURITY STATUS

SHANG, X., AREDE, J., LEITE, N.

UNIVERSIDADE DE TRÁS-OS-MONTES E ALTO DOURO

INTRODUCTION: The development of young athletes is not only influenced by skill level and training but also by their biological maturity (Albaladejo-Saura et al., 2021; Malina, 2014). In basketball, where physical demand and technical execution are key, understanding how maturity levels affect a player's internal load, external load, and technical behaviour (Guimarães et al., 2019; Johnson et al., 2022; Towlson et al., 2021) can provide insights that help tailoring training programs and talent identification processes.

Small-sided games (SSGs) are widely recognized as an effective training modality to develop technical, tactical, and physical capacities in soccer (Arede et al., 2021; Clemente et al., 2019). Previous literature has predominantly focused on male players or larger group formats (e.g., 4v4, 5v5). However, limited research has been dedicated to female players and, in particular, to smaller formats such as 1v1 and 2v2 competitions.

This study aims to investigate these relationships by testing U14, U15, and U16 athletes in 1v1 and 2v2 game scenarios. The general aim of the scientific study is to investigate the internal and external loads experienced by female soccer players of different maturity levels during 1v1 and 2v2 small-sided games, in comparison to performance outcomes driven by technological methods or random-based approaches.

METHODS: 18 female soccer players between the ages of 13 and 17 was tested. PHV categories were determined using biological maturity to classify them into different maturity groups. This approach helps to address the influence of maturation status on performance.

After participating in each game scenario, players recorded their perceived exertion using the Borg scale, providing insight into subjective performance differences between the groups

RESULTS: Results showed that mean and peak heart rates were generally higher in the 1v1 format as compared to the 2v2 format across all maturity groups.

RPE scores corroborated the HR findings, External load metrics indicated that more mature players covered greater absolute total distances and engaged in more high-intensity sprints during both game formats.

1v1 formats showed a higher frequency of accelerations and decelerations per minute, consistent with greater changes of pace and direction required.

This was especially evident in pre-mature players, who spent more effort changing direction, reflecting their developing neuromuscular control abilities.

CONCLUSION: Game Format Differences show that it is Higher Intensity in 1v1, and Greater Distance in 2v2.

Post-mature players demonstrate higher absolute physical outputs (e.g., distance, sprints) due to their advanced physical development. However, when normalized to body mass or HR max, the relative loads are comparable across maturity groups.

This study demonstrates that 1v1 and 2v2 small-sided games impose distinct internal and external load demands on female soccer players, with significant differences observed across maturity levels.

SMALL-SIDED GAMES IN ELITE FEMALE FOOTBALL PLAYERS: THE IMPACT OF PLAYING AREA AND PLAYER NUMBER ON DIFFERENTIAL RPE AND LOCOMOTION

MCQUILLIAM, S., OLTHOF, S.

LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: Coaches use small-sided games (SSGs) to develop players skills. Varying pitch size, team numbers, and rules allow coaches to target specific objectives and influence workload. While these factors impact movement, they do/may not fully capture physiological load. Differential RPE (dRPE) can be used to discriminate between different dimensions of effort/ internal load; central, peripheral and cognitive. This study investigated the influence of team size and playing area on internal load and locomotion.

METHODS: 35 female academy soccer players (17±1 years) completed nine SSGs using 25%, 50%, and 75% of a competitive playing area with 5v5 (4x4 min), 7v7 (3x6 min), and 9v9 (3x8 min) formats (including goalkeepers). After each game, participants rated perceived exertion using CR-10 (RPE) and CR-100 scales (dRPE). Player tracking (Catapult S7) provided total distance (TD), high-speed running distance (HSRD; 12.5-19.0 km/h), very high-speed running distance (VHSRD; 19.0-22.5 km/h), sprint distance (SD; >22.5 km/h), and accelerations/decelerations (ACC-DEC). Goalkeepers were removed from the analysis and locomotor variables were normalised for SSG duration (m/min). A univariate ANOVA was conducted, with team size and playing area as fixed factors and post-hoc tests with Bonferroni corrections; (significance set at $p<.05$).

RESULTS: Team size did not impact any dRPE. However, there was a significant interaction between team size and playing area for central ($p<0.001$) and peripheral ($p<0.001$) RPE scores, which both peaked at 75% in 5v5, 50% in 7v7 and 25% in 9v9. Cognitive RPE showed a significant change with playing area ($p=0.02$), with smaller playing areas resulting in greater scores (25%: 44 ± 13 , 50%: 43 ± 12 , 75%: 39 ± 15). Team size and playing area had a significant interaction effect on TD and HSR. TD peaked at 75% in 5v5 (96 ± 43 m/min), 50% in 7v7 (136 ± 68 m/min), and 75% and 9v9 (150 ± 46 m/min). While HSR increased with playing area, there were greater demands placed on the smallest compared to the largest team size at 50% (21 ± 8 vs. 15 ± 8 m/min), and 75% (23 ± 10 vs 18 ± 8 m/min) of competitive playing area. Larger pitch sizes significantly increased VSHR and SD ($p<0.001$), irrespective of team size. Whereas the number of ACC-DEC decreased with larger team sizes ($p<0.001$) and larger playing areas ($p=0.004$), with no significant interaction.

CONCLUSION: There was a distinct difference in dRPE based on team size and playing area. Central and peripheral RPE depended on the interaction of team size and playing area but neither individually. Smaller areas would better develop agility and decision-making drills due to the increased cognitive and ACC-DEC demands and could be incorporated on less physically demanding training days. Larger pitch sessions should be incorporated into high-intensity training days due to the central and peripheral load, and to elicit greater HSRD and SD. Adjusting these variables helps optimize training intensity and recovery.

Invited Symposium

HUMAN PERFORMANCE OPTIMISATION (HPO) FOR THE WARFIGHTER: A KEY TO READINESS?

NEVIN, J.

BUCKINGHAMSHIRE NEW UNIVERSITY

The contemporary military operational environment places unique and intense physiological, psychological, and cognitive demands upon the modern warfighter which can negatively impact upon operational effectiveness. Therefore, the aim of this session will be to review the impact of these demands and to argue that a high level of physical readiness, psychological resilience, and cognitive capability developed under a conceptual Human Performance Optimisation (HPO) framework is essential to improve warfighter readiness and maintain operational performance.

MODERNIZED TRAINING FOR WOMEN IN GROUND CLOSE COMBAT ROLES

GREEVES, J.

MINISTRY OF DEFENCE

Servicewomen experience similar increases in strength and aerobic fitness as men with training, but still perform less well on most performance measures due to lower baseline physical performance. Fewer women than men can reach the Physical Employment Standards for ground close combat roles after three months of periodised strength and aerobic training, suggesting different strategies may be required to maximise performance of both sexes. Therefore, this session will aim to discuss potential training strategies by which to optimally prepare woman for ground close combat roles.

RESEARCH ON THE REDUCTION OF MUSCULOSKELETAL INJURIES

FRIEDL, K.

U.S. ARMY RESEARCH INSTITUTE OF ENVIRONMENTAL MEDICINE

A US Army report on training injuries "the hidden epidemic" thirty years ago led to a intensive body of research which aimed to define and solve the problem. Leading the effort was a focus on bone stress injuries, a problem that was relatively unique to military training. As a result major programs investigating the pathogenesis of bone stress fracture were conducted in both the US and UK militaries. This session will review the findings from this body of work and will discuss how several practical interventions to reduce the incidence of musculoskeletal injuries in military personnel have been applied. Part of this included simple changes/modernization of training programs as well as the need to address initial fitness of today's youth and prospective recruits. The problems are largely understood and await implementation of a range of solutions.

IMPACT OF SIMULTANEOUS MOTOR-COGNITIVE TRAINING ON MOTOR CAPACITIES IN OLDER ADULTS WITH OR WITHOUT COGNITIVE IMPAIRMENT: PRELIMINARY RESULTS OF THE COGAPA PROJECT

GODARD, J., HUET, A., ROZEC, M., BOILET, L., LE BERRUYER, L., CHARTIER, C., HUMEAU-HEURTIER, A., NOURY, B., DURAND, S.

UNIVERSITÉ DANGERS - LE MANS UNIVERSITÉ - UNIVERSITÉ CATHOLIQUE DE LOUEST DANGERS

INTRODUCTION: Ageing is associated with a progressive functional decline of various systems in the human body. Moreover, ageing is a risk factor in the development of several pathologies, including neurodegenerative diseases. The systemic decline negatively impacts motor and cognitive abilities which are associated with poor autonomy. Despite methodological heterogeneity, there is a growing scientific interest on motor-cognitive training to contribute on a healthy ageing [1]. Simultaneous combinations of trainings appear to be relevant [2] for motor abilities but the comparison of the effect of different modalities (additional and incorporated trainings [3]) in older adults (OA) has not been studied yet. The COGAPA project aims at testing the effects of two simultaneous motor-cognitive trainings (SMCt) on motor abilities in OA with or without cognitive impairment.

METHODS: Two groups of participants (n = 20) were included. People were aged 60 or older and had a score higher than 6 at the short physical performance and battery and a score higher than 22 at the mini mental state examination. OAs were randomized into two SMCt: dual-task (DT) and synergical (SYN). The DT group (n = 10) consisted of physical exercises with an additional cognitive task. The SYN group (n = 10) performed physical exercises with a cognitive task incorporated [3]. All groups practiced exercises for 8 weeks with one session/week. We compared the results of both groups before and after the intervention on the Berg balance scale (balance), the 6-minute walking test (walking capacity), the timed up and go test (functional mobility), and the 30-second chair sit to stand test (muscular strength).

RESULTS: All OAs (n = 20) completed the program. Mixed model with a covariate (initial level of physical activity) shows significant improvements on balance (p<0.01) and functional mobility (p<0.05) after both SMCt (DT and SYN) without any significant difference between groups.

CONCLUSION: Preliminary results of the COGAPA project reveal the potential effect of simultaneous motor-cognitive training (DT and SYN) on motor abilities like balance and functional mobility. However, no significant benefits were observed on walking capacity and muscular strength. Moreover, without any significant difference between groups, we cannot highlight a particular modality of SMCt. With a larger sample size and upcoming results of a group with 2 sessions/week of SMCt (DT and SYN) as well as a control group (physical exercises only), we will potentially demonstrate the incidence of adding a cognitive task simultaneously to physical exercises, the benefits of higher training frequency, and the optimal modality of SMCt for OAs with or without cognitive impairment.

EFFECTS OF PHYSICAL TRAINING ON COGNITIVE FUNCTION AND P300 IN OLDER ADULTS – AN ONGOING ERP-STUDY.

GERTEN, S., KOESTER, D., SCHACK, T.

BIELEFELD UNIVERSITY

INTRODUCTION: Various types of physical activity positively impact cognitive function (CF) and brain activity [1,2]. It is unclear whether additional forms of physical training - which emphasize technique improvement - also affect cognitive functions and brain activity. Therefore, this study evaluated the effect of a track and field athletic training (TFA; short put, long jump & sprint; motor skill training) on behavioral CF and brain activity of elderly, when compared to walking training (WT, cardiovascular training) and to relaxation and stretching training (RS, active control group).

METHODS: The 16-week training took place two times a week for one hour each. Participants were screened for physical or mental illness (PAR-Q) and dementia (Montreal Cognitive Assessment, MoCA). Pre and post intervention questionnaires, motoric and cognitive test batteries were completed in two separate days. CF were assessed in different domains: Global CF (MoCA), attention (d2-revision Test, Trail Making Test A, TMT), executive function (TMT B, Flanker- & Stroop-task) and working memory (n-back task). Brain activity was measured via Electroencephalography (EEG) during the flanker task. P3 was defined as the average electrical potential 350-550 ms after stimulus onset and was calculated at Fz, Cz, and Pz. Data were analyzed via mixed ANOVA.

RESULTS: Sixty-six older adults (age 64 ± 5 , female 33, MoCA 27 ± 2) were included in the study. There were 16 dropouts, and 7 individuals were excluded due to poor EEG data quality. A Flanker effect was shown in reaction times ($F(1,42) = 172.1$, $p \leq .001$, $\eta^2 = .804$). There was no interaction effect between the factors time (2) and group (3), but a main effect of group for MoCa: $F(2,41) = 4.54$, $p = .017$, $\eta^2 = .181$, TMT-A: $F(2, 42) = 3.50$, $p = .039$, $\eta^2 = .140$ and TMT-B: $F(2, 39) = 8.15$, $p \leq .001$, $\eta^2 = .295$ and a main effect for time for d2: $F(1, 42) = 26.07$, $p \leq .001$, $\eta^2 = .383$, TMT-A: $F(1, 43) = 4.56$, $p = .038$, $\eta^2 = .096$, and P3 amplitude in the incongruent condition at Pz: $F(1, 38) = 4.40$, $p = .043$, $\eta^2 = .023$.

CONCLUSION: The analyses so far do not indicate an interaction effect of CF or brain activity after 16 weeks of WT, TFA, or RS. However, we could show a group-independent improvement in concentration, attention and P3 amplitude (especially in the incongruent condition). A larger P3 amplitude indicates enhanced cognitive processing efficiency and increased attentional resources, which indicates an enhancement in CF. The results suggest that besides cardiovascular training also motor skill training, and relaxation and stretching training can lead to an improvement in CF and brain activity in elderly.

ASSOCIATION OF PHYSICAL FITNESS WITH COGNITIVE FUNCTION IN COGNITIVELY HEALTHY OLDER PERSONS

AKALP, K., BEŞIKCI, H., RAMA, L., FERREIRA, J.P., SILVA, A.R., COSTA, A., PIRES, L., RAINHO, A.M., RAINHO, M.A., COSTAS, B., RIBEIRO, M.J., TEIXEIRA, A.M.

UNIVERSITY OF COIMBRA

INTRODUCTION: Aging can be accompanied by decline in cognitive function and physical fitness. Exercise may prevent cognitive decline and improve physical fitness components (PFC) including body composition, physical functionality and cardiorespiratory fitness. Although research demonstrated the association between some PFC and cognitive functions [1] this relationship remains unclear and more research is needed looking at different PFC and cognitive domains. Exploring the associations between various cognitive domains and physical fitness may facilitate the development of effective exercise programs for preserving cognitive function during aging. Thus, this study aims to explore the association between body composition, physical functionality and cardiorespiratory fitness components with cognitive flexibility, sustained attention, and working memory cognitive domains.

METHODS: Seventy-two cognitively healthy participants (32 men and 40 women) with age 66 ± 6 years old participated in the physical and cognitive assessments. Body composition was assessed by bioimpedance (Inbody 770, Biospace), physical fitness using hand grip strength, 30 seconds chair stand test, time up and go test, and peak oxygen consumption capacity (VO2 Peak) with submaximal cycle ergometry (Lode Excalibur, Netherlands). The cognitive assessment was done with the following tests from the CANTAB Connect Research: Multitasking Test (MTT – cognitive flexibility), Rapid Visual Information Processing (RVP – sustained attention), and Spatial Working Memory (SWM).

RESULTS: Age-corrected correlations revealed small to medium size correlations: MTT incongruency cost negatively correlated with VO2 Peak ($r = -.292$, $p = .023$), and ventilatory threshold ($r = -.292$, $p = .017$). RVP median latency negatively correlated with the chair stand test ($r = -.308$, $p = .01$), VO2 Peak ($r = -.277$, $p = .023$), and positively correlated with fat percentage ($r = .294$, $p = .014$), fat mass ($r = .319$, $p = .008$), fat to muscle ratio (FMR) ($r = .346$, $p = .004$). SWM Strategy negatively correlated with hand grip strength ($r = -.267$, $p = .025$), and positively correlated with fat percentage ($r = .302$, $p = .012$) and FMR ($r = .275$, $p = .023$).

CONCLUSION: Our results suggested that, in cognitively healthy older persons, different aspects of physical fitness were associated with different features of cognition. Cardiorespiratory fitness was associated with increased processing speed; Lower extremity endurance and cardiorespiratory fitness were associated with better sustained attention, and muscle strength was associated with working memory accuracy and confidence. Finally, fat tissue was negatively associated with sustained attention and working memory abilities. These findings support an association between physical fitness and cognition, supporting the role of physical activity in the prevention of age associated cognitive decline.

CARDIORESPIRATORY FITNESS, WHITE MATTER, AND COGNITIVE PERFORMANCE IN OLDER ADULTS

TINNEY, E., WARREN, A., OBRIEN, A., ODOM, H., AI, M., SUTTON, B., JAIN, S., KANG, C., HUANG, H., WAN, L., OBERLIN, L., GROVE, G., JAKICIC, J., COLLINS, A., SEWELL, K., BURNS, J., VIDONI, E., MCAULEY, E., KRAMER, A., ERICKSON, K., HILLMAN, C.
NORTHEASTERN UNIVERSITY

INTRODUCTION: Age-related cognitive decline occurs, in part, due to diminishing white matter integrity. Higher cardiorespiratory fitness (CRF) may mitigate cognitive decline by preserving white matter structure and function, yet the mechanisms underlying these associations remain poorly understood. While prior studies have suggested that white matter microstructure mediates the relationship between CRF and cognition, they have been limited by the use of tensor-based diffusion imaging metrics, which are less sensitive to crossing fibers and complex white matter architecture.

METHODS: In this study, we leveraged a novel and more sensitive analytical approach, fixel-based analyses (FBA), to provide estimates of fiber density (FD), fiber cross-section (FC), and their combined measure (FDC) in multiple directions within each voxel. Using a uniquely large sample of 636 cognitively normal older adults aged 65–80 years (mean age = 69.8 years; 71% female), we hypothesized that FBA metrics would reveal robust relationships between CRF and white matter microstructure and mediate associations between CRF and cognition.

RESULTS: In whole-brain analyses, higher CRF was associated with greater FD, FC, and FDC. Furthermore, these FBA-derived metrics statistically mediated the relationship between CRF and cognitive performance in the domains of visuospatial abilities, processing speed, working memory, and executive function/attentional control, but not episodic memory.

CONCLUSION: These findings further highlight the potential for CRF to be associated with preserved cognitive function in aging through its relationship with white matter micro- and macro-structural properties, providing novel insights into the neurobiological mechanisms of fitness-related cognitive resilience.

EXPLORING DUAL SIMULTANEOUS COGNITIVE AND PHYSICAL TRAINING FOR OLDER ADULTS

QUAGLIAROTTI, C., PADULO, C., ROMAGNOLI, R., CAZZOLI, B., LI, Y., PIACENTINI, M.F., MANDOLESI, L., GIGLIOTTA, O., MANCINI, M., CHIRICO, A., LUCIDI, F., ZELLI, A., FAIRFIELD, B.
UNIVERSITY OF ROME - FORO ITALICO

INTRODUCTION: The increase in longevity, a dynamic relationship between health, cognition and social abilities of an individual, requires a re-valorisation and maintenance of skills fundamental to daily life and wellbeing in older adults. Training different cognitive abilities and physical activity, as well as social abilities, is crucial to enhancing wellbeing in older adults. Notably, reviews have highlighted how cognitive training [1] and physical exercise [2], separately and combined [3], improve cognitive and physical performance in healthy older adults, especially when tasks are progressive and based on individual performance [3].

This project aimed to develop a dual simultaneous cognitive and physical training for older adults, evaluating the effects on individual skills and behaviours.

METHODS: Five (three females) older adults (age: 70 ± 3.9 y) performed eighteen 30 minute training sessions over a period of six weeks. Training sessions included strength and aerobic exercises (2:1 ratio) and a modified categorization working memory span task. Before (Pre) and after (Post) training, participants were evaluated for total weight, body mass index (BMI), percentage of body fat, and for cognitive (Corsi Block-Tapping and Digit Span tests to evaluate visuo-spatial and verbal short term working memory, respectively) and physical skills (30-s chair standing and arm curl tests). The Positive and Negative Affect Schedule scale and the International Physical Activity Questionnaire for Elderly were administered to evaluate social and physical behaviours Pre and Post. Non-parametric statistical analysis was performed to evaluate differences between Pre and Post.

RESULTS: A significant decrease in total weight (-2.9% : Pre 66.6 ± 17.9 kg, Post 64.7 ± 19.2 kg), BMI (-2.4% : Pre 24.7 ± 4.4 , Post 24.1 ± 4.2) and body fat (-2.3% : Pre $30.4 \pm 10.5\%$, Post $29.7 \pm 10.5\%$) were found. Increased visuo-spatial working memory ($+50.0\%$: Pre 4 ± 1.5 , Post 6 ± 4.5) but not verbal (Pre 7 ± 2.5 , 8 ± 1) were found after training. An improvement in 30-s chair standing ($+9.1\%$: Pre 16.5 ± 7.5 , Post 18 ± 11) and 30-s arm curl right side ($+23.8\%$: Pre 21.0 ± 14.5 , Post 26 ± 14.2) but not left side (Pre 17.5 ± 13.5 , Post 23.5 ± 10.7 , $p = .066$) was found. A significant decrement of weekly seated time (-36.4% : Pre 330 ± 120 min, Post 210 ± 165 min) was found, as well as a tendency, but not significant, increase of moderate activity (Pre 60 ± 179.5 min, Post 120 ± 277 min) and positive affects (Pre 32 ± 8.5 Post 36 ± 3.5) and a decrease of negative affects (Pre 16 ± 3 , Post 15 ± 9.5).

CONCLUSION: Although these data are preliminary, the simultaneous dual cognitive and physical training resulted in an improved visuo-spatial working memory and physical skills in older adults. The training seems suitable for improving general well-being in older adults, and future applications should be explored, such as in an augmented reality environment [4].

OP-BM18 Muscle Disuse and Ageing

ALTERATIONS IN MOTOR UNIT PROPERTIES FOLLOWING 14 DAYS OF STEP REDUCTION PRECEDE FUNCTIONAL DECLINE AND ARE COUNTERACTED BY EXERCISE TRAINING

GHASEMI, M., MARTINO, G., GATTI, M., CARBONARO, M., MARCIANO, A., FRANCHI, M.V., BOTTER, A., PORCELLI, S., NARICI, M.V., DE VITO, G., BOTTINELLI, R.

UNIVERSITY OF PADOVA

INTRODUCTION: Periods of short-term physical inactivity are experienced by nearly all individuals during their lives and can cause several health issues (1). Recent studies employing unilateral lower limb suspension as a model of muscle disuse (2,3) have shown signs of neural alterations at the level of the neuromuscular junction (NMJ) and motor unit (MU) behavior. In step reduction (SR), a milder model of physical inactivity, the change of neural components of muscle control remains largely unknown. In this study, we aim to characterize neuromuscular alterations induced by SR and investigate whether a subsequent exercise intervention can guarantee an adequate recovery.

METHODS: Fifteen healthy young subjects (7 females, age 22 ± 2.3 years) participated in the study. Measurements were taken at baseline, after a 2-week of SR (<1500 steps/day), and following a 3-week exercise training (ET) intervention (3 sessions/week, 1 hour/session). At each time point, we assessed maximal voluntary isometric contraction (MVIC) of knee extensors, and vastus lateralis (VL) muscle activity during trapezoidal isometric contractions at 25% (5s ramp up, 20s steady state, 5s ramp down) and 50% (10s ramp up, 10s steady state, 10s ramp down) of MVIC. Muscle activity was recorded using high-density electromyography (HDEMG, OT Bioelettronica). HDEMG signals were decomposed into individual motor unit (MU) firings, from which we calculated absolute recruitment threshold (RT), derecruitment threshold (DT), and mean discharge rate (DR) at steady state. Statistical analysis included one-way ANOVA for comparing MU properties across time points at the same contraction level, and repeated measures ANOVA for MVIC values, with Bonferroni post-hoc correction (significance at $P < 0.017$).

RESULTS: In total, 735 MUs were identified and reconstructed. The MVIC torque did not change among the three sessions ($P = 0.339$). A difference was observed between SR and ET for RT at 25% of MVC ($P = 0.027$), although it was not significant after Bonferroni correction. No significant differences were found for DT. The DR was reduced from baseline to SR at 25% and 50% of MVC ($P = 0.010$ and $P < 0.001$, respectively), and it recovered after ET only at 25% of MVC ($P = 0.005$).

CONCLUSION: Knowledge of the pathophysiological mechanisms related to short-term physical inactivity is fundamental to overcome its deleterious effects. Muscle force production greatly depends on MU properties and their discharge rate. This is the first study assessing MU adaptations after a period of SR. Our findings suggest that neural degeneration might precede alterations in functional capacity, and exercise can successfully overcome this negative effect.

The study was funded by PRIN project (InactivAge n. 2020EM9A8X) and NextGenerationEU/MUR PRIN 2022 PNRR, (ReActiveAge, Project n. P2022FNCPR).

ANALYSIS OF MUSCLE DIFFERENCES IN ACTIVE AND INACTIVE ELDERLY SUBJECTS: TARGETING ERRα TO COUNTER AGE-RELATED ATROPHY

CARIATI, I., BONANNI, R., ROMAGNOLI, C., CAPRIOLI, L., TARANTINO, U., PADUA, E., ANNINO, G., TANCREDI, V.

UNIVERSITY OF ROME TOR VERGATA

INTRODUCTION: Muscle atrophy is a debilitating condition that significantly affects quality of life. Recent studies suggest estrogen-related receptor alpha (ERRα) as a potential therapeutic target to counteract muscle decline associated with aging or inactivity, as it is known to regulate mitochondrial function and contribute significantly to skeletal muscle exercise capacity. The purpose of this study was to evaluate the targeting of ERRα, by treatment with an agonist, SLU-PP-332, in myoblasts isolated from inactive elderly women, to mimic the muscle conditions found in active elderly women.

METHODS: 20 women with a mean age of 70 years undergoing hip arthroplasty for coxarthrosis were enrolled and divided into two groups based on self-reported physical activity: 10 women who practiced moderate physical activity, such as walking or bicycling, at least 30 minutes a day three times a week, and 10 women who did not practice regular, structured physical activity. A clinical and instrumental assessment was conducted during hospitalization, measuring bone mineral density, visual analogue scale (VAS) values, harris hip score (HHS) and handgrip strength test. During surgery, muscle biopsies were taken for histological and western blotting analysis. In addition, primary cultures of myoblasts were set up from the muscle tissue of inactive women and were treated with SLU-PP-332 for subsequent qualitative and quantitative investigations.

RESULTS: The clinical and instrumental evaluation revealed that inactive women were characterized by osteopenic/osteoporotic T-score values, higher VAS values, reduced hip function and significantly lower handgrip strength values. In agreement, the histological and morphometric analysis showed a reduced fiber diameter and increased ex-

pression of NADPH oxidase 4 (NOX4), a producer of oxidative stress, in association with reduced expression of sirtuin 1 (SIRT1), peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC-1α), ERRα and fibronectin type III domain-containing protein 5 (FNDC5), all mediators of muscle adaptations to exercise. SLU-PP-332-treated myoblasts showed a reduction in cytotoxicity, intracellular reactive oxygen species (ROS) levels, and senescence β-galactosidase activity, as well as an increase in reduced glutathione. In addition, down-regulation of NOX4 and up-regulation of SIRT1, PGC-1α, ERRα and FNDC5 were detected in treated cells.

CONCLUSION: Exercise counteracts the onset and/or progression of muscle atrophy, presumably through the positive regulation of ERRs. The future perspective of this study is to investigate the modulation of ERRs as potential biomarkers in response to different training protocols to optimize muscle response to exercise.

SEX-SPECIFIC DIFFERENCES IN THE ASSOCIATION BETWEEN FORCE STEADINESS AND FUNCTIONAL PERFORMANCE IN PHYSICALLY ACTIVE OLDER ADULTS

CAMACHO VILLA, M., GIRALDEZ, M., RIVERA-MEJÍA, S., LÓPEZ, M., MADRUGA, G., SEVILLA, M., CARBALLEIRA, E.
UNIVERSIDAD DA CORUÑA

INTRODUCTION: Age-related neuromuscular decline impairs the ability to maintain a steady force during a submaximal voluntary contraction, a measure known as force steadiness (FS). Given its critical role in physical function, reduced FS has been linked to lower functional performance in older adults. This study aimed to investigate the association between FS in the hip abductor, knee extensor, plantar flexor, and performance in functional tests among older adults.

METHODS: Twenty physically active older adults (3275.0 ± 1800.3 METS/week) participated in this study. Participants completed the Short Physical Performance Battery (SPPB) and underwent a gait assessment using the OptoGait system. Additionally, strength tests were performed for hip abductor, knee extensor, and plantar flexor, along with steady submaximal isometric activations at 20%, 30% and 20% of maximum effort, respectively, using an isokinetic dynamometer (HUMAC NORM) on the non-dominant limb. Gait speed over 4m and 6m, Sit-to-Stand (STS) muscle power, Time Up and Go (TUG), coefficient of variation (ST_CV%) and Root Mean Square of the Successive Differences (ST_RMSSD) of step time were recorded to assess the association with FS variables, including CV% (FS_CV%) and RMSSD (FS_RMSSD) of the tested limb. Pearson and Spearman correlations were conducted to determine the strength of the these relationship.

RESULTS: Ten women (67.2 ± 1.3 years; Fat mass percentage $39.0 \pm 3.9\%$), and ten men (69.1 ± 1.4 years; Fat mass percentage $30.3 \pm 6.7\%$), classified as robust according to the SPPB score participate in the study. A moderate correlation was found between FS_RMSSD of hip adductor and ST_RMSSD in the whole sample ($r = -0.46$, $p < 0.05$). Interestingly, sex-specific differences in correlation patterns were observed. In women, a significant positive correlation was found between TUG time and FS_RMSSD of hip adductor ($r = 0.65$, $p < 0.05$) and FS_RMSSD of plantar flexor ($r = 0.68$, $p < 0.05$). In contrast, these correlations were weaker and non-significant in men (hip adductor, $r = -0.29$, $p > 0.05$; plantar flexor: $r = -0.48$, $p > 0.05$). Additionally, a strong negative correlation was found between ST_RMSSD and FS_RMSSD of the hip adductor in men ($r = -0.70$, $p < 0.05$), whereas this relationship was weaker and non-significant in women ($r = 0.38$, $p > 0.05$). A moderate negative correlation was also observed between ST_RMSSD and CV% of the plantar flexor in men ($r = -0.70$, $p < 0.05$), while in women, this association was weaker and not significant ($r = 0.21$, $p > 0.05$).

CONCLUSION: These findings highlight the role of FS in neuromuscular function and its link to functional performance, emphasizing the need for controlled variability in specific muscles to maintain gait stability. Moreover, they stress the importance of considering sex-specific neuromuscular differences when assessing FS and functionality in aging. Future research should explore these compensatory strategies and their impact on tasks challenging medio-lateral stability, such as obstacle stepping.

CHANGES IN MUSCLE CONTRACTILE PROPERTIES AND FUNCTION DURING 10-DAY BED REST, RECOVERY, AND POST-COVID-19 LOCKDOWN

ŠIMUNIC, B., FRANCHI, M., SARTO, F., MONTI, E., PIŠOT, R., NARICI, M.V.
SCIENCE AND RESEARCH CENTER KOPER

INTRODUCTION: Changes in muscle structure and function have been observed following periods of bed rest. When aging is combined with such disuse periods, these changes become more pronounced, with severely limited recovery. Tensiomyography (TMG), a method for assessing skeletal muscle contractile properties, has been shown to detect early, pre-atrophic changes, not seen by other methods. This study aimed to identify early TMG alterations during a 10-day bed rest, followed by a 30-day recovery, and to compare these changes to those observed after the COVID-19 lockdown.

METHODS: Ten young males (22.9 ± 5.0 years) participated in a 10-day horizontal bed rest followed by a 30-day recovery. After obtaining ethical approval (No. 0120-123/2023/9), all participants provided written informed consent. TMG was assessed at baseline (BDC), on the i-th day of bed rest (BRi), on the i-th day of recovery (R+i), and after the COVID-19 lockdown (Covid-19) in six muscles. Vertical jump performance was evaluated using countermovement (CMJ) and squat jumps (SJ). Lower back pain was assessed using a visual analog scale.

RESULTS: All participants completed the bed rest study and assessments without complications. By BR10, we found 1.5 kg mass loss, characterized by a 3.8% increase in fat mass and a 0.76 kg decrease in muscle mass. While all anthropometric parameters returned to BDC levels, by R+30, fat mass increased again by 3.9% at Covid-19. At BR10, CMJ height decreased by 10.1% recovered to BDC values by R+30, with no further changes observed at Covid-19. TMG-derived delay

and contraction times increased in the vastus lateralis at BR10 but decreased in the erector spinae. In the biceps femoris, similar increase was observed at BR10 and persisted during Covid-19. TMG amplitude increased in all lower limb muscles from BR1 to BR4, recovered to BDC levels, but increased again at Covid-19, albeit to a lesser extent. In the erector spinae, TMG amplitude initially decreased at BR1, returned to BDC levels by BR4, and was associated with increased lower back pain during the same period.

CONCLUSION: Changes in TMG delay time have not been previously reported. We show inconsistencies across the measured muscles. Electromechanical delay is influenced by action potential generation, the time it needs to reach the muscle, any slack within the muscle before detectable tension is produced. Contraction time followed a similar pattern to delay time, except in the biceps femoris, where it increased after BR4 without recovery. Given that contraction time is correlated with the proportion of MHC-I fibers and jumping power, this finding has significant implications for the ability to generate explosive power. The increase in displacement was consistent with previous studies; however, it was detected much earlier than atrophy with imaging techniques. Notably, this was the first study to report a decrease in Dm in the erector spinae, which was associated with lower back pain, commonly observed in initial days of bed rest or spaceflight.

MODERATE ENDURANCE TRAINING LEADS TO AN INCREASE IN MUSCLE MASS, STRENGTH AND POWER IN OLDER ADULTS FOLLOWING 10 DAYS OF BED REST

SCARPELLI, M., COLOSIO, M., SIMUNIC, B., PIŠOT, R., ALCAZAR, J., BONATO, M., PORCELLI, S., NARICI, M., FRANCHI, M.
UNIVERSITY OF PADOVA

INTRODUCTION: Periods of muscle disuse are becoming more common in modern society, either due to sedentary lifestyle, illnesses or hospitalization. Disuse can lead to significant loss of muscle mass, strength and power, especially in the older population. Resistance training (RT) is the modality of exercise commonly chosen to counteract such impairments in muscle mass and function. A recent study from our lab (1) has confirmed RT as a successful strategy for recovering functional and structural muscle properties after 10 days of disuse. However, transcriptomic profile analyses suggest that exposure to short-term muscle disuse could prompt the muscle to primarily restore its metabolic function. Given that endurance training is known to enhance oxidative metabolism, this study aims to investigate whether it may also be effective in restoring disuse-induced impairments to skeletal muscle.

METHODS: Ten healthy male older adults (69 ± 3 years) underwent 10 days of strict horizontal bed rest (BR) without countermeasures, followed by 21 days (9 sessions) of moderate intensity endurance exercising (AR). Sessions consisted of 15min of warm-up, followed by five 15s high intensity cycling sprints, and 30min of cycling at 80-100% of gas exchange threshold. Neuromuscular function assessments and muscle biopsies were performed both before (BR0) and after (BR10) bed rest, and after AR. An isokinetic dynamometer was used to assess maximum voluntary isometric contraction (MVIC) and maximum muscle power (PM) of the knee flexors. The quadriceps femoris (QF) was manually outlined on magnetic resonance imaging (MRI) images obtained every 12mm. QF volume (VOL) was calculated using the truncated cone formula (2). Muscle thickness (MT), fascicle length (FL) and pennation angle (PA) were measured on ultrasound images obtained from the vastus lateralis at 50% of femur length. Transcriptional (RNAseq) analyses on muscle biopsies are ongoing. One-way repeated measures ANOVAs were performed to detect differences over timepoints.

RESULTS: From BR0 to BR10 there were significant decreases in QF VOL (-6.2%, $p < 0.001$), MT (-7.4%, $p = 0.02$), PA (-7.7%, $p = 0.04$) and MVIC (-13.3%, $p < 0.001$). Changes in FL (-3.6%, $p = 0.06$) and PM (-1.4%, $p = 0.84$) were not significant. From BR10 to AR there were significant increases in QF VOL (11.2%, $p < 0.001$), MT (13.7%, $p = 0.003$), MVIC (8.9%, $p = 0.007$) and PM (25.9%, $p < 0.001$). Changes in FL (5.3%, $p = 0.09$) and PA (9.4%, $p = 0.12$) were not significant.

CONCLUSION: Ten days of bed rest resulted in significant muscle atrophy and strength loss. Compared to what is usually observed after endurance training, muscle volume was not only restored, but, surprisingly, its change after retraining exceeded the baseline values, along with marked improvements in muscle strength and power. Ongoing transcriptional analysis will help to elucidate the molecular mechanisms underlying this unexpected hypertrophic and functional gains.

EFFECTS OF DIFFERENT DOSES OF ANTIOXIDANT INTAKE ON EXERCISE-INDUCED OXIDATIVE STRESS, ANTIOXIDATIVE CAPACITY AND INFLAMMATORY RESPONSES

SUZUKI, R., YAMAKI, A., MURATA, H., HIRABUKI, K., HATA, N., HIRASAWA, A., MURAMATSU, K., MATSUDA, T., SHIBATA, S.
KYORIN UNIVERSITY

INTRODUCTION: It is unknown whether an appropriate amount of exogenous antioxidant intake is present to maximize the exercise benefit on lifestyle-related diseases. The purpose of this study was to investigate the effects of two levels of exercise stress and exogenous antioxidant doses on exercise-induced oxidative stress, antioxidant capacity, and inflammatory response.

METHODS: Wistar male rats were divided into two groups; sedentary (SED) and exercise (TR). The exercise was increased from 4 weeks of low-intensity (90 min/week) to 4 weeks of high-intensity (300 min/week). TR was subdivided into low (70 mg/kg: TR+N), medium (350 mg/kg: TR+VE-M), and high (700 mg/kg: TR+VE-H) according to the amount of vitamin E intake. Oxidative stress (d-ROMs), antioxidative capacity (BAP), and inflammatory response (hs-CRP: high sensitive C-reactive protein) were measured with blood samples before and after each exercise load PGC1- α was measured with muscle samples using real-time PCR.

RESULTS: d-ROMs increased as exercise intensity was augmented in all TR and was higher in TR+N and TR+VE-M than in SED after high-intensity exercise, while it was not different between SED and TR+VE-H. hs-CRP increased in TR+N and TR+VE-H after high-intensity exercise as compared with before. PGC1- α increased only in TR+VE-M after high-intensity exercise.

CONCLUSION: Only medium doses of vitamin E intake may suppress the inflammatory response to oxidative stress during a large amount of exercise without inhibiting the expression of the transcription factor PGC1- α , suggesting the presence of an appropriate dose for exogenous antioxidant intake during exercise.

EFFECT OF AMARANTHUS SUPPLEMENTATION ON AEROBIC CAPACITY AND EXERCISE PERFORMANCE IN COMBAT SPORTS ATHLETES.

CHAHAR, A., SINGH, N., PAREEK, A., PUROHIT, S.G.

CENTRAL UNIVERSITY OF RAJASTHAN

INTRODUCTION: This study investigated the effects of seven-week *Amaranthus hypochondriacus* supplementation on aerobic capacity and exercise performance in karate athletes participating in state and national-level tournaments. The research aimed to evaluate the impact of *Amaranthus hypochondriacus* supplementation as an ergogenic aid on cardiorespiratory fitness markers and muscular strength in combat sports athletes to improve their performance.

METHODS: Forty-three karate athletes (31 male and 12 female) aged (18 ± 0.53 years), with body mass index (BMI) of (21 ± 1.04) competing at national and state levels, participated in this study. Participants were randomly assigned to either an experimental group receiving *Amaranthus* supplementation ($n=27$) or a control group ($n=18$) for six weeks. The *Amaranthus* supplement was administered in a standard dosage of approx. 20g/d, accounting for body weight and training volume. Pre- and post-intervention assessments measured aerobic capacity and exercise performance using Cardiopulmonary Exercise Testing (CPET) (K5 COSMED). Using a hand grip dynamometer, muscle strength was measured through push-ups, hand grip, and squats.

RESULTS: The seven-week supplementation trial yielded notable improvements in the experimental group (EXP) versus the control group (CON). Cardiorespiratory markers showed significant improvements, with an increase of 9.10% in VO_{2max} (ml/kg/min) in the EXP group; CON (35 ± 1.2) and EXP (40 ± 1.12) ($p < 0.05$) and improved HR_{max} (bpm), recovery patterns including respiratory exchange ratio (RER): CON (1.02 ± 0.11), EXP (1.05 ± 0.02) ($p < 0.05$); Respiratory Quotient (RQ): CON (1.15 ± 0.05), EXP (1.21 ± 0.03) non-significant; Ventilatory Threshold (VT) (ml/min) CON (2244 ± 154), EXP (2274 ± 120) ($p < 0.05$). Strength parameters demonstrated marked progress in the EXP group, particularly a 2.61% increase in upper body strength. Anaerobic capacity (30-yard sprint) increased in EXP Group.

CONCLUSION: Seven-week *Amaranthus hypochondriacus* supplementation significantly improved karate athletes cardiorespiratory fitness and strength parameters. Notable enhancements were observed in VO_{2max} , respiratory markers (RER, VT), upper body strength, and aerobic and anaerobic capacity. These findings provide valuable insights for athletes, coaches, and sports nutritionists in optimizing performance through supplementation strategies.

TWO WEEKS OF PYCNOGENOL SUPPLEMENTATION HAS NO ERGOGENIC BENEFIT TO PHYSICAL PERFORMANCE IN TRAINED HYBRID ATHLETES

KUCEWICZ, S., GOVUS, A., DRILLER, M., VAN DER POEL, C.

LA TROBE UNIVERSITY

INTRODUCTION: Participation in hybrid athletic events, such as CrossFitTM and HyroxTM, has led to an increase in hybrid athletes that require well developed strength, endurance, agility, and power. There is a high prevalence of ergogenic aid consumption among hybrid athletes [1]. Understanding the effects of ergogenic aids in improving this performance is crucial. Pycnogenol (PYC) is a dietary supplement extracted from French maritime pine bark, which is marketed for its antioxidant, anti-inflammatory and blood flow modulating effects, which can impact on performance and recovery. This study investigated the effect of 2-week PYC supplementation on physical performance in trained hybrid athletes.

METHODS: In a randomised, single-blind, cross-over study design, 12 (7 female, 6 male, age = 26-38 years) hybrid classified athletes performed a graded exercise test, countermovement jump (CMJ), isometric mid-thigh pull (IMTP), 30 s Wingate test, and back squat 1 repetition maximum (1RM) before and after two weeks of either PYC (260 mg/day PYC) or placebo (PLA: 0 mg/day PYC) daily oral supplementation. Following a 14-day wash-out, participants repeated all tests, which served as the baseline performance for their second counter supplementation period. Post-testing was performed 2-weeks after initial second supplementation period began. Linear mixed models analysed the effect of the treatment $\times$ time, adjusting for potential sequence/carry-over effects, sex, and age. Results are expressed as the raw parameter estimate (β) $\pm$ 95% confidence intervals.

RESULTS: When controlling for sex and age, no time $\times$ treatment effect was present for VO₂peak (-0.5 mL/kg/min [-2.28, 1.30]). Fatigue index (-10% [-25, 4]), peak power (-2 W, [-110, 105]), relative peak power (-0.1 W/kg [-0.4, 0.3]), and average power (-0.1 W [-48, 5]) achieved during the 30 s Wingate test failed to display a time $\times$ treatment effect, when controlling for sex. Similarly, when controlling for age and sex, no time $\times$ treatment existed for CMJ height (0.1 cm [-2.7, 2.9]), IMTP rate of force development 200 ms (86.9 N/s [-1016, 1190]), IMTP relative peak vertical force (-1.81 N/kg [-4.16, 0.54]), and back squat 1RM (0.2 kg [-4.08, 4.50]).

CONCLUSION: In our cohort and sample size, 2-weeks of 260 mg/day PYC supplementation provided no benefit compared to a PLA on VO₂peak, countermovement jump height, IMTP measurements, 30s wingate measurements and 1RM back squat. Therefore, 2-week PYC (260 mg/day) had no impact on physical performance of hybrid athletes. Future studies should aim to investigate the effect of dosage and supplement duration on hybrid athlete performance.

EFFECTS OF 7-DAY TART CHERRY JUICE CONSUMPTION ON RECOVERY, METABOLIC RESPONSE, AND CARDIOVASCULAR FUNCTION IN TRAINED CYCLISTS

KAVIANI, M., KNOWLES, S.

ACADIA UNIVERSITY

INTRODUCTION: Tart cherry contains two key antioxidants (anthocyanin and polyphenol) which have been shown prevent/reduce the onset of exercise induced oxidative stress, muscle damage and fatigue. The purpose of this study was to investigate the effects of tart cherry juice on recovery outcomes, metabolic responses, and cardiovascular function in trained cyclists.

METHODS: This study was a randomized, double-blind, placebo-controlled, cross-over design. Seven participants received 30 ml of tart cherry (TC) juice or a placebo (G) twice a day for seven days with a wash-out period of one month. Participants visited the lab 3 times during each supplementation period. On day 1, anthropometric measurements were obtained. Participants completed three 10km time trials on days 1, 6, and 7 with blood glucose and lactate measurements obtained pre- and post-trial. Additionally, on day 6 participants completed a 90-minute cycling test at 65% max heart rate before the 10km time trial. Blood glucose and lactate measures were obtained at baseline and again at 15,30,60 and 90 minutes.

RESULTS: The results showed blood lactate levels decreased after the 90-minute cycling test and increased post 10 km time trial in the TC condition. The 10 km time trial results on the last day of supplementation showed a $.31 \pm 0.1$ faster time in the TC condition compared to G condition. Also, heart rate decreased in the TC condition (118.3 ± 9.6) compared to G condition (121.4 ± 17.1) and stroke volume increased (99.9 ± 24.6) in TC condition compared to G (95.6 ± 22.2).

CONCLUSION: In conclusion, tart cherry supplementation appears to improve time trial performance, maintains metabolic response and improves cardiovascular function within trained cyclists. The two key antioxidants (polyphenol and anthocyanin) have anti-inflammatory and free radical reducing properties that help reduce oxidative stress and muscle fatigue, enhances overall performance amongst cyclists.

SWEET RELIEF: EVALUATING THE EFFECTIVENESS OF DARK CHOCOLATE FOR MENSTRUAL AND HORMONAL CONTRACEPTIVE CYCLE SYMPTOMS MANAGEMENT IN FEMALE ATHLETES

CHICA-LATORRE, S., MCKUNE, A., LINDLEY, M., MINEHAN, M.

UNIVERSITY OF CANBERRA

INTRODUCTION: Menstrual cycle symptoms (MCS), such as cramps, fatigue, and mood changes, affect over 80% of active women. These symptoms impact the wellbeing, quality of life, sports participation, and perceived performance of female athletes, making it a critical issue for athlete availability and long-term success. An immune-mediated inflammatory response has been suggested as a potential trigger for MCS. To address this, dark chocolate, rich in flavanols (polyphenols with antioxidant and anti-inflammatory properties), was tested as a practical strategy to manage MCS by its potential effect on inflammatory marker modulation.

METHODS: Healthy naturally cycling (NC group, $n = 20$, 29.5 ± 6 y/o) and hormonal contraceptive using (HC group, $n = 8$, 27.5 ± 4.6 y/o) female athletes were randomised to consume either 40 g of 70% or 25% cacao chocolate for eight consecutive days across two menstrual or HC cycles, following two baseline measure cycles. Menstrual cycle symptom (MCS) frequency and severity were evaluated using a Menstrual Distress Questionnaire (MDQ) (1). Serum C-reactive protein (CRP), a key marker of systemic inflammation, was used as an indicator of the immune response magnitude to MCS in the presence and absence of chocolate. Factors such as body composition, athlete calibre, diet and training load, were accounted for.

RESULTS: Menstrual cycle symptoms (MCS) frequency or severity did not significantly correlate with consuming chocolate ($p = 0.269$; $p = 0.482$) or the type of chocolate consumed ($p = 0.187$; $p = 0.84$). Nevertheless, there was a trend towards a negative relationship, with lower overall MCS frequency and severity reported during cycles when chocolate was consumed, and surprisingly with consuming 25% cacao chocolate compared to 70% cacao chocolate ($r_{pb} = -0.05$, $r_{pb} = -0.06$, respectively). CRP levels followed a similar trend, showing a non-significant negative correlation with consuming

chocolate (rpb = -0.04, $p = 0.316$) and type of chocolate consumed, favouring 25% cacao over 70% cacao chocolate (rpb = 0, $p = 0.928$). Furthermore, as shown through mediation analysis, neither chocolate consumption, type of chocolate, nor CRP levels appeared to be significant predictors of MCS frequency or severity. Interestingly, MCS frequency/severity outcomes and CRP levels reduced as athlete calibre increased (Tier 2 > Tier 3 > Tier 4 athletes).

CONCLUSION: A desire for chocolate is common prior to menstruation or bleeding. Higher cacao chocolate consumption (70% cacao) did not reduce MCS. However, a non-significant trend suggested that lower cacao (25%) chocolate consumption might be associated with a small reduction in MCS frequency and severity. CRP levels had a tendency to be lower when 25% cacao was consumed. The capacity of chocolate to mediate MCS warrants further investigation.

COGNITIVE AND PHYSIOLOGICAL FACTORS IN RESPONSE TIME TASKS: DIFFERENTIATING TEAM SPORT ATHLETES

SEIPP, D., KLATT, S.

GERMAN SPORT UNIVERSITY COLOGNE

INTRODUCTION: Athletes who can perceive situations more quickly and execute movements more rapidly have a significant advantage in team sports. In particular, decision making and perceptual abilities are frequently identified as crucial factors that differentiate between different levels of playing ability. However, the underlying mechanisms remain largely unknown [1]. This study aims to investigate the role of cognitive and physiological factors in response time tasks using general stimuli and their influence on expertise differences in female team sport athletes.

METHODS: A total of $n = 23$ high-level (2nd-4th league, age: 23.80 ± 2.95 years) and $n = 22$ low-level (7th league, age: 28.80 ± 7.60 years) female team handball athletes performed an Eriksen-Flanker-Task and four measurements on the SpeedCourt (a sensor-based system for assessing speed and reactive performance). Jump height, five-second tapping, and response times under both simple and complex conditions were assessed. Reaction and movement time were measured following a sport-specific response. Simple mean comparisons and correlation analyses were conducted to examine the relationships between dependent variables. The influence of test complexity and performance level was analyzed using a repeated-measures multivariate analysis of variance (rmMANOVA).

RESULTS: Reaction and movement time in the response time tasks increased significantly with increasing test complexity ($p < 0.001$). Only movement time distinguished between high- and low-level team handball players, with high-level players demonstrating significantly shorter movement times (MDiff = -0.037 s, 95%-CI [-0.001 s, -0.072 s], $p < 0.05$). Faster movement times were significantly correlated with jump height (moderate, $r = -0.48$, $r^2 = 0.24$, $p < 0.01$). Other cognitive-psychological factors, such as performance on the Eriksen-Flanker-Task, showed no significant group differences or a correlation with reaction time in the complex response time task ($p > 0.05$).

CONCLUSION: In conclusion, physiological factors, as indicated by movement time, contribute to differentiating female team sport athletes in response time tasks using general stimuli. These findings reflect sport-specific requirements for optimizing response time tasks and highlight implications for improving reactive agility. Future studies should incorporate sport-specific stimuli to systematically analyze the impact of anticipation and visual search behavior on movement times and expertise differences, which could provide valuable insights for training interventions in team sports.

EFFECTIVENESS OF AN 8-WEEK SPORT VISION TRAINING PROGRAM ON VISUO-MOTOR REACTION TIME AND OCULOMOTRICITY IN YOUNG FOOTBALL PLAYERS

ZERBINI, V., PIVA, T., RAISI, A., MENEGATTI, E., MANCIOPPI, S., BARDUCCO, A., PARISI, A., LA PORTA, M., GRAZZI, G., MAZZONI, G., MANDINI, S.

UNIVERSITY OF FERRARA

INTRODUCTION: Football is a highly dynamic sport that requires players to rapidly process visual stimuli, make decisions, and execute motor actions under pressure. Sport Vision Training (SVT) has been proposed as a method to enhance visuomotor skills, yet its application in football remains underexplored. This study aimed to evaluate the effectiveness of an 8-week, field-based SVT protocol on Visuo-Motor Reaction Time (VMRT) and oculomotricity in young football players.

METHODS: Thirty-five male players (aged 11-12 years) were recruited for the study. Baseline orthoptic evaluation ensured normal visual function before intervention. VMRT was measured using BlazePod devices across upper- and lower-limb tasks, while oculomotricity was evaluated using the Northeastern State University College of Optometry (NSUCO) test. Participant competed an 8-week SVT intervention, consisting of twice-weekly 20-minute training sessions integrated into football practice. Exercises focused on peripheral vision, saccadic movements and visual-motor reaction drills. General-

ized linear mixed models (GLMMs) and cumulative link models (CLMMs) were used for statistical analysis, with p-values adjusted for multiple comparisons.

RESULTS: Post-intervention analysis revealed significant improvements in VMRT for upper-limb tasks, with reductions in reaction times for right hand ($\beta = -0.15$; $p < 0.001$), left hand ($\beta = -0.14$; $p < 0.001$), and both hands ($\beta = -0.11$; $p < 0.001$). However, no significant improvements were detected in lower-limb reaction time ($p > 0.05$).

The NSUCO test showed significant improvements in saccadic movement precision ($\beta = 2.11$; $p = 0.02$) and reduced head/body movement during saccadic tasks ($\beta = 0.11$; $p < 0.001$), but no notable changes in pursuit movement precision ($\beta = -0.62$; $p = 0.37$).

CONCLUSION: Findings suggest that field-based SVT can effectively enhance upper-limb visuomotor reaction time and saccadic eye movement precision, supporting the integration of SVT in football training. However, its impact on lower-limb reaction time remains inconclusive, suggesting that additional training or a longer intervention period may be necessary to enhance reaction times in the lower extremities. Further investigation is needed. The study highlights the potential of integrating cost-effective SVT programs into football teams training routines, allowing coaches to systematically enhance athletes' visual-motor processing without disrupting standard practice sessions. Future research should explore longer intervention periods and assess the transferability of SVT improvements to match performance. And assess long-term retention of visual-motor adaptations.

Appelbaum, L.G.; Erickson, G. Sports Vision Training: A Review of the State-of-the-Art in Digital Training Techniques. *International Review of Sport and Exercise Psychology* 2018, 11, 160–189, doi:10.1080/1750984X.2016.1266376.

THE EFFECTS OF A SOCCER-SPECIFIC IMMERSIVE TECHNOLOGY TRAINING INTERVENTION ON PERCEPTUAL-COGNITIVE SKILLS OF YOUTH SOCCER PLAYERS

CHANG, W., FERNANDEZ-NAVARRO, J., FORD, P., CAUSER, J., IGA, J., ANDREW, M., MCROBERT, A.

LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: Innovative soccer-specific training tools, such as SoccerBot360 (SB360), offer multidimensional perceptual-cognitive training (PCT) using soccer-specific motor tasks with 360-degree stimuli. These technologies can overcome the limitations of conventional PCT tools that often isolate perceptual-cognitive skills from physical activity, such as virtual reality systems [1]. However, evidence on the effectiveness of SB360 and other PCT using these technologies is still limited, particularly among skilled populations. Therefore, this study evaluated the effects of a 6-week SB360 PCT intervention on perceptual-cognitive-motor task performance in skilled youth soccer players.

METHODS: Thirty-one male youth soccer players from a Category One English Premier League Youth Academy (age = 13.7 ± 0.9 years) participated in a longitudinal crossover design. They were divided into two groups: one group completed a 6-week block of SB360 PCT (15-mins/week) followed by another 6-week control block where they continued their regular soccer training, whereas the sequence was reversed for the other group. Following familiarisation, intervention effects were assessed before, between, and after each training/control block using standardised SB360 motor tasks designed to test choice response time, cognitive flexibility, anticipation, and inhibition. Linear mixed models were employed for analysis of test response accuracy (RA) and response time (RT), reporting r-squared values as an effect size measure. Significance was set at $P < 0.05$.

RESULTS: RT in all four tasks was significantly faster at the 6-week mid-point and the end of the 12-week study compared to baseline. However, there were no between-group differences in RT at any test, including at the 6-week mid-point, where the intervention group was hypothesised to show faster RT than the control group. RA in the anticipation task was significantly greater at the end of the 12-week study compared to baseline. RA did not significantly differ across tests for the other three tasks, and again, there were no between-group differences in RA across all tasks. Effect size analysis indicated that individual differences accounted for the largest proportion of variance (0.54–0.80) when compared to time and group factors (0.00–0.10). Additionally, six of nine testing variables showed significant improvements ($P < 0.05$) between familiarisation and first cognitive test.

CONCLUSION: Individual variation between players had a stronger effect on SB360 testing performance than the intervention. Therefore, we recommend a longer duration and increased frequency of SB360 training, as well as tailoring task difficulty and specificity to individual needs, so as to minimise individual variation and maximise training effects. Future study should also incorporate a familiarisation test to minimise misinterpretation of cognitive intervention results.

MOTOR-COGNITIVE INTERFERENCE APPLIED TO TABLE TENNIS

MALAGOLI LANZONI, I., RUSSO, G., MARCORA, S.M.

UNIVERSITY OF BOLOGNA

INTRODUCTION: In fast-paced sports like Table Tennis, athletes must allocate cognitive resources to process multiple stimuli, potentially impairing performance under dual-task conditions [1][2]. This study examined how table tennis athletes manage single- and dual-task conditions and in particular their ability to balance motor and cognitive demands.

METHODS: Thirteen expert table tennis players (M age = 20.4 ± 5.3 years) participated in this study. Each athlete completed three single-task and two dual-task conditions. The single tasks included an Auditory Free-Recall Memory Task (MT), in which participants memorized 20 words and recalled them at the end of the task, and two table tennis tasks. These in-

cluded a SimpleTask (ST), where participants returned ball throws by a robot using a Simple technique (drive), and a Complex Task (CT), using a Complex technique (top spin). In the dual-task conditions, participants performed the MT simultaneously with either ST (MT+ST) or CT (MT+CT). The NASA-TLX scale was used to assess physical demand (PD) and mental demand (MD) after each trial.

RESULTS: Significant differences were found in memory performance across conditions ($p < .001$). MT performance was higher in the single-task condition and significantly declined in both dual-task conditions. However, no significant differences were observed between MT+ST and MT+CT. When analyzing word recall patterns, performance was significantly lower in both dual-task conditions compared to the MT single-task for the first five words. No differences emerged between the two dual-tasks. For the last five words, MT recall was superior to both dual-task conditions, and MT+CT performance was better than MT+ST.

Mental and physical demands varied significantly across conditions ($p < .001$). The lowest PD was registered in MT, and the highest were recorded in CT and MT+CT. MD was significantly higher in MT+CT compared to all the other conditions.

CONCLUSION: Results indicate significant cognitive-motor interference even in expert Table Tennis players: the more difficult the Table Tennis task becomes, the fewer words are remembered. These data are also supported by the higher PD and MD detected in MT + DT compared to all the other sessions. These findings highlight the role of cognitive-motor interference in table tennis and display the challenges athletes face when distributing attentional resources in demanding conditions.

OPTIMIZING FENCING COORDINATIVE ABILITIES: INSIGHTS FROM INTERMITTENT VISION TRAINING AND EYE MOVEMENT ANALYSIS

DI LIBERO, T., D'ERMO, A., COSENTINO, G., RICCIO, C., FALESE, L., RODIO, A.

UNIVERSITY OF CASSINO AND SOUTHERN LAZIO

INTRODUCTION: Rapid visual processing and reaction time are crucial in fencing. Stroboscopic training, which intermittently occludes vision, may enhance visuomotor coordination. This study evaluated the effects of stroboscopic glasses training on eye-tracking parameters and reaction time, comparing an experimental group (EG) to a control group (CG) undergoing conventional training.

METHODS: Twenty-four experienced fencers (age: 16.1 ± 2.5 y; BMI: 21.8 ± 3.19 kg/m²) were randomly assigned to two groups: an experimental group (EG) and a control group (CG). The 5-weeks intervention included three phases: initial assessment; training; and final assessment. Performance measurements included the reaction time evaluation by administering 5 trials using the Electronic Fencing Target (EFT-1) and 5 Ruler Tests (RT). During the trials, an eye tracker was used to record visual behavior, and monitor fixation count, saccades, and gaze dispersion. Both groups followed the same training protocol using EFT-1 while wearing stroboscopic glasses. The training protocol required the experimental group to alternate between the ON condition, where intermittent occlusion limited vision, and the OFF condition, with unrestricted vision. The occlusion mode and frequency, randomly administered, were chosen to create a more demanding perceptual environment and enhance visual and reaction abilities.

RESULTS: Eye-tracking data showed a significant increase in fixation count ($p=0.05$) and saccadic movements ($p=0.01$) in the experimental group. Gaze azimuth and elevation shifted toward a more centralized focus on the target, reducing deviations (pre: $2.5^\circ \pm 4.3^\circ$; post: $1.2^\circ \pm 2.1^\circ$; pre: $3.0^\circ \pm 3.8^\circ$; post: $1.5^\circ \pm 1.9^\circ$, respectively). EFT-1 results indicated an average 8.6% improvement in reaction times (pre: $290\text{ms} \pm 15$; post: $265\text{ms} \pm 12$), with the ON-ON-OFF-OFF sequence proving particularly effective. The control group showed no statistically significant changes. The Ruler Test did not reveal any significant differences between pre- and post-training results in either group, suggesting that this test may not accurately capture the sport-specific reflex demands of fencing.

CONCLUSION: Stroboscopic training improved gaze efficiency and reaction time in fencers, while the control group showed no notable progress. The stroboscopic effect likely enhances feedforward mechanisms, forcing athletes to refine anticipatory and perceptual strategies under visually challenging conditions. The lack of significant changes in RT suggests that general reaction time assessments may not effectively measure sport-specific visuomotor improvements in fencing. This could be because the test used was not specific to the motor task required nor sufficiently discriminative to capture the perceptual-motor skills developed in this sport. These findings support the use of stroboscopic glasses as a tool to optimize training and pre-competition preparation. Future studies should explore long-term effects and refine training protocols to validate these promising results further.

OP-AP19 Training and Testing V - Hyrox, CrossFit and Rowing

HYROX® - PHYSIOLOGICAL DEMANDS AND PERFORMANCE PREDICTORS OF A NOVEL HIGH INTENSITY FUNCTIONAL FITNESS TREND

BRANDT, T., EBEL, C., LEBAHN, C., SCHMIDT, A.

INSTITUTE OF SPORT SCIENCE, UNIVERSITY OF THE BUNDESWEHR MUNICH

INTRODUCTION: Hyrox® is a fitness modality combining 8 functional exercises with running in a comprehensive competition format. Within this first scientific study on Hyrox®, acute physiological responses, relative perceived exertion (RPE), and possible performance determinants were assessed during a simulated Hyrox® competition to derive training recommendations and potential practical applications.

METHODS: Eleven recreational Hyrox® athletes (27 % women, Hyrox® experience (median (interquartile range): 18 (19) months) participated. In a pre-test, height, body composition, hand grip strength (HGS), maximum oxygen consumption (VO₂max), and volume of resistance and endurance training were assessed. After 48 hours rest, a simulated Hyrox® was conducted according to the competition-standards of the "Individual Open Division". Heart rate (HR) was tracked throughout the Hyrox®. Blood lactate (BL) and RPE were recorded at the beginning and after each run and exercise station. Differences between runs and exercise stations for HR, BL, and RPE were analyzed via Wilcoxon signed rank test. Spearman's rank correlation test was conducted to identify associations between completion times (Hyrox®, runs, exercise stations) and participant characteristics. Values are given as median (interquartile range).

RESULTS: Completion time of the Hyrox® was 86.5 (14.5) minutes, whereby runs (51.2 (14.1) minutes) were significantly longer than the exercise stations (32.8 (6.1) minutes) ($p = .003$). Most of the Hyrox® was performed at very hard and hard intensities (79.5 (21) % and 19.6 (20.7) % of maximum HR). Maximum BL was higher during the exercise stations (8.5 (5.4) mmol/L) compared to the runs (7.7 (4.6) mmol/L) ($p = .006$). Similar results were found for maximum RPE (exercise stations: 18 (2), runs: 16 (2), $p = .003$). The highest values for HR, BL, and RPE occurred during the last exercise (wall balls). The exercise stations with the heaviest loads were completed the fastest (sled push: 128 (34) seconds, sled pull: 155 (38) seconds). Faster Hyrox® completion correlated significantly with higher VO₂max ($p = .01$), greater endurance training volume ($p = .04$), and lower body fat percentage ($p = .03$).

CONCLUSION: Hyrox® is a HIFT modality with an emphasis on endurance capacity and moderate to low requirements in terms of maximum strength, coordination, and mobility when compared to other forms HIFT. Hyrox® may be suitable for health promotion and tactical population training.

THE LONGITUDINAL IMPACT OF CROSSFIT ON STUDENTS GOAL-SETTING, RESILIENCE, AND ACADEMIC SUCCESS: A THREE-SEMESTER STUDY

LAZZARI, J., BARDINI, S., GINESTRETTI, L., SANTAMBROGIO, M.

POLITECNICO DI MILANO

INTRODUCTION: CrossFit, a dynamic fitness program, significantly impacts students physical health, psychological well-being, and academic performance. By enhancing essential qualities like goal-setting, self-awareness, and resilience, CrossFit provides students with the tools to overcome challenges in both physical and academic areas, supporting their overall development. This study, part of the Leonardo project at Politecnico di Milano, explores the intersection of physical fitness and academic success, investigating how CrossFit can help students improve their academic performance while fostering personal growth.

METHODS: To assess the longitudinal impact of CrossFit on students goal-setting and self-awareness over time, we conducted a study spanning three semesters, involving an experimental group and a control group. The experimental group participated in CrossFit three times a week throughout the semester, while the control group maintained their usual activities. The impact of CrossFit was measured using validated psychological questionnaires that assessed students psychological resilience, stress management, and coping strategies. Additionally, academic goal-setting behaviors were evaluated through questionnaires designed to gauge how realistic and attainable students were in setting their academic objectives.

At a statistical level, we implemented statistical tests to compare the results of the two groups. These analyses allowed us to examine the relationships between participation in CrossFit and changes in psychological resilience, stress management, and goal-setting behaviors. By comparing the outcomes between the experimental and control groups, we could assess whether the CrossFit program had a significant impact on students ability to set realistic academic goals and manage the psychological challenges associated with academic life. The threshold for statistical significance was set at 0.05, and we used this criterion to evaluate the results of our tests.

RESULTS: The results indicated that students in the experimental group demonstrated improved psychological resilience, which was reflected in their ability to manage academic challenges such as exams. These students showed a higher degree of realism in setting achievable targets. They also exhibited better stress management and coping strategies.

The statistical tests showed that the differences between the experimental and control groups were significant, with p-values significantly below the significance level, indicating that the improvements observed in the experimental group were significant.

CONCLUSION: Incorporating CrossFit into the academic experience provides students with a powerful framework for developing essential skills such as goal-setting, resilience, and self-awareness. The study demonstrates that physical training through CrossFit can complement academic growth by helping students refine their goal-setting abilities and become more resilient to challenges.

PERFORMANCE PREDICTION AND ATHLETE CATEGORIZATION USING THE ANAEROBIC POWER RESERVE FRAMEWORK IN ROWING

RAPPELT, L., DONATH, L., WIEDENMANN, T., MICKE, F., MÜHLENHOFF, S., HELD, S.
GERMAN SPORT UNIVERSITY COLOGNE: DEUTSCHE SPORHOCHSCHULE KOLN

INTRODUCTION: With the rowing distance reduced to 1500 m for the 2028 Olympic games, the anaerobic power reserve (APR) framework [1] has been proposed to evaluate anaerobic performance and differentiate physiological profiles [2]. This study investigated performance predictions and athlete profiles using the APR framework and related physical performance measures.

METHODS: Thirty-one female (simulated 2000m performance ($P2k$) = 285.1 ± 36.0 W) and 63 male ($P2k$ = 422.8 ± 62.2 W) German rowers competing at a national level or higher (53 highly trained [Tier 3], 21 elite [Tier 4], and 20 world-class athletes [Tier 5]) [3] completed tests for maximal oxygen uptake (VO_{2max}), maximal lactate accumulation rate (cl_{amax}), peak power output (PPO), power output at VO_{2max} (MAP), 2 mmol·L⁻¹ ($P2$) and 4 mmol·L⁻¹ blood lactate ($P4$), and $P2k$. Backwards stepwise regression models and commonality analyses were used to predict $P2k$ and assess the contribution of each predictor, while k-means clustering based on the power reserve ratio ($PRR = PPO \cdot MAP^{-1}$) identified athlete subgroups.

RESULTS: For $P2k$ prediction, $P4$, PPO, and VO_{2max} in females ($P2k$ [W] = $22.42186 + 0.7254 \cdot P4$ [W] + $0.09277 \cdot PPO$ [W] + $16.10299 \cdot VO_{2max}$ [L·min⁻¹] + ϵ , $R^2 = 0.91$, SEE = 11 W), and $P4$, MAP, and PPO in males ($P2k$ [W] = $15.95316 + 0.64991 \cdot P4$ [W] + $0.24085 \cdot MAP$ [W] + $0.11641 \cdot PPO$ [L·min⁻¹] + ϵ , $R^2 = 0.94$, SEE = 16 W) showed excellent model fits. Commonality analyses revealed ~90% shared variance contributions among predictors. K-means clustering identified sprint-type (females: $PRR \geq 1.52$; males: $PRR \geq 1.66$) and endurance-type rowers (females: $PRR \leq 1.43$; males: $PRR \leq 1.62$) along the PRR continuum. Male rowers identified as sprint-type showed statistically significant higher PPO (845.4 ± 102.8 vs. 686.8 ± 142.6 W, $p < 0.001$) and cl_{amax} (0.45 ± 0.10 vs. 0.35 ± 0.11 mmol·L⁻¹·s⁻¹, $p < 0.001$), while exhibiting a lower VO_{2max} (60.4 ± 5.2 vs. 69.4 ± 7.0 ml·kg⁻¹·min⁻¹, $p < 0.001$) compared to endurance-type athletes. In females, sprint-type athletes showed statistically significant higher PPO (474.8 ± 28.7 vs. 431.6 ± 68.4 W, $p = 0.020$) and cl_{amax} (0.31 ± 0.05 vs. 0.24 ± 0.07 mmol·L⁻¹·s⁻¹, $p = 0.006$), while exhibiting a lower VO_{2max} (50.9 ± 5.7 vs. 55.8 ± 4.6 ml·kg⁻¹·min⁻¹, $p = 0.013$) and MAP (290.5 ± 27.5 vs. 337.8 ± 51.3 W, $p = 0.002$) compared to endurance-type athletes. Interestingly, in both sexes, world class performance was identified in both clusters.

CONCLUSION: Key predictors of $P2k$ highlight the interplay between the aerobic and anaerobic energy systems. Moreover, the identification of distinct sprint- and endurance-type clusters underscores the physiological diversity within highly trained rowers, even among athletes with similar performance outcomes. Longitudinal PRR assessments may support talent identification and facilitate individualized training strategies.

PREDICTING THE RATE OF PERCEIVED EXERTION IN ROWING: ENHANCING TRAINING MONITORING AND FATIGUE DETECTION.

STAUDNER, J., MÖLLER, T., PETERSEN, P., TREFF, G., HAUTSCH, N.
UNIVERSITY OF VIENNA

INTRODUCTION: The Rating of Perceived Exertion (RPE) is a widely used metric in sports science and an accepted measure of internal load in athletes. RPE is closely related to other internal load variables (e.g., heart rate (HR)) and external load (e.g., mechanical power output (watt)). This allowed us to develop a regression model giving an expected RPE for national elite-level rowers solely based on external load features that a coach can know and influence before a session.

Assuming sufficient reliability of the models opens the possibility of predicting an expected RPE based on other training variables. A subsequent analysis comparing predicted and reported RPE enables valuable interpretations of shifts in training status and athlete performance, i.e., a higher reported RPE suggests a decline in an athlete's performance.

METHODS: 2,160 ergometer training sessions from 20 female and 11 male rowers were considered. We used mean power output, duration, and training type as features in our model. Rowing experts have refined the features to ensure the model captures more detailed shifts in the underlying relationships. Finally, to avoid bias through non-exercise-related effects, we excluded particularly good or bad days based on self-reported well-being for training the model.

We selected the best-fitting regression from an ensemble of models for every new data point to make reliable predictions on an individual level. Based on the data, we determined a 95% confidence interval (CI) for the prediction accuracy of 1.16 au.

We also analyzed which factors had the largest influence on the prediction using Gradient Boosting machine learning models in Python.

RESULTS: This study is the first to predict RPE in rowing. Our ensemble method identified training sessions where the actual RPE fell outside the confidence interval for 71% of the athletes, indicating a shift in training status on those days.

Regarding predictive power, our method achieved an RMSE of 0.81 RPE units and an MAE of 0.62 RPE units across the entire dataset. Notably, our approach outperforms more complex models from various sports disciplines by 5-64%.

The feature importance analysis showed that for 84% of the athletes, power output had the biggest impact. For the rest, the session duration or type played a more substantial role.

CONCLUSION: Navigating the complexities of sports-tracking data poses considerable challenges; thus, leveraging domain-expert insights is crucial in developing robust models. Their contributions have led our models to outperform numerous more complex machine learning alternatives in accuracy and practical application.

Further, we show that most athletes correctly understand RPE as a measure of intensity rather than duration.

This research connects sports with applied data science by categorizing training status as decreasing, stable, or improving. Integrating insights on training status with individual factors influencing RPE, we deliver a scalable, interpretable, and actionable tool for practitioners.

THE RESEARCH ON PACING CHARACTERISTICS OF WOMENS QUADRUPLE SCULLS AT TOP INTERNATIONAL REGATTAS

WANG, W., ZI, W.

CHINA INSTITUTE OF SPORT SCIENCE

INTRODUCTION: As a competitive sport, rowing requires athletes to distribute their energy effectively throughout the race. The pacing characteristics exhibited by athletes during the race, which reflect how energy is allocated, have a significant impact on the final results. This study aims to investigate the pacing characteristics of world-class rowing events and explore their influence on final performance, with the goal of enhancing rowing outcomes.

METHODS: The data for this study were sourced from www.worldrowing.com, analyzing the race time data for each 500m segment from all teams in the A-finals of the Womens Four-Person Double Sculls (W4+) event at the Olympic Games and World Championships from 2013 to 2024. The analysis compared the 500m segment times, speed variations, and the coefficient of variation (CV) of normalized speeds, as well as the sum of relative differences, between the medalist groups (1st to 3rd place) and non-medalist groups (4th to 6th place). A t-test was used to explore differences between medalists and non-medalists, and Pearson correlation analysis was conducted to examine the relationship between speed metrics and final performance.

RESULTS: (1)Over the past decade, the primary pacing strategies used by teams in the finals were Reverse J-shaped, J-shaped, Fast start and fade, and Other. The medalist teams predominantly employed the Reverse J-shaped strategy, while non-medalist teams were more likely to use the Fast start and fade strategy. Since 2017, higher-ranked teams have increasingly adopted the Reverse J-shaped pacing strategy.(2)In terms of pacing stability, medalist boats (CV=1.96%) demonstrated greater stability than non-medalist boats (CV=2.10%), though the difference was not statistically significant ($t=-0.83$, $p=0.41$). Furthermore, after 2018, there was a significant improvement in pacing stability among athletes ($p=0.00404$). (3)In terms of speed across race segments, the correlation between speed and total time was negative for each segment: the start phase ($r=-0.94$), the middle phase ($r=-0.97$), and the sprint phase ($r=-0.90$). This suggests that faster speeds (shorter times) are associated with better overall performance.(4)Regarding speed variation, the correlation was negative for the start phase ($r=-0.43$) and positive for the sprint phase ($r=0.43$), indicating that faster speeds in the start phase lead to shorter total race times, and that accelerating in the sprint phase contributes to improved overall performance.

CONCLUSION: This study highlights the importance of pacing strategies in the Womens Four-Person Double Sculls. The findings offer practical insights for coaches to optimize pacing stability and speed management, helping athletes effectively distribute energy throughout the race for better performance.

OP-MH11 Mental Disabilities

UNRAVELING THE DOSE-DEPENDENT LINK BETWEEN MOTOR COMPETENCE AND PHYSICAL FITNESS TRAJECTORIES IN YOUTH WITH INTELLECTUAL DISABILITIES

TAN, X., CHEN, S., WU, X.

SHANGHAI UNIVERSITY OF SPORT

INTRODUCTION: Intellectual disability is the most common disability among children and adolescents, typically associated with lower physical fitness (PF) and delayed fundamental movement skills (FMS) [1-2]. Improvement in FMS plays a crucial role in supporting PF development [3]. However, existing research primarily focuses on the linear correlation between physical activity and FMS [4] or specific characteristics of children with intellectual disabilities [5]. We hypothesize that PF is associated with FMS levels in a dose-response relationship in this population.

METHODS: FMS was assessed using the Test of Gross Motor Development, 3rd Edition (TGMD-3). PF indicators included body mass index (BMI), cardiopulmonary function, muscular strength and endurance, speed and agility, balance, and flexibility. Logistic regression and segmented linear regression analyses were performed using R (4.4.0) to explore the relationship between FMS and PF.

RESULTS: A total of 191 participants (135 boys and 56 girls) aged 7–18 years were included in the study. Regression analysis indicated a significant positive correlation between FMS and PF. Across all age groups, object control skills showed a slightly stronger correlation with PF compared to locomotor skills. After adjusting for age, regression analysis demonstrated a dose-response relationship between FMS and PF, where higher FMS levels corresponded to better PF levels (trend test, $P < 0.001$). Further threshold analysis identified a significant nonlinear relationship between FMS and PF, with inflection points of 17 and 27 observed in boys and the total sample, respectively ($P < 0.001$). This suggests that the impact of FMS on PF varies significantly across different threshold levels ($P < 0.001$). However, no similar nonlinear relationship was observed in girls.

CONCLUSION: Age-stratified analysis revealed fluctuations in the correlation between FMS and PF, with the strongest effect observed during adolescence. After adjusting for age, a clear dose-response relationship between FMS and PF was identified, with a nonlinear trend at specific FMS thresholds. These findings underscore the importance of designing individualized physical activity intervention strategies that consider gender differences to enhance motor skills and overall physical fitness, particularly in the intellectual disabilities.

COMPARISON OF COGNITIVE AND PHYSICAL ABILITIES IN AUTISTIC AND NON-AUTISTIC CHILDREN

GUEUGNEAU, N., AYMARD, N., DEMARIA, R., RUFFINO, C., GROSPRÊTRE, S.

UNIVERSITÉ MARIE ET LOUIS PASTER

INTRODUCTION: Autism is characterized by atypical cognitive and motor development [1]. While research generally explores these domains separately, few studies have directly compared physical and cognitive performances in autistic (AC) and non-autistic children (NAC) [2, 3]. This study aims to investigate potential differences between these groups across physical, sensorimotor and cognitive tasks, providing insights into potential intervention strategies.

METHODS: A total of 41 children (19 AC and 22 NAC; matched for age: 14.5 ± 4.02 years old) participated in this study. Physical performance was assessed using the Handgrip Strength Test, 200-Meter Fast Walking Test, and Standing Broad Jump. Sensorimotor abilities were measured with a Fitts Task (speed-accuracy trade-off), and a Mental Rotation Test (spatial cognition). Cognitive aptitudes were tested by using the Bells Test (visual attention), Go-NoGo Test (inhibitory control), and Trail Making Test (cognitive flexibility). Statistical analyses were conducted to compare group performances.

RESULTS: Our results revealed significant differences between AC and NAC in all physical variables. Autistic children performed worse than their non-autistic peers in the Handgrip Strength Test, Standing Broad Jump, and 200-Meter Walking Test. In sensorimotor tasks, AC exhibited longer movement durations than NAC in the Fitts' Task and longer reaction times in the Mental Rotation Task. Finally, NAC outperformed AC in the Go-NoGo and Trail Making Tests, although performance in the Bells Test was similar across groups.

CONCLUSION: The results indicate that AC may experience both motor and cognitive difficulties compared to their non-autistic peers. Specifically, our data highlight impairments in overall physical fitness, motor planning and control, as well as executive functions. However, it is noteworthy that visual attention performance was similar between groups. Understanding these differences is crucial for developing targeted interventions that combine both motor and cognitive training. Future studies should investigate the effects of integrated cognitive-motor programs to improve the overall functioning of children with autism.

RELIABILITY OF THE SPORT-SPECIFIC TEST FOR IN INTELLECTUALLY IMPAIRED PARA-KARATE ATHLETES

AUGUSTOVICOVA, D., HADZA, R., HRUBY, M.

COMENIUS UNIVERSITY

INTRODUCTION: Para-karate has emerged as a competitive sport for athletes with intellectual impairments (II) and Down Syndrome (DS), supported by classification systems to ensure fair participation. Following the re-inclusion of II athletes in the Paralympics (London 2012), the IPC mandated evidence-based classification systems to enhance fairness in competition. To support the WKF's goal of including para-karate in the Paralympic program, this study aimed to develop reliable kata memory-specific tests to assess memory determinants in para-karate.

METHODS: The study included 41 para-karate kata athletes with II or II and DS, who participated in the WKF World Championships in Budapest 2023. Assessments took place before the competition, on a 6x6m Tatami Mat, recorded from three perspectives. Athletes practiced a karate sequence three times before performing it independently. Performance was evaluated on: (1) correct execution of movements according to the original pattern, (2) correct direction of movements, (3) errors involving incorrect limb use (-0.5 per error), and (4) hesitations disrupting flow (-0.5 per hesitation). Kata memory scores were calculated as the sum of correctly executed and directed movements, with penalties for errors.

To assess intra-rater reliability, performances were evaluated by the same observer via video analysis with a one-week interval. Statistical analysis included Cohen's Kappa for ordinal data and the Wilcoxon T-test to evaluate differences, with significance set at $p < 0.05$ was conducted.

RESULTS: Descriptive analysis showed a mean kata memory test score of 8.75 ± 1.1 in the first assessment and 8.80 ± 1.0 in the retest, with scores ranging from 5 to 10 across participants. It indicates minimal variability, underscoring the tests reliability in assessing kata memory performance. The consistency of scoring across different time points supports the potential for its inclusion in official classification processes.

A Kappa value of 0.98 indicated almost perfect agreement between test and retest evaluations, demonstrating exceptional intra-rater reliability. No significant differences were found between test and retest evaluations ($p > 0.05$), supporting the consistency of the specific memory test.

CONCLUSION: The developed test demonstrates high reliability for assessing memory determinants in para-karate athletes with II or DS. These findings highlight the robustness of the test, suggesting it could play a vital role in standardizing classification systems for para-karate.

Future research should focus on validating the test across a broader population and exploring its sensitivity to subtle differences in cognitive performance, ensuring its applicability in diverse competitive environments. This will further enhance the fairness and transparency of para-karate classification processes.

The study was supported by the Ministry of Education, Science, Research, and Sport of the Slovak Republic, VEGA project no. 1/0611/23.

EFFICACY OF A SLOW WALTZ-BASED PROGRAM ON GAIT AND BALANCE PROBLEMS IN PARKINSON'S DISEASE

SPIANTINI, M., GHIZZARDI, V., GALVANI, C.

UNIVERSITÀ CATTOLICA DEL SACRO CUORE - MILANO

INTRODUCTION: Parkinson's disease (PD) is a progressive neurodegenerative disorder characterized by motor impairments such as tremor, rigidity, bradykinesia and postural instability which significantly impair daily functioning and quality of life¹. While pharmacological treatments primarily address motor symptoms, non-pharmacological therapies like exercise have gained recognition for their potential to improve motor function, mobility and mental health². Among various form of physical activities, studies reported that dance positively influences motor functions in Parkinson's disease³. The primary aim of this study was to examine whether an adapted waltz-based program could improve gait and balance in patients with PD.

METHODS: The project involved 12 subjects (age 72 ± 9 yrs; MMSE score ≥ 24 ; H&Y stages 1-4; ability to stand unaided). Participants attended 8 sessions of slow waltz and basic technique exercises at home for 8 weeks. Assessments were conducted at the beginning (T0) and at the end of the program (T1) using Body Sway test, Gait analysis, Stepping in place and Timed Up and Go (TUG) tests.

RESULTS: Data are expressed as median and interquartile range (IQR) and compared using Mann-Whitney test in 9 out of 12 participants. Results showed that Mean distance A/P (T0: 3.9 ± 5 vs T1: 3.4 ± 3.4 mm), Mean distance M/L (T0: 1.5 ± 1 vs T1: 0.8 ± 0.8 mm) and Area (T0: 158.8 ± 349 vs T1: 82.7 ± 109.1 mm²) in Body sway test with opened feet improved during the 8 weeks. The same trend was shown with closed feet in Mean distance A/P (T0: 5.3 ± 2 vs T1: 4.8 ± 2.1 mm), Mean distance M/L (T0: 4.8 ± 3 vs T1: 2.6 ± 3.8 mm) and Area (T0: 755 ± 646 vs T1: 271.8 ± 476.1 mm²). Parameters of Gait analysis showed an enhancement in Stride time (T0: 1.5 ± 0 vs T1: 1 ± 0.2 s), Cadence (T0: 0.9 ± 1 vs T1: 1 ± 0.1 steps/sec), and Velocity (T0: 1 ± 0 vs T1: 1.1 ± 0.4 m/s), while Stride length (T0: 123.4 ± 31 vs T1: 113.8 ± 12.1 cm, $p=0.001$) decreased. Stepping in place test revealed significant improvements in A/P Displacement (T0: 1.5 ± 1 vs T1: 0.4 ± 1.5 cm, $p=0.0077$) as well as improvements in R/L Displacement (T0: -0.2 ± 1 vs T1: 0.1 ± 0.5 cm) and Area (T0: 10.7 ± 9 vs T1: 9 ± 10.2 cm²). Lastly, significant positive shifts in performance were observed in the TUG as indicated by the reduced task completion time (T0: 13.4 ± 8 vs T1: 8.6 ± 2.1 s, $p=0.0051$) and the increased score in the assessment of biomechanical strategies tool (T0: 43 ± 2 vs T1: 44 ± 2 score, $p=0.018$).

CONCLUSION: The data are highly encouraging, indicating that a slow waltz-based program can improve gait and balance in patients with PD. However, a longer experimental period should likely lead to even more marked improvements.

COMBINING EXERCISE AND BRAIN STIMULATION FOR MOTOR AND NON-MOTOR SYMPTOMS IN PARKINSON'S DISEASE.

VENTURELLI, M., MENDO, M., PATERNO, A., BARBI, C., DI VICO, I.A., WANG, E., TINAZZI, M., SCHENA, F.

UNIVERSITY OF VERONA

INTRODUCTION: Promising results have been reported for the use of intermittent theta-burst transcranial stimulation (iTBS) or exercise training on Parkinsons Disease (PD) symptoms. Moreover, maximal strength training (MST) is showing positive results on locomotor force. However, it is not clear the effectiveness of these 2 treatments on upper limb. With the aim to investigate the efficacy of MST and iTBS in the upper limb symptoms of PD, we have hypothesized that the combination of iTBS with MST can unlock central-mediated neuromuscular limitations and consequently magnify the positive results of the single treatments.

METHODS: 16 patients with PD were randomly assigned to 8-week treatment sessions (3xW) including: a) sham (s-iTBS), inducing any significant effect on the brain. b) iTBS, consisting of brain stimulation at 80% resting motor threshold; for 3 minutes. c) s-iTBS+MST, immediately after s-iTBS stimulation, patients performed MST with lat-machine executed at maximal force mobilization at 90% of 1RM. d) iTBS+MST, was the combination of the iTBS and MST protocols.

PRE-POST assessments following the interventions and **PRE assessment** for CTRL group of 6 healthy volunteers utilized the following tests:

UPDRS for assessing PD severity, maximal voluntary contraction (MVC) was determined via isometric ergometer. The resting twitch (RT) force was generated using muscle electrical stimuli. Voluntary activation (VA) was determined via the interpolated twitch technique. The cross-sectional area (CSA) of the elbow flexor muscles was measured by ultrasound.

RESULTS: At baseline, MVC normalized for the CSA was 10.5 ± 1.4 Nm/cm² in the PD group while the CTRL exhibited $20 \pm 4\%$ greater force ($p < 0.01$). After the training, the MVC for the s-iTBS+MST and iTBS+MST showed significant ($p < 0.05$) improvements, with greater results for the latter ($+11.2 \pm 1.4\%$ and $+15.8 \pm 1.7\%$, respectively). At baseline, PD patients exhibited significantly impaired VA ($79 \pm 3.4\%$), in comparison to the CTRL ($97 \pm 2.4\%$) $p < 0.01$. After the training period only the iTBS+MST showed significant improvements in VA ($91 \pm 2.5\%$ $p < 0.05$) in comparison to the s-iTBS ($78 \pm 2.8\%$), iTBS ($81 \pm 3.5\%$) and s-iTBS+MST ($85 \pm 3.8\%$). In PD the RT was significantly reduced before treatments ($-18 \pm 2.2\%$ $p < 0.05$) in comparison to the CTRL but was tempered after the training with iTBS+MST ($+13 \pm 4.3\%$). The UPDRS, were lessened for motor symptoms in the s-iTBS+MST ($-8.0 \pm 2.2\%$), and ($-12.0 \pm 2.3\%$) for iTBS+MST. Significant correlations were retrieved between pre- to post-intervention changes in the UPDRS and both MVC and VA ($r = 0.83$ and 0.78 , respectively).

CONCLUSION: The results of the current investigation indicate the efficacy of a program of MST and iTBS in the upper limb motor and non-motor symptoms of PD. Indeed, the combination of iTBS with MST generated a neuroplasticity that unlocked central-mediated neuromuscular limitations and boosted the positive effect of the MST intervention.

ORTHOREXIA ATHLETICA IN FORMAL AND INFORMAL SPORT: AN EXPLORATION OF DEVIANT BEHAVIOURS AND ATHLETE WELLBEING

VAREA, V., PENNEY, D., EVANS, V., OHARA, E.

EDITH COWAN UNIVERSITY

Orthorexia Athletica (OA) is a relatively new condition that is yet to be formally recognised by the American Psychiatry Association (APA). OA is characterised by the compulsive use and abuse of healthy food and obsessive exercise. This paper reports on research that is directed towards sport and exercise professionals and providers who seek to support individuals to establish and maintain active and healthy lifestyles. As a sociological study, it advances knowledge pertaining to OA by exploring incidence of different behaviours and societal influences in both formal and informal sport; that is, sport participation occurring both within and beyond established sporting structures and organisations.

Using the concept of healthism and Becker's (1963) sequential model of kinds of deviance and recognising its limitations, this paper explores new possible hybrid models of deviant behaviours related to OA and healthism in formal and informal sport. Photo elicitation interviews with vignettes were conducted with nine participants who were regular exercisers. We constructed three different hybrid scenarios from the interview data and the theoretical approach: 1. Anna: The pure secret deviant, 2. John: The enjoyable semi-deviant, and 3. Maria: The healthy critical semi-deviant. These scenarios demonstrate the complexity of OA, particularly in informal sport.

The participants are also shown to be highly reflective and critical in terms of (un)healthy behaviours. They were well informed about (Western) health and they were critical towards health information sources. The definitions of and bounda-

ries between deviant and non-deviant behaviours related to exercise and eating seem to be notably fluid. However, we are now also witnessing these extreme behaviours and extreme self-surveillance being normalised among recreational exercisers and in informal sport participation. This adoption and/or alignment in behaviours points towards arguably interesting social and cultural tensions, in that recreational and/or informal sport contexts are often portrayed as contrasting to the elite and/or formal contexts that the norms have previously been associated with. In this regard our data prompts further exploration of the social and cultural influences shaping behaviours in different sport participation contexts.

This paper demonstrates the need for more evidence-based foundations for targeted educational initiatives that focus on increasing awareness and understanding of eating and exercise disorders amongst key stakeholders, including participants who can be regarded as everyday exercisers. In evidencing the incidence of OA in participants engaging in both formal and informal sport, this research also calls for stakeholder engagement that goes beyond formal sporting structures and organisations.

BOOSTING SUSTAINABILITY IN FEMALE COACHING: WHAT ORGANISATIONS CAN DO

EISCHEN, S., BADHUR, K.

LUNEX

INTRODUCTION: Sports governing bodies, national and international policymakers have highlighted the need for greater access and opportunities for female coaches. Despite efforts, female coaches remain underrepresented and struggle with long-term career sustainability. The organisational mindset plays a key factor in retention. It directly shapes operational functioning. Therefore, a shift in mindset is necessary to drive meaningful structural change. This study explored female coaches' perspectives on organisational strategies for improving retention and career sustainability.

METHODS: Forty-four female coaches completed an online questionnaire covering demographics, experience, and organisational strategies to improve retention. Descriptive statistics were used to present the findings.

RESULTS: Results highlight key areas for improving support for female coaches. Top needs include individual support (75%), better hiring practices (65.91%), and equal pay (63.64%). Other priorities are access to coaching courses (59.09%), education for federation stakeholders (47.73%), and support for mothers (45.45%). Policies on sexism (36.36%) and harassment (31.82%), along with diversity education for players (29.55%), were also emphasised.

Discussion: Governance structures and policies impact coaching environment, opportunities, support and are important in addressing systemic barriers for female coaches. This study did not include a description of support, but previous research has highlighted that support must be tailored to each individual's needs and with acknowledgement of both overlapping and unique challenges. HR are key role players who can restructure hiring practices, ensure equal compensation and begin the process of educating and training all organisation employees in factors related to creating safe and welcoming spaces for female coaches. This should be accompanied by practical and relevant policies for safeguarding of female coaches. Opportunities and investment of upskilling of female coaches also require attention. Additional training costs can often hinder female coaches continued professional development. Support for coaches who are mothers reflects the broader societal challenge of balancing professional and caregiving responsibilities. Implementing family-friendly policies, such as flexible scheduling and childcare support, could make coaching a more viable and attractive career path. Diversity education for players offers a proactive way to shift cultural norms within teams, fostering respect and inclusion from the ground up. Federations can empower female coaches with the skills and confidence needed to thrive, while also educating decision-makers on the value of gender diversity in coaching roles. Implementing and acting on the identified strategies would ensure a comprehensive support system, increase career sustainability, valuing their expertise while simultaneously addressing structural barriers that hinder long-term retention.

RESEARCH ON SPORTS AND LEISURE ACTIVITY EXPERIENCES OF IMMIGRANTS AND REFUGEES IN MONTREAL, CANADA

OZGIDER, C., KOCH, J., SHAIKH, S.H.

CANAKKALE ONSEKIZ MART UNIVERSITY

Research on Sports and Leisure Activity Experiences of Immigrants and Refugees in Montreal, Canada

Ozgider, C. 1, Koch, J. 2, Shaikh, S. H. 3

1 Canakkale Onsekiz Mart University; 2 McGill University; 3 University of Montreal

INTRODUCTION: Turkey currently hosts over 3.7 million refugees, making it one of the countries with the highest number of refugees globally [1]. It was argued that migration is a social phenomenon that has significant effects on the social structures, economies, and cultures of nations, causing major changes in society [2]. Recent research indicates that participation in sports activities positively impacts the integration and peaceful coexistence of migrants and refugees in their newly resettled countries [3]. Canada has been accepting immigrants for many years and has implemented sports and recreation programs to aid in the integration of refugees and immigrants into society. Therefore, we aim to investigate individuals participating in leisure and sport activities could provide insight into their effectiveness in addressing the problems caused by Turkey's large migration flow.

METHODS: 16 refugees/immigrants living in Montreal from various countries including Afghanistan, Bangladesh, Belarus, Denmark, Ghana, Iran, India, Mexico, Nigeria, Syria, and United States of America took part in semi-structured interviews.

All participants were older than 18 years old and participating different sports and leisure activities in Montreal. Thematic analysis was used for data analysis.

RESULTS: The findings showed that there were three main themes: Lack of Time and Money to Attend Leisure and Sport Activities in Montreal, including the themes, paperwork for permanent residency, settling down, job search, cold weather. Feelings of Marginalization by Newcomers, including the themes, not feeling welcomed generally by locals, feeling more comfortable around racialized people, language barrier makes it difficult to communicate. Merging the French Courses with Leisure and Sports Activities.

CONCLUSION: The study reveals key challenges newcomers in Montreal face in leisure and sports, mainly due to time, financial constraints, and harsh winters. They feel unwelcome and alienated, often finding support within racialized communities due to language barriers. A solution could be combining language courses with leisure activities for better social interaction. Adapting this model in Turkey might involve incorporating cultural activities to create inclusive environments, easing newcomers social and economic burdens and aiding their integration.

EXPERIENCES OF INCLUSION AND ACCESSIBILITY OF RECREATION CENTRES AMONG THE LGBTQIA+ COMMUNITY

RIVERA, E., RENEHAN, S., VERSWIJVEREN, S.J.J.M., HESKETH, K.D.

CENTRAL QUEENSLAND UNIVERSITY

INTRODUCTION: The substantial health and wellbeing benefits of physical activity participation are well established, and global physical activity guidelines have been developed that align with attaining these benefits. However, individuals identifying as lesbian, gay, bisexual, transgender, queer, intersex, asexual, and other diverse (LGBTQIA+) are more likely to be insufficiently active and have poorer health compared to their counterparts. Recreation centres offer physical activity opportunities but are under-utilised by LGBTQIA+ persons, who may disproportionately face barriers to using these settings. Little is known about LGBTQIA+ individuals' recreation centre experiences and perceived strategies for improving the inclusion and accessibility of recreation settings to enhance access to physical activity opportunities. This study sought to explore recreation centre experiences of LGBTQIA+ individuals and strategies for enhancing inclusion and accessibility.

METHODS: Nineteen qualitative interviews were conducted with adults (68% aged <35 years) who identified as LGBTQIA+ and who were employees, regular visitors, or residents of a Melbourne municipality. An interview schedule with questions based on an adapted version of the 7 Pillars of Inclusion framework was used to conduct the interviews. Participants were asked about their views on using three recreation centres but were not required to have had previous experience at these centres and could be current or previous users of recreation centres elsewhere. Interviews were audio-recorded, transcribed verbatim, and analysed using content analysis.

RESULTS: The key themes spanned providing accessible and inclusive facilities, tailored programs, accessible communications (e.g., marketing materials personalised to LGBTQIA+ community), welcoming centre culture for all users, and partnerships with organisations affiliated with LGBTQIA+ community. Although most participants mainly had positive experiences with the recreation centres' programs and facilities, they identified accessibility barriers (e.g., inaccessible changing rooms, lack of privacy) and offered recommendations for improvement (e.g., offering classes tailored to LGBTQIA+ community, gender-neutral changing facilities, private cubicles) of recreation centres generally. Participants also recommended having events for the LGBTQIA+ community and their allies, staff training on inclusion, displaying rainbow signage, using inclusive language, and an ongoing commitment to LGBTQIA+ inclusion.

CONCLUSION: This research adds essential knowledge regarding LGBTQIA+ individuals' experiences of recreation centres and provides actionable recommendations for improving inclusion and accessibility in recreational settings. These results may be applicable to other recreation and physical activity contexts (e.g., sport, physical education) and may potentially improve physical activity and health outcomes among the LGBTQIA+ community.

NAVIGATING THE CHALLENGES OF EXTREME SPORTS FANDOM IN CHINA: AN ANALYSIS OF DISTORTED PRACTICES AND GOVERNANCE STRATEGIES

ZHANG, B.

TSINGHUA UNIVERSITY

INTRODUCTION: Sports fandom plays a critical role in the sports ecosystem, fostering community engagement, enhancing athlete visibility, and contributing to the commercialization of the industry. However, in recent years, a phenomenon known as sports fanquan (饭圈) has emerged in China, representing an extreme and irrational form of sports fandom that has developed alongside the growth of the internet. Characterized by online conflicts, privacy invasions, and irrational behavior, sports fanquan has led to negative incidents and increasing societal concern. This study explores the characteristics of sports fanquan, investigates its underlying causes, and proposes governance strategies.

METHODS: This study adopts a qualitative approach, combining in-depth interviews and participant observation. Interviews were conducted with 16 sports fanquan members from table tennis and diving, as these two sports are particularly

prone to the sports fanquan, each lasting between 20 and 50 minutes. Additionally, a six-month participant observation was carried out on 30 highly active sports fanquan social media accounts on platforms such as Sina Weibo and Red Note, where fan engagement is particularly intense.

RESULTS: Findings indicate that sports fanquan is rooted in excessive personal idolization, displaying exclusivity and irrational behavior. Unlike traditional sports fans, who focus on athletic performance, sports fanquan members prioritize athletes' private lives, interpersonal relationships, and emotional affairs, showing limited interest in sports competitions or participation in physical activities.

Several factors contribute to the emergence of sports fanquan. First, China's emphasis on elite sports has heightened athlete visibility, increasing public interest. Second, athletes' marketable images and physical appeal have attracted commercial investment, leading to their portrayal as entertainment celebrities. Third, sports journalism and social media have increasingly shifted towards entertainment-focused narratives. Lastly, widespread societal anxiety has led to athletes becoming emotional focal points for public identification and attachment.

Discussion: Addressing sports fanquan issue requires a dual governance approach: regulatory enforcement and cultural intervention. Strict administrative measures, legal frameworks, and platform monitoring are necessary to curb the excessive influence of sports fanquan. Meanwhile, mainstream media and athlete communication can help reshape fandom culture by promoting rational and constructive support. Establishing a collaborative governance network—led by sports authorities and supported by media, social platforms, and academic institutions—will be crucial in mitigating sports fanquan's negative impact. While regulatory measures offer immediate containment, sustainable solutions require a long-term cultural shift through media influence, education, and responsible athlete engagement.

OP-SH15 Physical Education II

THE EFFECT OF COGNITIVELY ENRICHED SHOTOKAN KARATE TASKS ON CHILDRENS WORKING MEMORY PERFORMANCE: A RANDOMIZED CROSSOVER CLINICAL TRIAL

SILVÉRIO, L., BORGES, L., COSTA, R., MORALES, J., LAMAS, L.

UNIVERSITY OF BRASÍLIA

INTRODUCTION: Shotokan Karate (SK) is a martial art originally conceived to promote holistic (i.e. motor, affective and cognitive) human development. Cognitively enriched SK tasks may enhance executive functions (EFs), improving goal-directed behaviors, and transferring them to life skills [1]. However, scientific support for EFs parameters manipulation is scarce [2]. This study compared the effects of distinct parameters manipulation to cognitively enrich SK tasks on performance of a particular EF domain –working memory (WM).

METHODS: Twenty-four neurotypical children (11 girls; mean age: 9.73 ± 1.27 years), with at least two years of practice of SK took part in three trials (AE – addition of elements; AS – alteration of sequences; CO – control condition). In each trial, they individually performed twelve bouts of the kata – i.e. a sequence of 21 blocks of SK techniques – manipulated according to AE and AS cognitive enrichment parameters focused on WM. The WM was ecologically assessed with the Behavior Rating Inventory of Executive Function (BRIEF). Acute effects of enriched tasks on WM were assessed with pre- and post-trials performance in the Corsi Block test. Real-time evaluation of WM demands of SK's enriched tasks was analyzed through notational analysis, assessing executive errors such as intra- and inter-block errors, omissions/additions, and buffer episodes. Data notation occurred on four time points - bouts one (time 1), six (time 2), seven (time 3) and twelve (time 4) - of the 12 katas' executions. A single observer (sports scientist, black belt SK coach) collected all data (reliability assessment - Cohen's Kappa: 1.0). Generalized Estimating Equations (Tukey adjusted post-hoc) were used to compare WM performance within and between trials ($\alpha = 0.05$).

RESULTS: BRIEF scores were within acceptable range: WM Scale (54.39 ± 9.07), Metacognition Index (55.43 ± 10.46), and Global Executive Composite (54.52 ± 8.98). Corsi Block accuracy did not change across conditions (negative time effect, $p < 0.05$). WM manipulation during kata in AE, AS, and CO trials presented significant interactions among conditions, times, and error types ($p < 0.05$): i) AS had a lower performance than AE in time 1 for intra-block errors and buffers; ii) In AE, intra-block errors increased from times 1 to 3; iii) In AE, buffers increased from times 1 and 3-4, 2 and 3-4.

Discussion: This study cognitively enriched SK's tasks with precise dose parameters. A main time effect in Corsi Block test indicated a general WM decline after trials. Enrichment strategies (AE and AS) differed in cognitive demands as indicated by error types and increment rates, particularly from time 1 to 3-4 since cognitive demands progressively increased [2]. Evidences should contribute to parameterization of cognitively enriched sportive tasks design by coaches and on-task performance evaluation approaches.

ORIGINAL PE CRITERIA-BASED TESTS BATTERY FOR THE ASSESSMENT OF K-8 STUDENTS' FUNDAMENTAL MOTOR SKILLS: VALIDATION PROCESS AND INTEGRATION INTO THE PEDAGOGICAL ASSESSMENT-TEACHING-LEARNING SEQUENCES

IANCU, H., PICARD, Y., RICHARD, J.F., BÉLANGER, M., RICHARD, J., SAVOIE, R., HEBERT, P.A., CORMIER, B.

ÉCOLE DE KINÉSIOLOGIE ET DE LOISIR - UNIVERSITÉ DE MONCTON

Introduction: A key role of quality school physical education (PE) is to enable children to learn and control motor skills. The assessment of fundamental motor skills (FMS) therefore becomes essential. Limitations of existing measurement tools include being designed exclusively for clinical and sport contexts, having age restrictions (3 - 10 years old) and not emphasizing, as much as it should, the pedagogical purposes of PE learnings. Accordingly, we developed an original battery of 25 representative tests for the evaluation of students fundamental psychomotor (13) and sociomotor (4) skills.

Objective: To assess the feasibility, validity and reliability of the battery's 25 FMS tests.

Methods: Following established standards of the psychomotor domain's tests development, we identified the skills to be assessed, developed assessment parameters by focusing on the performance's execution process (quality) rather than the product (quantity), and determined the tests procedures. Extensive testing took place in 9 schools (n = 4706 students, 5 to 14 years old). Each test was administered to targeted age groups students (in the last grade level of each learning cycle K-2, 3-5 and 6-8) to assess the test's feasibility, content validity and to refine evaluation parameters. This process was repeated following modifications of testing procedures aimed at improving psychometric properties. Inter-rater reliability and construct validity (more precisely, concomitant validity) were assessed with Kendall's W tests, Pearsons chi-squared and Kappa statistics, and Cramers V symmetric measurements.

Results: After the first test administration and the first feedback from PE teachers on test parameters, we modified instructions to improve clarity and adjusted the estimated time of administration for some tests of certain grade levels and the training of raters. Following the 2nd and 3rd school's visits and modifications of testing procedures, moderate to very good indices of inter-rater reliability (Kendall's W = 0.596-0.935) and construct validity (Pearsons Khi-square χ^2 = 124.732-186.631, likelihood ratio L2 = 120.592-178.090, linear by linear association χ^2 = 78.047-106.214, Cohens Kappa = 0.696-0.798 and Cramers V symmetric = 0.703-0.850) were found for final versions of the tests.

Conclusions: Our study shows that the development of this criteria-based test battery following a rigorous methodological process was complex and time intensive (over 7 years). Nevertheless, the statistical analyses led to an appropriate validity and intra-rater reliability. Also, a process of establishing standardized measuring procedures is already in place. This test battery could become a standard measuring tool for assessing the FMS related to the PE learning outcomes, either for diagnostic, formative or summative purposes, within different assessment-teaching-learning sequences (ATLS) for each learning cycle of the French school curricula in New Brunswick, Canada.

SYSTEMATIC AUDIT OF EXISTING PROFESSIONAL STANDARDS – SETTING THE SCENE FOR INTERNATIONAL SPORTS SCIENCE STANDARDS

REEVES, N., COMYNS, T.

GRIFFITH UNIVERSITY

Sports scientists are in high demand internationally and employment in the field continues to grow to satisfy the ever-increasing focus within the sporting world on optimising performance. In a number of countries, sports science practice is founded on a set of standards that outline base level knowledge, skills and competencies to define the roles and scope of practice for the profession. Standards additionally guide certification and accreditation frameworks. Despite the practice of sports science having many common features regardless of the country in which it is conveyed, and the workforce being highly internationalised, a harmonised set of international standards does not exist. **PURPOSE:** To systematically audit the professional standards that underpin a national certification system of the five countries identified through an environmental scan as having existing national certification systems for Sports Scientists. **METHODS:** The audit process was conducted using a modified scoping review protocol based on the documentation provided by British Association of Sport and Exercise Sciences (BASES), Canadian Society for Exercise Physiology (CSEP), Exercise & Sports Science Australia (ESSA), National Strength and Conditioning Association (NSCA), and Sports and Exercise Science New Zealand (SESNZ). Three reviewers independently extracted data from the standards documents and results were cross checked by relevant experts from each jurisdiction. **RESULTS:** There was commonality of themes for 43% for all content extracted. The overall coverage of themes was 22%, 27%, 38%, 54% and 76% from UK, US, Australia, NZ and Canada respectively. Two of the five sets of standards relied on a pre requisite foundational exercise science set of professional standards and this, in the US and Australia, accounted for an additional 3% and 38% of the elements respectively. **CONCLUSION:** There is a common core of themes covered by all current national standards for Sports Science across the five nations audited, but there is variable coverage in the remaining 57%. Whilst in some countries a portion of this can be attributed to a foundational set of exercise science professional standards, these findings are important for understanding the differences in current training and certification of Sports Science professionals, and how this might influence the internationalisation of the profession. It could be proposed that this audit of Sports Science standards sets the foundation for developing an international set of Sports Science professional standards that will promote harmonisation of the profession across jurisdictions.

DOES SPORTS COMPETENCE INFLUENCE ENJOYMENT IN PHYSICAL ACTIVITY IN PREADOLESCENCES?

SCARPA, S.1, NART, A.2, LUCCHETTI, C.3, BIANCALANA, V.3

1. UNIVERSITY GIUSTINO FORTUNATO OF BENEVENTO, 2. UNIVERSITY OF PADUA, 3. UNIVERSITY CARLO BO OF URBINO

In the sport and physical activity (PA) field, enjoyment is (Scanlan & Simons, 1992) and it can also be considered an important factor in promoting active lifestyles and regular PA among school-aged children (Carraro, Young, & Robazza, 2008). Although PA enjoyment depends primarily on intrinsic factors, sport competence may influence PA enjoyment (Carroll & Loumidis, 2003). We investigated here the effects of perceived sport competence on PA enjoyment, initially, expecting that perceived sport competence could be predictive of high levels of PA enjoyment. This study was carried out to increase the existing body of knowledge about the relationship between perceived sport competence and enjoyment.

Participants were 794 pupils (403 boys and 391 girls) aged between 12 and 14 years ($M = 13.2$; $SD = .86$) and recruited from a randomized number of schools located in a northeastern region of Italy. They completed an Italian version of the Physical Activity Enjoyment Scale (PACES; Carraro et al., 2008) and the Physical Self-description Questionnaire-Short (PSDQ-S; Marsh, 1996). The Italian version of the PSDQ-S (Scarpa, Gobbi, Paggiaro, & Carraro, 2010) contains five factors of physical self-concept which are used to assess perceived sport competence: endurance, flexibility, strength, coordination, and sport skill.

Questionnaires were completed in groups in the classroom. All respondents and their parents gave their informed consent and were assured that individual data would be kept confidential.

Pearson's correlation test was used to measure the association between variables. Multiple linear regression analysis was conducted to investigate the correlation between PSDQ-S scores (independent variables) and PACES total score (dependent variable). Pearson's correlation test revealed the following positive associations between PSDQ-S variables and PACES total score: endurance ($r = .828$, $p < .0001$); flexibility ($r = .507$, $p < .001$); strength ($r = .665$, $p < .0001$); coordination ($r = .427$, $p < .001$); sport skill ($r = .546$, $p < .001$). Multiple linear regression analysis showed the following score indices: $SE = 8.86$; $t = 22.81$; $R^2 = .455$; $F(1, 794) = 64.13$; $p < .001$. Our results highlighted positive associations between physical self-concept scales and PA enjoyment, and our hypothesis that perceived sport competence can be considered a good predictor of PA enjoyment was confirmed. The results could contribute to our understanding of the processes involved in the promotion of active lifestyles and regular PA among young people.

THE INFLUENCE OF PHYSICAL EXERCISE ON IDEOLOGICAL AND POLITICAL EDUCATION: A QUANTITATIVE STUDY ON THE EXAMPLE OF BADMINTON PROGRAM

SUI, X., NAZARUNDIN, M.N., MU, Y., JIANG, S., ZHANG, G., YU, M., MA, T., WU, R.

THE NATIONAL UNIVERSITY OF MALAYSIA

Chinese higher education faces the challenge of improving students comprehensive quality, and ideological and political education is an important part of cultivating correct values and moral standards. Meanwhile, the role of physical exercise in students lives has been increasingly emphasized, but its impact on ideological and political education has still not been fully explored. Badminton is a popular sport among Chinese college students, which not only enhances physical fitness but also positively influences students ideological and political literacy through teamwork and sportsmanship. Using a quantitative research design, 320 college students were randomly divided into two groups: an experimental group (160 students) and a control group (160 students). The experimental group participated in a 12-week structured badminton training program, while the control group did not participate in any organized sports activities other than their daily activities. Data were collected at four-time points: baseline (T1), immediately after the intervention (T2), and at 2-month (T3) and 4-month (T4) follow-ups using standardized questionnaires, behavioral observation checklists, and learning records. The experimental group received a 12-week badminton training program with two 90-minute sessions per week focusing on basic skills, team training, and competitive play, followed by discussions on sportsmanship and strategic thinking. To assess the impact of the badminton intervention on ideological and political education, a repeated measures analysis of variance (RM-ANOVA) was conducted with group (experimental vs. control) as the between-subjects factor and time (T1, T2, T3, T4) as the within-subjects factor. Repeated-measures analysis of variance (RM-ANOVA) indicated that significant between-group interactions existed for all three ideological outcomes, with associated F-values, p-values, and effect sizes reflecting both statistical significance and practical importance. Post hoc tests indicated that the experimental group showed significant improvements in all outcomes at T2, T3, and T4 compared to T1, while the control group showed no significant change. This study demonstrates the positive and sustainable impact of badminton training on the ideological and political education of university students, highlighting the importance of sport in an integrated educational approach. The findings provide valuable insights for educational policymakers and practitioners, emphasizing the role of physical activity in promoting the holistic development of students. Future research should further explore the mechanisms underlying the relationship between physical activity and ideological and political education, assess the long-term impact of different sports on students development, and explore the potential synergies between physical education and other educational interventions.

Plenary Session

PS-PL02 Mechanisms of Human Skeletal Muscle Hypertrophy: Sorting the Wheat from the Chaff

MECHANISMS UNDERPINNING HUMAN HYPERTROPHY: FROM APPLICATION TO OMICS

PHILLIPS, S.

MCMASTER UNIVERSITY

Human skeletal muscle hypertrophy is a complex and multi-faceted process primarily driven by mechanical overload facilitated through resistance exercise. This talk will investigate the current understanding of the mechanisms that underpin hypertrophy and strength gain with resistance training (RT). A key focus will be on the role of external factors – protein, resistance training variables, and certain supplements – used in combination with RT to shift the balance towards net protein accretion, leading to hypertrophy and the development of strength.

This talk will also address practical applications, discussing how specific training variables—such as load, frequency, and volume—modulate the hypertrophic response. These variables directly influence intracellular signalling cascades, demonstrating the interaction between applied training methods and the underlying molecular mechanisms. This knowledge is essential for designing optimal training programs for athletes and older adults looking to maintain muscle mass and strength.

This presentation is particularly relevant for the ECSS community, which focuses on improving athletic performance and physical health. Understanding the biological basis of hypertrophy allows for more effective training prescriptions, rehabilitation strategies, and nutritional interventions. It also opens the door for personalized approaches to muscle growth, making it highly applicable to both sports scientists and clinical practitioners.

By combining traditional knowledge with the latest in an understanding of hypertrophy mechanisms, this talk will offer a comprehensive overview of skeletal muscle hypertrophy and strength gains. Attendees will gain a deeper understanding of both the applied and underpinning mechanisms driving muscle growth, bridging the gap between practical training techniques and advanced scientific discovery.

DON'T FORGET, HYPERTROPHY IS NOT JUST FOR THE BEACH - THE STRUCTURAL AND CELLULAR DRIVERS AND FACILITATORS OF HYPERTROPHY

MACKEY, A.

UNIVERSITY OF COPENHAGEN, AND BISPEBJERG HOSPITAL

In addition to protein turnover measures and OMICS type data, the cellular and structural aspects of the entire muscle-tendon unit are key to understanding the full picture of mechanisms driving skeletal muscle hypertrophy. This talk will build on Professor Phillips' comprehensive coverage of the topic and delve into: 1. Changes in whole muscle architecture 2. Myofibre and myofibril addition 3. The role of muscle damage 4. The key cell types facilitating adaptation and their memories 5. Hypertrophy is not just for the beach Skeletal muscle hypertrophy is defined as increases in the cross-sectional area (CSA) of a single muscle or group of muscles. However, load-induced growth of muscle alters muscle architecture, including pennation angle and muscle length, which necessitate adaptation of the muscle extracellular matrix and its attachment to the tendon for safe and effective transmission of forces. Activity of many cell types is therefore required. Hyperplasia, the addition of myofibres, remains the stuff of legend as a key factor in reaching extreme muscle hypertrophy. This talk will examine the evidence for and against hyperplasia as well as the potential cellular mechanisms facilitating this feat in the adult. Zooming in on individual myofibres, changes in myofibril size and number during hypertrophy will also be considered. Myofibre damage will also be explored – from the point of view of mechanism or consequence of load-driven hypertrophy. As the increased protein synthesis translates into larger myofibres, extra myonuclei are required to sustain further growth. Elegant animal models have shown that satellite cells are the sole source of these new myonuclei, and it is becoming increasingly clear that other cell types in the muscle interact with satellite cells to regulate adaptation of the muscle as a whole. In this context, immune cells, fibroblasts, tenocytes and the motoneurone itself will be considered. Lastly, hypertrophy is not just for the beach. This talk will end by putting hypertrophy into the perspective of healthspan and lifespan. Building muscle mass is possible at any stage of life. However decades of inactivity may lead to accelerated loss of myofibres. Depending on whether new myofibres can be added in the adult state, myofibre loss may be a permanent event and therefore a severe limitation to the capacity to develop hypertrophy later in life and even in midlife. Furthermore, cells remember previous events, so building up "positive memories" by mechanical loading throughout life may provide a valuable resource for rebuilding muscle lost during periods of forced inactivity such as illness or injury. Attendees of this session will be presented with evidence for and against the fundamental mechanisms driving, facilitating and remembering hypertrophy, as well as the broader perspectives for muscle health.

OP-PN33 Physiology of Fatigue IV

TRYPTOPHAN METABOLITES AS POTENTIAL MARKERS OF FATIGUE IN PROFESSIONAL FOOTBALL PLAYERS

KSIAZEK, A., ZAGRODŃA, A., ANTOSIEWICZ, J.

WROCŁAW UNIVERSITY OF SPORT AND HEALTH SCIENCES, POLAND

INTRODUCTION: Chronic fatigue can lead to inflammation, resulting in disruptions in tryptophan metabolism [1]. The majority of tryptophan is metabolized via the kynurenine pathway [2]. Increased kynurenine levels, observed under stress conditions, may contribute to mood deterioration and impaired psychophysiological function [1,2], significantly affecting the athletic performance of players. This study explored the potential role of tryptophan metabolites as biomarkers of fatigue in professional athletes.

METHODS: Thirty male professional football players from the highest Polish league participated in the study. Blood samples were collected throughout the season: after transition (P1, P6), preparatory (P2, P7), and competitive periods of the Fall (P3–P5) and Spring Rounds (P8, P9). Tryptophan metabolites – kynurenine (KYN), 3-hydroxykynurenine (3HK), kynurenic acid (KA), xanthurenic acid (XANA), quinolinic acid (QA), picolinic acid (PA), anthranilic acid (AA), and 3-hydroxyanthranilic acid (3HAA) were quantified using liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS). Data normality was assessed with the Shapiro-Wilk test, variance homogeneity with Levene's test, and differences in tryptophan metabolite concentrations between different training periods were analyzed using Welch's t-test.

RESULTS: The study results indicated changes in the levels of pro-inflammatory tryptophan metabolites during the annual training cycle in football players. 3-HK levels were significantly higher during the competitive period compared to the transition period (8.4 ± 3.2 nmol/L – P5 vs. 6.8 ± 2.6 nmol/L – P1; $p = 0.04$). Similarly, QA reached its highest concentration during the competitive period and its lowest after the transition phase (157.6 ± 57.6 nmol/L – P5 vs. 119.3 ± 31.4 nmol/L – P1; $p = 0.006$).

Furthermore, changes in the levels of anti-inflammatory tryptophan metabolites were observed throughout the training macrocycle. XANA concentrations were lowest at the end of the competitive period of the Fall Round (13.2 ± 3.69 nmol/L – P5), while AA levels progressively decreased across training periods (94.0 ± 22.6 nmol/L – P1 vs. 29.3 ± 13.8 nmol/L – P9; $p < 0.001$).

CONCLUSION: In conclusion, the study indicates an increase in pro-inflammatory and a decrease in anti-inflammatory tryptophan metabolites during the competitive period in football players. Elevated 3-HK and QA levels may result from intense physical exertion, contributing to fatigue. Further research is needed to confirm these associations and clarify kynurenine pathway regulation under prolonged physical effort.

This study was funded by the National Science Centre, MINIATURA_7 grant no. 2023/07/X/NZ4/00199.

THE THRESHOLD OF LOW-INTENSITY ECCENTRIC CONTRACTIONS OF THE ELBOW FLEXORS TO INDUCE MUSCLE DAMAGE

CHEN, T.1, CHEN, H.L.2, NOSAKA, K.3

1 NATIONAL TAIWAN NORMAL UNIVERSITY, 2 NATIONAL CHIAYI UNIVERSITY, TAIWAN, 3 EDITH COWAN UNIVERSITY, AUSTRALIA

INTRODUCTION: An acute bout of 30 low-intensity (10% of maximal voluntary isometric contraction strength: MVC) eccentric contractions of the elbow flexors did not induce significant changes in indirect markers of muscle damage [1]. However, lowering a dumbbell of 9% of MVC 1800 times resulted in significant changes in MVC, range of motion (ROM), upper arm circumference, delayed onset muscle soreness (DOMS) and plasma creatine kinase (CK) activity [2]. These suggest that low-intensity eccentric contractions (LIECs) still induce muscle damage when the number of the contractions exceeds a certain level. However, the threshold number of contractions to induce muscle damage is unknown. The present study investigated how many LIECs would result in significant changes in muscle damage markers.

METHODS: A pilot study to compare 30, 60, 120, 240, 480 and 960 LIECs using a dumbbell set at 10% MVC at 90° elbow flexion showed that 960 LIECs resulted in significant changes in all muscle damage markers, but no such changes by 30-480 LIECs. Thus, 52 sedentary young men performed a bout of 600, 720, 840 or 960 LIECs ($n=13$ per group) using their non-dominant arm consisting of many sets of six eccentric contractions per set until the total number reached to 600, 720, 840 or 960. The participants lowered a dumbbell from an elbow flexed (90°) to a fully extended position (0°) in 3 s, and the investigator removed the dumbbell at the extended position and the arm was returned to the flexed position without load. The interval was 10 s between contractions, and 2-min between sets. Changes in maximal voluntary concentric contrac-

tion torque (MVCcon), ROM, DOMS, plasma CK activity, and echo-intensity (EI) were assessed before, immediately after, 1, 2, 3, 4 and 5 days post-exercise. Changes in these variables over time were compared among the groups by a mixed-design of two-way ANOVA.

RESULTS: All variables changed significantly ($P < 0.05$) after 960 LIECs (MVCcon: -14%, ROM: -3% at 1-day post-exercise, peak DOMS: 21 mm in a 100-mm visual analogue scale, peak CK: 786 IU/L, peak EI increase: 10%), but they returned to the baseline by 3-4 days post-exercise. The 600, 720 and 840 LIECs showed a significant decreases in MVCcon and ROM at immediately post-exercise (-10 - -2%), without significant changes in DOMS, CK and EI.

CONCLUSION: These results indicate that the threshold was 960 repetitions, but the magnitude of muscle damage was minor. Considering the fact that 30 maximal-intensity eccentric contractions of the elbow flexors induce large changes in the muscle damage markers (e.g., MVCcon: -49%, ROM: -11%, peak DOMS: 66 mm, peak CK: 6192 IU/L, peak EI increase: 39%) lasting for more than 10 days (3), the muscle damage etiology seems different between low-intensity and high-intensity eccentric contractions.

EXPLORING THE EFFICACY OF SODIUM BICARBONATE SUPPLEMENTATION ON REDUCING MARKERS OF ACUTE KIDNEY INJURY (AKI) DURING PHYSICAL WORK IN THE HEAT

SIEGLER, J., BUTTERICK, B., FREIRE, R., SPECHT, J., AMORIM, F.

ARIZONA STATE UNIVERSITY

INTRODUCTION: Many workers worldwide are exposed to prolonged and hazardous heat stress, physical activity, or a combination of both. Occupations such as mining, farm work, construction, and wildland firefighting involve various physical tasks that impose different degrees of metabolic, ergonomic, and cognitive stress, which can be worsened by adverse environmental conditions. The stress imposed by either the climate or the physical demands of these vocations can be dangerous, potentially limiting human productivity and performance and exacerbating pre-existing conditions like high blood pressure, obesity, and. One organ particularly at risk is the kidney. Numerous studies have documented that prolonged exposure to heat and physical activity can lead to acute kidney injury (AKI). Repeated episodes of AKI induced by such exposure have been linked to chronic kidney disease, particularly chronic kidney disease of unknown origin (CKDu).

Research on effective strategies to reduce the incidence of AKI has explored various approaches, including heat acclimation, hydration and pre-cooling, and adjustments to physical work rates and durations (e.g., increasing rest periods or breaks). A novel and relatively low-cost strategy that has not been widely studied is using sodium bicarbonate (SB) to maintain hydration, and potentially improve exercise tolerance. While SB has traditionally been used in athletic settings to enhance performance, it has also been shown to increase plasma volume and reduce markers of oxidative and inflammatory stress. Given these effects, SB's potential impact on kidney function under prolonged heat stress and physical activity merits further investigation. As such, this pilot study investigated whether SB supplementation could mitigate AKI during moderate-intensity outdoor work in a hot environment.

METHODS: Fourteen healthy adults were randomized into SB or placebo (PLA) groups using a double-blind crossover design. Participants completed two experimental trials, during which they rotated through a circuit of five workstations over two hours. During the circuit, participants were encouraged to maintain a moderate intensity effort (e.g., 11 - 13 RPE (Borg 6 - 20)), and the stations consisted of digging, wheelbarrow pushing, cinderblock carry, and shoveling activities. All work was completed outdoors in the Sonoran Desert during June, with an average wet bulb globe temperature of 34.8°C.

RESULTS: SB supplementation significantly increased blood bicarbonate (mean difference: 4.5 ± 0.7 mmol/L, $p < 0.001$) and base excess (mean difference: 4.5 ± 0.6 meq/L, $p < 0.001$). Core temperature increased slightly with SB compared to PLA (mean difference: $0.2 \pm 0.1^\circ\text{C}$, $p < 0.05$), as did heart rate (mean difference: 9 ± 3 bpm, $p < 0.01$). However, as measured by urine-specific gravity, hydration status and fluid intake did not differ significantly between conditions ($p = 0.72$). No significant differences were found between SB and PLA for kidney stress markers, including IGFBP-RP1 (condition $p = 0.51$; time $p = 0.74$; interaction $p = 0.87$), TIMP-2 (condition $p = 0.13$; time $p = 0.11$; interaction $p = 0.81$), and NGAL (condition $p = 0.64$; time $p = 0.88$; interaction $p = 0.54$).

CONCLUSION: These preliminary findings suggest that while SB improved buffering capacity, there was no influence on markers of kidney injury across the two-hour work session in the heat. This study integrated mitigation strategies (e.g., ensuring hydration, following NIOSH work-to-rest guidelines for working in the heat, etc.) that may be present in a standard work environment which could have contributed to the lack of changes in markers of kidney injury. As multiple factors contribute to the development of AKI, future research should explore the relationship between duration and intensity.

ROLE OF H⁺ AND PI IN DEPRESSING CROSS-BRIDGE FUNCTION OF HUMAN SKELETAL MUSCLE AT 15°C AND 30°C: INDIVIDUAL OR SYNERGISTIC EFFECTS?

ROYER, N., SUNDBERG, C.

MARQUETTE UNIVERSITY

INTRODUCTION: Studies on chemically permeabilized muscle fibers have observed that the effects of elevating both hydrogen (H⁺) and inorganic phosphate (Pi) on force and power are greater than what would be predicted from the sum of

the individual metabolite effects – suggesting that these metabolites contribute to fatigue by acting synergistically to depress cross-bridge function. However, this theory comes from studies on rabbit and rodent muscles where the individual and combined metabolite effects were studied on different fibers from multiple investigators, rather than studying the individual and combined conditions on the same fiber. Moreover, it is unclear whether elevated Pi, or just H⁺, alters the shortening velocity of the cross-bridge. The aim of this study was to investigate the individual (pH 6.2 vs. 30 mM Pi) and combined (pH 6.2 + 30 mM Pi) effects of elevated H⁺ and Pi on single muscle fiber force, velocity, and power in adult human skeletal muscle fibers at 15°C and 30°C. The second aim of this study was to investigate the effects of elevated Pi (0, 4, 15, 30 mM) on shortening velocity at 15°C.

METHODS: The contractile mechanics (force, velocity, and power) of muscle fibers (n = 126) isolated from the vastus lateralis of 7 young adults (20-23 yrs, 3 women) were compared under six different conditions of elevated Pi and/or H⁺ at 15°C. At near physiological temperatures (30°C), 4 different conditions were evaluated on contractile function with elevated Pi and/or H⁺ (n = 46).

RESULTS: In both temperatures conditions, the depression in maximal isometric force (Po), peak power, and unloaded shortening velocity (Vo) was greatest in the combined pH 6.2 + 30 Pi compared to all the individual metabolite conditions in both slow and fast fibers, except for the Po of slow fibers at 15°C where the combined pH 6.2 + 30 Pi did not differ from the 30 mM Pi condition (p=0.99). There was no evidence that the depressive effects from the combined pH 6.2 + 30 Pi was greater than what would be predicted from the sum of the individual metabolite effects, suggesting that the metabolites do not act synergistically to depress cross-bridge function in human skeletal muscle, at cold or near physiological temperatures. Increasing Pi progressively depressed the Vo of both slow and fast fibers, where the depression in Vo at 30 mM Pi either did not differ or exceeded the depression from elevating H⁺ alone (pH 6.2).

CONCLUSION: These data suggest that H⁺ and Pi both individually and collectively are important mediators of skeletal muscle fatigue in humans by directly impairing cross-bridge function, but the combined effects of the metabolites are not synergistic at 15°C or 30°C. We also provide novel evidence that elevated Pi depresses shortening velocity in human skeletal muscle to a similar, or greater, extent than elevated H⁺.

INNOVATIVE DOSE-RESPONSE CURVE TO ASSESS THE METABOREFLEX IN HUMANS WITH CONTROL OF INTRAMUSCULAR METABOLIC PERTURBATION

KOUZKOUZ, N., MALLARD, J., HUCTION, E., SCHOTT, R., PIVOT, X., DUCROCQ, G.P., HUREAU, T.J.

INSTITUTE OF CANCEROLOGY STRASBOURG EUROPE

INTRODUCTION: The metaboreflex plays a critical role in the cardiovascular adjustments occurring during exercise. While the post-exercise circulatory occlusion technique (PECO) is well-established, studies using this non-invasive methodology do not control for the level of peripheral fatigue and usually investigate only one level of activation of the metaboreflex. The lack of control of peripheral fatigue, which reflects the level of intramuscular metabolic perturbation (1), is a key limitation in studies comparing groups, as exercising at a similar relative intensity does not guarantee identical levels of peripheral fatigue between individuals (and therefore similar levels of metaboreflex activation) (2). Therefore, we designed an innovative test to assess the metaboreflex that provides a dose-response curve while controlling for intramuscular metabolic perturbation.

METHODS: Thirty healthy subjects (15 females) visited the laboratory 3 times to complete a familiarization and 2 experimental visits, which aimed to validate the dose-response metaboreflex test and assess its reproducibility. During each experimental visit, participants executed 4 fatigue tasks (FT) interspersed with 2-min of PECO. Each FT involved a sustained isometric contraction of the quadriceps at 20% of the maximal voluntary contraction (MVC) during 1 min (block 1), 2 min (blocks 2 and 3) and up to task failure (block 4). Peripheral fatigue was assessed throughout the test via the pre-to-post exercise changes in quadriceps twitch force (Q_{tw}). Mean arterial pressure (MAP) was continuously recorded. The dose-response curve was determined by plotting post-PECO peripheral fatigue against the % change in MAP during PECO.

RESULTS: ΔQ_{tw} was similar between post-FT and post-PECO (P>0.99), indicating that PECO has successfully maintained exercise-induced intramuscular metabolic perturbation between each FT. Peripheral fatigue and MAP increased progressively across the four blocks (P<0.001), confirming that our test induced four distinct levels of intramuscular metabolic perturbation and graded activation of the metaboreflex. These graded levels were linearly associated, as evidenced by a significant correlation between ΔQ_{tw} and ΔMAP (r²=0.976; P=0.01). ΔMAP, ΔQ_{tw} values and their associated correlation were not statistically different between visit 1 and visit 2 (P=0.543 and P=0.449; r²=0.944; P=0.02, respectively; Fisher's r-to-Z test: Z = 1.58) and were associated with good to excellent reliability (ICC=0.89 for ΔQ_{tw} and ICC=0.78 for ΔMAP).

CONCLUSION: Our test provides a new method to evaluate metaboreflex activation in humans. Through the four graded levels of peripheral fatigue and MAP, we demonstrated a dose-response relationship between intramuscular metabolic perturbation and metaboreflex activation. These findings provide evidence that evaluation of the metaboreflex needs to be reconsidered, in particular when between group comparisons are made.

OP-PN34 Carbohydrates

EFFECTS OF CARBOHYDRATE INGESTION IN ELITE MARATHON RUNNERS: AN EVALUATION OF 60, 90 AND 120 G.H-1 AND IMPACTS ON SUBSTRATE METABOLISM AND GASTROINTESTINAL SYMPTOMS.

RAVIKANTI, S., SILANG, K., MARTYN, H., LOUIS, J., OWENS, D., BAMPOURAS, T., JONES, A., MORTON, J., PUGH, N.

LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: Carbohydrate (CHO) ingestion during endurance exercise improves performance (1). Peak exogenous CHO oxidation of 1.8 g·min⁻¹ has been shown when 2.0 g·min⁻¹ is ingested during cycling exercise (2). While such intakes were well tolerated in cyclists, the feasibility of 120 g·h⁻¹ during running exercise and at higher exercise intensities is unclear, with both being associated with higher gastrointestinal (GI) symptom prevalence (3). This study investigated the effect of varying CHO doses on exercise metabolism and GI symptoms in elite runners exercising in the heavy intensity domain.

METHODS: In a double-blind, randomised crossover design, 8 male marathon runners (PB 02:22:54 ± 00:05:37) completed three trials after a 24h high CHO (8 g·kg⁻¹) diet and pre-exercise meal (2 g·kg⁻¹). Trials consisted of a 120-min run, with 90 min at 94% of lactate turnpoint, flanked by 15 mins at 95% of lactate threshold. Every 15 minutes, subjects consumed U-13C enriched drinks at rates of 60 (1:0, maltodextrin: fructose), 90 (2:1), or 120 (1:1) g·h⁻¹. CHO and fat oxidation, blood glucose and lactate, running economy, and GI symptoms were measured. A one-way and two-way repeated-measures ANOVA analysis was used for peak exogenous CHO oxidation and time and trial differences, respectively, followed by Bonferroni post hoc analysis. Significance was set at P<0.05.

RESULTS: There was a significant main effect of condition (F2, 14 = 25.71, p<0.001), with mean whole body CHO oxidation higher in 120 g·h⁻¹ (3.06±0.19 g·min⁻¹) than 90 g·h⁻¹ (2.46±0.12g·min⁻¹; p=0.001) and 60 g·h⁻¹ (2.08±0.03 g·min⁻¹; p=0.004). A significant effect of time for whole body CHO (F7, 49 = 40.31, p<0.001) and exogenous CHO oxidation (F7,49 = 150.42, p<0.001) was found. A condition x time interaction for whole body (F14,98 = 2.32, p<0.008) and exogenous CHO (F14,98 = 9.60, p<0.001) oxidation showed that oxidation increased over time more with higher intakes. Peak exogenous oxidation rates were highest (p<0.001) at 120 g·h⁻¹ (1.78±0.2 g·min⁻¹) compared to 90 g·h⁻¹ (1.48±0.2 g·min⁻¹) and 60 g·h⁻¹ (1.02±0.1 g·min⁻¹). The incidence of moderate or severe (≥4) GI symptoms was high across all conditions, though not significantly different. All runners reported experiencing one or more moderate or severe symptoms.

CONCLUSION: Consuming 120 g·h⁻¹ increases whole-body CHO and exogenous oxidation compared to 60 and 90 g·h⁻¹, with no effect on the incidence of GI symptoms. The high prevalence of GI symptoms in all trials requires further investigation and may be due to the higher exercise intensity. Future research should investigate the impact on performance.

INCREASED CARBOHYDRATE AVAILABILITY ATTENUATES METABOLIC AND ENDOCRINE RESPONSES TO LOW ENERGY AVAILABILITY

KOEHLER, K., NUSSE, V., TEUBNER, J., BUERGER, S.A., FRODL, A., WASSERFURTH, P.

TECHNICAL UNIVERSITY OF MUNICH

INTRODUCTION: Low energy availability (LEA) is the underlying cause of the Female Athlete Triad and Relative Energy Deficiency in Sports (REDs) and has potentially detrimental effects on health and performance. LEA is typically associated with reduced availability of carbohydrates, a critical substrate for cellular metabolism, energy storage and energy supply of the brain. While current consensus statements on REDs highlight the importance of adequate carbohydrate availability (CA) as a mitigating factor, to our knowledge, no experimental study has directly assessed the effects of varying CA under conditions of LEA.

METHODS: In a randomized, cross-over study, participants (n=11, 36% male, 24±2years) underwent two 4-day intervention phases with a 2-week washout period between conditions. In both conditions, energy availability was reduced to 20 kcal/kg fat-free mass (FFM)/day by clamping energy intake at 45 kcal/kg FFM/day and exercise energy expenditure at 25 kcal/kg FFM/d, which was achieved by cycling at 60% of maximal oxygen uptake. CA, which was defined as the difference between carbohydrate intake and carbohydrate oxidation during exercise, was maintained either at 1.5g/kg/day (LEA-LC) or 4.0g/kg/day (LEA-HC). Assessments included changes in body weight and body composition, substrate utilization and selected metabolic hormones (leptin, insulin, IGF-1).

RESULTS: Both conditions resulted in similar weight loss (-0.6±0.6kg vs. -0.7±0.7kg; p=0.60). Maximal fat oxidation increased to a greater degree in LEA-LC than in LEA-HC (+39±31% vs. +7.3±17.9%; p<0.05). Changes in leptin (-40±21% vs. -26±29%) and IGF-1 (-24±8% vs. -10±13%) were significantly greater in LEA-LC when compared to LEA-HC (both p<0.05). In contrast, changes in insulin were similar between conditions (-15±36% vs. -18±26%; p=0.56).

CONCLUSION: Our findings demonstrate the differential effects of high and low CA under conditions of LEA on substrate utilization and endocrine pathways. Low CA amplifies metabolic shifts towards fat oxidation, paralleling metabolic changes seen with carbohydrate restriction at normal energy availability. On the other hand, increased CA preserves nutrient-sensing pathways such as insulin- and leptin-mediated production of IGF-1, thereby mitigating endocrine disruption associated with LEA.

THE EFFECTS OF HIGH CARBOHYDRATE DOSAGES FROM FRUCTOSE-GLUCOSE MIXTURES ON PERFORMANCE DURING PROLONGED SOCCER-SPECIFIC EXERCISE

FIELD, A., FISCHER, A., CORR, L., BIRDSEY, L.P., HEARRIS, M., MORGAN, P., HODSON, N., MARTINHO, D., FLEMING, J., MOHR, M., KRUSTRUP, P., RUSSELL, M., SALE, C., HARPER, L.D.

MANCHESTER METROPOLITAN UNIVERSITY

INTRODUCTION: Higher carbohydrate (CHO) availability is a key factor in enhancing endurance performance during prolonged exercise. The combination of fructose and glucose has been shown to improve CHO absorption and oxidation, offering an effective means of increasing overall CHO availability. However, the optimal dosage of this combination, particularly in the context of team sports like soccer, remains unclear. Studies on endurance cyclists have demonstrated that a 90 g·h⁻¹ fructose-glucose mixture can enhance performance, but its impact on prolonged intermittent exercise, such as the extra time phase in soccer, has not been well established. Extra time, a 30-min period added when matches are tied, is a common feature in major tournaments like the FIFA World Cup. This study aimed to investigate the effects of a higher CHO dose, provided in gel form through a fructose-glucose mixture (1:2 ratio), on performance during a 120-min simulated soccer match, compared to a lower dose of glucose only.

METHODS: Fifteen semi-professional soccer players (7 males, 8 females) participated in two 120-min soccer-specific exercise sessions, completed in a randomised, single-blinded crossover design. Participants consumed either 60 g·h⁻¹ glucose or a combination of 0.5 g·min⁻¹ fructose and 1.0 g·min⁻¹ glucose (90 g·h⁻¹) at pre-exercise, halftime, full-time, and midway through extra time. Assessments at 0, 45, 90, and 120 min included gastrointestinal (GI) discomfort, mental fatigue, passing accuracy, neuromuscular performance (reactive strength index, countermovement jump height, peak power output), and sprint performance (15 m and 30 m sprints). Blood glucose and lactate concentrations were measured every 15 min.

RESULTS: Countermovement jump height, peak power output, and sprint performance declined over time in both conditions ($p < 0.05$). Fructose-glucose co-ingestion increased blood glucose by 0.41 mmol·L from 105 min compared to glucose-only ingestion ($p = 0.006$, $d = 1.2$), but did not preserve performance ($p > 0.05$). GI symptoms were more pronounced with fructose-glucose, including greater fullness at 90 min (+9.9%, $p = 0.013$, $d = 0.9$) and increased abdominal cramps at 45 min (+9.3%, $p < 0.001$, $d = 1.7$) and 90 min (+9.0%, $p < 0.001$, $d = 1.6$). Glucose-only ingestion led to higher gastric reflux at 45 min (+7.8%, $p = 0.011$, $d = 0.9$) and flatulence at 120 min (+3.3%, $p = 0.003$, $d = 1.1$). No other variables were significantly affected ($p < 0.05$).

CONCLUSION: Fructose-glucose co-ingestion increased blood glucose availability during the latter stages of exercise but did not prevent declines in neuromuscular or sprint performance compared to glucose-only ingestion. Additionally, the higher CHO dose caused greater GI discomfort, which may limit its practicality for soccer players during extended match play. Future research should refine CHO intake strategies for intermittent sports, balancing performance benefits with GI tolerance.

DOSE-RESPONSE OF PRE-EXERCISE DIETARY CARBOHYDRATE AVAILABILITY FOR SKELETAL MUSCLE GLYCOGEN SYNTHESIS IN ENDURANCE TRAINED CYCLISTS

JONES, R., ARETA, J.L., PUGH, J.N., LOUIS, J.B.

LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: Carbohydrate (CHO) loading is a well-established strategy that enhances the limited endogenous muscle glycogen stores within the human body, resulting in improved exercise capacity and endurance performance (Bergström et al., 1967; Burke et al., 2017). Therefore, optimisation of pre-exercise CHO intake and resultant muscle glycogen synthesis is crucial for endurance athletes. As such, the current study investigated the dose-response relationship of dietary CHO intake and whole muscle glycogen synthesis.

METHODS: In a counterbalanced repeated measures design, 11 endurance trained participants (8 males, 3 females; 24±5 yrs, 71.2±12.0 kg, VO₂max 55.8±6.2 mL/kg/min) undertook 3 × 5-day periods of dietary control and prescribed exercise designed to mimic the pre-competition practices of competitive endurance cyclists. Days 1 and 2 standardised nutritional status and glycogen content with a moderate CHO intake (4 g/kg/d) followed by glycogen depleting cycling exercise and an acute re-feed of CHO (1.2 g/kg and 2 g/kg 2 h later). Participants consumed either 6, 8 or 10 g/kg/d of CHO for the next 48 h, completed light cycling sessions (one per day at 164±49 W) and subjective gut discomfort scales at regular intervals, before returning to the laboratory (day 5) for a total body water measurement using bioelectrical impedance, high CHO breakfast (2g/kg) and muscle biopsy of the vastus lateralis 2 h post-prandial.

RESULTS: Muscle glycogen content was significantly higher ($P < 0.03$) following 10 compared to 6 and 8 g/kg/d CHO intake (635.5±78.0, 460.9±100.7 and 506.1±124.0 mmol/kg dry mass, respectively), however there was no significant difference between 6 and 8 g/kg/d ($P = 1.00$). Stomach fullness was higher in 10 versus 6 and 8 g/kg/d ($P < 0.01$), however median scores were low in severity (<4). All other gut comfort symptoms were unaffected by CHO availability ($P > 0.05$). There were no changes in body mass (71.8±11.9, 71.5±11.3 and 71.6±11.3 kg, $P = 0.52$), total body ($P = 1.00$), extra- ($P = 0.25$) or intra-cellular water ($P = 0.58$) between conditions.

CONCLUSION: The current study suggest 10 g/kg/d of CHO is necessary to optimise muscle glycogen storage in real world training conditions. All levels of CHO intake were well tolerated, with minimal impact on gut comfort and body water.

FLUID RESTRICTION DECREASES EXOGENOUS GLUCOSE OXIDATION DURING PROLONGED CYCLING COMPARED TO MAINTAINING EUHYDRATION

MACRAE, H., REYNOLDS, K.M., SELLORS, C., WICKHAM, P., WALLIS, G.A., GOOSEY-TOLFREY, V.L., MEARS, S.M., FUNNELL, M.P., JAMES, L.J.

LOUGHBOROUGH UNIVERSITY, UNITED KINGDOM

INTRODUCTION: Dehydration during exercise is common amongst endurance athletes. Exercise in the heat with concomitant dehydration reduces exogenous glucose oxidation [1,2], but the independent effects of hydration are unclear. This study investigated the effect of low (dehydration) or high (euhydration) fluid intake during exercise on exogenous glucose oxidation during prolonged cycling in thermoneutral conditions.

METHODS: Nine trained male cyclists/triathletes (22 ± 4 y; 59 ± 6 mL/kg/min; 15 ± 7 h/week endurance training) completed a $\dot{V}O_{2\text{peak}}$ test and two experimental trials where they cycled for 160 min at 50% W_{peak} in a laboratory ($\sim 23^{\circ}\text{C}$) with minimal fluid intake (LOW) or fluid intake to replace sweat losses (HIGH) in a randomised order. A glucose drink enriched with 0.2% [U- ^{13}C]-glucose was provided in both trials (equal boluses every 20 min to provide 60 g/h). In HIGH, additional water was provided to maintain body mass ($<0.5\%$ mass loss). Subjective measures, skin and gastrointestinal (GI) temperature, and expired breath samples were collected every 20 min, whilst venous blood samples were collected pre- and 30 min post-exercise. Data are mean $\pm$ standard deviation, $P \leq 0.05$ indicated statistical significance.

RESULTS: Peak (HIGH: 0.79 ± 0.12 g/min; LOW: 0.70 ± 0.14 g/min; $P=0.041$) and mean 40-160 min (HIGH: 0.61 ± 0.09 g/min; LOW: 0.51 ± 0.11 g/min; $P=0.021$) exogenous glucose oxidation rates were reduced in LOW. The largest between-trial difference was observed at 60 min (HIGH: 0.49 ± 0.11 g/min; LOW: 0.33 ± 0.13 g/min; $P=0.015$). LOW, but not HIGH, produced significant body mass loss post-exercise (LOW: $-2.8 \pm 0.4\%$; HIGH: $-0.2 \pm 0.4\%$; $P<0.001$). There were trial*time interaction effects for plasma volume change, plasma osmolality, thirst and plasma glucose ($P \leq 0.048$), with LOW producing decreased plasma volume (HIGH: $+0.6 \pm 3.7\%$; LOW: $-3.5 \pm 3.9\%$; $P=0.034$), and increased plasma osmolality (HIGH: 290 ± 3 mOsmol/kg; LOW: 302 ± 5 mOsmol/kg; $P<0.001$), thirst (HIGH: 1 ± 1 ; LOW: 7 ± 2 ; $P<0.001$), and plasma glucose (HIGH: 5.9 ± 1.3 mmol/L; LOW: 7.0 ± 1.3 mmol/L; $P=0.021$) post-exercise. Thermal sensation, skin/GI temperature, GI discomfort, intestinal fatty acid binding protein (a marker of GI damage), plasma lactate and insulin concentration were not different between trials ($P \geq 0.05$).

CONCLUSION: Exogenous glucose oxidation was reduced with low fluid intake that produced significant dehydration post-exercise, with differences observed as early as 60 min (dehydration $\sim 1\%$ BML). This suggests that low fluid volume, rather than dehydration per se, might underpin these observations. Participants did not report increased GI discomfort with higher fluid intake, meaning matching fluid intake to sweat loss may benefit athletes looking to maximise the utilisation of glucose provided within a drink, at least where urination is possible.

TAPERING PRACTICES OF ELITE SWIMMERS LEADING INTO THE 2024 PARIS OLYMPIC AND PARALYMPIC GAMES: A DESCRIPTIVE STUDY

FARRELL, S., MCGIBBON, K., SAYERS, M., BUHMANN, R.

UNIVERSITY OF THE SUNSHINE COAST

INTRODUCTION: Tapering is an important aspect of swimmers competition preparation. It involves a planned reduction in training load before an event, aiming to optimise performance by maintaining intensity while decreasing overall workload (1). Despite well-established tapering recommendations, it remains unclear whether coaches adhere to these guidelines. Understanding whether the taper designed by elite coaches is consistent with current evidence is essential to determine if athletes are in peak condition for competition.

METHODS: This study examined the current tapering strategies of elite Australian swimmers ($n = 9$ males, $n = 7$ females) in the lead-up to the 2024 Australian Olympic and Paralympic Trials, as well as the 2024 Paris Paralympic Games and aimed to describe changes in training volume, intensity, frequency and duration during a taper. This study also described differences between non-disabled and para-athletes as well as sprint and middle distance athletes. Total training volume and distance in Zones 1-3 were collected during training using Commit Swimming and the AMS (Athlete Management System).

RESULTS: In the lead-up to the Australian Swimming Trials, the Paralympic group reduced total training volume by 42.2% (sprint) and 45.6% (middle distance), while the Olympic group tapered volume by 43.3% (sprint) and 30.8% (middle-distance). Paralympic swimmers reduced training in Zone 1 by 34.8% (sprint) and 42.0% (middle-distance), in Zone 2 by 68.2% (sprint) and 72.0% for (middle-distance), and in Zone 3 by 54.9% (sprint) and 47.0% (middle-distance). Olympic swimmers decreased Zone 1 volume by 41.1% (sprint) and 29.7% (middle-distance); Zone 2 volume by 67.7% (sprint) and

55.3% (middle-distance); and Zone 3 volume by 50.6% (sprint) and 53.2% (middle distance). Leading into the Paralympic Games, training volume was reduced by 54% (sprint) and 61.8% (middle-distance). Para sprint swimmers decreased Zone 1, 2, and 3 training by 44.6%, 73.2 % and 83.5%, while middle-distance athletes reduced Zone 2 and 3 training volume by 88.9% and 89.0%. Across all groups, high-intensity training (Zones 2 and 3) experienced the largest reductions, often exceeding 70% in the lead-up to both Trials and the 2024 Paralympic Games.

CONCLUSION: Several groups exhibited tapering strategies inconsistent with the current guidelines. Reduction in total training volume was often lower than recommended, and reductions in high intensity training were mainly responsible for reduced overall training volume. These observations suggest performance may be optimised in these swimmers through more effective tapering strategies, particularly in sprint swimmers. These findings provide valuable insights into real-world tapering practices and their potential effects on elite swimming performance, informing future programming strategies for future Olympic and Paralympic athletes.

THE IMPACT OF A 12-WEEKS SLEEP EDUCATION PROGRAM ON SLEEP AND RECOVERY IN COMPETITIVE SWIMMERS

BRANDTS, M., SKORSKI, S., MEYER, T.

SAARLAND UNIVERSITY

INTRODUCTION: Swimmers have been shown to experience larger sleep deficits than athletes in most other sports [1]. Chronic sleep deficiencies may impair recovery and, in turn, performance, particularly given the role of sleep loss in the development of functional overreaching [2]. While a sleep education program has led to a temporary increase in sleep duration in athletes without sleep deficiency [3], its impact on chronically sleep-deprived athletes has not been investigated yet. Therefore, the aim of the current study was to assess the effect of a 12-week sleep education program on sleep and perceived recovery in swimmers.

METHODS: Nine national level swimmers (1F, 8M; age: 17 ± 1 y) completed two phases of 12 weeks each: a baseline phase followed by an intervention phase during which sleep education was administered. The sleep education program consisted of three ~ 1-hour sleep seminars held in weeks 0, 4 and 8 and two sleep podcasts in week 2 and 6 during the intervention phase. Sleep duration, sleep regularity and perceived sleep quality were measured using a combination of actigraphy (Actigraph wGT3X-BT, Actigraph LLC, Pensacola, FL, USA) and a sleep diary. Perceived recovery was assessed daily using the Short Recovery and Stress Scale for Sport.

RESULTS: A significant interaction between phase and weekday was observed for sleep duration ($F_{6,1042} = 2.84$; $P < 0.01$; $\eta^2p = 0.02$). Sleep duration was significantly longer on Friday nights during the intervention phase compared to baseline phase (baseline: 8.2 ± 0.3 h vs. intervention: 9.2 ± 0.3 h; mean difference (md): 1.0 ± 0.4 h; $P < 0.01$). On the other hand, sleep regularity significantly decreased during the intervention phase (baseline: $81 \pm 1\%$ vs. intervention: $78 \pm 1\%$; md: $-3 \pm 1\%$; $P = 0.02$; $\eta^2p < 0.01$). There were no significant effects of phase on sleep quality ($F_{1,992} = 0.79$; $P = 0.37$; $\eta^2p < 0.01$), perceived recovery ($F_{1,1025} = 2.94$; $P = 0.09$; $\eta^2p < 0.01$) or perceived stress ($F_{1,1035} = 0.54$; $P = 0.46$; $\eta^2p < 0.01$).

CONCLUSION: Administering a 12-week sleep education program was associated with increased sleep duration on Friday nights but decreased sleep regularity. This may reflect athletes adjusting their sleep schedules within the constraints of school and training, extending sleep when possible but increasing sleep variability. Coaches might consider sleep education to extend sleep duration in competitive swimmers, but scheduling constraints should be taken into account.

EFFECTIVENESS OF SLEEP-ENHANCING STRATEGIES DURING TAPER: IMPACT ON PERFORMANCE IN ELITE SWIMMERS WITH ACUTE AND HIGH FATIGUE LEVELS

BRETONNEAU, Q., MORALES-ARTACHO, A., PLA, R., BOSQUET, L.

UNIVERSITE DE POITIERS

INTRODUCTION: In swimming, tapering is implemented before major competitions to enhance performance. However, its effectiveness varies depending on the athletes pre-taper fatigue level. While tapering increases performance in swimmers with acute fatigue ($+1.8 \pm 1.4\%$ [1]), it is less effective or ineffective for those with high accumulated fatigue ($-0.5 \pm 1.6\%$, $p < 0.05$ [1]). Given the critical role of sleep in recovery, we aimed to evaluate the combined effects of tapering and sleep-enhancing strategies on performance in elite swimmers with acute and high fatigue levels.

METHODS: Physiological, psychological, and biomechanical profiles were assessed in 27 elite swimmers at T0 and T1, scheduled respectively 10 and 3 weeks before their major competition. Sleep profile was evaluated at T0, T1, and throughout the subsequent two taper weeks. External training load was monitored daily. Race times were officially recorded at T1 and during the major competition. Between T0 and T1, athletes participated in a sleep education program [2]. During

tapering, they slept on a high-thermal-conductivity mattress topper and underwent daily cryostimulation (3 min) or contrast baths (28 min) during the first week.

RESULTS: Based on changes in physiological, psychological, and biomechanical profiles from T0 to T1, 13 swimmers (17 ± 2 years old; best performance: $88 \pm 3\%$ of the world record) exhibited acute fatigue (AF), and 14 swimmers (17 ± 2 years old; best performance: $89 \pm 3\%$ of the world record) demonstrated functional overreaching (F-OR). External training load did not differ between groups. Taper-induced changes in performance were $+1.2 \pm 1.6\%$ in the AF group and $+0.4 \pm 2.3\%$ in the F-OR group ($p > 0.05$). Notably, 82% of athletes in the AF group and 67% in the F-OR group showed a performance improvement exceeding 0.5% ($p > 0.05$). These changes in performance were positively correlated with changes in total sleep time from T0 to T1 and, specifically in the F-OR group, with the average sleep duration during tapering.

CONCLUSION: In overreached swimmers, the combination of tapering and sleep-enhancing strategies resulted in a 0.4% performance improvement, whereas tapering alone was associated with a 0.5% decline [1], thereby mitigating the previously observed disparity in tapering benefits between AF and F-OR swimmers. Furthermore, in the current study, 67% of F-OR swimmers achieved a performance gain exceeding 0.5% (the smallest meaningful enhancement impacting final rankings), compared to 50% with tapering alone [1]. Finally, taper-induced changes in performance observed in this study were linked to changes in sleep duration before tapering. Interestingly, it was also linked to average sleep duration during tapering in F-OR swimmers. These findings highlight the importance of assessing and optimizing sleep before and during tapering, especially in overreached swimmers, to achieve peak performance.

1. Bretonneau et al. (2024) 10.3389/fspor.2024.1353817 2. Pasquier et al. (2023) 10.1123/ijsp.2023-0018

HEART RATE VARIABILITY AND BLOOD LACTATE LEVELS AFTER INTENSIVE INTERVAL SPRINT LOADING ON ELITE SWIMMERS: THE RECOVERY EFFECT OF FOAM ROLLING

ARABACI, R., ACIKGOZ, E., RODOPLU, C., ARABACI, M.

BURSA ULUDAG UNIVERSITY, FACULTY OF SPORT SCIENCES

INTRODUCTION: Considering the intensity of swimmers' training, their bodies need to recover physically and mentally between two loads. Therefore, proper management of post-exercise recovery processes plays a key role in maintaining performance. There are many methods and techniques that accelerate the recovery process. Stretching, massage, hot and cold applications, passive rest are some of them. Foam rolling (FR) have become popular in the recently years. FR creates a series of effects on athletes' physiological, morphological and neuromuscular functions by increasing blood flow in the area where it is applied. However, it is still unknown whether FR is superior to other recovery methods. The main aim of present study was to examine the acute effects of FR on heart rate variability (HRV) and blood lactate (BL) in elite swimmers after intensive interval sprint swimming load.

METHODS: A total of fifteen female and male elite swimmers between the ages of 15-26 participated in the study voluntarily (mean age 17.5 ± 3.1 years, height 178.2 ± 7.6 cm, weight 69.3 ± 7.9 kg). The volunteers participated in three sessions, one week apart with a "randomized-crossover" method from experimental research designs. The first session was defined as the familiarization session. In the second and third sessions; warm-up, pre-test, swimming (50m), test-1, swimming (3 x 50 m), test-2, recovery and post-test were performed. In one of these sessions (FRS), active rest (750 m low tempo swimming; 10 min) and foam rolling (10 min) were applied during recovery. In the other session (ARS), only active rest was performed (1500 m low tempo swimming, 20 min). HRV time-domain (RR, RMSSD and SDNN) and frequency-domain (VLF, LF and HF) parameters were determined using a Polar H7 V800. BL were taken from the fingertips with Lactate Pro2 device. The obtained data were analyzed using Two Way ANOVA repeated measures variance analysis test (2 experiment x 4 time) in SPSS 29.0 for Windows statistics program. Bonferroni test was used for pairwise comparisons.

RESULTS: A statistically significant difference was found in favor of all HRV parameters and BL recovery in the changes depending on time in FRS and ARS protocols. There were no significant differences between FRS and ARS protocols for RR ($F = 1.526$; $\eta_p^2 = .122$), SDNN ($F = 1.197$; $\eta_p^2 = .325$), RMSSD ($F = .361$; $\eta_p^2 = .029$), VLF ($F = .152$; $\eta_p^2 = .012$), Blood Lactate ($F = 1.302$; $\eta_p^2 = .098$) and RPE ($F = .704$; $\eta_p^2 = .055$). Statistically significant differences were found between FRS and ARS protocols in terms of changes in LF ($F = 17.6$; $\eta_p^2 = .595$) and HF ($F = 2.43$; $\eta_p^2 = .169$).

CONCLUSION: In conclusion, from our findings FR applied to elite swimmers after intensive interval swimming load during active recovery is effective on some time-domain parameters and frequency-parameters of HRV and BL. These suggest that FR can be useful tool for enhancing recovery and autonomic modulations of cardiovascular and nervous systems.

INTER-EFFORT HYPOXIA RECOVERY EXACERBATES INTERNAL LOAD DURING ACUTE SPRINT INTERVAL TRAINING SESSIONS WITHOUT COMPROMISING PERFORMANCE IN SWIMMERS

PAPOTI, M., ESEQUIEL, G.H.S., RIBEIRO, F.A., MIRANDA, D.R.M., CARVALHO, C.D., FORESTI, Y.F., GOBATO, C.A., MACHADO-GOBATO, F.B., FIGUEIRA, T.R.

UNIVERSITY OF SÃO PAULO, UNIVERSITY OF CAMPINAS-UNICAMP

INTRODUCTION: Considering that exercise intensity can be reduced when performed under continuous hypoxia, we recently argued that adding hypoxia exclusively during the recovery periods between efforts in interval training sessions [i.e., inter-effort hypoxia recovery (IEH)] could be a more effective approach than performing the entire training session under hypoxia to avoid decreases in external training load [1]. This study aimed to compare the acute effects of IEH during two sprint interval training (SIT) sessions on swimming performance and psychophysiological markers of internal training load.

METHODS: Eight trained/developmental swimmers (22.0 ± 1.8 yrs; 178 ± 10 cm; 74.0 ± 10.2 kg) performed two SIT sessions in front crawl, each consisting of twenty 25-m efforts separated by ~ 1.5 min of recovery (SIT20x25m). Additionally, sixteen highly trained/national-level swimmers (20.9 ± 3.0 yrs; 177 ± 6 cm; 69.0 ± 10.5 kg) performed two SIT sessions, each consisting of ten 50-m efforts separated by ~ 3 min of recovery (SIT10x50m). For the SIT10x50m protocol, specific in-water resistance training equipment was used to enhance swimmers engagement. In a randomized order, one session was performed in normoxia (NOR; $\text{FiO}_2 = 20.9\%$), while the other included the addition of normobaric hypoxia (IEH; $\text{FiO}_2 = 13.3\%$) during the recovery periods. Swimming velocity (Sv), heart rate (HR), peripheral oxygen saturation (SpO_2), blood lactate concentration ([La]), and ratings of perceived exertion (RPE) were compared using Students t-test for paired samples. The level of statistical significance was set at $p < 0.05$.

RESULTS: Swimming velocity was not significantly different between conditions (SIT20x25m: $\text{NOR} = 1.63 \pm 0.19$; $\text{IEH} = 1.66 \pm 0.19$ m·s⁻¹ and SIT10x50m: $\text{NOR} = 1.71 \pm 0.23$; $\text{IEH} = 1.72 \pm 0.22$ m·s⁻¹, $p > 0.05$). During recovery, HR values were higher in IEH condition (SIT20x25m: $\text{NOR} = 127.1 \pm 27$; $\text{IEH} = 141.1 \pm 19$ bpm and SIT10x50m: $\text{NOR} = 127.0 \pm 17$; $\text{IEH} = 134 \pm 13$ bpm). SpO_2 was lower in IEH (SIT20x25m: $\text{NOR} = 95.0 \pm 2.2\%$; $\text{IEH} = 77.2 \pm 6.2\%$, $p < 0.05$ and SIT10x50m: $\text{NOR} = 96.0 \pm 1.14\%$, $\text{IEH} = 89.0 \pm 5.2\%$, $p < 0.05$). Blood lactate concentration values were not significantly different between conditions (SIT20x25m: $\text{NOR} = 10.1 \pm 5.0$; $\text{IEH} = 11.3 \pm 3.6$ mM) and SIT10x50m: $\text{NOR} = 14.9 \pm 4.5$; $\text{IEH} = 17.9 \pm 4.9$ mM). Similarly, RPE was not significantly different between NOR and IEH (SIT20x25m: $\text{NOR} = 6.4 \pm 1.4$; $\text{IEH} = 6.5 \pm 1.4$ and SIT10x50m: $\text{NOR} = 8.7 \pm 0.1$; $\text{IEH} = 8.5 \pm 0.1$).

CONCLUSION: Our findings indicate that IEH during SIT sessions in swimming induces hypoxemia and additional exercise stress; however, it preserves exercise performance of swimmers.

Invited Symposium

WHEN MUSCLES TALK BACK TO THE BRAIN: THE REGULATION OF NEUROMUSCULAR FATIGUE AND PERFORMANCE DURING EXERCISE

HUREAU, T.

UNIVERSITY OF STRASBOURG

Neuromuscular fatigue compromises exercise performance and is determined by central and peripheral mechanisms. Central fatigue is defined as a decrease in neural activation of muscle that can occur at cortical and/or spinal level, while peripheral fatigue is associated to biochemical changes at or distal to the neuromuscular junction that cause an attenuated contractile response to neural output. Interactions between the two components of fatigue can occur via neural pathways, including feedback and feedforward processes. This talk discusses the influence of feedback and feedforward mechanisms on exercise limitation. In terms of feedback mechanisms, particular attention is given to group III/IV sensory neurons which link limb muscle with the central nervous system. Central corollary discharge, a copy of the neural drive from the brain to the working muscles, provides a signal from the motor system to sensory systems and is considered a feedforward mechanism that might influence fatigue and consequently exercise performance. We highlight findings from studies supporting the existence of a 'critical threshold of peripheral fatigue', a previously proposed hypothesis based on the idea that a negative feedback loop operates to protect the exercising limb muscle from severe threats to homeostasis during whole-body exercise. While the threshold theory remains to be disproven within a given task, it is not generalisable across different exercise modalities. The 'sensory tolerance limit', a more theoretical concept, may address this issue and explain exercise tolerance in more global terms and across exercise modalities. The 'sensory tolerance limit' can be viewed as a negative feedback loop which accounts for the sum of all feedback (locomotor muscles, respiratory muscles, organs, and muscles not directly involved in exercise) and feedforward signals processed within the central nervous system with the purpose of regulating the intensity of exercise to ensure that voluntary activity remains tolerable. Using an integrative physiology approach, this talk will provide a structured synthesis of recent insights into the limit of exercise in humans and should be of interest for a large audience, from scientists interested in exercise performance in athletes to those concerned by exercise tolerance in patients.

NON-INVASIVE BRAIN STIMULATION: IMPLICATIONS FOR EXERCISE SCIENCE RESEARCH AND APPLICATIONS FOR PHYSICAL AND MENTAL HEALTH

ANGIUS, L.

NORTHUMBRIA UNIVERSITY

The brain-muscle interaction has always been an area of interest among researchers due to its importance for exercise regulation and for the development of exercise induced fatigue in healthy and clinical population. Despite its importance, some aspects of the feedforward mechanism from the motor system to recruit the muscle (i.e. neural drive) are still poorly understood. Experimental evidence provided by brain imaging techniques are mostly correlative and crucial for identifying the neural processes for motor task. Over the last three decades, the current understanding of brain function for motor execution has been significantly increased by research involving non-invasive brain stimulation (NIBS) techniques. NIBS

are laboratory techniques capable of altering brain function in a safe, reversible and temporary manner by delivering magnetic field or electrical current to targeted neural networks. As such, the manipulation of neural networks allows researchers to establish cause-effect relationships between brain function and motor performance. This unique property of NIBS application has opened new possibilities for understanding the role of different neural networks relevant for exercise regulation and for the development of fatigue. The application of transcranial magnetic stimulation (TMS) provided important knowledge about the neural mechanisms within the motor pathway responsible for the development of central and supraspinal fatigue. More recently, another NIBS technique called transcranial direct current stimulation (tDCS) has been used in exercise science. tDCS can alter spontaneous firing rate of targeted neurons beyond the stimulation time as its effect can last over 1 hour for acute administration (i.e. single administration) or months when administered repeatedly (i.e. over several days). Collectively, the tDCS administration demonstrated significant enhancement of maximal voluntary strength, sport-specific motor performance and endurance performance alongside a significant reduction in perceived exertion. The current knowledge provided by NIBS led to groundbreaking findings on the neural basis of brain function during exercise with the possibility to develop novel non-pharmacological interventions in healthy and clinical populations for improving exercise tolerance. In this talk, I will present the most updated findings and applications for NIBS in healthy populations and their relevance to understand the role of neural component on feedforward mechanism for exercise regulation and fatigue related mechanisms. Furthermore, I will provide experimental evidence on novel network-based approaches to optimise the synergy between NIBS and physical exercise for improving physical and mental health. By covering a research topic related to the role of the brain during exercise and NIBS, this talk aims to attract the interest of audience including physiologists, clinicians and neuroscientists.

NEUROPLASTICITY MEETS FATIGUE AND PAIN: EXPLORING NEUROMODULATION IN CLINICAL POPULATIONS

SIDHU, S.

THE UNIVERSITY OF ADELAIDE

Physical fatigue and pain are common and complex symptoms experienced by many clinical populations including Multiple Sclerosis (MS), cardiovascular disease, cancer and older adults. Its development can be influenced by physiological and psychological factors. Neuromodulation is an emerging therapeutic approach for managing psychophysiological fatigue. It involves the use of techniques such as repetitive transcranial magnetic stimulation (TMS) and transcranial direct current stimulation (tDCS) that alter nerve activity and neurotransmitter function to improve physical function and ameliorate fatigue and pain. Studies concerning the viability of neuromodulation applied to the brain have yielded positive, yet, often variable results in both responsiveness of the brain and motor behaviour (e.g. exercise performance and pain ratings). High intra and inter-individual variability in response to neuromodulatory techniques is thought to be related to both intrinsic (e.g. age and sex) and extrinsic (e.g. experimental parameters) factors. For example, more robust and less variable neurophysiological outcomes have been produced in studies involving the application of priming neuromodulation prior to subsequent application of neuromodulation, with a short interval in between; a concept known as metaplasticity. In the treatment of clinical fatigue and pain, application of tDCS for example has been shown to be potentially efficacious, but, understanding of the exact mechanisms is incomplete, and the evidence on the influence of priming and subsequent neuromodulation application on fatigue remains scarce. In this talk, I will discuss some of the underlying factors that contribute to the variable neurophysiological and sensorimotor responses seen with different neuromodulatory approaches. I will also provide some limited experimental evidence of metaplastic responses to neuromodulation and fatiguing exercise in people with MS and older adults. As the field of neuromodulation continues to evolve, it is imperative to address the variable outcomes through future research focused on enhancing efficacy and applicability of neuromodulation therapies. I will provide a critical appraisal of these key areas including individualised treatment approaches, longitudinal studies, standardised protocols for comparison across studies and clinical populations, neurological and non-neurological mechanistic insights, study of diverse clinical populations, and combination with other therapies (pharmacological and lifestyle modifications).

OP-AP20 Training and Testing VII - Middle age and older adults

THE IMPACT OF HOME-BASED HIGH-INTENSITY INTERVAL TRAINING ON PHYSICAL FUNCTION IN HEALTHY OLDER ADULTS

SEILER, H., FOSSTVEIT, S.H., FERON, J., JOYCE, K.E., SEGART, K., LUCAS, S.J.E., BERNTSEN, S.

UNIVERSITY OF AGDER

INTRODUCTION: Resistance training is widely recommended to enhance physical function (PF) in older adults (1). High-velocity resistance training receives particular attention due to the strong link between muscular power and functional movement (2). High-intensity interval training (HIIT) has also shown promise for improving power-related adaptations in older populations (3). As a time-efficient and generally well-tolerated training modality, HIIT offers a viable exercise option for older adults (4). However, its efficacy in enhancing PF among this population remains unclear. Furthermore, the effectiveness of HIIT under free-living conditions as part of broader public health strategies has not been adequately investi-

gated (5). Therefore, the present study aimed to assess the impact of a 6-month home-based HIIT program on PF in healthy older adults.

METHODS: Healthy older adults ($n=233$, aged 60–84, 54% female) from Norway and the UK were randomly assigned to either a HIIT group (mean age $\pm$ SD: 67.6 $\pm$ 5.9yr) or a non-exercising control group (mean age $\pm$ SD: 67.0 $\pm$ 5.2yr). The exercising group participated in a 6-month, thrice weekly HIIT intervention (2 interval and 1 circuit sessions per week).

PF measures at pre- and post-intervention included Grip strength, 30-sec-chair-stand, Chair-sit-and-reach, Back scratch, Timed-up-and-go, and One-leg standing. Additionally, PF was calculated as a composite Z-score (PF Z-score) based on all aforementioned tests.

General Linear Models were used to assess between-group differences in post-intervention scores for each standardized test and the PF Z-score, with pre-intervention scores, age, sex, and country of residence as covariates, and group as a fixed factor. Effect sizes (ES) were calculated using mean differences (pre-post), pooled standard deviations, and sample sizes for the exercise and control groups. Alpha level of 5% was chosen for statistical significance, with 95% CI presented.

RESULTS: Significant between-group differences at post-intervention were observed for PF Z-score ($\beta=0.24$, [0.17;0.30] (ES:0.97), Grip-strength ($\beta=1.8$ [0.8;2.8] kg (ES:0.48), 30-sec-chair-stand ($\beta=1.3$ [0.7; 1.8] repetitions (ES: 0.63), Back scratch ($\beta=2.1$ [0.8;3.5] cm (ES:0.43), and Timed-up-and-go ($\beta=-0.3$ [-0.4;-0.2] seconds (ES:0.71).

No significant between-group differences post-intervention were observed for Chair-sit-and-reach and One-leg standing tests.

CONCLUSION: These findings indicate that healthy older adults can enhance their PF through a 6-month home-based HIIT intervention. However, no significant effects were observed in joint flexibility of the lower extremities or static balance ability. Nonetheless, these findings reinforce the potential of HIIT as a valuable component in public health strategies for promoting physical function in healthy older adults.

EFFECTS OF VIVIFRIL D-LEVEL EXERCISE PROGRAM ON FUNCTIONAL FITNESS AND VASCULAR HEALTH IN HEALTHY OLDER ADULTS

FU, S., CHEN, I., TSAI, H., SU, C., NIEN, Y.

UNIVERSITY OF TAIPEI

INTRODUCTION: The Vivifrail D-Level exercise program is a multicomponent training approach designed to maintain functional capacity and prevent frailty in older adults. However, previous evidence suggests that standard Vivifrail protocols may be insufficiently challenging for healthier older adults (D-level), thus potentially limiting training adaptations [1,2]. This study investigated the effects of an Vivifrail D-level exercise regimen on functional fitness, peripheral arterial stiffness, and body composition in healthy older adults.

METHODS: Forty-one participants aged ≥ 65 years (including 55–64 years for Indigenous people) classified as D-level via the Short Physical Performance Battery (SPPB) were divided into an Advanced Health Group (AHG, $n = 22$) and a General Health Group (GHG, $n = 19$), based on sit-to-stand performance. Both groups underwent an enhanced 12-week Vivifrail D-level exercise program (1 supervised session/week plus 4 self-administered sessions/week). Outcome measures included brachial-ankle pulse wave velocity (baPWV), ankle-brachial index (ABI), handgrip strength, biceps curl (30 s), 30 s sit-to-stand, 4 m walk, 2 min step test, and DXA-assessed body composition at baseline and post-intervention.

RESULTS: Following the 12-week intervention, the GHG showed significant improvements in biceps curl ($p = .002$), 30 s sit-to-stand ($p < .001$), 4 m walk speed ($p = .012$), and 2 min step test ($p = .040$), as well as left-side ABI ($p = .015$). In contrast, the AHG exhibited only a modest improvement in biceps curl ($p = .031$), with no significant changes in other variables.

CONCLUSION: This study's findings indicate that an advanced Vivifrail D-level exercise program effectively enhances functional fitness and peripheral vascular health in older adults with lower baseline performance. The General Health Group showed significant gains in muscular endurance, walking capacity, and improved ankle-brachial index, aligning with previous multicomponent exercise research [1] (Courel-Ibáñez et al., 2022). In contrast, the Advanced Health Group's limited adaptation suggests a "ceiling effect," pointing to the need for higher-intensity or more personalized protocols [3]. Recent studies further underscore the value of progressive, individualized training for older adults of varying fitness levels [4,]. Future interventions should incorporate greater overload and modality variety, particularly for those with higher initial capacity, to maximize neuromuscular and cardiovascular benefits in older populations.

THE EFFECT OF FAMILIARIZATION ON SQUAT POWER AND VELOCITY IN OLDER ADULTS USING A FLYWHEEL DEVICE

STERMECKI PUKL, M., SMAJLA, D., SPUDIC, D.

UNIVERSITY OD PRIMORSKA

INTRODUCTION: Flywheel (FW) devices are becoming an increasingly popular tool for improving muscle power, strength and functional abilities, particularly in older adults. Despite the proven benefits of eccentric training on these devices, it remains unclear how quickly individuals adapt to the specific demands of the exercise. Notably, our study is the first to investigate the familiarization process of performing squats on FW device in older adults. We hypothesized that the group completing the 5-weeks familiarization protocol would demonstrate significantly greater squat velocity and force during the eccentric phase compared to the group that did not undergo the familiarization protocol.

METHODS: Thirty-nine participants were randomly assigned to two groups. Group S1 performed a squat assessment on a flywheel (FW) machine during weeks 1 and 2, followed by a 2-week familiarization protocol focused on performing the squat movement with controlled concentric and eccentric phases, with an emphasis on tempo. Group S2 performed assessments only during weeks 1 and 2. Both groups underwent a follow-up assessment during week 5 to assess changes in squat performance. Measurements included 2 initial squat repetitions followed by 6 maximal intensity work repetitions and 2 final squat repetitions designed for safe stopping.

RESULTS: The results showed increased F, v P mechanical outputs over visits 1, 2, and 3. The F, v, P variables increased significantly more for the F group between visits 2 and 3. Moreover, CV decreased from visits 1-2 to 2-3 where F groups showed significantly decreased within-set, between-sets and between-visits variability in comparison to control groups (CV: 15% vs. 10%).

CONCLUSION: Individuals familiar with the FW device are likely to achieve superior performance outcomes compared to those without prior familiarization. The familiarization process enhances technical execution, increases eccentric overload, and improves movement velocity, ultimately optimizing training adaptations. These findings underscore the importance of structured familiarization when implementing FW-based resistance training in older adults to maximize safety, efficiency, and effectiveness. Future research should investigate the long-term impact of familiarization on neuromuscular adaptations and functional performance, as well as its potential applications in rehabilitation and fall prevention strategies for aging populations.

IDENTIFYING HEMODYNAMIC DIFFERENCES DURING VASCULAR OCCLUSION TEST BY TIME-DOMAIN NEAR INFRARED SPECTROSCOPY IN OLD TRAINED AND UNTRAINED POPULATION

NABACINO, M., RE, R., AMENDOLA, C., CONTINI, L., CONTINI, D., SPINELLI, L., PILOTTO, A., ALCAZAR, J., LAURETANI, F., FRANCHI, M.V., BOTTER, A., PORCELLI, S., TORRICELLI, A.

POLITECNICO DI MILANO

INTRODUCTION: In this work, we assess the capability of time domain (TD) near infrared spectroscopy (NIRS), to detect differences between sedentary and trained old subjects by means of vascular occlusion test (VOT). The acquisitions were performed in the framework of the Trajector-AGE project.

METHODS: 15 healthy old trained (OT; 71.0 ± 4.3 y) and 15 old sedentary (OS; 78.0 ± 4.3 y) subjects took part to this study. VOT consisted in 2 min of rest, maximum 5 min of prolonged ischemia and 3 min of recovery. TD-NIRS sensor was placed on the distal vastus lateralis (VL) of the right leg during the whole acquisition. Absolute values for the time courses of oxy-(O₂Hb), deoxy-(HHb), total- hemoglobin and tissue oxygen saturation (StO₂) were obtained by using the solution of the photon diffusion equation for homogeneous media, since the average adipose tissue (ATT) thickness was 3.2 ± 1.0 mm and 3.1 ± 1.7 , respectively. A diffuse correlation spectroscopy (DCS) sensor providing the blood flow index (BFI) was used to verify the validity of the VOT (BFI-0). Specific parameters were calculated from all the hemodynamic parameters time courses: 1) average baseline in the last 10 s before the VOT (BAS); 2) desaturation slope during the first 60 s of the VOT by means of a linear fit (DS60); 3) re-saturation slope after the VOT in the first 10 s, as calculated by a linear fit (RS10); 4) same as point 3 but in the first 30 s (RS30). Since the two populations were not normally distributed, as revealed by a Two-sample Kolmogorov-Smirnov test, statistically significance differences were tested with Mann-Whitney method (threshold $p < 0.05$).

RESULTS: For the O₂HB concentration during baseline for OS was 63.0 ± 12.7 μ M, while for OT was 86.7 ± 17.9 μ M, showing a significance difference ($p = 9.6 \cdot 10^{-4}$). Same situation for basal StO₂ which was 60.8 ± 7.0 % for OS and 67.3 ± 3.9 % for OT ($p = 7.0 \cdot 10^{-3}$).

For the DS60 the only significant difference was found for StO₂, which was -0.109 ± 0.077 for OS and -0.080 ± 0.058 for OT ($p = 5.6 \cdot 10^{-2}$). The desaturation slope is negative, so a higher value means a slower response. No significant differences were found for RS10 and RS30 parameters.

CONCLUSION: The main differences ($p < 0.05$) between trained and untrained OLD population were observed for the baseline values of O₂Hb and StO₂ and for the desaturation slope for StO₂, higher for trained OLD. We do not expect that these differences are due to the effect of the ATT on NIRS data. The ATT for OS and OT are equal, and TD NIRS do not suffer of contamination from the surface signal for these ATT values. Differences in SO₂ baselines could indicate a greater physio-

logical reserve at rest while differences in desaturation slope a more efficient O₂ utilization in the trained old population compared to their untrained counterparts.

REMOTE PILATES TRAINING IS EFFECTIVE IN IMPROVING PHYSICAL FITNESS IN HEALTHY WOMEN: A RANDOMIZED CONTROLLED STUDY

LAZAROWITZ ZANZURI, C., HADAS, D., HUTZLER, Y., GORAL, A., TSUK, S.

LEVINSKY-WINGATE ACADEMIC CENTER - WINGATE CAMPUS: THE ACADEMIC COLLEGE LEVINSKY

INTRODUCTION: Despite its positive impact on physical and mental well-being, adults may refrain from performing regular physical activity, due to inadequate time, accessibility, or funds. Yet remote platforms could overcome such obstacles and increase participation. This study evaluated the effectiveness of remote-synchronous group-Pilates classes compared to in-studio classes in healthy sedentary women.

METHODS: In a randomized controlled design, 40 women, aged 20–45, were assigned to a Zoom or studio group-Pilates training. The intervention included twice-weekly 45 min sessions over an eight-week period. Attendance (adherence) was recorded, and the participants completed physical motor tests (plank, curl-up, stork, push-up, and V-sit and reach), Profile of Mood State Surveys, and Nordic Musculoskeletal Pain Questionnaires. Evaluations were performed at baseline, mid-intervention (4 weeks), and post intervention (8 weeks).

RESULTS: Adherence to training was high in the Zoom and studio groups (80% and 74%, respectively). Improvements in physical motor tests were seen in both groups following the Pilates interventions, thereby indicating the effectiveness of group-Pilates Zoom training.

CONCLUSION: In conclusion, remote online physical activity such as Pilates offers a good alternative to in-studio trainings, as a means for improving physical fitness and promoting a healthy lifestyle in adults, by offering a more accessible and less timely alternative to in-studio physical activity programs.

HIGH ALTITUDE AND PHYSICAL EFFORT: IMPACT ON THE DEVELOPMENT OF SUBCLINICAL INTERSTITIAL PULMONARY OEDEMA IN SUBJECTS WITH DIFFERENT LEVELS OF ACCLIMATIZATION. THE HIGH ALTITUDE PROJECT CAMP

PARENZA, M., DANIELO, G., CARIA, E., SPREAFICO, F., TAGLIAPIETRA, G., POMPILIO, P.P., RANUNCOLI, C., MRKIC SPOSTA, S., AGAZZI, G., SPINABELLI, S., COGO, A., NANNIPIERI, M., MARCORA, S., PRATALI, L.

UNIVERSITY OF PISA

INTRODUCTION: Subclinical interstitial pulmonary oedema is characterized by the accumulation of fluid in the pulmonary interstitial space. Lung ultrasound (LUS) detects this condition through an increase in lung B-lines. This study aims to evaluate the effect of exercise and high-altitude hypobaric hypoxia exposure on increasing lung B-lines in subjects with different levels of acclimatization.

METHODS: This observational study, conducted in collaboration with the Italian Army, enrolled 36 subjects divided into three groups (A, B, C) based on their level of acclimatization and previous mountaineering experience. Group A (n=12) consisted of young officers from the school of Applied military science assigned to the Alpine Troops, with limited mountaineering experience. Group B (n=12) included highly specialized military alpinists from the Alpini brigade "Taurinense" and the 4th Alpini Paratroopers Regiment Group C (n=12) comprised Military Alpine Guides from the Alpine training center, with extensive high-altitude experience. The study lasted four days, with one day at Pollein, Aosta, (551 m) and three at Rifugio Torino, Monte Bianco, 3.375 m. LUS was performed at both locations, before and after exercise, following a standardized 16-zone thoracic ultrasound scanning protocol.

RESULTS: B-lines Score increased after exercise in both sea level (T0) and high altitude (T1, T2). Hypobaric hypoxia further intensified this effect, with a further increase after each standardized exercise activity that simulated military action. At T0, the mean rest score was 3.28 ± 2.65 (T0 Rest), significantly increasing to 11.19 ± 3.12 after exercise (T0 Exe) ($p < 0.01$), showing that physical effort alone contributes to subclinical interstitial pulmonary oedema. Following high-altitude exposure, the mean score was 9.69 ± 2.99 on the first day (T1 Rest) ($p < 0.01$), increasing further to 15.14 ± 3.80 after exercise (T1 Exe) ($p < 0.01$). On the second day, the baseline score reached 14.08 ± 5.20 (T2 Rest) ($p < 0.01$), rising post-exercise to 18.08 ± 3.16 (T2 Exe) ($p < 0.01$). By the third day, the baseline value stabilized at 12.75 ± 4.23 (T3 Rest) ($p > 0.05$). Group A consistently exhibited a higher mean LUS B-Lines Score than the other two groups at all time points, except for T3 Rest, where levels were similar to those of Group B but remained higher than those of Group C.

CONCLUSION: Exercise and hypobaric hypoxia are cumulative key factors in the development of interstitial pulmonary oedema. Prior experience in mountain activity appears to mitigate the impact of these factors, potentially influencing performance both at sea level and at high altitude. Further studies are needed to determine whether development of LUS B-lines could serve as a predictive marker for high altitude acclimatization and for high-altitude pulmonary oedema (HAPE) in athletes, mountaineers, high-altitude workers, and military personnel.

EFFECTS OF ACUTE HYPOBARIC HYPOXIA ON OXY-INFLAMMATION AND SYSTEMIC RESPONSE IN ITALIAN ALPINE SOLDIERS

RANUNCOLI, C., VEZZOLI, A., MONTORSI, M., AGAZZI, G., PRATALI, L., NAVA, C., SPINABELLI, S., MARCORA, S.M., TAGLIAPIETRA, G., D'ANGELO, G., CARIA, E., COGO, A., MRAKIC SPOSTA, S.

SCUOLA REGIONALE DELLO SPORT CONI

INTRODUCTION: The progressive reduction of atmospheric pressure and therefore of the partial pressure of O₂, triggers a series of compensatory mechanisms implemented by the body to adapt to the resulting tissue hypoxia. Rapid exposure (via mechanical means: cable car and/or helicopter) to altitude induces rapid functional molecular changes, such as the generation of reactive oxygen species (ROS), with consequent oxidative and systemic damage. The military activities are characterized by a rigorous and challenging lifestyle, demanding to military personnel a constant commitment and a remarkable capacity for adaptation to hypoxia and cold. Aim of the study was the assessment of biological markers, indicators of oxidative stress, inflammation, systemic stress, and appetite hormones.

METHODS: Italian Alpine soldiers (n=18; males) were studied during 72h "Campo Alta Quota 2023" in the magnificent scenario of the glacier Mont Blanc at 3500m sl. Saliva and urine samples and psychometric scale were collected at 7:00 am pre (baseline at Aosta), every day during camp (Rifugio Torino) and 15 days post (Aosta). By biofluids we assayed: ROS, Total Antioxidant Capacity (TAC), Lipid Peroxidation (8-isoprostane), DNA oxidation (8OH-dG), Interleuchin-6 (IL-6); Cortisol, Leptin and Ghrelin concentration.

RESULTS: Observed at rest modifications of the parameters of oxy-inflammation, and changes in the hormonal response: both of the stress and appetite hormones, in the 3 days spent at high altitude, compared to the baseline values were recorded. The peak of the modifications of the parameters investigated was observed 72 hours after the ascent to altitude: ROS significantly increased during sojourn (T0: 0.31 ± 0.06 ; T1 0.34 ± 0.07 ; T2 0.39 ± 0.07 ; T3 0.47 ± 0.07 ; T4 $0.30 \pm 0.06 \mu\text{mol} \cdot \text{min}^{-1}$); with consequent increase in lipid peroxidation (T0: 0.52 ± 0.13 ; T1 0.66 ± 0.17 ; T2 1.09 ± 0.11 ; T3 1.44 ± 0.32 ; T4 $0.52 \pm 0.11 \mu\text{g} \cdot \text{g}^{-1} \cdot \text{creatinine}$), DNA damage (T0: 3.04 ± 0.83 ; T1 4.57 ± 1.51 ; T2 5.09 ± 2.79 ; T3 7.78 ± 2.42 ; T4 $4.37 \pm 2.05 \text{ ng} \cdot \text{mL}^{-1}$), inflammatory status (T0: 4.68 ± 1.07 ; T1 4.65 ± 0.97 ; T2 6.26 ± 1.8

CONCLUSION: The findings of this study highlight the bio-physiological adaptability of Alpine soldiers in response to the extreme environmental conditions of high-altitude and cold exposure. Their ability to endure hypoxia and cold is a testament to their resilience, discipline, and physical preparedness. The observed increase in oxidative stress markers, inflammation, and hormonal shifts underscores the body's complex response to such challenges, necessitating precise physiological adjustments. The rise in cortisol and leptin levels further reflects the metabolic and endocrine demands imposed by altitude.

These preliminary results contribute to a deeper understanding of the biological responses to extreme conditions and reinforce the importance of targeted training and acclimatization strategies. Ultimately, this research not only advances scientific knowledge but also honors the exceptional adaptability of military personnel in extreme environments.

PHYSICAL FATIGUE INDUCED BY MILITARY OPERATIONS IN HYPOXIC AND COLD ENVIRONMENT

MARCORA, S., ELIPANNI, L., MARTINEZ-GONZALEZ, B., RANUNCOLI, C., MRAKIC SPOSTA, S., PRATALI, L., NAVA, C., SPINABELLI, S.

UNIVERSITY OF BOLOGNA

INTRODUCTION: The Arctic environment is a strategic area in the military context. However, it also features different extreme environmental stressors, such as cold and hypoxia, which combined could affect soldiers' physical performance, especially when considering prolonged military tasks. The purpose of this study was to explore the effects of operating in a hypoxic and cold environment (HCE) on the physical fatigability of three different groups of alpine soldiers.

METHODS: Thirty-four soldiers specialized in mountain warfare (Alpine Corp) were tested before, during and after 3 days of military training (1-2-3/12 2024), on the Mont Blanc (3375m). Additional tests were conducted at 551m, four days before and 14 days after training. Soldiers were divided in 3 different groups, based on their experience and operational role: A (alpine lieutenant), B (alpine special forces), C (alpine specialized guides). Each day, soldiers were tested before and after the military operation session consisting of trekking and survival skills. Pre-operation measures included the Groningen Sleep Quality and the Fatigue scales, a 5-min psychomotor vigilance task (PVT), and a 5-min Astrand-Rhyming step test. After operating, soldiers repeated PVT and the step test. In addition, they rated the effort (session RPE), the workload (NASA-TLX) experienced during the operating session and the subjective fatigue changes compared to pre-military operation (Fatigability scale). Mixed ANOVAs were used to test the effects of Group, Day and, when relevant, Time. Significance was set at $p < 0.05$.

RESULTS: All the NASA-TLX variables were significantly higher in HCE compared to low altitude, confirming that military operation was perceived significantly more effortful and more physically demanding in HCE ($p < 0.05$). All the step test variables deteriorated in HCE (main effects of Day $p < 0.001$) and further increased after the military operation sessions in this environment. There were no significant difference between groups in these responses.

CONCLUSION: These results show that even soldiers specifically trained for mountain warfare suffer from negative effects of HCE which include higher physical demands during military operation and greater fatigability. Furthermore, we demonstrated that hypoxia has increased heart rate, blood lactate, perceived leg effort and dyspnea. Operating in this hypoxic,

cold and challenging environment has further exacerbated those negative effects. Countermeasures are warranted for the negative effects of hypoxia and of operating in HCE on soldiers' physical performance.

TEMPORAL EFFECTS OF ACUTE EXPOSURE TO A SUB-PLATEAU REGION ON THE AEROBIC CAPACITY OF ELITE MALE COLLEGIATE ATHLETES IN CHINA

FENG, J., WU, W., NING, F., TAO, Y.

BEIJING SPORT UNIVERSITY

INTRODUCTION: Upon acute entry into altitude regions, particularly sub-plateau areas, an athlete's aerobic capacity does not exhibit a linear change. This study aims to investigate the time-sequenced effects of acute entry into sub-plateau regions on the aerobic capacity of elite collegiate athletes.

METHODS: Ten male collegiate athletes, aged 19–23 years, who are native to lowland areas and hold national first-class or higher sports qualifications, were recruited for this study. Their specialized events included middle- and long-distance running and race walking. None of the participants had a history of high-altitude training in the past six months. Before traveling to the training base at an altitude of 1,300 meters, baseline tests were conducted in Beijing (altitude: 50 meters). After 48 hours of rest, the participants traveled by plane together and arrived at the sub-plateau base in the evening. Participants were instructed to avoid strenuous exercise the day before each test, refrain from consuming alcohol or other stimulants, and not take any medications that could influence test results. They were also required to maintain adequate sleep and a regular diet. To simulate the preparation process for marathon races held in sub-plateau regions, a longitudinal tracking study was conducted. Testing time points were as follows: T0: Baseline test in a lowland region (altitude: 50 meters), T1: Morning of the second day post-arrival, T2: Morning of the fourth day post-arrival, T3: Morning of the sixth day post-arrival. The ambient temperature was maintained at 23–25°C, and the wind speed remained at a gentle breeze level. Maximal oxygen uptake ($\text{VO}_2 \text{ max}$) was measured using a progressive incremental load field test. After a 15-minute jogging warm-up, participants rested for 20 minutes before undergoing an incremental load test while wearing a cardio-pulmonary exercise testing device (Cortex, MetaMax3B R2, Germany). The testing protocol consisted of running one lap each at speeds of 6 km/h and 8 km/h, followed by two laps at 10 km/h. Thereafter, the speed was increased by 2 km/h every two laps.

RESULTS: The $\text{VO}_2 \text{ max}$ at T1 decreased compared to T0, but without statistical significance. The $\text{VO}_2 \text{ max}$ at T2 was significantly lower than at both T0 and T1 ($p < 0.05$), while at T3, it decreased compared to T0, but without statistical significance. The maximal running speed at T2 was significantly lower than at T0, whereas no significant differences were observed across other test sessions. No significant differences were found in maximal heart rate among all test sessions. At speed of 14 km/h, running economy at T2 was significantly lower than at T0 and T1, and the blood lactate concentration at T2 was significantly higher than at T1 and T3.

CONCLUSION: The negative impact on aerobic capacity was most pronounced on the fourth day after arrival at the sub-plateau region. It is recommended that marathon participation be scheduled on the second or sixth day post-arrival, while avoiding competition on the fourth day.

NO INCREASE IN TOTAL HEMOGLOBIN MASS FOLLOWING 21 DAYS OF LIVE HIGH TRAIN HIGH ALTITUDE TRAINING IN ELITE TRIATHLETES

FAUCHER, C., CARIN, R., MARTIN, M., DUCRAY, M., LAGARDE, H., CONNES, P., TRESSIÈRES, B., ESCOFFIER, C., LIBICZ, S., LALIRE, P., BIRAT, A., GASTON, A.-F., LACROIX, J., DOUCENDE, G., STAUFFER, E., BRUGNIAUX, J., VERGES, S., BROCHERIE, F., NADER, E., ROBACH, P., PICHON, A.

UNIVERSITY OF POITIERS

INTRODUCTION: Live High Train High (LHTH) altitude training can increase total hemoglobin mass (Hbm_{ss}). However, this response is not systematically observed. Several factors such as training load, prior environmental exposure (heat, hypoxia), season period or iron supplementation, may influence this response. This study aims to assess the hematological effects of an altitude training camp in elite athletes.

METHODS: Elite triathletes ($n=9$, 2 women) completed a three-weeks altitude training camp (1850m) with additional nocturnal exposure in a hypoxic chamber ($2299 \pm 204\text{m}$). Blood samples were collected before (Pre) and after (Post) altitude training to assess reticulocyte percentage (%Ret), CD71 positive red blood cells (CD71, %), hematocrit (Hct, %) and hemoglobin concentration ([Hb], g/dL). Plasma volume (PV) and Hbm_{ss} (g) were measured using the CO-rebreathing method. Training load (TL, Foster method) and hypoxic dose (HD, km.h) were monitored. Paired t-tests or Wilcoxon tests were used to compare Pre and Post values.

RESULTS: After altitude training, PV significantly decreased (-734.9 mL ; $p < 0.05$), while Hct ($+5.0\%$) and [Hb] ($+1.5 \text{ g/dL}$) significantly increased ($p < 0.05$). However, Hbm_{ss} remained unchanged (Pre = $1028 \pm 168\text{g}$; Post = $1029 \pm 173\text{g}$; $p = 0.944$). %Ret showed a trend toward an increase ($+0.22\%$; $p = 0.062$), indicating ongoing erythropoietic activity, further supported by an increase in CD71 (Pre = $0.18 \pm 0.13\%$; Post = $0.71 \pm 0.40\%$; $p < 0.05$). Finally, training load was not significantly different between the 3 weeks preceding altitude training (13293 ± 4200) and the altitude period (15672 ± 2839) ($p = 0.965$).

CONCLUSION: Despite a substantial hypoxic stimulus ($\text{HD} = 1043 \pm 39\text{km.h}$), no increase in Hbm_{ss} was observed following altitude training. This altitude training camp was planned between two competition periods and athletes already had a high baseline Hbm_{ss} values, which may have limited the potential gains. This unexpected result occurred despite ongoing

ing erythropoietic activity and could be also explained by prior plasma volume expansion due to heat acclimation during the weeks preceding altitude exposure. Indeed, in the 3 weeks before altitude exposure, temperatures were significantly higher ($26.3 \pm 2.4^\circ\text{C}$ vs. $20.5 \pm 0.0^\circ\text{C}$ during altitude camp; $p < 0.05$). The contraction of PV in altitude may have limited any additional increase in Hbmass.

Despite a typical hypoxic stimulus, no significant improvement in Hbmass was observed in elite triathletes following altitude training. Prior heat exposure and seasonal context may have influenced the hematological response and should be considered when designing altitude training protocols.

LEAN MASS TRAJECTORIES IN CHILDREN AND ADOLESCENTS AND THEIR IMPACT ON BONE HEALTH: IOWA BONE DEVELOPMENT STUDY

BAPTISTA, F., MARQUES, M.1, BAPTISTA, F.1, RYSAVY, R.2, PENDLETON, C.2, LEVY, S.M.2,3, JANZ, K.F.2,4

1 FACULDADE DE MOTRICIDADE HUMANA, UNIVERSIDADE DE LISBOA, PORTUGAL; 2-4 UNIVERSITY OF IOWA, USA

INTRODUCTION: The development of lean and fat mass during childhood and adolescence plays a crucial role in lifelong musculoskeletal health. Lean mass contributes to bone loading and remodelling, while fat mass affects hormonal and inflammatory pathways that can influence bone density. However, the specific effects of various lean mass trajectories on bone health remain unclear. This study aimed to examine the trajectories of lean mass development in children and adolescents and their effects on bone health in young adulthood. Utilising the appendicular lean body mass index (aLBMI) and the ratio of aLBMI to trunk fat mass (aLBMI/TrFM), the objective was to identify risk profiles for sarcopenia during growth, with bone mineral density (BMD) in adulthood measured for the whole body less head (WBLH), femoral neck, and trochanter; additionally, the BMD ratio of arms to legs and body height were included as outcomes.

METHODS: The sample consisted of 323 participants (both sexes) aged 8 to 23 years from the Iowa Bone Development Study (IBDS), assessed at ages 8, 11, 13, 15, 17, and 23. Lean mass indices (aLBMI, aLBMI/TrFM) and bone mineral densities (BMDs) were measured using whole-body and proximal femur DXA scans. Z-scores for lean mass indices were calculated based on published values (aLBMI) or derived data (aLBMI/TrFM). Participants who consistently followed the same trajectory throughout the follow-up were included in the analysis (116 for aLBMI and 67 for aLBMI/TrFM trajectories) and were categorised into sarcopenia risk (Z score ≤ -1), average (Z score between -1 and 1), and robustness (Z score > 1) trajectories.

RESULTS: Compared to the average trajectory, linear regression analyses adjusted for sex and height indicated that the aLBMI risk trajectory was associated with decreased BMD: 9% in the WBLH ($p=0.001$), 12% in the femoral neck ($p=0.001$), and 12% in the trochanter ($p=0.002$). Conversely, the robustness trajectory was linked to increased BMD: 4% in WBLH ($p \leq 0.001$), 7% in the femoral neck ($p \leq 0.001$), and 6% in the trochanter ($p=0.002$). For aLBMI/TrFM, the robustness trajectory showed a 9% increase in WBLH BMD ($p=0.031$). No other differences were observed.

CONCLUSION: A low aLBMI trajectory is a significant risk factor for bone mineralisation in the whole body and femoral regions. Conversely, a low lean mass to fat mass ratio appears to have no risk to bone health. These findings underscore the importance of early identification and monitoring of lean mass trajectories to support optimal bone health during growth.

ANALYSIS OF THE CHANGES IN THE OVERWEIGHT AND OBESITY STATUS AND INFLUENCING FACTORS AMONG CHILDREN AND ADOLESCENTS IN MACAU FROM 2005 TO 2020

CHEN, J.

CHINA INSTITUTE OF SPORT SCIENCE

INTRODUCTION: To analyze the prevalence trends and influencing factors of overweight and obesity among children and adolescents in Macau from 2005 to 2020, and to provide a basis for formulating targeted intervention strategies.

METHODS: Based on the physical fitness monitoring database of Macau residents, a stratified random sampling method was used to select 21,031 children and adolescents aged 6 to 22 years old. Through frequency analysis, chi-square test and multiple logistic regression, the changing trends of the detection rates of overweight and obesity and their influencing factors were explored.

RESULTS: From 2005 to 2020, the total detection rate of overweight and obesity among children and adolescents in Macau increased from 17.2% to 26.9% ($\chi^2=182.3$, $p<0.001$). The growth rate of males was significantly higher than that of females, and females showed a downward inflection point for the first time in 2020. The age distribution showed that the prevalence rates of overweight and obesity were higher in the groups aged 6 to 11 years and 18 to 22 years, while it showed a downward trend in the group aged 12 to 18 years. Multiple regression analysis showed that poor performance in physical education classes (OR = 2.337 - 2.390), and parental obesity (father: (OR = 2.070), mother: (OR = 1.771)) were risk factors for overweight and obesity; doing warm-up exercises before sports (OR = 0.373), participating in non-sports interest classes (OR = 0.459) and moderate physical exercise (OR = 0.524 - 0.597) were protective factors. In addition, using electronic

products for ≥ 4 hours on weekends ($p = 0.003$) and not participating in interest classes ($p = 0.016$) were significantly associated with an increased risk of obesity.

CONCLUSION: These findings highlight that adolescence is a crucial transitional period for weight management intervention. Gender-specific prevention strategies should prioritize the male population while maintaining the positive trend among the female population. Family-school collaborative interventions targeting the reduction of screen time, cultivation of an active lifestyle, and parental health models show particular promise. Policy recommendations suggest integrating a mandatory physical activity monitoring system and establishing community-based family health programs to counteract the environmental factors contributing to obesity.

EVALUATION OF A CO-CONSTRUCTED MULTI-LEVEL INTERVENTION TO REDUCE SEDENTARY BEHAVIOUR IN PRIMARY SCHOOL CHILDREN: A CLUSTER-RANDOMIZED CONTROLLED TRIAL.

LAUJAC, S., GAVARRY, O., FRANCESCHI, J., ROZAND, A., PALLIER, L., DELPIERRE, C., CARAYOL, M.
UNIVERSITY OF TOULON

INTRODUCTION: Sedentary behaviour is linked to negative health outcomes, including unfavourable body composition and chronic diseases like cancer, diabetes, and obesity. A large proportion of French children do not meet WHO activity guidelines (66% of 11-17 and 37% of 6-10 year-olds). Therefore, interventions reducing sedentary time (ST) in children are a major public health priority. This study evaluates the CIPRES multi-level intervention, grounded in socio-ecological and trans-contextual models, using a cluster-randomised controlled trial.

METHODS: This study involved 1042 children in Years 4 and 5 (aged 8-10) from 13 primary schools across four French municipalities randomly assigned to the CIPRES or Control group. The intervention lasted for 6 weeks and consisted of activities grounded in the trans-contextual model. The activities were designed for children and implemented by teachers, educators and parents. The primary outcome was ST, assessed by GT3X+ accelerometers, across weekly (7:00 am-10:00 pm), school days (4:30-10:00 pm), and non-school days (7:00 am-10:00 pm) periods. Secondary outcomes included moderate to vigorous physical activity (MVPA), Quality of Life, and body mass index. Data were collected at baseline and 6 weeks follow-up.

RESULTS: For the entire week (7:00 am-10:00 pm), significant group-by-time interactions were evident for both ST ($p=0.029$) and MVPA percentage ($p=0.015$). For weekly ST, no significant change was observed in the CIPRES group compared to a significant increase in the control group (0.1 Pp, $p=0.820$ and 1.4 Pp, $p=0.001$, respectively). Weekly MVPA showed a trend towards increase in the CIPRES group and a trend towards decrease in the control group (0.4 Pp, $p=0.099$ and -0.4 Pp, $p=0.073$, respectively). During school days (4:30-10:00 pm), a significant group-by-time interaction was found for both ST ($p=0.005$) and MVPA percentage ($p=0.004$). The CIPRES group demonstrated a significant reduction in ST (-1.5 percentage points [Pp], $p=0.026$) and a significant increase in MVPA (0.8 Pp, $p=0.025$), whereas the control group showed a trend towards increased ST (1.2 Pp, $p=0.078$) and decreased MVPA (-0.7 Pp, $p=0.058$). However, during non-school days, no significant group-by-time interactions were found. In addition, body mass index or quality of life were not significantly changed.

CONCLUSION: CIPRES intervention effectively reduced ST and increased MVPA during school days (4:30-10:00 pm), with these benefits extending across the entire week (7:00 am-10:00 pm). Significant changes, however, were not observed on non-school days. CIPRES intervention, anchored on both the trans-contextual and the socio-ecological model, therefore offers a novel framework for future school-based interventions to promote more active and less sedentary behaviour in primary school children.

WEIGHT STATUS AND BASIC MOTOR COMPETENCIES IN ITALIAN SCHOOLCHILDREN: CROSS-SECTIONAL RESULTS FROM THE MOTION STUDY

GIURIATO, M., GATTI, A., PIRAZZI, A., CAVALLO, C., CARNEVALE PELLINO, V., DEL BIANCO, M., DEL BIANCO, L., CALCATERRA, V., ZUCCOTTI, G., CODELLA, R., LOVECCHIO, N., VANDONI, M.
UNIVERSITY OF PAVIA

INTRODUCTION: The rise in pediatric obesity is a growing concern, leading to higher healthcare costs (NCD Risk Factor Collaboration (NCD-RisC), 2024). The development of motor competence (MC) appears to influence physical activity participation, and previous studies suggest a negative relationship between MC and obesity; however, these studies are often limited to specific age groups.

Basic motor competence (BMC), a fundamental component of the broader motor competence (MC), is an essential prerequisite for engagement in physical activity and the development of more complex motor skills, especially in physical education (Herrmann et al., 2015)

The present study aims to investigate the relationship between basic motor competence (BMC) and obesity in children from preschool to class 6, examining how this relationship varies across school classes.

METHODS: The BMC of 1495 children in Northern Italy was assessed using the MOBAC test, which evaluates object control and self-movement skills. BMI z-scores were computed to determine weight status. Logistic regression was used to calculate adjusted odds ratios for obesity risk based on BMC levels. Bivariate correlation examined the relationship between BMC and BMI z-scores, while linear regression analyzed how object control, self-movement, and combined BMC scores correlated with BMI.

RESULTS: A strong inverse relationship was found between all BMC domains and obesity odds, independent of sex. Self-movement skills showed a stronger association with obesity than object movement skills. The association between BMC and BMI z-scores remained consistent across classes 3–5 after adjusting for sex.

CONCLUSION: This study highlights the inverse relationship between BMC and BMI z-scores in Italian schoolchildren, particularly in grades 3–5. The stronger association observed with self-movement skills suggests that obesity prevention strategies should prioritize the development of these competencies. Moreover, to ensure that children with higher BMI perceive themselves as capable, it is essential to adopt assessment methods that consider their body composition and functional abilities.

LINKING METABOLIC SYNDROME AND PHYSICAL FITNESS IN CHILDREN WITH OBESITY: A CROSS-SECTIONAL STUDY FROM THE PODIACAR PROJECT

CAVALLO, C., GATTI, A., ROSSI, V., VANDONI, M., MARIN, L., CARNEVALE PELLINO, V., FIORE, G., TOSI, M., VERDUCI, E., MANNARINO, S., CAMPOY, C., ESCUDERO-MARIN, M., BONILLO-LEÓN, R., PAGANI, V., CORBELLINI, C., ZUCCOTTI, G., CAL-CATERRA, V.

UNIVERSITY OF PAVIA

INTRODUCTION: Paediatric obesity is a major public health issue, recognised by the World Health Organization. Metabolic syndrome (MetS), linked to cardiovascular (CV) morbidity and mortality, affects about 29.2% of children with obesity [1]. Physical fitness (PF) is a key indicator of long-term health, impacting CV risk and mortality; yet only few studies have examined its association with MetS. This study aims to analyse the relationship between PF and MetS in children with obesity [2].

METHODS: We performed a cross-sectional study evaluating 55 children with obesity (11.96 ± 2.35 years; 21 [38%] girls; mean BMI 29.5 ± 4.81 kg/m² and BMI z-score 3.15 ± 0.78). Physical fitness was assessed with the 6-minute walking test (6MWT), standing broad jump (SBJ), and 4x10 m shuttle run test (SHT). MetS z-score assesses MetS, using sex-specific formulas (cut-off > 0.75). A fasting blood sample was collected and analysed for total cholesterol, HDL-C, triglycerides, fasting glucose (FG), and insulin. Insulin resistance was estimated using HOMA-IR and TyG index.

RESULTS: In both sexes, the SBJ test was inversely correlated with MetS odds independent of age (OR: 0.18, 95% CI: 0.04–0.53). The 6MWT and SHT were not related to the odds of MetS. The SBJ showed an inverse association (BMI z-score: $\beta = -0.528$; SBP: $\beta = -0.397$; MetS z-score: $\beta = -0.299$; all $p < 0.05$) with the MetS z-score and its components, except for HDL, FG and triglycerides (respectively $\beta = 0.335$, $\beta = 0.429$ and $\beta = 0.354$) showing a positive association. The SHT was associated with BMI z-score ($\beta = 0.419$), systolic blood pressure ($\beta = 0.419$), and FG ($\beta = -0.331$; all $p < 0.05$), while the 6MWT was inversely related to BMI z-score ($\beta = 0.295$; $p < 0.05$).

CONCLUSION: Our findings highlight an inverse relationship between PF and MetS, showing the strongest association with lower limb strength, assessed with the SBJ. These results reveal the importance of including PF assessments into the clinical evaluation of children with obesity. Future research should explore the mechanisms underlying this relationship and assess targeted exercise programs for MetS prevention in children with obesity.

OP-AP42 Statistics and Analyses I - Endurance Sports

A NOVEL BIOENERGETIC MODEL OF SPRINT RUNNING PERFORMANCE

BRIAND, J., DI PRAMPERO, P.E., OSGNACH, C., THIBAUT, G., TREMBLAY, J.

UNIVERSITÉ DE MONTRÉAL

INTRODUCTION: While the short duration and high-intensity nature of sprint events hinder direct measurement of metabolic demands, a robust bioenergetic model can illuminate the interplay among aerobic, anaerobic lactic, and anaerobic alactic pathways. Although existing bioenergetic approaches indirectly capture sprinting's energy contributions, they often

underestimate the anaerobic alactic component. For instance, di Prampero et al. [1,2] noted that early acceleration phases present high metabolic power peaks, likely driven by alactic energy expenditure. Building on these insights, the aim of the present study is to propose a comprehensive bioenergetic model of sprint running, detailing the time course of aerobic, anaerobic lactic, and anaerobic alactic contributions across 100–400 m distances.

METHODS: Velocity data from the 2009 World Athletics Championships [3] were used to estimate the metabolic power of men's and women's winning 100, 200, and 400 m performances, following the approach by di Prampero et al. [1,2]. Aerobic, anaerobic lactic and alactic power contributions were each represented by distinct mathematical functions: exponentially rising (aerobic), bi-exponential (anaerobic lactic) and log-normal (anaerobic alactic) functions. From these fits, total anaerobic lactic and alactic energy expenditures were derived, enabling the calculation of maximal anaerobic capacities for male and female athletes. Model validation involved simulating each race distance and comparing the simulated performances to actual results [3].

RESULTS: The model accurately predicted metabolic power trajectories for all sprint distances, with R^2 ranging between 0.94 and 0.98. Estimated anaerobic alactic capacities were 376 J/kg (men) and 259 J/kg (women), while anaerobic lactic capacities were 1314 J/kg (men) and 1194 J/kg (women), consistent with theoretical expectations [2]. Anaerobic metabolism accounted for ~95%, 88%, and 70% of total energy in the men's 100, 200, and 400 m events, and ~93%, 86%, and 69% for the women's events. Mean percentage differences between actual and simulated distances was 0.31% (men) and 1.05% (women), with higher discrepancy in the women's results potentially reflecting an underestimation of anaerobic lactic contributions.

CONCLUSION: This bioenergetic model provides a detailed account of aerobic and anaerobic energy contributions during sprinting, aligning closely with theoretical and empirical data. Its framework offers insights into sprint bioenergetics, informing future modelling efforts and performance optimization. Further investigation across a broader range of distances is warranted to refine model functions and parameter estimates.

UNDERSTANDING PERFORMANCE VARIABILITY IN ELITE TRAIL RUNNERS ACROSS DIFFERENT COMPETITIONS

BETTEGA, S., FORNASIERO, A., CALLOVINI, A., PELLEGRINI, B., SCHENA, F., ZOPPIROLI, C.
UNIVERSITY OF VERONA

INTRODUCTION: Identifying the smallest worthwhile performance improvement is essential for coaches and researchers to assess the impact of training strategies and tapering in elite sports. This improvement is typically defined as 0.3 times the standard deviation of an athlete's race-to-race performance variability, which corresponds to gaining one additional medal every 10 competitions for those already competing at the highest level. However, since performance variability varies considerably across sports (ranging from 0.3% to 7.0%), sport-specific assessments are necessary to determine meaningful improvements. Therefore, this study aimed to estimate the variability between- and within- athletes, as well as the predictability of performance times across competitions in elite trail running [1]

METHODS: For the purpose of this study, we considered elite male athletes with an ITRA score of 825 or higher ($n = 941$). We collected race results from the main international trail running events, including the Golden Trail World Series, Skyrunning World Series, World Mountain Running Association, major championships (World and European), and key ultratrail races from the 2024 season (56 races). A MATLAB script matched each athlete with his race times, and races were classified into ITRA categories: uphill-only (UP), XS, S, M-L, and XL-XXL (based on length and elevation profile). Between-athlete variability was expressed as the standard deviation (SD) of the coefficient of variation (CV) across athletes, while within-athlete variability was assessed using CV and SD of performance times. Performance predictability was evaluated with the intraclass correlation coefficient (ICC), with uncertainty expressed as 90% confidence limits. All analyses were performed using Hopkin's spreadsheet [2]

RESULTS: Between-athlete variability ranged from 5.43% in the UP category to 8.49% in XL-XXL, with XS (5.96%), S (7.24%), and M-L (6.66%) in between. Within-athlete variability was lower, with values ranging from 3.18% in XS to 5.34% in S, and 3.98%, 4.46%, and 4.32% for XS, M-L, and XL-XXL, respectively. ICC for performance predictability were moderate for UP (0.46) and S (0.45), and very high for XS (0.71) and XL-XXL (0.73), with M-L showing a high ICC (0.55).

CONCLUSION: This study provides a detailed analysis of performance variability and predictability in elite trail running. Between-athlete variability was highest in the XL-XXL category, while within-athlete variability was relatively lower across all categories. Performance predictability was moderate to high across most categories, with the highest ICC values observed in the XS and XL-XXL groups. These findings highlight the importance of sport-specific assessments for evaluating performance improvements and understanding the variability in elite trail running. Coaches and researchers can use these insights to tailor better training and tapering strategies for athletes at the highest competitive levels.

AN EMPIRICAL STUDY ON THE PACING PROFILES OF FEMALE 20KM RACE WALKERS AT THE PARIS OLYMPICS

DUAN, Y., YUAN, T., WEI, P., HU, B., GUO, Q.

CHINA INSTITUTE OF SPORT SCIENCE

INTRODUCTION: Pacing profiles play a critical role in race walking performance. This study aims to analyze the differences in pacing profiles, speed control capabilities, and the correlation between the ability to reproduce personal best performances and race results among female 20km race walkers of different competitive levels at the 2024 Paris Olympics.

METHODS: This study utilized competition data from 43 female athletes who completed the 20km race walk at the 2024 Paris Olympics. Data were sourced from the official websites of the Paris Olympics and World Athletics. A quasi-experimental design was adopted, with athletes divided into four groups based on their final rankings (Group A: 1st–11th; Group B: 12th–22nd; Group C: 23rd–32nd; Group D: 33rd–43rd). Key variables included split times for each 1km segment, average speed per 5km, starting speed (average speed over the first 2km), peak speed, and the coefficient of speed variation. When data exhibited a normal distribution, analysis of variance (ANOVA), Pearson correlation analysis, and independent samples t-tests were employed to explore differences in pacing profiles, starting speed, peak speed, and the ability to reproduce personal best performances among the groups.

RESULTS: ANOVA results for 5km split speeds across groups revealed significant differences ($p < 0.05$), with the disparities becoming more pronounced as the race progressed. Athletes in Group A exhibited significantly higher peak speeds compared to other groups ($p < 0.05$). While the starting speeds of Group A and Group B athletes showed no significant difference ($p > 0.05$), Group A's starting speed was significantly higher than that of Groups C and D ($p < 0.05$). The time at which athletes fell below their starting speed varied across groups, with Group A maintaining their starting speed longer than other groups. The race results at the Paris Olympics showed a significant positive correlation with peak speed ($r = 0.805$, $p < 0.001$) and starting speed ($r = 0.880$, $p < 0.001$). Additionally, the ability to reproduce personal best performances was positively correlated with final Olympic rankings ($r = 0.518$, $p < 0.01$).

CONCLUSION: Athletes in different groups demonstrated distinct pacing profiles. Group A athletes primarily adopted a negative-split strategy, maintaining a conservative pace in the first half of the race, gradually increasing speed, and finishing with a strong sprint. In contrast, athletes in Groups B, C, and D tended to adopt a positive pacing strategy, reaching their peak speed earlier and subsequently slowing down. Higher-ranked athletes exhibited superior speed control, characterized by smaller variations in starting speed, peak speed, and split speeds, later occurrence of peak speed, and a delayed drop below starting speed, which contributed to their stronger finishing capabilities. These athletes were also more capable of delivering performances close to their personal bests in the Olympic setting.⁴

ASSOCIATION BETWEEN AMBIENT TEMPERATURE AND COMPETITION PERFORMANCE OF WORLD-CLASS 20KM RACE WALKERS: DIFFERENT RESULTS ACROSS SEGMENTS

CUI, D., ZHANG, X.2, YANG, W.2, JIANG, Z.3

CHINA INSTITUTE OF SPORT SCIENCE

INTRODUCTION: Ambient temperature has a significant impact on endurance sport performance, which is why world-class elite race walkers undergo heat acclimatization training before the Olympics and World Championships, with a cooling program for each 1km during the competition [1]. But how much did the ambient temperature affect the performance of each segment in the competitions? There is still a lack of quantitative evidence. The aim of this study was to assess the association between ambient temperature and competition performance of world-class 20km race walkers on a segmental scale, to provide a more accurate reference for heat acclimatization and cooling down.

METHODS: The investigated competitions were the mens and womens 20km race walking in the 7 Olympic Games and World Championships during the years 2015-2023. The top 8 athletes of each race were included. Ambient temperature variables were pre-race and post-race temperatures, with data collected from official reports or the Weather Spark platform, and ICC was calculated to confirm their consistency. Performance variables were marks per km, with data collected from official reports or official videos. 3 analyses were conducted. 1) 2-sided Pearson correlation analysis was performed with significance set at $p < 0.05$. 2) Causal path diagrams were plotted by conditional independence test. And 3) linear regression models were fitted based on the previous 2 analyses results.

RESULTS: (1) Both mens and womens overall mark had the strongest correlation with pre-race temperature ($r(56)=0.770$, $r(56)=0.691$, $p < 0.001$). Womens first half was even stronger ($r(54)=0.782$, $p < 0.001$), but the second half weaker ($r(54)=0.576$, $p < 0.001$). Mens first half was also stronger ($r(52)=0.756$, $p < 0.001$), but the second half turned insignificant. Womens 1-2km segment was the strongest ($r(32)=0.947$, $p < 0.001$), so was mens 2-3km segment ($r(32)=0.875$, $p < 0.001$). Here, the analysis of 1km segments only included years 2019-2023 with an average temperature of 27.4°C.

(2) The female data showed a path from the pre-race temperature, via the first half performance, and then to the second half performance. But the male data did not.

(3) The regression model for female athletes showed that for every 1°C increase in pre-race temperature, it resulted in a decrease of about 15.5 seconds in the first half performance ($R^2=0.61$); the male model showed that for every 1°C increase in pre-race temperature, it resulted in a decrease of about 13.3 seconds in the first half performance ($R^2 = 0.56$).

CONCLUSION: With the trend of increasing temperatures in race walking 20km competitions, world class athletes, especially women, should pay more attention to heat acclimatization and cooling down in the first half of the race to achieve the expected performance.

HOW SEX AFFECTS OXYGEN MANAGEMENT IN MUSCLE AFTER HIGH-INTENSITY AEROBIC INTERVAL TRAINING: INITIAL OBSERVATIONS

GIURIATO, G., DORELLI, G., PEDRINOLLA, A., SCHENA, F., VENTURELLI, M.
UNIVERSITY OF VERONA

INTRODUCTION: High-intensity interval training (HIIT) improves maximal oxygen uptake ($\text{VO}_{2\text{max}}$), primarily through cardiac adaptations. However, positive adaptations should also happen in muscle oxidative capacities, which notably differ for sex. This study investigates how near-maximal HIIT affects $\text{VO}_{2\text{max}}$ and mitochondrial oxidative capacity in sex differences.

METHODS: A running incremental test and intrinsic mitochondrial respiration in permeabilized vastus lateralis fibers were conducted in 8 young healthy males and 5 females, one week before and 3 days after a 6-week HIIT program (3 days/week). The HIIT consisted of 4x4 min of interval running (4min of running at 90-95%HRmax followed by 3min of active resting at 70%HRmax).

RESULTS: HIIT significantly increased females' (49.4 ± 5.6 to 52.9 ± 6.9 L/min, $p=0.046$) but not males' (6.2 ± 3.2 vs. 60.9 ± 4.1 L/min, $p=0.381$) $\text{VO}_{2\text{max}}$. Unexpectedly, the mitochondrial net oxidative capacity decreased significantly in females by $17.3 \pm 9.7\%$ ($p=0.01$) and in males by $33.0 \pm 21.8\%$ ($p=0.01$). In females, the decline in mitochondrial performance was apparent as early as the Complex I-linked substrate state following ADP addition (all, $p<0.022$). In contrast, males exhibited significant differences only at the point of maximal coupled and uncoupled mitochondrial respiration (mitochondrial surrogate for $\text{VO}_{2\text{max}}$) (all, $p<0.040$), where the Complex II-linked substrate state is predominant.

CONCLUSION: Near-maximal HIIT increased $\text{VO}_{2\text{max}}$ in females, but unexpectedly reduced mitochondrial oxidative capacity. In contrast, males maintained their $\text{VO}_{2\text{max}}$ but experienced a more pronounced decline in muscle oxidative capacity, primarily driven by reductions in Complex II-linked respiration. These responses may reflect increased mitochondrial O_2 affinity (reduced $p_{50\text{mito}}$), as shown by Larsen, et al. [1]. The statistical power of the study will be further strengthened as participant recruitment remains ongoing.

EFFECTS OF A 16-WEEK DIGITAL INTERVENTION ON SPORTS NUTRITION KNOWLEDGE AND RELATIVE ENERGY DEFICIENCY IN SPORTS (REDS) MARKERS AMONG SWISS NATIONAL TEAM CROSS-COUNTRY SKIERS AND BIATHLETES

GRAEFNINGS, M., MELIN, A., SCHMIDT-TRUCKSÄSS, A., HOFFMAN, E., STEINER, T., BUCHER, E., KLUNGLAND TORSTVEIT, M.
BASEL UNIVERSITY

INTRODUCTION: Endurance athletes with high training loads have increased risk of low energy availability (LEA) and Relative Energy Deficiency in sport (REDs). The aim of this study was to evaluate the effects of a 16-week nutritional digital intervention on sports nutrition knowledge and REDs markers among Swiss national team cross-country skiers and biathletes.

METHODS: Swiss national team cross-country skiers and biathletes (21 females, 13 males; 24 ± 4 years, training 19 hours/week, $\text{VO}_{2\text{max}}$ 63 ± 8 ml/kg/min) were evaluated of REDs severity using the International Olympic Committee Clinical Assessment Tool (CAT) 2; menstrual disturbances (MD), risk of eating disorders (Eating Disorder Examination Questionnaire (EDE-Q)), levels of testosterone (males), triiodothyronine (T3), cholesterol, bone mineral density (DXA) and bone stress injury (BSI) history. Nutrition knowledge was assessed by a validated 78-item questionnaire for endurance athletes. The Food and nUtrition for Endurance athletes—a Learning (FUEL) program, comprising 16 weekly online lectures and individual athlete-centered nutrition counseling every other week, was administered to athletes both with and without REDs. Data was analyzed with McNemar test, Repeated Measures ANOVA and dependent t-tests.

RESULTS: Four males and nine females (39%) were categorized with REDs (12 mild, 1 moderate, 0 severe) PRE intervention and two males and three females (15%) (5 mild, 0 moderate, 0 severe) POST the intervention ($p=0.02$). Nutrition knowledge improved from PRE to POST for athletes with REDs ($p=0.002$, $d=1.4$ 95% CI [0.50, 2.2]) and without REDs ($n=9$ males and 12 females), ($p=0.007$, $d=1.2$ 95% CI [0.6, 1.8]). Athletes with REDs decreased their (EDE-Q) total global score (1.0 ± 0.9 versus 0.5 ± 0.6 ; $p=0.03$, $d=-0.8$ 95% CI [-1.3, -0.08]) while no changes were seen among the athletes without REDs. Male athletes with REDs increased their testosterone levels (free 280 ± 94 vs. 418 ± 37 pmol/L; $p=0.01$, $d=1.9$ 95% CI [0.1, 3.5], and total 14 ± 6 vs 20 ± 4 nmol/L; $p=0.003$, $d=2.9$ 95% CI [0.50, 5.3]), from PRE to POST while no changes were seen among male athletes without REDs. The number of female athletes with MD (24 %, $n=5$) PRE decreased to 10 % $n=2$ POST intervention. No changes in T3, BSI, body weight, body composition estimates, or cholesterol levels were found in either group.

CONCLUSION: Athletes with REDs improved their sport nutrition knowledge and decreased their eating disorder pathology after participating in the FUEL program. Furthermore, male and female athletes with REDs improved testosterone levels

and menstrual status, respectively, indicating a decreased risk of clinical markers of REDs after participation in the FUEL program. However, further research with a larger sample is needed to confirm these findings.

PHASE ANGLE IN THE CONTEXT OF LOW ENERGY AVAILABILITY – IS IT A GOOD PREDICTOR OF FEMALE CROSSFIT® ATHLETES' HORMONE LEVELS?

NAKAMOTO, F., SILVA, N., MANCINI, S., AGUIAR, V., ALVARES, L., FERREIRA, R., SANTOS, R., QUARESMA, M.

CENTRO UNIVERSITÁRIO SÃO CAMILO

INTRODUCTION: The assessment of phase angle (PhA) is significant in the context of sports, as it plays a crucial role in potentially identifying functional impairments, such as overtraining syndrome (OTS), muscle injury, and related changes in fluid distribution. OTV and Relative Energy Deficiency in Sport (REDs) share symptom similarities initiating from a hypothalamic-pituitary origin, that can be influenced by low energy availability (LEA). Thus, the aim of the study is to verify if the PhA may be used as T3, leptin, and IGF-1 predictor in the scenario of LEA.

METHODS: This is a cross-sectional study with nonprobability sampling. Inclusion criteria: healthy female CrossFit® (CF) practitioners aged 18-39 years, training experience ≥ 1 year; 5-7 training sessions (5-7 hours) per week for ≥ 6 months for the recreational practitioners' group (RG); ≥ 12 hours of practice per week for ≥ 6 months for the elite group (EG). Subjects visited the laboratory once. They answered health, sociodemographic, and the Low Energy Availability in Females (LEAF-Q) questionnaires. Resting energy expenditure (REE) via indirect calorimetry and body composition (bioelectrical impedance analysis) were assessed in a fasting state, followed by blood test. Data were analyzed using Jamovi® 2.3.21 version.

RESULTS: Data of 43 subjects are presented as mean (SD). Students t-test showed no differences regarding age (33.1 (5.2) and 30.3 (6.2) years), body mass index (24.0 (1.8) and 25.9 (1.5) kg/m²), and REE (1618.8 (168.9) and 1647.8 (173.2) kcal/day) between RG (n=30) and EG (n=13), respectively. Body fat percentage (BF%: 23.3 (3.4) and 19.1 (2.7); $p < 0.001$), T3 levels (1.0 (0.3) and 0.8 (0.1) ng/mL; $p < 0.05$), and leptin levels (10.4 (7.5) and 2.4 (1.3) ng/mL; $p < 0.001$) were significantly lower in the EG. Fat free mass (FFM: 48.5 (4.2) and 55.2 (3.8) kg; $p < 0.001$) and IGF-1 levels (168.8 (48.6) and 207.2 (42.4) ng/mL; $p = 0.018$) were significantly higher in the EG. Energy availability was 22.0 (9.8) for RG and 21.4 (12.9) kcal/kg of FFM for EG. PhA was significantly different between EG and RG ($t=4.94$; $p < 0.001$; MD: 1.20; $d=1.66$). PhA was positively correlated to FFM ($r=0.56$; $p=0.005$), FFM% ($p < 0.001$), and LEAF-Q score ($r=0.341$; $p=0.029$), and IGF-1 levels ($r=0.318$; $p=0.045$), but negatively correlated to T3 ($r=-0.342$; $p=0.029$) and leptin ($r=-0.372$; $p=0.017$) levels. After controlling for group, the linear regression model showed that group (EG) was positively associated with PhA, independently of FFM (B: 0.87; 95% CI: 0.31-3.16; 0.003). However, when controlling for variables of adjustment, PhA was not associated to T3 (B=-0.04; $p=0.400$), leptin (B=0.778; $p=0.571$), and IGF-1 (B=8.2; $p=0.435$) levels.

CONCLUSION: PhA was positively correlated to female CF athletes' FFM, the LEAF-Q score, and levels of T3, leptin, and IGF-1 and positively associated to the EG, but no association to hormone levels was found. More studies are necessary to verify the usefulness of PhA as a predictor of hormone levels in the LEA scenario.

QUALITY OF LIFE IN FEMALE ENDURANCE ATHLETES AT RISK OF RELATIVE ENERGY DEFICIENCY IN SPORT: THE FUEL STUDY

SOLSTAD, B., FAHRENHOLTZ, I.L., GARTHE, I., HOLLEKIM-STRAND, S.M., KOEHLER, K., LOGUE, D., MADIGAN, S., MELIN, A.K., WASSERFURTH, P., TORSTVEIT, M.K.

UNIVERSITY OF AGDER

INTRODUCTION: Quality of life (QOL) is an important research outcome measuring an individual's perception of their position in life. However, evidence concerning QOL in female endurance sports is lacking. Female endurance athletes are at high risk of Relative Energy Deficiency in Sport (REDs), a syndrome of impaired physiological and/or psychological functioning caused by problematic low energy availability (LEA). Thus, the aim of this study was to assess QOL in female endurance athletes with symptoms of REDs and investigate whether the Food and nUtrition for Endurance athletes – a Learning (FUEL) program affected QOL in this group of athletes.

METHODS: Female endurance athletes from Norway (n=60), Sweden (n=84), Ireland (n=17), and Germany (n=47) were recruited to the FUEL intervention consisting of 16 weekly online lectures combined with sports nutrition counseling every-other-week. Fifty athletes with symptoms of REDs [LEA in Females Questionnaire (LEAF-Q) score ≥ 8] and with low risk of eating disorders, no use of hormonal contraceptives, and no chronic diseases, were allocated to either the intervention (FUEL) condition (n=32) or the control (CON) condition (n=18). All but one completed the FUEL intervention, while three participants dropped out of the CON condition. Athletes completed the WHOQOL-BREF pre- and post-intervention and data were analyzed using a Bayesian mixed factor analysis of variance.

RESULTS: Self-rated QOL were 4.3 ± 0.5 for CON and 4.3 ± 0.8 for FUEL at pretest, which did not change after the intervention period (CON: 4.2 ± 0.7 , FUEL: 4.4 ± 0.9). Likewise, satisfaction with one's health were 4.2 ± 0.8 for CON and 4.0 ± 0.7 for FUEL at pretest and did not change after the intervention period (CON: 4.1 ± 0.5 , FUEL: 4.2 ± 0.9). Comparing CON and FUEL, no evidence for differences in change were found for Physical domain (CON pre: 79.6 ± 7.0 , CON post: 82.7 ± 6.9 ; FUEL pre: 76.8 ± 13.5 , FUEL post: 82.4 ± 13.0), Psychological domain (CON pre: 71.5 ± 10.6 , CON post: 74.3 ± 12.2 ; FUEL pre: 73.6 ± 10.3 , FUEL post: 75.9 ± 15.7), Social domain (CON pre: 68.1 ± 17.3 , CON post: 65.4 ± 18.4 ; FUEL pre: 72.5 ± 15.7 , FUEL post: 76.4 ± 16.1), or Environmental domain (CON pre: 80.7 ± 8.6 , CON post: 84.6 ± 10.4 ; FUEL pre: 81.7 ± 10.9 , FUEL post: 85.3 ± 12.8).

CONCLUSION: When comparing the FUEL and CON conditions, the results revealed that QOL did not change after the intervention period. This finding might be attributed to the context-specific nature of the FUEL intervention. The intervention content focused exclusively on information related to health and performance outcomes in endurance sport. Another explanation might be attributed to the complexity between various psychological reactions to problematic LEA exposure as they interact with other factors, such as the social environment and level of competition. Nevertheless, future studies need to focus on investigating prospective variability of QOL among female endurance athletes at risk of REDs.

THE IMPACT OF A FIVE-WEEK RESISTANCE TRAINING PROGRAM WITH TIMED NUTRIENT INTAKE ON BODY COMPOSITION AND EXTRACELLULAR VESICLE-ASSOCIATED MIRNA PROFILES.

CSALA, D., ÁDÁM, Z., HORVÁTH-SZALAI, Z., SEBESI, B., GARAI K., KVELL, K., WILHELM, M.

UNIVERSITY OF PÉCS, FACULTY OF SCIENCES

INTRODUCTION: The anabolic window hypothesis suggests that there is a limited time frame following exercise for optimized nutrient uptake and utilization. Prior research indicates that microRNAs (miRNAs) transported in extracellular vesicles (EVs) may play a crucial role in post-exercise adaptation, since small nucleic acids finely regulate protein synthesis. The aim of the present study was to examine the impact of physical exertion on conventional physiological parameters and expression profiles of miRNAs transported in EVs.

METHODS: Twenty male participants (age: 22 ± 2 years) voluntarily engaged in a five-week hypertrophy-specific resistance training program with timed nutrient intake (maltodextrin, whey protein). Participants were assigned to one of three groups based on the timing of nutrient consumption relative to exercise: immediately post-exercise (AE), three hours post-exercise (AE3), or no nutrient intake (CTRL). We assessed body composition and quadriceps femoris muscle strength. Additionally, following the isolation of platelet-free plasma, we extracted small extracellular vesicles. Subsequently, total RNA was isolated from pooled vesicular samples, followed by miRNA profiling.

RESULTS: Compared to baseline measurements, skeletal muscle mass significantly increased in the AE ($p=0.001$) and AE3 ($p=0.028$) groups, while quadriceps femoris strength improved significantly in the AE group ($p=0.032$). Additionally, body fat percentage was significantly reduced in all three groups: AE ($p=0.005$), AE3 ($p=0.024$), and CTRL ($p=0.005$). The isolation of EVs was validated using transmission electron microscopy, exosome antibody array, and nanoparticle tracking analysis. Between-group comparisons revealed distinct expression profiles of EV-associated miRNAs. Specifically, 39 miRNAs exhibited differential expression in AE, whereas 13 miRNAs were differentially expressed in both AE3 and CTRL relative to baseline. Notably, let-7d-5p, hsa-miR-181b-5p, hsa-miR-222-3p, and hsa-miR-324-5p were differentially expressed between the AE and CTRL groups.

CONCLUSION: The observed increases in skeletal muscle mass in AE and AE3 groups suggest that both the resistance training program and macronutrient intake contributed to alterations in body composition. Findings further indicate that the timing of nutrient intake is closely associated with the efficacy of exercise in modulating body composition and quadriceps femoris strength. Additionally, the miR-181 family appears to be a key regulator of angiogenesis, while miR-222-3p and miR-324-5p may be involved in the mTOR pathway, a critical regulator of hypertrophy. These data suggest that EV-associated miRNAs may provide insight into the molecular mechanisms underlying the observed differences between groups.

ENERGY EXPENDITURE OF MALE SOCCER PLAYERS FROM THE ENGLISH PREMIER LEAGUE DOES NOT DIFFER BETWEEN ONE-GAME AND TWO-GAME PER WEEK MICROCYCLES: A DOUBLY LABELLED WATER INVESTIGATION

FOO, W., MARKAKIS, P., ARETA, J.L., CLOSE, G.L., SPEAKMAN, J.R., TESTER, E., MORTON, J.P.

LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: Determining energy requirements is vital for developing nutritional guidelines for elite soccer players (1). Research on total daily energy expenditure (TDEE) of English Premier League (EPL) players is limited, with one study reporting a mean TDEE of 3566 ± 585 kcal·day⁻¹ (2). Since then, the physical match demands (e.g. high-speed running (HSR) and sprint distances) of match play have increased significantly (3). Additionally, two-game per week (2GW) microcycles impose greater physical demands than one-game per week (1GW) microcycles (4). However, no studies have directly compared TDEE between these microcycles. Therefore, this study aimed to assess TDEE, dietary intake and external physical load in male EPL players during 1GW and 2GW microcycles.

METHODS: Nine male players from an EPL club were assessed over a 15-day in-season period, including a 1GW followed by a 2GW. TDEE was measured using the doubly labelled water (DLW) method and external physical loading was monitored via global positioning system. Self-reported energy intake was assessed using weighed food inventory and the remote food photographic method (RFPM) (5). Energy intake (EI) derived from DLW method was calculated through the adjustment of TDEE for changes in energy stores (6).

RESULTS: No differences were observed in accumulative total (25552 ± 3502 m vs 26360 ± 5462 m), HSR (1744 ± 536 m vs 1705 ± 752 m), or sprint distances (372 ± 150 m vs 324 ± 252 m) between 1GW and 2GW (all $p < 0.05$). Mean TDEE was 3551 ± 507 kcal·day⁻¹, with no difference between 1GW (3554 ± 963 kcal·day⁻¹) and 2GW (3467 ± 821 kcal·day⁻¹, $p = 0.781$). Self-reported EI using RFPM (2975 ± 292 kcal·day⁻¹) underestimated DLW derived EI estimates (3663 ± 665 kcal·day⁻¹) by 724 ± 722 kcal·day⁻¹ (18% error, $p = 0.026$). Carbohydrate (CHO) intake was significantly higher on match day (MD) (5.0 ± 1.1 g·kg BM⁻¹·day⁻¹) compared to the day before the match (MD-1) (3.5 ± 1.3 g·kg BM⁻¹·day⁻¹), the day after the match (MD+1) (3.0 ± 1.0 g·kg BM⁻¹·day⁻¹) and training day (3.0 ± 1.1 g·kg BM⁻¹·day⁻¹) (all $p < 0.05$).

CONCLUSION: TDEE in male EPL soccer players does not differ between 1GW and 2GW microcycles, likely due to similar weekly accumulative external load metrics, including total distance, HSR and sprint distances. Players practiced CHO periodization, with higher intake on MD, but intakes were below the recommended levels on MD-1, MD, MD+ 1 and training days. Practically, the lack of significant differences in TDEE between microcycles suggest that the current CHO guidelines (4-6 g·kg⁻¹·day⁻¹ on rest and training days and 6-8 g·kg⁻¹·day⁻¹ for MD-1, MD and MD+1) may adequately support the demands of elite soccer players during both microcycles.

OP-SH16 Mentoring / Coaching

EFFECTIVE COACHING PRACTICES AND BEHAVIOURS OF EXPERT PROFESSIONAL TENNIS COACHES

BLOOM, G., CLARKE, H., GLAUDE, M.

MCGILL UNIVERSITY

Introduction: Tennis ranks among the most widely followed sports globally, with a fanbase exceeding one billion and media revenues approaching \$700 million. In light of its popularity and global success, it is not entirely surprising that professional tennis players and coaches face challenges inherent to the sport, including extensive travel, social isolation, and an income structure heavily reliant on performance outcomes. Although there is a large body of literature dedicated to effective coaching across different contexts (i.e., sport type, geography), little research has specifically explored coaching within the professional tennis environment.

Methods: The purpose of this study was to explore professional tennis coaches' perspectives of their unique coaching context, including how this context influenced their coaching practices. We conducted individual semi-structured interviews with five professional tennis coaches, each of whom was coaching a top 20 ranked player at the time of the study. On average, these coaches had over 15 years of tour coaching experience and had collectively guided male and female players to win four singles grand slam titles and one grand slam doubles title. Furthermore, this group of coaches had achieved more than 15 ATP titles with their current players. Using a reflexive thematic analysis, interviews were transcribed verbatim and arranged into codes, themes, and overarching themes (Braun et al., 2016).

Results: Our reflexive thematic analysis highlighted coaches' perceptions of a unique power-dynamic in which their player was their employer, potentially affecting the style and content of their coaching feedback. Coaches also emphasized the demanding nature of the tour on players, highlighting the importance of providing social support while also recognizing the importance of taking time apart to avoid relationship burnout. Furthermore, participants underlined the challenges incoming coaches face in learning to navigate this unique context, noting that the sport's competitive nature often made established coaches hesitant to provide mentorship.

Conclusions: Overall, this study is among the first to present qualitative data from an elite sample of professional tennis coaches who shared their perceptions of coaching within this distinctive coaching context. The findings provide valuable information to current and prospective professional individual-sport coaches by highlighting how some of the world's best tennis coaches navigate their environment, offering coaching strategies to enhance their coaching effectiveness and success.

THE ROLE OF WOMENS FOOTBALL ACADEMIES IN SPORT DEVELOPMENT AND EDUCATION

BOGNÁR, J., DÉRI, D.V., TRZASKOMA-BICSÉRDY, G.

ESZTERHÁZY KÁROLY CATHOLIC UNIVERSITY

Research on youth and talent development has increased significantly; however, women remain substantially underrepresented (Williams et al., 2020). The rapid global expansion of women's soccer is evident in its growing geographical reach, the number of registered players, and the establishment of soccer academies. In Hungary, a new talent development system was introduced in 2021 with the launch of six sports academies. This study focuses on the experiences of selection processes and expectations of players, coaches, and parents regarding the female academy system.

Data were collected from all six sports academies in Hungary. The sample comprised 262 female players, 37 coaches, and 218 parents (78%, 100% & 65% of the total population). A structured questionnaire using a 4-point Likert scale, along

with a document analysis of the academies pedagogical programs, was utilized. Data analysis included descriptive statistics, ANOVA, and qualitative content analysis.

Results revealed that both female players and parents rated “hope of success” ($M=3.23\pm0.804$) and “sense of talent” ($M=3.16\pm0.789$) as the most significant factors motivating their entry into the academy system. Factors such as the accessibility of soccer ($M=2.03\pm1.078$), its relative rarity among girls ($M=2.01\pm1.089$), and media influence ($M=1.89\pm1.003$) were considered less important. Moreover, parents placed significantly greater emphasis on expectations related to a sense of talent, a healthy lifestyle, and the hope of popularity compared to players ($p<0.05$), whereas players more strongly valued role modeling in soccer ($p<0.05$).

Regarding recruitment, 38% of players were automatically recruited from collaborating clubs, 31% were self-recruited, and a scout or coach selected 31%. Both players and parents expressed high expectations for high-level development opportunities provided by the academy ($M=3.51\pm0.770$). Additionally, coaches identified the professional support team ($M=3.43\pm0.728$) as their primary motivation for working within the academy system. The preparedness of coaches ($M=3.63\pm0.740$) and the effectiveness of the professional support team ($M=3.57\pm0.784$) were highlighted as key contributors to the academies’ high level of functioning. Notably, 20.5% of respondents underscored the need for ensuring equal treatment and conditions between men and women in academies.

The academies’ educational programs not only aim to develop successful soccer players but also prepare athletes for civil professions and promote further education. In addition to a dual career focus, these programs emphasize team spirit, mutual respect, and cooperation. The findings suggest that while the academies are considered important in all-around development by all parties, they also reveal important areas for future development.

OFF THE BEATEN TRACK: HOW COACHES AND ATHLETES NAVIGATE FEMALE-SPECIFIC TOPICS

AUSLAND, Å., KJÆR, J.B., IVARSSON, A., TORSTVEIT, M.K., SOLSTAD, B.E., MELIN, A.K., AUGUSTSSON, S.R., RADOVAN, F., LINNÉR, S., BJÄRSHOLM, D., LAXDAL, A.G.

UNIVERSITY OF AGDER

INTRODUCTION: Communication between coaches and female athletes is essential when addressing six key topics: puberty, menstruation, injuries, body composition, coach-athlete relationships, and within-group communication. However, some coaches may experience challenges in communicating these topics due to limited knowledge or confidence. Effective communication on these issues can strengthen coach-athlete relationships, foster trust, and contribute to athlete well-being. This study examines (1) how female athletes and coaches perceive the importance of feeling safe communicating about these topics, (2) how coaches evaluate their own comfort and ability to address these topics, and (3) how coaches perceive their athletes’ comfort in communicating personal thoughts.

METHODS: Two digital surveys were conducted: one with 779 coaches of female athletes (306 female coaches, mean age = 44 years, SD = 11.5 years) and one with 1,323 female athletes aged 16 to 24 years (mean age = 19 years, SD = 2 years) in Norway and Sweden. Coaches rated the importance of feeling safe communicating about these six topics (rated from 1 = unimportant to 7 = very important). Athletes answered three questions: (1) how important they thought these conversations are, (2) how comfortable they felt engaging in the conversations, and (3) how comfortable they believed their athletes felt when communicating with them about the six topics. Latent profile analyses were conducted using Mplus.

RESULTS: Athletes rated communication on all six topics as highly important ($M = 5.87$ – 6.27 , $SD = .82$ – 1.23). Coaches recognized this ($M = 5.86$ – 6.21 , $SD = 0.86$ – 1.13) but reported lower comfort levels in communicating about these topics ($M = 4.76$ – 5.96 , $SD = 1.10$ – 1.75). Individual sport coaches felt generally more comfortable than team sport coaches. The largest gaps were found in menstruation and body composition, where coaches felt significantly less comfortable. Coaches also rated their athletes’ comfort in sharing as lower than their own, with female coaches perceiving their athletes as less comfortable than male coaches.

Discussion: Findings revealed a gap between the perceived importance of communication and coaches’ comfort in addressing these topics. While athletes highly value these conversations, coaches—especially in team sports—often feel unprepared. Coaches also perceived their athletes as less comfortable sharing than they are in engaging, suggesting a misalignment in communication expectations. These findings highlight the need for fostering environments where athletes feel safer expressing personal concerns and where coaches are better prepared to respond effectively.

EFFECTS OF 12-WEEK MINDFULNESS-BASED INTERVENTION ON EXECUTIVE FUNCTIONING SKILLS, BRAIN OXYGENATION, AND BIOMARKERS OF COGNITIVE FUNCTION IN BASEBALL PLAYERS: A RANDOMIZED CONTROLLED TRIAL

HUANG, J., CHEN, W., YANG, Y., HE, S., LENG, L.

GUANGZHOU SPORT UNIVERSITY

Purpose: While mindfulness has demonstrated efficacy in enhancing executive function in non-athletes through improved present-moment awareness and acceptance of current experiences, particularly regarding attention regulation and cognitive control, its neurocognitive mechanisms and the effects and underlying mechanisms of mindfulness-based intervention (MBI) on different executive functioning skills in athletic populations remain poorly understood. The purpose of this

randomized controlled trial tackles a novel and important topic by investigating the beneficial effects of 12-week MBI on executive functioning skills in baseball players—a population that faces unique cognitive and physical demands, and the associated neurophysiological and biochemical regulation mechanisms.

Methods: Thirty-four baseball players were randomly divided into the MBI group (11M/6F) and the control group (11M/6F). Executive functioning skills (N-back task for working memory, Stroop task for inhibitory control, and Switching task for cognitive flexibility) were tested before and after the intervention. Functional near-infrared spectroscopy (fNIRS) was used to record quantified hemodynamic responses in the prefrontal cortex through oxygenated hemoglobin concentration (Oxy-Hb) monitoring during the performance of executive function tasks. Biomarkers of cognitive function, including BDNF, IL-6, TNF-, and cortisol, were measured using enzyme-linked immunosorbent assays (ELISA).

Results: MBI improved all three executive function skills, with increased Oxy-Hb level in L-FPA during the task of working memory, increased Oxy-Hb level in R-VLPFC during the task of inhibitory control, and decreased Oxy-Hb level in R-FPA, M-FPA, and L-DLPFC during the task of cognitive flexibility. Furthermore, MBI increased circulating BDNF level and decreased IL-6 and cortisol levels. In addition, our correlation analyses showed that improvement in executive function (improved behavioral performances and changes in Oxy-Hb levels) were associated with changes in cortisol and inflammatory cytokines (TNF- α and IL-6).

Conclusion: A 12-week MBI improved three components of executive function in baseball players. This enhancement may be attributed to the MBI-induced reductions in cortisol and inflammatory cytokines (such as TNF- α and IL-6), which altered blood oxygen contents in specific brain regions, thereby promoting executive function.

TALENTED ATHLETES' PERSPECTIVES ON TALENT DEVELOPMENT PROGRAMS: A COMPARATIVE ANALYSIS ACROSS SPORTS

HEERSCHOP, M., BALK, L.

MULIER INSTITUUT

INTRODUCTION: While traditional talent development models predominantly emphasize physical and technical aspects of athlete development (1, 2) less attention has been given to the broader developmental context, including environmental and policy-related influences (3, 4). Understanding how these external factors shape an athlete's experience and long-term success is crucial for optimizing talent pathways. Therefore, this study investigated talented athletes' perceptions on national sport federations' talent development programs, focusing on aspects such as training infrastructure, coaching quality, athlete health, and safe sport environments.

METHODS: A total of 1149 athletes (565 male, 581 female) from various sports completed a questionnaire about their federation's program, wellbeing and their sports environment.

RESULTS: Talented athletes rated their elite sport environment with an average of 7.8 (scale 0-10), with handball and field hockey receiving the highest scores. The quality of trainers and coaches received the highest ratings in gymnastics, hockey and handball. Athletes in athletics, cycling, and gymnastics most often report insufficient physical health, while those in athletics, skiing, and swimming most often express concerns about mental health. Further analysis is ongoing to examine associations between training environment and wellbeing, and sport-specific trends in greater detail.

CONCLUSION: This study showed that there are large differences between sports in athletes' experiences and perceptions regarding training environment and wellbeing. The results indicate that some sports have structured a large part of their trainings programs effectively, whereas others still fall short on multiple areas. These findings will contribute to the optimization of talent development programs by identifying their strengths and areas requiring improvement. Additionally, these insights will serve as foundation for further exploration into how federations implement talent development models in practice and how these align with athletes' experiences.

SMARTWATCH ASSESSMENT OF CPR PERFORMANCE ADMINISTERED TO AN INSTRUMENTED MANNEQUIN

ULBRICH, A., BORBA, E.F., RODACKI, A.L.F., HOFFMANN, G., HONORATO, S., PEREZ, L.H.G.

FEDERAL UNIVERSITY OF PARANA

INTRODUCTION: Cardiac arrest is a critical medical emergency often requiring effective cardiopulmonary resuscitation (CPR) to preserve life. While smartphones have been used to provide CPR feedback for training purposes, their practicality is limited during active resuscitation. Smartwatches, with embedded sensors and their proximity to the wrist joint, offer the potential for real-time feedback of CPR performance. This study aimed to determine if a smartwatch's accelerometer sensors can provide a valid assessment of CPR parameters.

METHODS: Nineteen medical students performed CPR on an instrumented mannequin while wearing a smartwatch (sampling at 200 Hz). CPR parameters were computed from the smartwatch's accelerometer data using custom algorithms to determine compression depth, recoil, frequency, and cycle duration. The determined parameters were compared with kinematic measurements determined from video analysis (60 Hz). Agreement between the two measurement methods (smartwatch and video analysis) across 3,005 CPR cycles was assessed using Bland-Altman analyses.

RESULTS: Smartwatch assessment demonstrated good agreement with video analysis for cycle duration (0.00s, 95% CI: -0.05 to 0.05s) and compression depth (-0.31 cm, 95% CI: -1.61 to 0.98 cm). The smartwatch also reliably tracked cycle frequency (1.88 Hz) and number of cycles with negligible variation compared to video analysis. Only 45.8% of CPR cycles adhered to the recommended depth range (5–6 cm).

CONCLUSION: Smartwatch assessment was able to accurately monitor CPR performance administered to a mannequin. Further research is needed to validate their application in real-world scenarios, as well as develop a means for them to provide instantaneous feedback of CPR performance.

IMPROVING ADULT CPR EFFICIENCY AND EFFICACY: A SYSTEMATIC REVIEW OF RESCUER POSTURE AND MECHANICAL AND PHYSIOLOGICAL FATIGUE

MORGADO, J., BHUDARALLY, M., FEBRA, C., PEREIRA, H., PALMEIRA, A., ALEIXO, P.

UNIVERSIDADE LUSÓFONA DE HUMANIDADES E TECNOLOGIAS

INTRODUCTION: The posture and position of rescuers, as well as the height at which a patient is positioned during chest compressions, significantly influence the efficacy and efficiency of cardiopulmonary resuscitation (CPR). Despite this, there are no established guidelines regarding optimal rescuer posture or patient height placement, highlighting the need to systematize existing knowledge and explore the potential benefits of exercise interventions on CPR performance.

This systematic review aims to evaluate the impact of rescuers posture and the height at which a patient or manikin is positioned during chest compressions. It focuses on mechanical and physiological fatigue indicators to determine how these factors affect the efficacy and efficiency of CPR.

METHODS: Adhering to PRISMA guidelines and registered with PROSPERO, the review included peer-reviewed articles that compared different rescuer postures and patient heights during chest compressions. Databases such as MEDLINE Complete, SPORTDiscus, Cochrane Reviews, and CINAHL Complete were searched. The methodological quality was assessed using the Quality Assessment Tool for Quantitative Studies.

RESULTS: The search yielded 6543 articles, with 34 meeting inclusion criteria. All studies were observational, utilized manikins, and were deemed weak in methodological quality. No studies specifically addressed exercise intervention impacts. The kneeling posture was found to enhance the efficacy and efficiency of chest compressions compared to standing, particularly when performed on the ground rather than a bed. Research on optimal patient height relative to rescuer anthropometrics remains scarce. The contact hand does not significantly impact compression quality, and chest compressions should not be performed while moving.

CONCLUSION: The review found no studies on exercise interventions effects on CPR efficiency. There are no specific recommendations for rescuer posture based on patient height. Fitness levels may influence the duration of effective chest compressions, as physical function, muscle strength, mass and morphology tend to decline with age. Understanding physiological effort and recovery could optimize CPR techniques. Future research should investigate how exercise programs can affect CPR efficiency and fatigue in first aiders.

OUTCOMES OF CARDIOVASCULAR SCREENING IN THE LARGEST MANDATORY SCREENING PROGRAMME IN THE UK FOR FEMALE SOCCER PLAYERS

YAMAGATA, K., COWIE, C., SHARMA, S., MALHOTRA, A.

INSTITUTE OF SPORT, MANCHESTER METROPOLITAN UNIVERSITY

INTRODUCTION: Elite sporting organizations in the Western world advocate cardiac screening to mitigate sudden cardiac death (SCD) risks. Data relating to the diagnostic yield of such programmes in sport are dominated by male athletes. Soccer is associated with the highest prevalence of SCD among young male athletes. A previous study on 11,168 soccer

players, primarily males, revealed a 0.38% prevalence of cardiac disorders associated with SCD, and a 2% prevalence of minor cardiac disorders. The aim of this study was to investigate the prevalence of serious cardiac diseases and subsequent outcomes amongst female soccer players in the UK. We also report ECG and echocardiogram characteristics in this previously underreported population.

METHODS: From 2000 to 2024, 3,121 female soccer players underwent the English FA cardiac screening programme, which comprised a health questionnaire, physical examination, 12-lead ECG, and transthoracic echocardiogram. The FA registry was reviewed for cardiac morbidity and SCD over a 6.8-year follow-up period. ECG and echocardiogram characteristics compared.

RESULTS: Athletes had a mean age of 19.8 ± 5.4 years, with 749 (24%) aged 12–16 years, and 2,716 (87%) were white. 284 (9.1%) athletes reported one or more cardiac symptoms, and 165 (5.3%) required additional investigations. Six (0.2%) athletes were identified with significant cardiac disorders associated with SCD, and 33 (1.1%) had minor cardiac conditions. Over a follow-up of 5.0 ± 4.7 years (15,507 cumulative person-years), there were no cases of SCD, and one (0.03%) case of non-ischaemic cardiomyopathy.

Compared with age- and ethnicity-matched male soccer players, females had lower rates of sinus bradycardia (39.1 vs 45.3%; $p < 0.001$), sinus arrhythmia (15.0 vs 38.5%; $p < 0.001$), left ventricular hypertrophy (8.7 vs 24.8%; $p < 0.001$), and right ventricular hypertrophy (0.4% vs 2.3%; $p < 0.001$), but a longer PR interval (150 ± 24 vs 140 ± 14 ms; $p < 0.001$) and QTc interval (417 ± 26 vs 398 ± 16 ms; $p < 0.001$). T-wave inversion (TWI) was more common in females (13.4 vs 2.8%; $p < 0.001$), with a distribution of 12.2% in anterior leads, 1.1% in inferior leads, and 0.2% in lateral leads. Echocardiography revealed smaller left ventricular diameters (47.3 ± 3.7 vs 52.4 ± 3.9 mm; $p < 0.001$) and right ventricular diameters (34.0 ± 5.2 vs 36.6 ± 4.8 mm; $p < 0.001$) in females compared to males.

CONCLUSION: Despite more frequent cardiac symptoms in female athletes, the occurrence of life-threatening conditions was lower compared to males. Electrical diseases were the most common significant cardiac disorders, and no cases of sudden cardiac arrest were recorded during the six-year follow-up.

ANAMNESIS VS. ECG DATA FROM PRE-PARTICIPATION PHYSICAL EVALUATION TO IDENTIFY MEDICAL EXAMINATION FOLLOW-UP: A MACHINE LEARNING APPROACH

RAIMO, M., BERTOLLO, M., GUERRA, G., KOMICI, K., PAPINI, G., SARTOR, F.

UNIVERSITÀ OF MOLISE

INTRODUCTION: Pre-participation physical evaluation (PPE) is critical in reducing the risk of Sudden Cardiac Death in athletes and healthy individuals (1, 2). In Italy, PPE is mandatory for sport practice, and it usually includes anamnesis, electrocardiogram (ECG), it may include spirometry, and echocardiogram. In other countries, such as the USA, PPE mainly includes medical history and physical examination, excluding ECG(2). However, it is still disputed whether adding ECG to PPE is cost-effective. Over the past two decades, significant advancements in data digitalization and availability have led to the widespread adoption of Machine Learning (ML) algorithms in various fields. Supervised ML has shown excellent results in identifying follow-up recommendations(3).

This study aimed to compare two supervised ML models, one using anamnesis data (Anamnesis_Model) and a second ECG data (ECG_Model), to evaluate their efficacy in identifying PPE medical examination follow-up need.

METHODS: We used the PPE Cardarelli Campobasso Hospital database. From a total of 1116 subjects present in the database, 630 subjects were selected based on data completeness (i.e., competitive sport certificate). Data were preprocessed using the MissForest method to imputation residual missing values. Continuous variables were centered and scaled. Recursive feature elimination was applied to select the most relevant variables in both anamnesis and ECG case separately. The data set was divided into training (70%) and test sets (30%) and modeled using a logistic regression and k-fold crossvalidation (10-fold repeated 5 times). Accuracy, sensitivity, specificity of both models were compared. Data analysis and modeling were conducted in RStudio using caret package.

RESULTS: Anamnesis_Model achieved a ROC AUC of 0.74 and setting sensitivity at 90% showed a specificity of 43% on the test set, with a balanced accuracy of 59.8%. ECG_Model outperformed Anamnesis_Model, achieving a ROC AUC of 0.79 and setting sensitivity at 90% showed a specificity of 70% with a balanced accuracy of 74.9%.

CONCLUSION: PPE's ECG information improved the prediction of medical examination follow-up need as set by the physician compared to anamnesis alone. These findings seem to be in favor of ECG inclusion in PPE. A major limitation of this study was not having access to follow-up examination's results.

MYOCARDIAL BRIDGING AND INDUCED ISCHEMIA: A CONTROVERSIAL ISSUE DURING THE PREPARTICIPATION SCREENING IN MASTER ATHLETES

SCARFÒ, G., BIANCHI, M., MAZZARISI, A., FALCETTA, G., COLLI, A., FRANZONI, F.
UNIVERSITY OF PISA

INTRODUCTION: Myocardial bridging (MB) consists of the intramyocardial course of a coronary artery. The evaluation of the MB-induced ischemia, caused by the compression of the "tunneled" tract during the systolic phase, represents a debated issue during preparticipation screening. Specifically, the assessment of MB hemodynamic effects becomes a crucial factor in athlete management. Indeed, participation in competitive sports, according to ESC and Italian guidelines, should be considered only in the absence of induced ischemia. The issue becomes of relevance in master athletes (> 35 years old) in which impaired vasomotor adaptations, inflammation, myocardial remodeling and atherosclerotic phenomena can alter compensation mechanisms and trigger an ischemic condition downstream of the tunneled segment. The aim of the study was to evaluate the correlation between myocardial perfusion data and the coronary anatomy in asymptomatic master athletes.

METHODS: 25 master endurance athletes (mean age: 66±3.4; Males: 20, Females: 5) came to our attention due to the finding of stress ECG abnormalities (ST-T tract depression or premature ventricular beats) performed during the annual preparticipation screening. None of them reported symptoms, cardiovascular risk factors or previous cardiovascular diseases. In order to precisely identify the cause of these findings, they were all subjected to a myocardial Single Photon Emission Computed Tomography (SPECT) and subsequently to a coronary CT angiography (CCTA).

RESULTS: In these athletes, myocardial SPECT detected a mild perfusion defect (<5%) in absence of left ventricular dysfunction. Anatomical data obtained by CCTA showed the relationship between the ischemic area and the presence of a MB, involving the left anterior descending artery in 21 athletes. In 18 patients, the systolic phase caused the total occlusion of the tunneled segment, thus demonstrating a severe hemodynamic impact on ventricular myocardium.

CONCLUSION: The evidence of mild inducible ischemia is generally not an indication for further diagnostic investigation; however, our data showed that restricted perfusion defect could be associated with the presence of hemodynamically significant MBs. Therefore, during preparticipation screening it is crucial to perform the anatomical study of coronary arteries of master athletes, even in the presence of mild inducible ischemia to prevent cardiovascular adverse events during exercise.

INJURY SURVEILLANCE PRACTICES IN PRIORITISED UNIVERSITY SPORTS CODES IN SOUTH AFRICA

SCHIPPERS, R., ANDREWS, B., MEEUSEN, R., VERHAGEN, E., TASSIGNON, B., LEACH, L.
THE UNIVERSITY OF THE WESTERN CAPE

INTRODUCTION: Injury surveillance and the practice thereof is the first step in the development of injury prevention strategies. Utilising injury definitions, study designs and methods of data collection in injury surveillance studies that are not standardised can immensely affect the results of the injury surveillance data. Therefore, the aim of this study is to assess the current injury surveillance practices and data collection methods of prioritized university sport codes in South Africa.

METHODS: The study utilised a cross-sectional study design within prioritized university sport codes competing in an annual university sports tournament in South Africa. An online questionnaire was designed by using previous studies that assessed injury surveillance practices and data collection. The online questionnaire was piloted using physiotherapists and sport physicians using a previously validated critical appraisal assessment tool (CAAT). The final questionnaire consisted of nine (9) sections and 39 questions covering personal information (age, gender, sport, etc.), knowledge and attitudes on injury surveillance, sports injury incidence data, definitions of sports injury, barriers and facilitators of injury surveillance, and experiences of medical staff when collecting and reporting injury surveillance data. The questionnaire was distributed online to the medical personnel/staff responsible for injury surveillance.

RESULTS: Forty medical staff from 16 universities across 5 prioritized university sport codes responded (response rate = 40/56 = 71%) to the questionnaire. Eighty percent of respondents (32/40 = 80%) indicated that their institutions collected information on sports injuries during matches (32/40 = 80%) and training (30/40 = 75%). The majority (29/40 = 72.5%) of respondents reported that their institutions have no intention of collecting sport injury information in future. Injury prevention and management (30/40 = 75%) was the main reason for institutions collecting injury data. Time, and introducing a standardized sports injury recording form, as well as appointing designated medical staff were the main barriers to injury surveillance. The most common facilitators to injury surveillance were training of staff, introducing a standardized sports injury recording form, and appointing designated medical staff on injury surveillance. Thirty-point eight percent of the respondents indicated both training in injury surveillance and funding (12/40 = 38%) as important factors when collecting and reporting injury surveillance data.

CONCLUSION: Medical staff reported that collecting, recording and reporting of injury information was important. Providing adequate resources to medical staff and using a standardised injury recording form, with clearly defined injury defini-

tions and data collection methods, would enhance injury surveillance in the future. Continuous training of medical staff would also improve injury surveillance and help to develop effective injury prevention initiatives.

A LONGITUDINAL STUDY OF INJURY EPIDEMIOLOGY AND ATHLETIC TRAINING SERVICES AT THE INTERCOLLEGIATE TENNIS ASSOCIATION DIVISION I REGIONAL CHAMPIONSHIPS

HAN, K.

CALIFORNIA STATE UNIVERSITY, NORTHRIDGE

INTRODUCTION: The role of athletic trainers and sports medicine teams in supporting athlete safety, injury prevention, emergency care, clinical diagnosis and treatment during sports events should never be overlooked. There are over 1,700 collegiate tennis programs the Intercollegiate Tennis Association (ITA), including over 300 womens programs and 240 mens programs in Division I, and more than 8,000 players participated in ITA tournaments in 2023. The purpose of this study was to investigate athletic training (AT) services provided at ITA Division I womens tennis tournaments over the past 6 years, and to analyze tennis injuries and physical discomforts that occurred during the tournament.

METHODS: The data used in this study included the past 5 years of ITA Regional Championships in Division 1 womens tennis held annually from 2018 to 2023, excluding the 2020 tournament which was canceled due to COVID-19. Participants were from 19 colleges in the Northwestern United States. The number of singles and doubles players who participated in the tournaments and the number of players who withdrew and/or retired from play due to injury or illness were collected based on ITA tournament records.

RESULTS: A total of 637 players participated in the singles (632 matches), there were 7 walkovers (4-injury and 3-illness: 1.11%) and 8 retirements (7-injury and 1-illness: 1.27%). In doubles (309 matches), there were 6 workovers and no retirements (4-injury; 2-illness: 1.94%). AT services were primarily injury assessment and athletic tapings of joints and/or areas complaining of pain/discomfort. The top 3 AT services for the lower extremities were ankle inversion sprains, toe blisters, and foot blisters; for the upper extremities wrist compression, lower abdominal muscle strains, and finger blisters and elbow hyperextension; other services included hot packs, lower back stretching, and hamstring stretching. A total of 31 medical timeouts (6.2 medical timeouts per tournament) were requested during the 5-year tournament, the most common being the ankle-related complains (7 medical timeouts), with 6 conditions requested 2 or more medical timeouts, and 1 timeout for a finger, shoulder, and head. Unusually, 1 case of anxiety related dyspnea was included.

CONCLUSION: This study found that higher performing ITA D1 women's tennis players had lower injury rates, which allowed them to perform better in singles and doubles. In the 5 years of tournament, there has never been a walkover or retirement after players advanced to the quarterfinals in singles and the round of 16 in doubles. As medical support in other sport events, the role of on-site athletic trainers is essential at tennis tournaments, and most AT services provided to players consist of assessment injuries or physical discomfort and providing necessary treatments such as athletic tapings/wrappings and injury treatment.

REALLOCATING SEDENTARY TIME TO PHYSICAL ACTIVITY, AND GENETIC SUSCEPTIBILITY: PROSPECTIVE ASSOCIATIONS WITH MAJOR ADVERSE CARDIOVASCULAR EVENTS IN INDIVIDUALS WITH DIABETES OR PREDIABETES

SHI, Q., JANG, H., COLLINGS, P., WANG, M., CHEN, Z., LUO, S., AU YEUNG, S., SHARP, S., GRIFFIN, S., BRAGE, S., KIM, Y.

THE UNIVERSITY OF HONG KONG LI KA SHING FACULTY OF MEDICINE

INTRODUCTION: Individuals with diabetes or prediabetes face a substantially elevated risk of major adverse cardiovascular events (MACE). Modifiable lifestyle factors, such as sedentary behavior (ST) and physical activity (PA), hold potential to mitigate this risk. However, little evidence exists on how reallocating ST to PA of varying intensities is associated with incident MACE in these at-risk populations. This study investigates the prospective association between time reallocation of movement behaviors and MACE risk among individuals with diabetes or prediabetes across strata of genetic susceptibility.

METHODS: This study is based on data from 15,229 adults with prediabetes or diabetes from the UK Biobank, free of baseline cardiovascular disease and with valid accelerometer-derived movement data. A cross-ancestry coronary heart disease (CHD) polygenic risk score (PRS) was computed using 144 genome-wide significant genetic markers ($r^2 < 0.001$) identified through a multi-ancestry genome-wide association study. Isotemporal substitution models with Cox regression were performed to estimate hazard ratios (HRs) of MACE when replacing ST with equivalent durations of light PA (LPA) or moderate-to-vigorous PA (MVPA).

RESULTS: Over a median follow-up of 8.1 years, 1,280 incident MACE cases were identified. MVPA, relative to other behaviors, was associated with a 12% reduction in MACE risk (HR 0.88, 95% confidence interval [CI] 0.82–0.95). ST, relative to other behaviors, was associated with a 31% higher risk of MACE (HR 1.31, 95% CI 1.11–1.54). Additional adjustment for PRS made no material change to the associations. LPA had no evidence of associations. Isotemporal substitution analysis revealed that reallocating ST to equivalent durations of MVPA was associated with a lower risk of MACE, with longer durations of reallocation corresponding to a greater risk reduction, across strata of genetic risk.

CONCLUSION: Reallocation of ST into an equivalent amount of MVPA is associated with lower risk of MACE in individuals with diabetes or prediabetes, irrespective of their genetic risk of coronary heart disease. The consistent associations across genetic risk strata suggest that ST replaced by MVPA could benefit MACE prevention not only in all individuals with diabetes or prediabetes but in those at high genetic risk. Clinical trials of individuals with diabetes or prediabetes including those at high genetic risk should focus on increasing PA in exchange for ST for primary prevention of MACE.

INTERMENSTRUAL PAIN AND ITS IMPACT ON SPORT AND EXERCISE IN PREMENOPAUSAL FEMALES: A MIXED-METHODS STUDY

ROMERO-PARRA, N., KOLIC, P., SIMS, S., BADENHORST, C.
UNIVERSIDAD REY JUAN CARLOS

INTRODUCTION: The knowledge of intermenstrual pelvic pain (IPP) is limited despite being experienced by 20-70% of premenopausal women [1]. This study aimed to determine whether IPP influenced sport and exercise practice in premenopausal females.

METHODS: 1576 naturally menstruating (NM) females and 210 hormonal and non-hormonal contraceptive (HC/NHC) users of >16 years of age, experiencing menstrual bleed at the time of study participation, volunteered to complete an online survey that consisted of 20 questions. The survey was created on Qualtrics software and hosted by Massey University. A 10-point numerical rating scale was used to determine the self-reported severity of the participants IPP. The self-reported perceived impact of IPP on sport and exercise was obtained through close-ended and open-ended questions. Mann-Whitney U tests were used to analyse quantitative data in SPSS software for Macintosh, version 25. Qualitative data (i.e., free-text answers) were analyzed through thematic analysis, allowing for the identification and subsequent coding and grouping of meaningful information into themes.

RESULTS: Results from our participants indicated that 88.4% (n=1393) of NM and 89.7% (n=122) of HC/NHC experienced IPP. There were no differences in IPP pain ratings (5.52 ± 2.03 and 5.78 ± 1.89 , respectively) between groups. In the HC/NHC group, 81.1% who reported IPP were currently using or had used an IUD Mirena. The self-reported negative impact of IPP on sport and exercise for NM and HC/NHC groups was 56% and 62.2% respectively. Thematic analysis noted that over 60% of participants perceived a negative impact of IPP on their sport and exercise performance, which was managed through complete avoidance of exercise practice or adaptation of training schedules, intensity, volume or types of exercises. However, not all participants were negatively impacted by IPP. Some participants reported that they exercise normally and experienced relief from bothersome IPP symptoms with regular exercise practice.

CONCLUSION: In this mixed-methods study, a high percentage of active women both NM and users of HC/NHC, especially of IUD Mirena, experienced IPP. Pain severity was rated ~5 out of 10 and seemed to negatively impact their sports and exercise practice. Although this research sheds light on the occurrence, intensity, and effects of IPP, additional studies are essential to achieve a more comprehensive understanding of this phenomenon and its impact not only on exercise and sport engagement, but also on activities of daily life.

EPIDEMIOLOGY OF INJURIES IN ELITE MALE VOLLEYBALL PLAYERS: A 39-WEEK LONGITUDINAL STUDY

MASHIMO, S., ICHIHARA, S., TAKEGAMI, A., NISHIDA, S., ITO, A., WAKI, H., HOSOI, S., HOGAN, T., YOSHIDA, N.
RITSUMEIKAN UNIVERSITY

INTRODUCTION: Volleyball is a limited-contact sport; however, it involves repetitive jumping, overhead motions, and rapid directional changes [1]. These characteristics contribute to both traumatic and overuse injuries. Although several studies have examined volleyball-related injuries, most have relied on the narrowest definition—time-loss injury—focusing only on injuries that prevent players from participating in sport [2]. However, this approach may underestimate the true burden of injuries. This study aimed to investigate both traumatic and overuse injuries in elite male volleyball players using the broadest injury definition to provide a more comprehensive understanding of injury prevalence and patterns.

METHODS: This descriptive epidemiological study monitored traumatic and overuse injuries among 47 elite Japanese male volleyball players over 39 weeks. Each Sunday, injuries were assessed using the Japanese version of the Oslo Sports Trauma Research Center (OSTRC) Questionnaire on Health Problems (OSTRC-H2.JP) [3]. An injury was defined as any injury sustained by a player during a match or training, regardless of whether it received medical attention or necessitated time loss from sports activities (any complaint definition). The weekly response rate of the OSTRC-H2.JP was presented as a percentage with a 95% confidence interval (95% CI). The prevalence of all injuries and substantial injuries was calculated weekly based on OSTRC-H2.JP responses. This was determined by dividing the number of players reporting any type of injury or substantial injury by the number of questionnaire respondents.

RESULTS: The average OSTRC-H2.JP response rate was 52.8% [95% CI; 50.4–55.2%] throughout all weeks. A total of 100 injuries were recorded, comprising 43 traumatic and 57 overuse injuries. The average weekly prevalence of all injuries was 23.8% [95% CI; 21.4–26.3%], with 9.3% [95% CI; 7.6–11.0%] classified as substantial. The average weekly prevalence of traumatic injuries was 10.7% [95% CI; 8.6–12.8%], with 3.4% [95% CI; 2.2–4.5%] considered substantial. The prevalence of overuse injuries was 16.0% [95% CI; 14.0–18.0%], with 6.2% [95% CI; 4.8–7.7%] classified as substantial. The most affected body regions were the knee (n = 33, 33.0%) and the lumbar-sacral spine/buttock (n = 19, 19.0%). Overuse injuries accounted for 87.9% (n = 29) of knee injuries and 57.9% (n = 11) of lumbar-sacral spine/buttock injuries.

CONCLUSION: This study found that over 20% of elite male volleyball players experienced symptoms of injury each week, demonstrating the high injury burden in this population. Moreover, the prevalence of all and substantial overuse injuries exceeded that of traumatic injuries, highlighting the importance of using the broadest injury definition in volleyball injury surveillance. Injury prevention efforts should prioritise the knee and lumbar-sacral spine/buttock.

OP-SH05 Physical Education III

IMPACT OF THE QUALITY OF BASIC PHYSICAL EDUCATION CURRICULUM ON MOTIVATION TOWARDS PHYSICAL ACTIVITY PARTICIPATION

KARWAMBA, M., SOÓS, I., HAMAR, P.

HUNGARIAN UNIVERSITY OF PHYSICAL EDUCATION AND SPORT SCIENCE

Introduction

Physical Education (PE) and Sport is one of the major contributors to improving the quality of health required by all citizens across the world. PE forms the basis of learning sports skills that one can apply throughout their life and motivate participants towards lifestyle choices in terms of career and recreation choices, which impacts their lifelong engagements. This study analyzed the motivational impact of PE towards participation in Physical Activity (PA) among university students.

Methodology

This quantitative study employs a survey method. Questionnaires were used to collect data from 106 university students (35 female; 71 male) from Kenya. Behavioural Regulation in Exercise Questionnaire -3 (Markland & Tobin, 2004) was used to measure motivation in PA participation, while the Global Physical Activity Questionnaire (WHO, 2021) was used to measure the amount of PA participation. The Physical Education Quality Assessment Questionnaire was used to measure the quality of PE curriculum undertaken by the respondents. Data was analyzed using SPSS version 23.0. Pearson and Spearman's rho were used to determine correlations, while Crammer's V was used to determine the degree of association.

Results

Male respondents had higher PA levels in MET minutes ($M = 10,832$) compared to females ($M = 9,677$). Male students also recorded a higher intrinsic regulation ($M = 42.20$; $SD = 7.61$) compared to their female counterparts ($M = 41.62$; $SD = 9.65$). Female students showed a higher external regulation ($M = -2.29$; $SD = 4.06$) against the males ($M = -4.76$; $SD = 6.86$). Quality of basic physical education curriculum showed significant impact on intrinsic regulation among male students, with Crammer's V association value of ($V = 0.72$) while among the female students, external regulation was significantly affected by the quality of PE ($V = 0.655$). Generally, quality of PE showed significant impact on introjected regulation across the sample ($\chi^2(N=106) = 695.63$, $p < 0.001$, $V = 0.66$).

Discussion and CONCLUSION: The results indicated that quality PE has an effect on three aspects of motivation: intrinsic regulation, external regulation, and introjected regulation. Among the female students, the need for physical activity participation is driven mainly by external pressures and external rewards and punishments. Male students are more likely to express genuine interest in physical activity and integrate it in their daily lives, as indicated by intrinsic regulation results.

THE IMPACT OF PHYSICAL EDUCATION TEACHERS HEALTH EDUCATION LITERACY ON STUDENTS HEALTH LITERACY: MEDIATING ROLE OF CURRICULUM QUALITY

LYU, K.

WUHAN SPORTS UNIVERSITY

Background:

Physical education teachers play an indispensable role in the process of school health education. Although previous studies have focused on the impact of physical education teachers health education literacy on students health literacy in China, few have explored the role of health education curriculum implementation quality in this process.

Method:

To investigate the impact relationship and mechanism between physical education teachers health education literacy and students health literacy in China, this study utilized the Health Education Literacy Assessment Scale for Physical Education Teachers, the Health Education Curriculum Implementation Quality Assessment Scale, and the Student Health Literacy Assessment Scale. Measurements were conducted on 614 middle school students from three schools designated as the first batch of national health school construction units by the Chinese Ministry of Education. The collected data were analyzed using structural equation modeling and the bias-corrected Bootstrap method.

RESULTS: The results indicated that physical education teachers health education literacy had a significant positive effect on both students health literacy ($\beta = 0.18$, $p < 0.01$) and the quality of health education curriculum implementation ($\beta = 0.59$, $p < 0.01$). Furthermore, the quality of health education curriculum implementation had a significant positive effect on

students health literacy ($\beta = 0.67$, $p < 0.01$). The quality of health education curriculum implementation partially mediated the relationship between physical education teachers health education literacy and students health literacy (indirect effect = 0.39, $p < 0.01$).

Discussion:

As the primary implementers of school health education, physical education teachers need to enhance their health education literacy by improving both pre-service and in-service training systems. Health education courses, as key carriers of school health education, should include teaching methodology courses to strengthen physical education teachers health education teaching knowledge while integrating the relationship between physical education and health education to ensure the quality of health education curriculum implementation. As the beneficiaries of school health education, students urgently require the establishment of scientific, objective, and actionable evaluation standards and supervision mechanisms for health education curricula, in order to promote the development of students health literacy.

LEVELS OF PHYSICAL ACTIVITY AND SEDENTARY BEHAVIOR DURING PHYSICAL EDUCATION LESSONS AMONG CHILDREN 10-14 YEARS –OLD.

AL-HADABI, B., YETGIN, M., DERVENT, F., ALJUHANI, O.

SULTAN QABOOS UNIVERSITY

INTRODUCTION: Low levels of physical activity (PA) are negatively associated with general health. However, one of the most important settings that can enhance PA levels in children and adolescents is physical education (PE) by enhancing the time that children spend in moderate and vigorous physical activity (MVPA).

METHODS: Consequently, this cross-sectional study aimed to objectively measure PA levels and sedentary (SED) time during physical education classes in Turkey. Accelerometers have been used to measure PA of 274 children and adolescents aged 10-14 (49.6% girls). To determine time spent in PA and sedentary, accelerometer counts per minute were used (SED < 25; light physical activity (LPA): 26 - 574; and MVPA > 574).

RESULTS: The percentage of time spent in SED, LPA, and MVPA during PE lessons was 44.5%, 12.3%, and 43.2%, respectively. The percentage of participants who met the recommended 50% of PE time in MVPA was 45.6% (44.2% were male and 47.1% were female). The results showed that sedentary time was higher among overweight participants and time spent in LPA and MVPA was higher among non-overweight participants (all $P < 0.05$). The percentage of LPA time was higher in female compared to male participants ($P = 0.003$).

CONCLUSION: It is concluded that increasing the time of MVPA and replacing sedentary time with PA during PE time is important, especially among overweight students.

THERE IS EDUCATION, THERE IS PHYSICAL EDUCATION: RECAPITULATE THE MARGINALISATION OF PHYSICAL EDUCATION

PENG, B.

THE CHINESE UNIVERSITY OF HONG KONG

Physical education (PE) finds itself trapped in a paradox in the contemporary education system and society: recognised as essential yet persistently marginalised. This precarious position is not merely practical or policy-driven but reflects deeper philosophical and cultural tensions embedded within education itself. Dominant dualistic paradigms exemplified by Western frameworks such as the Peters-Hirst and Chinese traditional cultural hierarchies like Zhong Wen Qing Wu (重文轻武, valuing the literary over the martial, physical), relegating bodily activity below propositional knowledge pursuits. These biases are further amplified by the pervasive instrumental logic of neoliberalism, which reduces education to a utilitarian enterprise geared towards economic productivity. In this vein, PE is narrowly framed as a tool for improving health outcomes and developing workforce development, neglecting its potential for embodied understanding, moral development, and social cohesion. Health-centric policies, while well-intentioned, risk reinforcing this narrow focus, transforming PE into a mechanistic and outcome-driven subject disconnected from its cultural and philosophical roots.

Reclaiming PE requires a paradigm shift, in particular, ancient Chinese thought offers a counter-narrative to the dominant neoliberal and dualistic paradigms. The Confucian principle of Shen Xin Yi Zhi (身心合一, unity of body and mind) and Daoist notions of harmony between humans and nature present a holistic understanding of the body, not as an isolated instrument but as a relational entity deeply embedded in social and ecological systems. These philosophies challenge late capitalism's disembodied logic, positioning PE as a site for embodied, relational, and transformative learning. By fostering harmony between body, society, and nature through traditional Chinese thought, PE can transcend its reductive framing, addressing existential and ecological challenges. This reconceptualisation is urgent as neoliberal reforms increasingly marginalise economically undervalued disciplines.

Further, situated in the global neoliberal context, aligning PE with roader market dynamics, such as emerging opportunities in the sports industry, may provide strategic pathways for elevating its societal status. However, these efforts must remain grounded in a philosophical commitment to preserving its intrinsic educational value. Navigating this delicate balance involves leveraging market forces to enhance PE's visibility and institutional recognition without succumbing to the commodification of its core principles. This paper advocates for reimagining PE as a discipline that integrates physical and intellectual development while promoting ecological and social awareness. By embracing its potential to cultivate embodied subjectivities and holistic well-being, PE can evolve from a marginalised subject into a vital foundation for fostering harmony in a fragmented world.

QUALITATIVE ANALYSIS OF FUNDAMENTAL MOTOR SKILL PATTERNS IN 7-YEAR-OLD CHILDREN BY SEX

FONT-LLADÓ, R., VASILEVA, F., LÓPEZ-ROS, V., JÓDAR-PORTAS, A., PRATS-PUIG, A.

UNIVERSITAT DE GIRONA

INTRODUCTION

There are sex differences in total fundamental motor skill (FMS) proficiency in children. Boys tend to be more skilled than girls overall. However, while girls generally excel in locomotor skills (LS), boys outperform them in object control skills (OCS). Furthermore, these differences gradually increase with age (1). To explain this trend, this study aimed to qualitatively analyze the fundamental motor skills patterns in 7-year-old children by sex.

METHODS: A total of 183 participants were eligible for analysis (84 boys and 87 girls; mean age: 7.41 ± 0.32 years). The CAMSA test was used to assess FMS in a dynamic environment, taking into account completion time. (2). The test evaluates: LS patterns (2-foot jumping - horizontal force, force precision; Sliding - right direction, left direction, change of direction; Skipping - hop-step pattern, alternation-swing arm; 1-foot hopping - lateral force, lateral balance), and OCS skill patterns catching; throwing - overhand precision, transfer-rotation tunk, kicking - approach and precision, elongated last stride (2). The CAMSA test was video recorded as previously described (3) to perform a qualitative analysis. The unadjusted effect of sex on the 14 binary categorical dependent variables (1 = correct, 0 = incorrect) was analysed using a comparison of two proportions via the Wald z-test for independent groups. The p-value for the two-tailed test and the effect size were measured by Cramér's V (4).

RESULTS: Regarding skill outcomes, girls performed significantly better than boys in 2-foot jumping-force precision ($p=0.030$, $ES=0.12$), and skipping-hop-step pattern ($p=0.024$, $ES=0.12$), albeit with a weak effect size. Conversely, boys performed significantly better than girls in catching ($p<0.001$, $ES=-0.24$), throwing - transfer-rotation tunk ($p<0.001$, $d=-0.31$), kicking - approach and precision ($p<0.001$, $ES=-0.24$), and kicking - elongated last stride ($p<0.001$, $ES=-0.37$) with moderate effect size, except for throwing - overhand precision ($p=0.005$, $ES=-0.37$), which exhibited a weak effect size. Among children in general, the skill outcomes with 50% or more correct performance were, in descending order of performance: 2-foot jumping - horizontal force, 2-foot jumping - force precision, kicking - approach and precision, skipping - hop-step pattern, 1-foot hopping - lateral force, catching, and kicking - elongated last stride.

CONCLUSION: The findings suggest that boys perform moderately better in the FMS patterns related to catching, throwing, and kicking. In contrast, girls perform slightly better in FMS patterns associated with jumping and running techniques. These results highlight the importance of tailored physical education programs and early sports training that focus on improving specific FMS patterns by sex.

OP-SH23 Sociology III

THE CAUSES AND GOVERNANCE OF EXTREME CHINESE TABLE TENNIS FAN CULTURE

SONG, Y., JIN, Y., WU, F.

PEKING UNIVERSITY

Table tennis, esteemed as the national sport of China, has long been a symbol of numerous glories and a focal point of extensive public attention. Nevertheless, the problem of abnormal fan culture within the table - tennis fan community has been growing more severe. During the Paris Olympics, extreme manifestations of "fandom culture" emerged. The aftereffects of these incidents still persist, triggering extensive discussions and widespread aversion in society.

The concept of the "table - tennis fandom" can be defined and classified into four distinct categories. Firstly, there are "fandom - oriented fans" who show a high level of concern for the appearance and daily lives of table - tennis athletes. Secondly, "competition - centered fans" concentrate on the technical and tactical aspects of the sport and athletes performances in competitions. Thirdly, "comprehensive fans" possess characteristics of both types. Fourthly, "bandwagon fans" are influenced by popular trends or the content on social media. The object of this study is specifically the "fandom culture" formed by "fandom - oriented fans".

Regarding the chaos in the Chinese table - tennis fandom, it is mainly characterized by several prominent issues. These include hyperbolic idolization of athletes, the "singles - supremacy" concept, the binary opposition of "exclusive love", intense data - driven rivalries, invasions of athletes privacy, and disorderly behavior during matches. By taking the interaction ritual chain as a theoretical model, this paper explores the causes of the "table - tennis fandom" phenomenon from

four essential components: group assembly, boundary - setting for outsiders, the focus of mutual attention, and shared emotions. It also examines how these factors influence the behaviors of fans and the dynamics within the fan community.

The internet serves as the primary medium for expressing social public opinion. Social network analysis can identify the crucial nodes in the information - dissemination process. These nodes are characterized by high connectivity and significant influence, and they have the ability to facilitate cross - circle communication and homogeneous information diffusion. Given the large user base of Weibo, public opinion regarding unexpected events spreads rapidly on this platform. By writing a Python - based program to crawl relevant texts for topic extraction and emotional analysis, an early - warning mechanism can be established. For negative information, different intervention measures are implemented based on its degree of deviation from the facts.

Finally, to address the chaos in the table - tennis fandom, a multi - faceted approach is proposed. This includes strengthening the construction of relevant regulations, leveraging the guiding role of opinion leaders, promoting the collaborative efforts of multiple parties, and returning to the essence of sportsmanship.

POLITICS, SPORT AND GLOBALISATION: CHINESE STRATEGY AND POLICY FOR SPORT TALENTS CROSS-BOUNDARY MOVEMENTS

LIANG, Y.

HEBEI SPORT UNOVERSITY

INTRODUCTION: The relationship between sport and politics plays a significant role in shaping and reflecting society. A comprehensive long-term sport development strategy is essential for a state seeking to realise its political objectives. This article examines how China has implemented various strategies and policies to attain sport success. Notably, it highlights the countrys efforts to attract global sports talent and foster international collaboration since the establishment of the Peoples Republic in 1949.

Methods:

To explore China's sport migrates cross-border movements the research employs Ravenstein's Push-pull Migration Law with the world-system theory of sport diffusion to combine a theoretical framework. Additionally, it also examines sport talents' self-identification over migration naturalisation issue through the lens of social identification theory in the process. The article collects premier data from a total 10 semi-structured interviews (consisting of five senior Chinese sport administrators - from the State Sport General Administration and five from relevant athletes and coaches); interview questions were designed to answer - how the sport migration trends have been shaped by state strategies and policies? Secondary data (focused on state mainstream media platforms, such as China Central Television, China Daily, State Council, etc.) to unveil the impact of state strategies and policies on its sport talents international movements.

RESULTS: International exchanges and the movement of talent encompass various dimensions that evolve and are influenced by different development strategies and policies. This evolution has shifted from a predominantly one-way flow to a more reciprocal exchange. Sports strategies and policies can be understood through push-pull factors that align with governmental interests and overarching goals. Notably, Chinas naturalization practices have transitioned from the 'jus talenti' model, which emphasizes athletes talent, to the 'jus sanguinis' model, which is based on bloodlines and heritage. This trend is expected to persist in the foreseeable future.

Discussion:

The findings highlight the practices of Chinese state governance, the strategy, and policy changes for sports development under the communist regime. Although the government has made substantial efforts to attract global sports talent, its historical perspectives and attitudes throughout this evolutionary process are overlooked. This research not only enriches the existing literature on sports migration but also sheds light on established sport migration theories as they apply to the Chinese context, enhancing the understanding of Chinas overall sports strategy. These elements are two sides of the same coin; the recent controversy illustrates the governments desire to attract global sports talents as part of its ambitious China Dream project, while simultaneously disregarding its own Nationality Law to benefit a selected elite few.

DRUG BAN INCIDENT IN CHINESE SPORTS DURING THE NEW CORONAVIRUS OUTBREAK:MEDIA REPRESENTATION OF SUN YANG'S SUSPENSION AND PATRIOTISM OF CHINA

LEI, Y.

HUAZHONG UNIVERSITY OF SCIENCE AND TECHNOLOGY

Introduction: On September 4, 2018, staff from the IDTM representing the WADA went to Sun Yangs residence for an out-of-competition doping test. Due to issues with the testing personnels qualifications, Sun Yang and his team had a disagreement with the testers. WADA believed that Sun Yangs behavior constituted "violent resistance to testing" and appealed to the CAS. On June 22, 2021, the final ruling of CAS was made, reducing Sun Yangs eight-year ban to four years and three months, which also confirmed that Sun Yang would be unable to participate in the Tokyo Olympics and the 2022 Asian Games in Hangzhou.

Methods: Based on six Chinese print medias and six western print medias from the United States, the United Kingdom, and Australia relatively from February to June, 2020 for text analysis, using the Critical Discourse Analysis (CDA) proposed by van Dijk as the research method.

Results: Chinese and Western media presented completely different ideology and positive/negative evaluation on the "Sun Yang ban incident". Western media denigrated and satirized Sun Yang's performance and personal image, emphasizing that the justice of the swimming pool had been served: (1) Position binding: FINA's "protection" of Sun Yang; (2) Historical connections: The manipulation of sports in Communist countries; (3) Rule understanding: the difference between Chinese and Western interpretation. On the contrary, Chinese media's sympathy and support for Sun Yang is determined to shape a positive image of Sun Yang as a "sunshine boy": (1) United Report: Sun Yang's suspension ruling and Sun Yang's appeal; (2) Official Voice: The support of the Chinese Swimming Association and the anti-doping efforts of the Chinese sports governing body; (3) WADA's authority: CAS's contradictory ruling.

Discussion: Under the guidance of different political backgrounds, ideologies and public opinion orientation between China and the West, the occurrence of "Sun Yang's Suspension" has reinterpreted the cognition and interpretation of Chinese competitive sports and patriotism, and arouse people's reflection and reconstruction of the relationship between competitive sports and patriotism. In China, the increasing control of the ruling party in the political, cultural, ideological, social and other fields make people more often stand in the perspective of patriotism subjective cognition issues. Chinese people generally believe that the Western media's smearing of Sun Yang is ultimately due to the prejudices and stereotypes of Westerners based on their hearts and minds. Ironically, however, this ideological perception seems to be the bias that Chinese people hold when they look at the negative coverage of Sun Yang's ban in the Western media. When the Chinese official media with the ideology of patriarchy patriotism "reproduce" Sun Yang's ban incident, the Chinese people's understanding and cognition of the incident will inevitably be marked by a profound brand of patriotism.

RUNNING CULTURE, INSCRIPTION DEVICES AND TRANSLATION: A STUDY OF "SERIOUS RUNNERS" BASED ON ACTOR-NETWORK THEORY

BI, X., HUANG, L., CHAI, J.

BEIJING SPORT UNIVERSITY

INTRODUCTION: Using smart watches and apps while running, especially in long-distance, has become a common practice among amateur runners. This practice of using technological devices for self-monitoring is conceptualized as self-tracking or the quantified self (Lupton, 2014; 2016; 2020). Bale (2004) believes that it is impossible to understand running without considering the cultural context in which running occurs, and that running needs to be studied as a body/cultural phenomenon. Based on the actor-network theory (ANT) from the perspective of sociomateriality, this study explores: (1) How are inscription devices produced and what is the circulation of inscription? (2) How is a heterogeneous actor-network of serious runners formed through the four stages of translation?

METHODS: To answer the research questions, this study conducted semi-structured interviews of approximately 60 minutes with each of 15 runners in a running club and conducted participatory observation of the club (online and offline) for more than 3 months.

RESULTS: The study firstly found that when runners use devices, they call themselves "serious runners", indicating that hardware (such as smart watches), software (such as apps) and data (monitored indicators and social media contents) are inscribed in running culture and become inscription devices, which are then circulate to runners. Inscriptions are identified as: success and victory, body aesthetics, pain/injury and health, the relationship between the body and nature, etc., and develop into "athlete identity". Secondly, through the four stages of translation (Callon, 1986), namely, problematization (the inscription devices as initiators), interessement (the desire to obtain the identity of a serious runner), enrollment (the participation of human and non-human actors) and mobilization (becoming spokespersons), various actors negotiate and eventually form a network of serious runners with the inscription of running culture as the order. This combined effect is that the running culture is maintained and inherited through the acquisition of runners' social identity.

DISCUSSION: The actor network is an alliance of human and non-human actors with common interests. After four stages of inscription and translation, an immutable serious runner actor-network is formed. Digital technology and devices, as non-human actors, are the carriers of runner inscriptions and the "necessary point of passage" (Callon, 1986) of the actor-network. Actors who take inscription as the starting point build the network. This brings a new understanding of the relationship between emerging technologies and running culture.

THE IMPACT OF THE GIG ECONOMY ON THE PROFESSIONAL DEVELOPMENT OF ATHLETES: AN EMPIRICAL STUDY BASED ON A QUESTIONNAIRE ON PERCEIVED CAREER STABILITY

MU, Y., NAZARUDIN, M.N., MA, T., JIANG, S., ZHANG, G., SUI, X., YU, M.

UNIVERSITI KEBANGSAAN MALAYSIA

INTRODUCTION: With the rapid rise of the gig economy, more and more professional athletes are trying to increase their economic flexibility through diversified income channels. This trend provides athletes with financial support and the possibility of career transformation. However, the short-term flexibility brought by the gig economy is often accompanied by income fluctuations and challenges in professional identity, especially in Asia. In this context, the impact of the gig economy on athletes' perception of career stability and how athletes can find a balance between gig work and traditional professional development have become topics worthy of research. This study aims to reveal the specific impact path of the gig economy on professional athletes' perception of career stability and analyze the main motivations for athletes to participate in the gig economy and the opportunities and challenges.

METHODS: The study focuses on how athletes view the dual impact of the gig economy on their income sources, professional time allocation, and professional identity, and explores how to optimize strategies for participating in the gig economy. Through questionnaire empirical analysis, the study strives to quantify the effects of the gig economy on athletes' career development and put forward suggestions for improving career stability and security. The study collected quantitative data through questionnaires, covering multiple dimensions. The questionnaire was distributed through athlete social media groups and local sports associations, and a total of 457 valid samples were collected, covering a variety of sports and age groups.

RESULTS: The results of the data analysis revealed the complex impact of the gig economy on the career development of athletes. The higher the proportion of gig income, the lower the perceived career stability of athletes. At the same time, some advantages of the gig economy have been verified, including the role of alleviating economic pressure and expanding career transformation opportunities. Among the main types of gig tasks, the flexibility of private lessons and online live broadcasts makes them more popular among athletes, but it has a certain negative impact on career stability due to time conflicts.

CONCLUSION: The study also found that the degree of athletes' adaptation to the gig economy is closely related to their time management ability. Athletes who can reasonably allocate their main career and gig tasks have relatively higher career satisfaction. Based on the research findings, this study puts forward several optimization suggestions. This study systematically reveals the multi-dimensional impact of the gig economy on professional athletes and expands the scope of research on the gig economy for special occupational groups. In addition, the study provides a new perspective for understanding the relationship between the gig economy and career stability and a clear direction for athletes to participate in the gig economy and related policy formulation.

Invited Symposium

IS-MH05 Effort and its perception: current knowledge and perspectives

AN EFFORTFUL TASK: DEFINING AND MEASURING PERCEPTION OF EFFORT

HALPERIN, I.

TEL AVIV UNIVERSITY

Rating of perceived effort (RPE) scales are widely used in exercise science as simple and practical tools for monitoring and prescribing exercise intensity. However, there are certain methodological challenges when using these scales due to the multiple definitions of perceived effort, and insufficient standardization in current measurement practices. In this presentation, I will address these challenges by discussing common definitions of perceived effort, highlighting their circular nature and the insufficient differentiation between perceived effort and other perceptual experiences. I will also address the varied and often conflicting instructions associated with using RPE scales, specifically focusing on two key issues: First, the lack of uniformity in instructions regarding the time domain for RPE reporting. That is, are subjects expected to rate their effort instantaneously or as a summary of the experience during the task? Second, I will cover the significant variability induced by inconsistent application of the scale's upper anchor (i.e., what 10 on a 0-10 scale signifies). I propose distinguishing between imposed and self-selected anchors, noting that inconsistent use of these could influence the ratings. To overcome these limitations, I propose two strategies: first, adopting a clear, consistent, and narrowly focused definition of perceived effort to avoid the pitfalls of existing definitions and to facilitate collaborative research across disciplines and the transferability of results beyond sports science; second, defining and standardizing the reporting of the time domain and the meaning of upper anchors when collecting and reporting RPE data. Implementing these strategies will enhance the validity of RPE measurements in exercise science and broaden their applicability in other fields.

EFFORT COST AND EFFORT AVERSION: TWO DIFFERENT PERCEPTIONS OF EFFORT

ANDRÉ, N.

UNIVERSITÉ DE POITIERS

Effort is an important part of daily life for nearly everyone. Managing effort is often a key to health and well-being, as well as to reaching goals, achieving successes, and sustaining good interpersonal relationships. In sport settings, effort is an important component of perseverance in sports training and competitive performance. Understanding the nature of effort is therefore crucial. A large part of the literature on effort claims that effort is perceived as aversive, and this would lead people to systematically avoid exerting effort or to choose the less effortful means of reaching the same goal. Yet, this principle of least effort (Hull, 1943) or principle of minimization of effort does not entail aversion: cost is enough. A parallel "principle of least money" would be that people often prefer the lower price for exactly the same item—and money is clearly a cost, not an aversion. Same with effort. Effort aversion occurs only when costs outweigh benefits. People may choose to exert effort when doing so avoids other kinds of costs such as pain or obtain meaningful reward. If effort is

perceived as a cost (rather than an aversion), it follows, however, that people do not avoid effort itself just as they do not always avoid spending money. Rather, they try to avoid the waste of effort, akin to overpaying. Positing that people avoid the waste of effort rather than effort itself can improve the understanding of how, when, and why people exert effort, indeed including even very high effort as in elite athletes. Understanding the factors influencing effort commitment can help athletes engage more efficiently. Focusing on avoidance of wasting effort removes the seeming paradox that people sometimes willingly exert high, even extreme effort. Hull, C. (1943). *Principles of behavior*. Appleton-Century.

THE NEUROPHYSIOLOGY OF PERCEPTION OF EFFORT AND ITS LINK WITH PERFORMANCE

PAGEAUX, B.

UNIVERSITÉ DE MONTRÉAL

Effort is a common experience in our voluntary behaviour, whether we are walking or running, drinking a cup of tea, imagining a movement, or engaging in cognitively demanding tasks like solving a complex puzzle. The experience of effort can be described as "the sensation of expending energy" (1), and "is accompanied by a sensation of labour, a sensation that intensifies as we increase our investment in the task" (1). The perception of effort provides information about the intensity and difficulty of the task being performed. The perception of effort is involved in the regulation of behaviour and influences how the nervous system selects a precise movement from a multitude of possibilities. Thus, the perception of effort is intrinsically linked to performance. In this presentation, I will provide an overview of the current knowledge on the neurophysiology of perceived effort and how this perception is a key determinant of physical performance. The integration of knowledge from different disciplines highlights the importance of studying effort as a perception dissociated from other perceptions we experience during physical exercise, such as pain or fatigue (2). The literature highlights the role of motor command in the perception of effort (2), particularly its corollary discharge. This corollary discharge, also named efference copy, can be defined as a copy of the central commands sent to the working muscles. The origin of the motor command also directs us to the anterior cingulate cortex (3), a key brain area at the interface of cognition, emotions, motor control, and decision-making (4). To illustrate the key role of effort and its perception in the regulation of physical performance, I will use the motivational intensity theory (5), a theoretical framework from the psychology literature used for ~ 15 years in sport science. The motivational intensity theory predicts that we maintain optimal performance in cognitive and motor tasks by increasing effort when task difficulty increases, and that performance decreases when we are no longer able or willing to invest additional effort – when task difficulty increases beyond our perceived capacity or when the value of outcomes/goals diminishes. As the physiological and psychological determinants of performance are task-specific, I will conclude by discussing how the motivational intensity theory could contribute to a better understanding of the regulation of maximal force-power-speed performance (e.g., sprint), endurance performance (e.g., time to exhaustion) and psychomotor performance (e.g., motor skills execution). MITOCHONDRIAL SUBSTRATE SENSITIVITY FOLLOWING ACUTE EXERCISE AND POST-EXERCISE RECOVERY: IMPLICATIONS TO GLYCOGEN CONTENT IN HUMAN SKELETAL MUSCLE

PETRICK, H., FUCHS, C.J.1, HERMANS, W.J.H.1, HENDRIKS, F.K.1, BELS, J.L.M.1, SENDEN, J.M.1, HOLLOWAY, G.P.2, VAN LOON, L.J.C.1

1. MAASTRICHT UNIVERSITY, MAASTRICHT, THE NETHERLANDS; 2. UNIVERSITY OF GUELPH, GUELPH, CANADA

INTRODUCTION: Muscle glycogen is an important substrate during moderate to high intensity exercise, while repletion of muscle glycogen after exercise is often prioritized during recovery. The enzymatic regulation of glycogen breakdown and resynthesis is directly impacted by cytosolic ADP and glycolytic flux. This raises the possibility that the sensitivity of mitochondria to oxidative substrates may represent an important control point in glycogen breakdown and resynthesis. We therefore examined muscle glycogen content and the sensitivity of mitochondria to ADP, pyruvate, and ketone bodies (KB) in human skeletal muscle following exercise and during prolonged post-exercise recovery with or without carbohydrate intake.

METHODS: 12 endurance-trained male cyclists (25 ± 5 y, $\text{VO}_{2\text{peak}}$: 67 ± 5 mL/kg/min) performed two test-days in a randomized cross-over design. On both test-days, a standardized glycogen depletion protocol was performed on a cycle ergometer in a fasted state. The protocol lasted 125 ± 13 min and 124 ± 14 min, consisting of 2 min blocks alternating between high and low intensity cycling. During the subsequent 12 h of post-exercise recovery, participants either remained fasted or consumed 10 g/kg body mass carbohydrate (CHO). Muscle biopsies were obtained from the vastus lateralis before and after exercise, and following 6 and 12 h of post-exercise recovery. Mitochondrial respiration and substrate sensitivity were measured in permeabilized muscle fibres using an Oroboros O2k Oxygraph. Muscle glycogen content was determined in freeze-dried whole muscle homogenate. Data were analyzed using a one-way repeated-

measures ANOVA with Tukey's post-hoc tests. Statistical significance was set at $P < 0.05$. All data are expressed as mean $\pm$ SD.

RESULTS: Following exercise, mitochondrial ADP sensitivity decreased $\sim 15\%$ on both trials ($P < 0.008$), correlating ($r = -0.587$, $P = 0.045$ fasted day; $r = -0.568$, $P = 0.054$ CHO day) with the extent of glycogen depletion during exercise. On the post-exercise fasted trial, mitochondrial ADP sensitivity returned to baseline after 6 h of recovery, but decreased once again after 12 h of post-exercise fasting ($\sim 15\%$ decrease, $P = 0.037$). Pyruvate sensitivity increased following exercise and declined with post-exercise fasting. However, neither pyruvate nor ADP sensitivity were altered during post-exercise recovery when consuming CHO. Furthermore, there were no relationships between changes in mitochondrial substrate sensitivity and muscle glycogen repletion during post-exercise recovery with CHO ingestion. Regardless of exercise, fasting, or CHO ingestion, KBs contributed minimally to respiration at all time-points ($\sim 2\text{--}6\%$ of maximal complex I+II-linked respiration).

CONCLUSION: Combined, the exercise-induced decrease in mitochondrial ADP sensitivity may be a mechanism promoting glycogen utilization during exercise. However, changes in mitochondrial substrate sensitivity do not appear to relate to glycogen resynthesis during post-exercise recovery when carbohydrates are ingested.

CHANGES IN NITRATE AND NITRITE CONCENTRATION IN SALIVA, BLOOD AND SKELETAL MUSCLE AFTER STEP REDUCTION AND RETRAINING

PORCELLI, S., MARCIANO, A.1, BLACK, M.I.2, GIUSTI, L.1, BUZZACHERA, C.F.3, VANHATALO, A.2, JONES, A.M.2

UNIVERSITY OF PAVIA

INTRODUCTION: Physical deconditioning has been shown to impact main conduit arteries and decrease post-occlusion hyperemic leg blood flow response, although findings vary depending on the duration and model of disuse (1,2). Endothelial nitric oxide (NO) release following a shear stress stimulus is a key mediator of vasodilatation, facilitated by the sequential conversion of nitrate (NO_3^-) to nitrite (NO_2^-) to NO (3). This study aimed to evaluate the effects of 14 days of step count reduction and subsequent retraining on nitrate and nitrite in different body compartments and skeletal muscle microvascular responsiveness.

METHODS: We recruited 16 ($n=8$ women) young, healthy, normally active participants. After baseline (BDC) data collection, they underwent 14 days of step reduction (SR; 1500 steps/day) followed by a retraining (RT) period incorporating endurance and strength exercises. Measurements were performed at BDC, post-SR, and post-RT. Resting diastolic (DBP) and systolic (SBP) blood pressure were assessed at each time point. Microvascular post-occlusive reactive hyperemia in the vastus lateralis muscle was assessed by near-infrared spectroscopy. During the 30 s post-ischemia, the rate of change in tissue oxygenation index (Slope 2) was calculated. Saliva, blood, and vastus lateralis muscle samples were collected and NO_3^- and NO_2^- concentrations were determined by chemiluminescence. One-way repeated measures ANOVA and post-hoc tests were used to determine differences in the investigated variables.

RESULTS: Daily step count was reduced by 82% during SR and increased with RT, but did not return to baseline (8429 ± 1659 , all $p < 0.001$). At BDC, DBP and SBP were 79 ± 5 mmHg and 122 ± 9 mmHg, respectively, and they did not change at any time points ($p = 0.12$). Slope2 decreased from BDC to SR ($1.40 \pm 0.69\% \cdot \text{s}^{-1}$ vs. $1.00 \pm 0.29\% \cdot \text{s}^{-1}$; $p < 0.01$) and partially recovered in RT ($1.03 \pm 0.51\% \cdot \text{s}^{-1}$; $p = 0.04$). At BDC, saliva [NO_3^-] and [NO_2^-] were 608 ± 253 μM and 102 ± 50 μM , respectively, with no changes across time ($p = 0.29$). Plasma [NO_3^-] was not affected by the interventions. Plasma and muscle [NO_2^-] significantly increased from BDC (115 ± 42 nM and 1.2 ± 0.3 nmol $\cdot\text{g}^{-1}$) to SR (160 ± 74 nM and 1.6 ± 0.8 nmol $\cdot\text{g}^{-1}$, all $p < 0.03$), and they partially recovered after RT. Muscle [NO_3^-] decreased ($-37 \pm 3\%$) at SR.

CONCLUSION: Fourteen days of SR impaired hypoxic vasodilation at the microvascular level without affecting resting blood pressure. While salivary nitrate-nitrite metabolism did not change, plasma and muscle nitrite concentrations increased during SR, and muscle nitrate content decreased, possibly reflecting a compensatory mechanism related to impaired endothelial NO production. Retraining partially restored NO metabolite distribution across body compartments.

ACUTE EFFECTS OF EXERCISE ON TOTAL CREATINE CONCENTRATIONS IN MULTIPLE HUMAN BRAIN REGIONS

PRATT, J., MUNDELL, O., HENTHORN, L., KENNERLEY, A., SALE, C.

MANCHESTER METROPOLITAN UNIVERSITY

INTRODUCTION: Creatine is well-known for supporting skeletal muscle function during periods of high-intensity exercise, through the rapid provision of high-energy phosphates. Despite growing interest in the role of creatine in supporting brain health, evidence of the response of creatine concentrations in the brain, to exercise, is limited. We aimed to determine the response of total creatine concentrations (tCr) in multiple brain regions to an acute bout of vigorous exercise in humans.

METHODS: Nine healthy adults aged between 23 and 30 years [6 female, age (mean $\pm$ SD) = 26.3 ± 2.8 years; body mass index = 22.7 ± 2.5 kg/m ^{2}] completed a graded cycle ergometry test lasting ~ 15 minutes and reaching $\sim 85\%$ of predicted heart rate maximum. Single-voxel proton magnetic resonance spectroscopy (1H-MRS; 20mm ^{3} voxel) was acquired at 3T on a Siemens MAGNETOM VIDA from the visual cortex and frontal cortex before (PRE), 15- (POST15) and 30-minutes (POST30) after exercise. Multi-voxel 2D proton chemical shift imaging (1H-CSI; 80mm ^{2} grid, 15mm slice thickness) was also

acquired across the midbrain PRE and 25-minutes after exercise (POST25, taken between repeated 1H-MRS measurements). OSPREY was used to determine tCr concentrations from 1H-MRS data and TARQUIN was used to examine tCr resonance signals from 1H-CSI data. Voxel tissue fractions and relocalisation accuracy were assessed. One-way repeated measures ANOVAs and paired t-tests were used to test for exercise-induced changes in tCr.

RESULTS: Following an acute bout of exercise, tCr concentrations decreased by 9.8% in the frontal cortex by POST15 (6.27 vs 6.95 mmol/L, $p < 0.001$), and remained significantly lower (by 5.2%) than PRE levels at POST30 (6.59 vs 6.95 mmol/L, $p < 0.001$), although there were signs of a gradual return to baseline concentrations. Multi-voxel 1H-CSI revealed that, overall, tCr resonance signals were significantly lower (by 8.7%) across the midbrain at POST20 compared with PRE levels (area under curve = 808.01 vs 737.80 a.u., $p = 0.044$), although region specific responses were shown. No significant responses to exercise were shown in the visual cortex at any timepoint (tCr concentrations = 7.84 vs 7.67 vs 7.81 mmol/L at PRE, POST15 and POST30; all $p > 0.05$).

CONCLUSION: tCr concentrations in certain regions of the young adult brain are dynamic and respond acutely to exercise, demonstrating the reliance of the brain, on creatine, for energy provision during high-intensity activity. From a broader, methodological perspective, our data highlight the importance of considering external factors, such as prior exercise, in standardisation protocols for repeated MRS studies of creatine concentrations in the human brain. Determining the response of creatine concentrations in brain to other types of exercise and, indeed, other stimuli, could provide additional insight into the dependence of the brain on creatine during periods of increased metabolic demand, supporting the development of therapeutic strategies to support brain function.

CHANGES IN LACTATE CONCENTRATION DO NOT PREDICT CHANGES IN FAT OXIDATION THROUGHOUT A TRAINING SEASON

BENÍTEZ, J., MURIAS, J.M., FLEITAS-PANIAGUA, P.R., CUPEIRO, R.

LFE RESEARCH GROUP. FACULTY OF PHYSICAL PHYSICAL ACTIVITY AND SPORT SCIENCE.

INTRODUCTION: Capillary lactate concentration [La-] presents a strong inverse correlation with fat oxidation (FatOx) across individuals with different metabolic characteristics (1). This has led to the suggestion that [La-] alone could be an effective way to assess changes in FatOx at different points through a training season. Hence, the aim of the present work was to determine whether changes in [La-] at two different points during a training season would allow to predict changes in FatOx.

METHODS: Fifteen males (76 ± 6.7 kg, 180.7 ± 8.3 cm, 60 ± 6.1 ml/kg/min) and eleven females (62.2 ± 4.6 kg, 164.8 ± 5.7 cm, 49.5 ± 3.9 ml/kg/min) performed a step incremental exercise test on a cycle ergometer at two points of the training season (spring and autumn). The test began at 50 W, followed by increments of 30 W for males and 25 W for females every 2 minutes until task failure. [La-] was measured during the final 30 s of each step and immediately after task failure, while mean FatOx during the last minute of each stage was estimated using indirect calorimetry. For each individual, Pearson's correlation was used to determine the relationship between [La-] and FatOx during the step incremental exercise test at each time of the training season. Subsequently, the difference in [La-] (Δ [La-]) and FatOx (Δ FatOx) between the two points of the training season at each power output during the step incremental test was calculated. Pearson's correlation was also used to determine the relationship between the changes in Δ [La-] and Δ FatOx.

RESULTS: [La-] was strongly and inversely associated with FatOx at both points of the training season in males (-0.812 ± 0.12 , range: -0.973 , -0.534) and females (-0.887 ± 0.101 , range: -0.968 , -0.521). Conversely, widely variable correlations were determined for the relationship between Δ [La-] and Δ FatOx in males (-0.236 ± 0.524 , range: -0.751 , 0.973) and females (-0.397 ± 0.478 , range: -0.866 , 0.65).

CONCLUSION: Assessing [La-] alone might be considered as an effective way to indirectly assess FatOx at specific points throughout the training season due to the strong agreement between these two variables. However, changes in [La-] do not predict changes in FatOx as the training season progresses. Thus, caution should be taken when trying to use [La-] as predictors of FatOx.

THE PREVALENCE OF REDS INDICATORS IN MALE ATHLETES

IHALAINEN, J.K.1,2, KOMONEN, R.2, MIKKONEN, R.1,3

1> FACULTY OF SPORT AND HEALTH SCIENCES, UNIVERSITY OF JYVÄSKYLÄ, FINLAND 2> FINNISH INSTITUTE OF HIGH PERFORMANCE SPORT KIHU, JYVÄSKYLÄ, FINLAND 3> SPORTS TECHNOLOGY UNIT VUOKATTI, FACULTY OF SPORT A

INTRODUCTION: There is a significant gap in evidence-based knowledge and attention to problematic LEA and REDs in male athletes although it has been recognized that male athletes experience hormonal, body composition, sexual and psychological changes when they are underfuelled.1 Given the need for further research, we investigated primary REDs indicators in male athletes competing in weight-sensitive and non-weight-sensitive sports and examined their relationship with sex drive.

METHODS: Seventy-nine national- and international-level male athletes (23.6 ± 3.9 years) participated during the preparatory season. Athletes were categorized into weight-sensitive (WS, $n=61$) and non-weight-sensitive (S, $n=18$) groups. The REDs indicators used in this study included low testosterone concentration, low blood free triiodothyronine concentration,

history of bone stress injury, low bone mineral density (Z-score <-1) at the lumbar spine analysed by Dual-energy X-ray absorptiometry (Lunar Prodigy Advance), and an elevated score for the EDE-Qs (eating disorder examination questionnaire short). The participants were divided into groups based on risk of REDs: no-risk (0 indicators), risk (≥ 1 indicators). Sex drive was assessed using the Low Energy Availability in Males Questionnaire. The differences of the points between groups were analysed with Mann-Whitney U Test and the differences of prevalence were tested Chi-Square Tests (SPSS 28.0.0).

RESULTS: REDs indicators were observed in 31% of participants. The prevalence of the indicators of REDs was significantly higher in WS compared to S ($p < 0.01$; 34% vs. 22%), driven by lower testosterone and higher bone stress injury rates in WS athletes. However, sex drive scores did not differ between no-risk and at-risk groups.

CONCLUSION: These findings highlight the need for increased research and support for male athletes at risk for REDs across all sports. While libido and morning erections may not be reliable indicators of REDs in a single measurement, their potential usefulness in longitudinal monitoring warrants further investigation.

Invited Symposium

IS-PN05 Effects of environmental heat stress on human performance and health across the lifecourse

ARE CHILDREN AT A THERMOREGULATORY DISADVANTAGE WHEN EXERCISING IN THE HEAT?

PÉRIARD, J.

UNIVERSITY OF CANBERRA

Global surface temperature is projected to increase by 3 to 5°C by 2100, along with the frequency, severity, and duration of life-threatening heatwaves. These changes in climate will present a significant challenge to human thermoregulation, especially in those with greater vulnerability to extreme heat. Historically, children have been suggested to have an underdeveloped sweating response (i.e. lower maximal sweat rate) and different regional sweat patterns to adults, increasing their vulnerability to hyperthermia during exercise under heat stress, wherein sweat evaporation is the primary avenue for heat loss. Biological sex and maturation have also been suggested to affect sweating during exercise in response to physiological changes that occur during puberty in males (i.e. elevated testosterone), as well as a greater sweat gland output in adult males relative to females and prepubertal boys. However, isolating the independent effect of sex and/or maturation on the sudomotor response to exercise is complex due to differences in physical and physiological characteristics between individuals. Indeed, previous research that has reported differences in thermoregulation between sexes or with maturation is often confounded by body size, aerobic fitness and body composition differences between participants. Few studies have addressed these confounding factors when comparing the sweating response and change in core temperature between boys and girls, and children and adults, to determine if children are truly at greater risk of exertional heat illness. This presentation will therefore: 1) contextualise the current understanding of age and biological sex-related differences in the sudomotor response and change in core temperature (i.e. risk of hyperthermia) during exercise in the heat, 2) highlight the importance of biophysical factors when comparing independent groups, and 3) present recent research findings demonstrating that children did not have a lower sweating capacity and greater vulnerability to heat stress than adults. Following the presentation, the audience (e.g. sports scientists, sports medicine physicians, allied health professionals) will have a better appreciation of the confounding effects of morphological differences and metabolic heat production on thermoregulatory sweating in compensable and uncompensable conditions; understand how to investigate the change in core temperature, whole-body sweat rate and local sweat rate when comparing independent groups; learn that active adolescents demonstrate thermal and cardiovascular heat adaptations following summer that are commensurate to those of adults; and that children are not at a thermoregulatory disadvantage. Ultimately, the content of the presentation will allow for the audience to better discern the impact environmental heat stress on performance and health in young athletes.

BLOWING HOT AIR – IMPACT OF ENVIRONMENTAL HEAT STRESS ON RESPIRATORY HEALTH AND PERFORMANCE

KIPPELEN, P.

LIVERPOOL JOHN MOORES UNIVERSITY

Changes in pulmonary function and ventilatory responses to exercise do occur when humans are exposed to environmental heat, yet airflow and ventilatory variables are under-reported in the literature and sport scientists often under-appreciate the consequences of heat-related respiratory changes. Further, coaches, support staff and athletes themselves often neglect the risk of bronchoconstriction associated with exercise in the heat (despite asthma/exercise-induced bronchoconstriction being the number one chronic medical condition in children and elite athletes). The aim of this presentation is to raise awareness within the sporting community of the significant changes happening to human lungs during prolonged exposure to environmental heat. In this presentation, we will first consider the influence of ambient temperature and humidity on the air conditioning process and exercise-induced bronchoconstriction. One of the primary functions of the lungs is to bring inhaled air to 37°C and 100% humidity before it reaches the alveoli. Exposure to hot environmental

conditions minimises conditioning requirements, thereby limiting thermal and osmotic stress within the airways. In children and young adults (incl. athletes) with asthma, breathing hot humid air (up to 37°C) during exercise has therefore been shown to be beneficial, i.e. reducing risk and severity of osmotic/inflammatory-driven bronchoconstriction. However, when outdoor temperature rises above 39°C, negative consequences may arise – i.e., those suffering from asthma are likely to develop (cholinergic-mediated) reflex bronchoconstriction. Beside bronchoconstriction, humans face another respiratory challenge during uncompensable heat stress – i.e. when core temperature rises, humans start spontaneously to hyperventilate. Through excess removal of carbon dioxide, hyperventilation disturbs acid-base balances and reduces cerebral perfusion and oxygenation. Whether hyperthermic-hyperventilation limits exercise performance remains however a matter of debate. Finally, during prolonged heat exposure, humans often get dehydrated. Under controlled laboratory conditions, we previously demonstrated that acute dehydration causes small airway impairment, and that rehydration reverses this impairment. We will therefore reflect on the biological plausibility of heat-induced dehydration to contribute to the high burden of morbidity and mortality from respiratory illnesses (particularly apparent in older adults) during heatwaves. Following this presentation, the audience will be able to: differentiate between hot and cold air-induced bronchoconstriction; consider implications of environmental conditions for exercise-induced bronchoconstriction treatment; recognise the multiple physiological consequences of heat-related respiratory changes; and better account for respiratory changes in the design of temperature-controlled laboratory-based experiments.

ELEVATED HEAT RISK IN OLDER HUMANS – WHAT CAN BE DONE ABOUT IT?

CRANDALL, C.

UNIVERSITY OF TEXAS SOUTHWESTERN MEDICAL CENTER

Cutaneous vasodilation and sweating are the primary mechanisms by which humans maintain body temperature within a relatively narrow range. However, should heat gain (e.g., exercise and/or environmental heat exposure) exceed the capacity of these heat loss mechanisms to dissipate the heat, body temperature will progressively rise, culminating in a heat-related injury or death. In parallel with the elevations in global temperatures, the number of individuals 65+ years is escalating. Thus, a greater number of older individuals will be exposed to progressively higher environmental temperatures, including more frequent and intense heatwaves, over the ensuing decades. Notably, older individuals are at a greater risk for heat-related injuries and death, likely due (in part) to age-related reductions in the aforementioned heat dissipating capabilities coupled with cardiovascular limitations. Given that background, the objectives of this presentation are to: 1) provide a comprehensive review on the effects of aging (65+ years) on thermoregulatory function and associated cardiovascular stress during extreme heat exposure, 2) provide insight on the mechanisms responsible for the greater heat-related risk in older individuals, and 3) present research findings on possible low-energy demand heat mitigation strategies to reduce the risk of heat-related injuries/death in older individuals exposed to extreme heat conditions. Upon the conclusion of the presentation the audience will have a greater understanding of how humans regulate body temperature during extreme heat conditions; will understand that in older adults impaired cutaneous vasodilation and sweating, coupled with cardiovascular limitations, are the primary mechanisms responsible for their greater risk for heat related injuries/death; and will learn about low-energy cooling approaches that can reduce excessive rises in core and skin temperatures for older adults facing extreme heat conditions. The provided information will be directed to an audience having a limited understanding of human thermoregulation and cardiovascular function.

IMPROVING ENDURANCE PERFORMANCE ASSESSMENT. CAN PEAK OXYGEN UPTAKE BE ASSESSED IN TIME TRIALS AND CRITICAL POWER TESTS?

WAGNER, J., BRUGGISSER, F., SCHOCH, R., INFANGER, D., NIEMEYER, M., SCHMIDT-TRUCKSÄSS, A., KNAIER, R.

UNIVERSITY OF BASEL

INTRODUCTION: Work efficiency, critical power, and cardiorespiratory fitness are the key determinants in assessing endurance performance. Cardiorespiratory fitness is commonly measured as the highest oxygen uptake (VO₂peak) during an incremental ramp test (RT). However, such protocols provide limited insight into sport-specific performance parameters. In contrast, Time Trials (TT) provide insight into pacing and aerobic capacity while critical power or short-duration All Out Tests (AOT) provide data on anaerobic work capacity, peak power, and fatigue index. Protocols that capture such performance parameters as well as VO₂peak would thus improve endurance performance assessment and increase testing efficiency. Previous studies have thus compared VO₂peak achieved during RT with TT and/or AOT. However, most studies used group mean comparisons using t-test or correlation analyses which are clearly not suitable to evaluate validity of a method. Those few studies correctly using Bland-Altman analyses, however, did not pre-specify an acceptable range which is essential for subsequent interpretation.

METHODS: Two studies were conducted. First, 18 males and 13 females well-trained endurance athletes performed two RT and two 4-minute TT on four different days, while measuring gas exchange parameters with a metabolic cart. In the second study, 23 males and 17 females semi-professional and professional athletes performed one RT followed by a 3-

minute AOT with an intervening 20-min recovery. The a priori defined tolerance limits for delta-VO₂peak between the exercise tests was set to ± 0.13 L/min (approximately $\pm 3.3\%$). This value derived from the day-to-day variation in VO₂peak measured in a previous study [1].

RESULTS: Participants' mean (standard deviation) age (years) was 23 (4) years in the first and 30 (4) years in the second study. The mean differences when comparing the first RT with the first TT and comparing the second RT with the second TT were 0.02 L/min ($p=0.93$) and 0.03 L/min ($p=0.87$), respectively, which indicates no significant differences as presented in previous studies. However, the respective tolerance limit for these comparisons were -0.35 to 0.31 L/min and -0.36 to 0.42 L/min and thus outside of the a priori defined limit. Likewise, for the comparison of RT and AOT the mean difference was 0.08 L/min ($p=0.64$), but the tolerance limit was -0.42 to 0.58 L/min. The respective Lin's concordance correlation coefficient for RT VO₂peak was 0.98 (95% CI: 0.96 to 0.99) for TT, and 0.95 (95% CI: 0.92 to 0.97) for AOT.

CONCLUSION: The TT and AOT show limited agreement with RT VO₂peak. However, considering the lack of systematic deviations in VO₂peak and the determination of further performance parameters emphasize the potential value of incorporating VO₂peak measurements during TT and/or AOT for investigating aspects of performance.

EFFECTS OF CORE STRENGTH TRAINING ON MAXIMAL TRUNK MUSCLE STRENGTH AND CYCLING ECONOMY IN FEMALE MOUNTAIN BIKERS

BLECHSCHMIED, R., GRANACHER, U., STRAHLER, J.

UNIVERSITY OF FREIBURG

INTRODUCTION: Performance in cross-country mountain biking (MTB) is primarily determined by athletes' aerobic capacity. However, with the reduction of race duration to 80 minutes, anaerobic capacity, along with muscle strength and power gained importance as key performance determinants. Adequate trunk muscle strength (TMS) is needed in MTB to facilitate force transfer between the lower and upper extremities, particularly during the start, inclines and finish sprints. There is preliminary evidence indicating that TMS training of the global, large and superficial trunk muscles can improve cycling economy (CE). Here, we examined the effects of global TMS training on TMS and CE in MTB athletes.

METHODS: Twenty-four female trained (Tier 2-3) mountain bikers aged 14-22 years participated in this study. They were paired by age and randomly assigned to a TMS training or an active control (CON) group. The training took place during the off-season, lasted for eight weeks with three weekly sessions. While TMS performed 30 minutes of TMS training targeting the global trunk muscles, CON did their regular upper- and lower-body strength training excluding trunk muscle exercises. Both groups had similar training volumes. Pre- and post-training, maximal isometric TMS and TMS endurance for ventral, dorsal and lateral trunk muscles were tested. Physiological CE (i.e., O₂/CO₂ per min/kg) and mechanical CE (e.g., lateral oscillations of the bike frame, torque effectiveness during pedalling) were assessed while performing a MTB race-course simulation for twelve minutes on a 3x5-m treadmill.

RESULTS: Group-by-time interactions were found for maximal isometric flexor ($p<0.0001$, $d=1.1$) and extensor ($p<0.0001$, $d=1.7$) TMS. Post-hoc tests revealed greater improvements for flexors ($p<0.001$, $d=2.2$, +32.2%) and extensors ($p<0.001$, $d=2.0$, +28.4%) following TMS training. Interaction effects were also observed for lateral TMS endurance ($p=0.03$, $d=0.47$), with post-hoc tests indicating greater progress in the TMS group ($p=0.03$, $d=0.74$, +18.2%). For mechanical CE, an interaction effect was found for bike oscillation ($p<0.001$, $d=0.8$) in favour of the TMS group ($p=0.01$, $d=0.9$, -24.4%).

CONCLUSION: TMS training improved maximal isometric flexor and extensor TMS, lateral TMS endurance and mechanical CE. Off-season global TMS training is a suitable recommendation for female MTB athletes.

PHYSIOLOGICAL ADAPTATIONS FOLLOWING REPEATED SPRINT TRAINING WITH VOLUNTARY HYPOVENTILATION: COMPARISON WITH THE TRAINING IN HYPOXIA

IMAI, A., YAMAGUCHI, K.2, GOTO, K.2

1 ASICS CORPORATION; 2 RITSUMEIKAN UNIVERSITY

INTRODUCTION: Repeated sprint training in hypoxic conditions has been shown to improve repeated sprint ability (RSA). Moreover, repeated sprint training with voluntary hypoventilation at low lung volume (VHL) is gaining attention as an alternative method for establishing a hypoxic environment in the body. Training with VHL has previously demonstrated a further increase in RSA compared to the same training with normal breathing [1]. However, a direct comparison between "repeated sprint training in hypoxia" and "repeated sprint training with VHL" has not yet been conducted. The purpose of the present study was to compare the training adaptations between "repeated sprint training with VHL" and "repeated sprint training in hypoxia".

METHODS: Twenty-four healthy, physically active males (age, 21.9 ± 0.4 years; height, 172.9 ± 1.2 cm; weight, 71.0 ± 21.9 kg) performed repeated cycling sprints (two sets of $6-8 \times 6$ -s maximal sprints with 24-s rest periods between sprints) twice per week for three weeks (six sessions in total). Subjects were randomly assigned to one of three different groups: (1) training in normoxia with normal breathing (NOR group; 23°C, $FiO_2 = 20.9\%$), (2) training in hypoxia with normal breathing (HYP group; 23°C, $FiO_2 = 16.4\%$), or (3) training in normoxia with breath holding (VHL group; 23°C, $FiO_2 = 20.9\%$). Before and after the training periods, subjects performed RSA test (12×6 -s maximal sprints with 24-s rest periods between sprints) and maximal oxygen uptake (VO₂max) test. Power output, systemic oxygen uptake, and cardiac function were monitored during the training and performance tests. Muscle oxygenation variables in vastus lateralis and respiratory muscles were also evaluated using near-infrared spectroscopy.

RESULTS: Over six training sessions, the minimum arterial oxygen saturation was significantly lower in the VHL and HYP than in the NOR (VHL: $84.8 \pm 1.6\%$, HYP: $82.8 \pm 1.0\%$, NOR: $92.1 \pm 0.7\%$, $P < 0.05$). Peak power output and mean power output did not differ significantly among the groups ($P > 0.05$). In the VHL, cardiac output (including the 24-s recovery between sprints) was significantly increased in session 6 compared with session 1 ($P < 0.05$), but not in the HYP and NOR ($P > 0.05$). Power output during RSA test was significantly increased in the VHL and HYP (VHL: 575 ± 21 W vs. 659 ± 30 W, $P < 0.05$; HYP: 604 ± 26 W vs. 671 ± 35 W, $P < 0.05$), whereas the NOR did not show significant changes after the training period (592 ± 32 W vs. 623 ± 30 W, $P > 0.05$). Additionally, $VO_{2\max}$ during the incremental pedaling test was significantly increased in the VHL ($P < 0.05$), but not in the HYP and NOR ($P > 0.05$).

CONCLUSION: Three weeks of repeated sprint training with VHL and repeated sprint training in hypoxia caused comparable decreases in arterial oxygen saturation during the training session and enhanced RSA performance. Furthermore, the increase in $VO_{2\max}$ observed after the training with VHL suggests that the physiological mechanisms for enhancing RSA may differ from those of hypoxic training.

PHYSIOLOGICAL RESPONSES TO DIFFERENT CYCLING CADENCES

YANG, C., TAI, J., CHEN, J., CHEN, Y., CHANG, Y., HUANG, C., HUANG, T.

NATIONAL CHENG KUNG UNIVERSITY

INTRODUCTION: Since the 21st century, professional cyclists comprehensively increase their pedaling cadence from 80 rpm to 90-100 rpm or higher. The physiological impacts caused by different pedaling cadences have not been well investigated.

This study aims to investigate how different pedaling cadences during cycling influence various physiological indices, including excess post-exercise oxygen consumption (EPOC), oxygen debt during cycling, gross efficiency, respiratory exchange ratio (RER) and power output.

METHODS: Amateur road cyclists ($n=20$ for men female) aged from 20 to 65 were recruited. Each participant completed two cycling tests, which were a standard functional threshold power test and a multiple-cadence test. Three days after the FTP test, all participants were required to ride a protocol consisting of continual trials with different gear ratios but consistently at an intensity of 95% personal FTP. Based on the personal selected gear ratio, seven different gear ratios were set, which would lead to different pedaling cadences (ranging from 65 to 115 rpm). Each trial consisted of a 3-minute ride followed by a standardized 3-minute rest period with low power output pedaling. Throughout the multiple-cadence test, various physiological indices of respiration, power output, and cadence were measured. Repeated measure of one-way ANOVA was used for data analyses ($\alpha = .05$).

RESULTS: For maintaining consistently power output at 95% personal FTP, pedaling at lighter gear ratios (lower pedaling torques) were associated with increased cadence the self-selected gear ratio was associated with a lower oxygen debt as well as lower EPOC. In contrast, pedaling at gear ratios with higher cadence demonstrated a higher oxygen debt and higher EPOC. In addition, with the increase of pedaling cadence, RER showed similar trends suggesting a shifting of macro-nutrients resources for energy metabolism. Gross efficiency showed a downward trend while the pedaling cadence increased.

CONCLUSION: For a 3-minute cycling pedal, relative lower pedaling torque accompanied by higher cadence might lead to a higher energy expenditure. However, lower pedaling cadence associated muscular loading might be a concern for long term cycling. Investigation regarding a balance between pedaling cadence and torque would be interesting for the practical applications in recreational as well as professional cycling.

COMPARISON OF DYNAMIC STABILITY BASED ON RIDING TIME AND SADDLE HEIGHT DURING CYCLING

YOON, S., KIM, D.1, KANG, J.1, PARK, S.1, RYU, S.1, LIM, H.S.2

1. KOREA NATIONAL SPORT UNIVERSITY 2. SEOKYEONG UNIVERSITY

INTRODUCTION: Research on finding the optimal saddle height for cycling has been continuously conducted since Hamley & Thomass inseam method (1) in 1967. The optimal saddle height is a crucial factor in preventing knee injuries and enhancing athletic performance during prolonged pedaling (2). Since cycle pedaling requires continuous coordination between lower extremity joints, it has been reported that consistent movement of lower extremity joints is essential (3). However, previous studies on cycling dynamic stability has focused on evaluating heart rate variability, pedaling time, and force, whereas studies comparing the variability of lower extremity movements based on optimized saddle height remain insufficient. Therefore, the purpose of this study was to analyze the effect of differences in saddle height and riding time on the dynamic stability of lower limb joints during pedaling.

METHODS: Total of 11 elite university cyclists (height: 174.2 ± 6.9 cm, weight: 67.4 ± 8.7 kg) participated in this study. The experiment was conducted over three days, with each day participant cycling for 60 minutes at randomly selected one of three different saddle heights. The cycling intensity was set at 3 watts/kg in this study. A three-dimensional motion analysis with eight infrared cameras (sampling rate: 200 Hz) was performed. A two-way RM ANOVAs between saddle heights and riding time were performed.

RESULTS: As cycling duration increased, the variability of knee joint angles also increased ($p < .05$). Post hoc analysis revealed that saddle heights of 106% and 108% showed the greater variability compared to 110%. Among the saddle heights, the 108% exhibited greater variability than both 106% and 110%. A significant interaction effect between cycling

duration and saddle height was observed ($p < .05$). Over time, the 110% saddle height showed less variability compared to the 106% and 108% saddle heights.

CONCLUSION: The results of this study indicate that, even as cycling duration increased, the 110% saddle height maintained a consistent lower limb joint movement pattern. Therefore, in competitive elite cyclists, a saddle height of 110% of inseam length may contribute to consistent pedaling and more efficient cycling performance.

OP-BM06 Rate of Force Development

ARTIFICIALLY-INDUCED SILENT PERIOD BY TMS INCREASES RATE OF TORQUE DEVELOPMENT IN SUBSEQUENT BALLISTIC CONTRACTIONS OF THE ANKLE DORSIFLEXORS.

RUGGIERO, L., HIERETH, F.C., ŠKARABOT, J., OßWALD, M., DEL VECCHIO, A., GRUBER, M.

UNIVERSITY OF KONSTANZ

INTRODUCTION: Explosive strength is a key neuromuscular capability, measured as the rate of torque development (RTD) from a muscle group (1). In ballistic contractions, faster motor units recruitment and higher discharge rates are associated with higher RTD (2). The presence of a pre-contraction silent period, defined as the absence of muscle activity and motor units firing prior to contraction onset, leads to higher discharge rates and increased RTD (3). However, the role of the synchronisation of descending drive after the silent period in improving RTD remains debated, with lacking experimental evidence. In this study, we artificially silenced descending neural drive to motor units and thereafter synchronised it by using transcranial magnetic stimulation (TMS) before the onset of ballistic contractions. We hypothesized that explosive efforts preceded by TMS would exhibit higher RTD, muscle activity, and motor units discharge rate, compared to control contractions.

METHODS: Nine participants performed 6 sets of 2 isometric ballistic ankle dorsiflexions (2 min rest between sets), separated by 20 s. Muscle activity of the tibialis anterior was recorded with high-density electromyography (EMG). Participants were instructed to contract as fast as possible when hearing the TMS discharge after a countdown. In the first contraction (w/SP), TMS was used (at rest) to induce a corticospinal silent period overlapping with the reaction time of the ballistic effort. For this reason, the TMS output was set up to induce a silent period recorded from tibialis anterior of ~180 ms during isometric contractions at 20% maximal voluntary contraction (MVC) torque. In the second condition (w/oSP), the TMS discharge sound was triggered, but no silent period was elicited. The order of w/SP and w/oSP was alternated between sets.

RESULTS: Reaction time (TMS trigger to EMG onset) was longer w/SP (172 ± 31 ms) than w/oSP (112 ± 29 ms; $P < 0.01$). Root-mean-square of the EMG 0-50, 0-100, and 0-150 ms from onset was higher w/SP (129 ± 74 , 94 ± 43 , and 63 ± 33 %, respectively; $P < 0.01$). Peak RTD (in a 30 ms-window, divided by MVC torque) was 22 ± 9 % higher w/SP than w/oSP (8.5 ± 2.0 vs. 7.0 ± 1.9 MVC torque/s; $P < 0.01$). The discharge rate of motor units (average from the first four discharges) was higher w/SP than w/oSP (62 ± 15 vs. 56 ± 11 Hz; $P < 0.01$).

CONCLUSION: By silencing corticospinal excitatory neurons in the primary motor cortex before ballistic efforts, and by delaying and synchronising descending neural drive, higher discharge rate of motor units and RTD was achieved. These findings highlight the simultaneous role of the silent period and following synchronised neural drive to motoneurons for muscle rapid force production.

MOTOR UNIT ACTIVITY AND MUSCLE CONTRACTILE PROPERTIES DURING RAPID CONTRACTIONS IN LONG-TERM RESISTANCE-TRAINED, ENDURANCE-TRAINED AND UNTRAINED INDIVIDUALS

THOMASON, H., FOLLAND, J., ŠKARABOT, J.

LOUGHBOROUGH UNIVERSITY

INTRODUCTION: Maximal rate of force development (RFD) is determined by neural (motor unit [MU] recruitment speed and discharge rate) and contractile properties (1,2). Chronic resistance training may confer neural adaptations including greater spinal cord output that facilitates faster RFD, whereas endurance trained (ET) individuals may have slower muscle contractile properties, resulting in limited increases in spinal cord output (3). Here, we assessed MU activity and intrinsic muscle contractile properties within RT, ET and UT individuals during maximal rapid contractions.

METHODS: Sixty-six RT, ET and UT (22 per group, 6 females) individuals produced maximal and rapid voluntary isometric dorsiflexion force to determine maximal voluntary force (MVF) and RFD, respectively. Supramaximal percutaneous nerve stimulation (300 Hz) was administered to the common peroneal nerve at rest to record maximal evoked force (MEF) and RFD. A 64-channel grid electrode was placed on the tibialis anterior muscle of the dominant leg to assess myoelectrical activity (EMG). The EMG signals were decomposed into individual MU spike trains using Convolution Kernel Compensation algorithm to calculate MU recruitment speed, and discharge rate (DR) in the initial and plateau period of rapid contractions.

RESULTS: MVF, MEF and maximal evoked RFD were significantly larger in RT (408.2 [358.0, 458.4] N, 151.3 [137.3, 165.3] N, 1998 [1776, 2220] N/s) compared to ET (346.6 [312.1, 381.0] N, 93.0 [78.2, 107.8] N, 1317 [1084, 1551] N/s, $p < 0.04$) and to UT

[301.4 [267.8, 335.0] N, 110.4 [96.7, 124.0] N, 1492 [1276, 1708] N/s, $p < 0.005$), respectively. When maximal evoked RFD was normalised to MVF, both RT (482 [434, 529] %MVF/s) and UT (494 [448, 540] %MVF/s) were greater than ET (383 [333, 433] %MVF/s, $p < 0.0157$). Greater absolute voluntary RFD was seen in RT compared to UT (1754 [1542, 1996] N/s vs. 1219 [1007, 1431] N/s, $p = 0.0031$) but not compared to ET (1469 [1258, 1681] N/s, $p = 0.1486$). However, when normalised to MVF, there were no differences between RT, ET or UT (437 [410, 464], 419 [392, 446], 403 [376, 430] %MVF/s, $p = 0.1984$). Initial DR was greatest in RT (71.7 [67.3, 76.2] pps) compared to UT (63.9 [59.4, 68.5] pps, $p = 0.0454$), but not compared to ET (64.8 [60.4, 69.2] pps, $p = 0.0773$). DR during the plateau phase was the highest in RT (33.1 [30.5, 35.6] pps) vs. ET (27.8 [25.3, 30.4] pps, $p = 0.0136$), but not compared to UT (31.0 [28.4, 33.6] pps, $p = 0.4949$). No differences were noted in recruitment speed between RT, ET or UT (290 [224, 355], 316 [250, 381], 259 [184, 333] MUs/ms, $p = 0.767$), respectively.

CONCLUSION: RT individuals exhibited greater maximal strength and absolute RFD. However, despite greater initial MU discharge rate, relative RFD was similar between groups, likely due to between-group similarity in MU recruitment speed, a key determinant of RFD.

EFFECT OF ANODAL TDCS ON RATE OF FORCE DEVELOPMENT, MOTOR UNIT DISCHARGE RATE, AND RETICULOSPINAL ACTIVATION, IN YOUNG AND OLD ADULTS.

WIGGINS, E., ZAAIMI, B., MARTINEZ-VALDES, E., JENKINSON, N., BREEN, L.

UNIVERSITY OF BIRMINGHAM

INTRODUCTION: The ability to produce maximal force in minimal time is a key function of the neuromuscular system. While training can enhance rapid force generation, factors like ageing and muscle unloading can cause significant declines. Despite rapid force generation being more important for human function than maximal strength, there is limited research on its decline and potential countermeasures.

The speed of motor neuron recruitment and maximal motor unit discharge rate are major contributors to rapid force generation. A startling cue, which activates the pontomedullary reticular formation neurons, can increase the maximal motor unit discharge rate. However, it's unclear whether age-related physical decline is linked to reduced excitability of descending motor pathways, such as the reticulospinal tract, which plays a role in gross motor output.

Transcranial Direct Current Stimulation (tDCS), a non-invasive brain stimulation technique, may be able to facilitate subcortical structures. If effective, tDCS could potentially mitigate the loss of rapid force production due to aging or bed rest, allowing for faster recovery and resumption of daily activities in older adults, for example.

METHODS: Forty-four adults participated in a single-blind, two-arm crossover study. They were asked to generate isometric knee extensor forces as rapidly and forcefully as possible from rest to 75% of maximal voluntary force. This was done in response to visual (VC; LED), visual-auditory (VAC; 80 dB), or visual-startling cue (VSC; 110 dB), both before and after receiving either anodal or sham tDCS. Rate of force development and reaction time were measured using a rigid custom-built isometric leg extension dynamometer. Motoneuron activity was estimated by analyzing high-density surface electromyogram recordings over the vastus lateralis muscle. reticulospinal tract gain was calculated by comparing reaction times to each of the three cues.

RESULTS: Twelve young males (means $\pm$ SD; age: 23 ± 4 yr, stature: 1.77 ± 0.07 m, body mass: 77.0 ± 10.7 kg), twelve young females (age: 21 ± 2 yr, stature: 1.67 ± 0.08 m, body mass: 59.6 ± 8.6 kg), ten old males (age: 71 ± 3 yr, stature: 1.78 ± 0.10 m, body mass: 83.2 ± 13.9 kg), and ten old females (age: 70 ± 4 yr, stature: 1.62 ± 0.04 m, body mass: 61.3 ± 7.5 kg) completed three visits to the School of Sport, Exercise and Rehabilitation Sciences, University of Birmingham. There were two to six days (2 ± 1 days) between experimental visits which were preceded by an initial familiarization visit and two to ten days (4 ± 1 days) before the first experimental visit. Further analysis will investigate key measures such as reaction time, rate of force development and motor unit decomposition.

CONCLUSION: This study will provide valuable insights into the potential of non-invasive brain stimulation as a method to counteract age-related weakness. Additionally, it will contribute to the understanding of reticulospinal tract excitability in healthy aging research.

DO INSTRUCTIONS MATTER? MOTOR IMAGERY TRAINING FOR RATE OF FORCE DEVELOPMENT AND MAXIMAL VOLUNTARY CONTRACTIONS IN YOUNG FEMALES

JAKOBI, J., CALKINS, C.A.

UNIVERSITY OF BRITISH COLUMBIA

INTRODUCTION: Instructions before a maximal voluntary contraction (MVC) effect the output of the effort. Emphasis on the word "hard" compared to "fast" will produce a greater force, and with the prominent instruction word of "fast" the rate of force development (RFD) is quicker. Motor imagery training (MIT) is the mental rehearsal of a task with no overt movements and can improve and maintain task performance over time. Mentally rehearsing an MVC maintains strength performance but the influence of instruction type is unknown. The purpose of this study was to understand whether MIT instructions influence strength and RFD similar to verbal instructions for the production of an MVC. It was hypothesized that the MIT

instructions with emphasis on “hard” would maintain strength throughout the session and that the MIT instructions with emphasis on “fast” would maintain RFD throughout the session.

METHODS: Thirty-six females aged 19-35 years were randomly assigned to one of four groups. The MIT group “hard and fast” and MIT group “fast and hard” (emphasis on the first word) visualized the contraction. The control groups received one set of emphasized instructions of “hard and fast” or “fast and hard” and executed the MVC contractions. The four groups completed a familiarization day where voluntary activation was assessed with the twitch interpolation technique and an experimental day which followed a block order. Blocks 1,3 and 5 involved three isometric elbow flexion MVCs separated by two minutes of rest. Blocks 2 and 4 involved MIT (MIT groups) or viewing a documentary (control groups). Participants self-rated their MIT blocks with a 7-point Likert scale. Data are reported for 8 participants.

RESULTS: MIT scores did not differ across blocks. Voluntary activation did not differ across groups ($98.7 \pm 0.7\%$ $p > 0.05$). The control groups “hard and fast” (approximately 7% decline) and “fast and hard” (approximately 10% decline) had an overall reduction in strength across blocks. The MIT groups “hard and fast” (approximately 6% decline) and “fast and hard” (approximately 4% decline) had an overall reduction in strength across blocks but less than the control groups. The RFD in the first block was approximately two-times faster for the MIT and control groups who received the “fast and hard” instruction compared to those who received “hard and fast”. The MIT “fast and hard” group maintained their RFD across blocks.

CONCLUSION: The instructions given for MIT influence the performance of MVC contractions in a similar manner to physical performance. With an emphasis on “fast”, the RFD is quicker compared with “hard”. The use of MIT in between sets could prove beneficial for the performing rapid or strong contractions.

GENDER DIFFERENCES IN RATE OF FORCE DEVELOPMENT UNDER FATIGUE CONDITIONS

SCINICARELLI, G., PECORI, L., WILKE, C.

GERMAN SPORT UNIVERSITY COLOGNE

INTRODUCTION: Rate of force development (RFD) is crucial for sports performance, especially in explosive lower-limb movements. Neuromuscular fatigue impairs RFD, leading to muscle imbalances, reduced joint stability and higher injury risk [1]. Knee flexion angle affects injury susceptibility, with low flexion ($<30^\circ$) increasing anterior cruciate ligament stress and high flexion ($>90^\circ$) raising meniscal and patellofemoral loading. Gender differences in fatigue resistance further influence these risks, emphasizing the need for tailored training [2]. However, the fatigue-induced decline in RFD across knee flexion angles remains unclear. This study aims to assess fatigue-induced changes in quadriceps and hamstring RFD at 30° , 60° , and 90° knee flexion, providing gender-specific comparisons and training implications.

METHODS: A cross-sectional study with 67 active adults was conducted (38 males: 24.3 ± 3.7 years, BMI 24.4 ± 2.3 kg/m²; 29 females: 23.9 ± 3.1 years, BMI 22.4 ± 2.2 kg/m²). Participants performed maximal voluntary isometric contractions (MVICs) at 30° , 60° , and 90° using an isokinetic dynamometer (Biodex System 4 PRO). RFD (N·m/s) was recorded pre- and post-fatigue after 5×30 maximal isokinetic contractions at $180^\circ/\text{s}$. Two-way repeated-measures ANOVA (fatigue $\times$ knee angle $\times$ gender) with Bonferroni post hoc tests were applied.

RESULTS: Fatigue significantly reduced RFD across all knee angles ($F(1, 66) = 28.74$, $p < .001$, $\eta^2 = 0.19$), with the largest declines at 90° and 60° . Men showed higher absolute RFD in both pre- and post-fatigue status ($F(1, 66) = 17.63$, $p < .001$, $\eta^2 = 0.16$). Women showed greater quadriceps fatigue resistance ($F(1, 66) = 5.84$, $p = .02$, $\eta^2 = 0.08$), conversely, men had lower hamstring RFD decline ($F(1, 66) = 4.96$, $p = .03$, $\eta^2 = 0.07$).

CONCLUSION: Fatigue reduces RFD, particularly at higher knee flexion angles, with hamstrings more affected than quadriceps. Women show greater hamstring fatigue vulnerability, while men exhibit higher quadriceps fatigue susceptibility. These findings support targeted explosive strength training strategies at determined knee flexions (e.g. 60° and 90°), emphasizing hamstring-focused exercises for women (e.g., Nordic curls, Romanian deadlifts) and quadriceps-strengthening for men (e.g., front squats, Bulgarian split squats). Future research should explore long-term fatigue adaptations and their impact on injury prevention.

EFFECTS OF INTERMITTENT EXOGENOUS KETOSIS ON OXYGEN UPTAKE KINETICS AND TISSUE OXYGENATION DURING MODERATE-INTENSITY EXERCISE ACROSS THREE DAYS AT HIGH-ALTITUDE

TOMINEC, D., STALMANS, M., NARANG, B.J., MILLET, G.P., POFFÉ, C., DEBEVEC, T.

FACULTY OF SPORT, UNIVERSITY OF LJUBLJANA

INTRODUCTION: High altitude-related impaired oxygen delivery to working muscles leads to decelerated oxygen uptake kinetics during exercise (1). We previously demonstrated that ketone monoester (KE) ingestion enhances oxygen uptake and mitigates tissue oxygenation reductions during moderate-intensity exercise under acute simulated high-altitude conditions (2). Under this premise, we aimed to evaluate the effects of intermittent exogenous ketosis on oxygen uptake kinetics and oxygenation responses during moderate-intensity exercise across three days at terrestrial high altitude.

METHODS: Healthy, recreationally active participants were randomized into an intermittent exogenous ketosis (IEK, $n = 17$) and a placebo group (PLA, $n = 17$). They completed four moderate-intensity exercise sessions; one near sea-level (295 m), and the other three on consecutive days at terrestrial high altitude (3375 m). To establish a true baseline, no supplementation was administered at sea level. At high altitude, IEK received daily KE supplements, while PLA received placebo supplements 30 minutes prior to exercise. Each session consisted of three 6-minute cycling intervals at 80% of the gas exchange threshold, separated by 6-minute active recovery periods at 0 W. Power output during high-altitude sessions was adjusted to account for predicted altitude-induced exercise capacity reductions (3). Pulmonary oxygen uptake, systemic oxygen saturation, and muscle tissue oxygenation were continuously measured during exercise transitions and steady-state phases. Group differences over time were evaluated using mixed-model ANOVA, with statistical significance set at $p < 0.05$.

RESULTS: Pre-exercise ketosis was consistently induced in IEK (~ 2.5 mM) compared to PLA (~ 0.3 mM) ($p < 0.001$). Relative to sea level, the amplitude of the oxygen uptake response decreased upon arrival at high altitude ($p < 0.001$), and remained reduced throughout early acclimatization ($p > 0.181$), with no between-group differences ($p > 0.05$). The time constant of the primary phase of oxygen uptake kinetics was not modified by either high-altitude exposure time ($p = 0.136$) or supplementation ($p = 0.823$). Systemic oxygen saturation declined significantly upon arrival at high altitude compared to sea level ($p < 0.001$), and progressively improved throughout acclimatization, yet again independent of the supplementation ($p = 0.169$). In contrast, muscle tissue oxygenation did not significantly change across time ($p = 0.102$), and no difference was seen between groups ($p = 0.591$).

CONCLUSION: These data suggest that pre-exercise ketosis at high altitude does not influence oxygen uptake kinetics, systemic oxygen saturation, or muscle tissue oxygenation during moderate-intensity exercise across three days of high-altitude acclimatization.

A COMPARISON OF KETOGENIC AND CARBOHYDRATE-FED ATHLETES ON A BATTERY OF PHYSIOLOGICAL TESTS.

PHILLIPS, R., BROUNER, J., SPENDIFF, O.

KINGSTON UNIVERSITY LONDON

INTRODUCTION: The high-carbohydrate (HC) diet is widely adopted to enhance endurance and power output, while KD has been suggested to impair high-intensity performance. KD shifts reliance towards fat oxidation, due to glycogen depletion. This study assessed the impact of athletes following habitual (>3 months) HC and KD diets on exercise performance.

METHODS: Nineteen recreationally active individuals (mean age: 35 ± 9 y; stature: 175.5 ± 10.5 cm; body mass: 79.5 ± 12.4 kg; body fat %: 20.3 ± 6.2 %; fat-free mass: 63.2 ± 11.6 kg) were stratified into those who followed either a KD (<50 g/day CHO, >60 % fat) or HC (225–325 g/day CHO, 45–65% CHO) diet for the preceding 3-months. Diets were verified via food frequency questionnaires and MyFitnessPal tracking during testing (KD: $n = 8$, HC: $n = 11$). A six-session battery of tests spanned three weeks under standardised conditions (≥ 3 h fasted, no prior training). Visit 1 (V1) included anthropometric assessment, arm crank VO_2 max (ACE VO_2 MAX), isokinetic dynamometry (ISODYNO) (30° – 240° /s), and a 30-second Wingate anaerobic test (30sWANT). V2 comprised an ACE one-hour endurance test (ACE1HR) and a 20-minute performance test (ACE20Min). V3 assessed maximal oxygen uptakes on a LODE cycle ergometer (LODE VO_2 MAX). V4 included a one-hour endurance test on the LODE cycle ergometer (LODE1HR) followed by a five-by-10-second repeat sprint Wingate test (10sWANT). Heart rate (HR), respiratory exchange ratio (RER), VO_2 (ml.kg.min $^{-1}$), power (PWR, W) and time to fatigue (s) were recorded, while blood glucose (BG, mg/dl), ketones (BK, mmol/L), and lactate (BL, mmol/L) were recorded at set intervals per test for group comparison. Data was analysed using SPSS 29 for normality. Independent t-tests compared between-group differences in VO_2 max, RER, heart rate, peak torque, average power, and fatigue factor, while a Repeated-

Measures ANOVA analysed time $\times$ diet interactions for HR, RER, VO_2 , BG, BK and BL. Significance was set at $p < 0.05$. Data are expressed as mean $\pm$ SD.

RESULTS: No significant differences were found in V1 for ACEVO_2max , peak HR, or ISODYNO average power. However, KD had lower RER ($p < 0.05$) and greater PeakTQBW at $120^\circ/\text{s}$ and $240^\circ/\text{s}$ ($p < 0.05$). In 30sWAnT, no differences were found in peak PWR, distance, or fatigue factor, though KD showed greater variance. During V2, VO_2 increased over time ($p < 0.05$) and was higher in KD ($p < 0.05$), while ACE1HR and ACE20MIN distance were similar. BK was higher in KD ($p < 0.05$). In V3/V4, no differences were found in LODE VO_2MAX or LODE1HR, but KD had higher BL ($p < 0.05$). In 10sWAnT, HC had higher cadence and speed in sprints 1–4 ($p < 0.05$), while peak PWR and distance were unchanged.

CONCLUSION: KD increased fat oxidation and VO_2 uptake during endurance exercise, while HC resulted in higher cadence and sprint speed. Although both diets elicit different metabolic responses there is little consequential difference between dietary approaches and exercise performance.

EFFECTS OF EXOGENOUS KETONE SUPPLEMENTATION ON POST-EXERCISE ERYTHROPOIETIN AND HEPCIDIN RESPONSES

HAYASHI, N., YAMADA, M., ISHIKAWA, A., KAMEMOTO, K., OKAZAKI, K., SAKAMAKI-SUNAGA, M.

OSAKA METROPOLITAN UNIVERSITY

INTRODUCTION: Hepcidin, an iron-regulating hormone, is thought to be downregulated by stimuli that promote erythropoiesis (Nemeth & Ganz, 2023). Ketosis, characterized by elevated β -hydroxybutyrate (βHB) levels, was reported to increase post-exercise serum erythropoietin (EPO) concentration following acute ketone supplementation in healthy men (Evans et al., 2023). Therefore, this study aimed to investigate the effects of βHB supplementation after exercise on EPO and hepcidin responses in active women.

METHODS: Eight women completed the experimental trials [means $\pm$ SD, age: 20 ± 1 years, height: 155.8 ± 7.9 cm, body mass (BM): 54.9 ± 6.2 kg, peak oxygen consumption ($\text{VO}_{2\text{peak}}$): 45.7 ± 4.3 mL/kg/min] under two different conditions during the early-follicular phase: either consuming 25.5 g of βHB (8.5 g/h, 3 times; βHB) or an equivalent amount of placebo (CON) after high-intensity interval exercise (3-minutes warm-up, 8 sets of 3-minutes cycling at 85% $\text{VO}_{2\text{peak}}$, 3-minutes cool-down). The βHB /placebo supplements (OKETOA®, Osaka Gas Co., Ltd.) were consumed immediately, 60 min and 120 min after exercise. A light meal (0.9 g/kg BM of carbohydrate, 0.1 g/kg BM of protein) was consumed with βHB /placebo supplements 60 min after exercise. Blood samples were collected before and after exercise (0, 30, 120, and 180 min); respiratory samples with a breath-by-breath method were collected before and after exercise (30, 120, and 180 min). A repeated-measures two-way ANOVA was applied, and significant interactions or main effects were followed up using Bonferroni post-hoc test. Significance was set at $p < 0.05$.

RESULTS: Significant differences were observed in serum βHB responses ($F = 43.523$, $p < 0.001$). Serum βHB concentrations were significantly higher in the βHB trial than in the CON trial (30 min: $p = 0.004$, 60 min: $p = 0.004$, 120 min: $p = 0.006$, 180 min: $p = 0.028$). The βHB trial showed a significantly lower mean blood glucose concentration than the CON trial ($F = 11.372$, $p = 0.012$). Significant differences were observed in changes in the respiratory exchange ratio (RER; $F = 3.994$, $p = 0.011$). The βHB trial exhibited a significantly lower RER 120 min after exercise than in the CON trial ($p = 0.002$). No significant differences were observed in serum hepcidin response between the trials ($F = 0.714$, $p = 0.427$). Significant differences were observed in serum EPO response between the trials ($F = 7.595$, $p = 0.020$); however, the post-hoc test did not reveal significant differences between the trials. Changes in serum EPO concentration (180 min minus pre-exercise) were significantly different between the trials (βHB : $+0.325 \pm 0.974$ mIU/mL, CON: -1.325 ± 1.400 mIU/mL; $p = 0.027$).

CONCLUSION: Exogenous ketosis via βHB supplementation influenced the EPO response and glucose metabolism but did not affect the hepcidin response following high-intensity interval exercise.

EFFECTS OF A TWO-WEEK SCHOOL VACATION ON PHYSICAL FITNESS, SLEEP, PHYSICAL ACTIVITY, AND SEDENTARY BEHAVIOR IN PRESCHOOL GIRLS AND BOYS

DAMBEL, L., LEVENEZ, A., SCHOTT, E., LARRIBAUT, J., ESTRELLA, J.P., SAIDI, O., DUCHE, P.

UNIVERSITÉ DE TOULON - CAMPUS DE LA GARDE: UNIVERSITÉ DE TOULON

INTRODUCTION: Physical fitness is a key determinant of children's health, closely linked to sleep, physical activity (PA), and sedentary behavior (SB) (Ortega et al., 2008). The Structured Days Hypothesis suggests that school vacations disrupt movement behaviors, contributing to increased SB and decreased PA (McCue et al., 2013). School provides a structured environment that supports these behaviors, while vacations may lead to altered sleep, reduced PA and increased SB (Brazendale et al., 2017). The effects of vacations on physical fitness components remain less explored. Additionally, few studies have assessed movement behaviors simultaneously. This study aimed to evaluate the impact of a two-week school vacation on physical fitness, sleep, PA, and SB in preschoolers.

METHODS: Forty-three children (21 girls, 22 boys, aged 9–11 years) from two French school classes participated in a pre-post study. Fitness tests included the one-mile run (cardiorespiratory fitness), countermovement jump (explosive power),

and 30m sprint (speed). Simultaneously, sleep, PA, and SB were continuously monitored for one month using wrist-worn accelerometers (ActiGraph GT3X+), worn 24h/day, to record movement behaviors during both school and vacation periods (P1: before vacation: P2 and P3: during two-weeks vacations and P4: after vacation). Linear mixed models were used to analyze time and gender effects, and correlations tested associations between behavioral shifts and fitness changes.

RESULTS: No significant changes were observed in cardiorespiratory fitness, sprint performance, or jump power between pre- and post-vacation assessments. However, movement behaviors shifted considerably. Sleep patterns changed, with delayed bedtimes observed particularly in girls. Moderate-to-vigorous physical activity (MVPA) declined sharply, with boys experiencing the greatest decrease (57.1% meeting guidelines in P1 vs. 9.5% in P3). SB increased across both genders, with less than 10% of children maintaining SB levels below 8 hours/day during the two-week school vacation. Despite these behavioral shifts, no associations were found between changes in sleep, PA, or SB and physical fitness.

CONCLUSION: A two-week school vacation did not affect physical fitness but led to significant disruptions in movement behaviors, supporting the Structured Days Hypothesis. Boys experienced a greater decline in MVPA, while girls had more pronounced sleep disruptions. These findings highlight the importance of structured routines such as school in maintaining healthy activity behaviors. Future research should explore potential moderators such as socioeconomic factors, seasonal variations, and baseline activity levels to better understand and mitigate vacation-induced inactivity.

COMPARISON OF THE EFFECTIVENESS OF SLEEP HYGIENE STRATEGIES ADMINISTERED IN WRITTEN FORMAT VS INDIVIDUAL SLEEP EDUCATION SESSION IN ATHLETES: A RCT STUDY.

BORGHI, S., IMPERIALI, L., VITALE, J.A., CODELLA, R., LA TORRE, A., TALLINI, E., SARUBBI, R., BIZZOZERO, S.
IRCCS ISTITUTO ORTOPEDICO GALEAZZI

INTRODUCTION: Sleep is fundamental for athletes' performance, enabling optimal recovery. Sleep Hygiene Strategies (SHS) offer evidence-informed recommendations to enhance sleep in athletes, but no studies compared different methods for administered them in athletes. This randomized controlled trial investigated how different methods of delivering SHS affect sleep hygiene and sleep parameters in track and field athletes. Specifically, the aim was to compare the effect of ten days of SHS in a standardized, written format versus individual sleep education sessions.

METHODS: This three-arm randomized controlled trial was approved by the Ethical Committee of Università degli Studi di Milano (ref. n.: 74/23), and conducted according to the Declaration of Helsinki. Sixty-six athletes were recruited during the 2022/2023 and 2023/2024 competitive periods and randomized into three groups: Control (CON, n=22), Written format SHS (W-SHS, n=22), and individual sleep Education Session SHS (ES-SHS, n=22). Sleep monitoring (total sleep time, sleep efficiency, sleep latency, wake after sleep onset, bedtime, wake-up time, sleep regularity index), including actigraphy and sleep diaries, was conducted at baseline (T0) and during the intervention period (T1) for 10 consecutive days for each monitoring. Participants also completed training diaries (number of trainings, minutes of training, training load) and the Sleep Hygiene Index (SHI) questionnaire. Between T0 and T1, a maximum of 7 days was allowed for data analysis and scheduling individual sleep education sessions for the ES-SHS group. During T1, the W-SHS and ES-SHS groups adopted the same SHS, while the CON group did not receive any SHS intervention.

RESULTS: Based on National Sleep Foundation guidelines, at T0, 18 participants were considered short-sleepers (total sleep time < 7h. CON: n=4; W-SHS: n=8; ES-SHS: n=6) and 2 were poor-sleepers (sleep efficiency < 85%. W-SHS: n=1; ES-SHS: n=1). At T1, 16 participants were short-sleepers (CON: n = 7; W-SHS: n = 3; ES-SHS: n = 6), and 3 (W-SHS: n = 2; ES-SHS: n = 1) were poor-sleepers. No statistical differences were found in sleep variables and training parameters. However, significant differences were observed in SHI scores from T0 and T1, with improvements in sleep hygiene in the W-SHS (T0: 28.3±4.5; T1: 22.1±4.2) and ES-SHS (T0: 29.2±5.2; T1: 22.7±4.6) groups.

CONCLUSION: While no significant differences were observed in sleep parameters across groups, the administration of SHS significantly improved SHI scores among athletes. These findings highlight the importance of SHS in enhancing sleep hygiene in athletes. Future research should explore long-term impacts and additional methods to optimize SHS delivery.

EXPLORING THE IMPACT OF HYPOPRESSIVE ABDOMINAL GYMNASTICS ON SLEEP QUALITY: INSIGHTS FROM A PILOT STUDY

CASTELLI, L., GALASSO, L.1, CASPANI, J.1,2, CIORCIARI, A.M.1,3, MONTARULI, A.1, PASTA, G.2, ROVEDA, E.1
 1 UNIVERSITY OF MILAN; 2 CENTRO DI CHINESIOLOGIA NUOVA GINNASTICA; 3 FREE UNIVERSITY OF BOZEN-BOLZANO

INTRODUCTION: Hypopressive Abdominal Gymnastics (HAG) is a postural technique developed to reinforce abdominal and pelvic floor muscles. It is mainly practised by pregnant and post-partum women and subjects with rectus abdominis diastasis, prolapse, urinary incontinence, pelvic floor dysfunction, and chronic low-back pain. This technique combines expiratory apnoea with abdominal contraction manoeuvres to relax the diaphragm and reduce intra-abdominal pressure while activating the abdominal and pelvic floor muscles (1). Since no studies have evaluated sleep in relation to HAG practice, this study assesses if HAG might exert beneficial effects on sleep quality.

METHODS: Twenty-eight women (mean age 43.23 ± 7.03 yrs) with rectus abdominis diastasis were randomised into an intervention (INT, 17 women) and control (CTRL, 11 women) group. INT underwent a 2-month HAG intervention, with one supervised HAG session per week, while CTRL was recommended to practice a 2-month home HAG. Both groups filled in the Mini Sleep Questionnaire (MSQ) to assess sleep subjectively and wore an actigraph to assess sleep objectively. MSQ and actigraphic assessment were performed one week before and one week after the HAG intervention. ANCOVA analysis (adjusted by age) evaluated differences in delta values between INT and CTRL groups.

RESULTS: Delta MSQ total score (INT: -2.67 ± 1.19 a.u.; CTRL: -0.94 ± 0.24 a.u.), delta sleep MSQ component (INT: -1.7 ± 0.92 a.u.; CTRL: -0.99 ± 0.74 a.u.), and delta wake MSQ component (INT: -0.97 ± 0.46 a.u.; CTRL: 0.05 ± 0.03 a.u.) showed a slightly greater reduction, indicating a sleep improvement, in INT group compared to the CTRL group. However, the differences were not statistically significant ($p = 0.67$, $p = 0.82$, $p = 0.63$, respectively). Among the actigraphic parameters, the delta percentages of sleep and immobile time were positive in the INT group (sleep time: 0.62 ± 0.35 %; immobile time: 0.43 ± 0.14 %) and negative in the CTRL group (sleep time: -0.38 ± 0.22 %; immobile time: -0.32 ± 0.25 %), indicating a trend of sleep improvement in the INT compared to the CTRL group. Also in this case, differences were not statically significant ($p = 0.49$, $p = 0.23$). No differences were visible for the percentage of sleep efficiency (INT: 1.48 ± 1.02 %; CTRL: 2.01 ± 1.49 %).

CONCLUSION: This pilot study shows that two-month HAG seems to contribute to some encouraging effects on sleep quality, showing some positive trends, especially on subjective sleep quality. However, no marked and significant results were visible, probably due to the shortness of the intervention protocol. A longer intervention and a bigger sample size could probably lead to more evident results.

INTERACTION EFFECTS OF PHYSICAL ACTIVITY AND SLEEP DURATION ON MOTORIC COGNITIVE RISK SYNDROME IN CHINESE OLDER ADULTS: A POPULATION-BASED COHORT STUDY

GU, L., ZHANG, S.

TSINGHUA UNIVERSITY

INTRODUCTION: Motor Cognitive Risk Syndrome (MCR) is a preclinical marker of dementia characterised by subjective cognitive complaints and slow gait [1]. Emerging evidence suggests that modifiable lifestyle factors are potential targets for intervention, with sleep patterns receiving particular attention. A prior study in Chinese older adults revealed an inverted U-shaped association between night sleep duration and MCR [2]. However, the role of physical activity (PA) in the pathogenesis of MCR remains unexplored. We hypothesise that higher activity levels interact with healthy sleep status to reduce MCR risk, rather than their independent effects.

METHODS: We recruited 2,459 participants aged ≥ 60 years from the China Health and Retirement Longitudinal Study (CHARLS). MCR syndrome was defined as cognitive complaints and slow gait speed without dementia or impaired mobility. PA was classified into three categories based on the IPAQ rubric: inadequate (< 600 MET-min/week), adequate (600–3000 MET-min/week), and high (> 3000 MET-min/week). Sleep was classified as inadequate (< 6 hours), adequate (6–9 hours), and excessive (> 9 hours). Multivariable logistic regression examined cross-sectional PA-sleep interactions on MCR prevalence, while Cox models assessed longitudinal associations with incident MCR over 3.5-year follow-up (2011–2015 waves), both adjusting for age, gender, education, smoking, alcohol, depression symptoms and chronic diseases.

RESULTS: In cross-sectional analyses ($n=2,459$), the combination of inadequate PA and short sleep duration demonstrated interaction effects, showing 2.5-fold higher odds of MCR in unadjusted models (OR: 2.53, 95% CI: 1.98–3.24, $p<0.001$), which remained significant after full adjustment (aOR: 2.18, 95% CI: 1.68–2.83, $p<0.001$). Longitudinal analysis ($n=1,793$, median follow-up 3.5 years) revealed that participants with both risk factors at baseline had 1.7-fold higher incidence risk in unadjusted models (HR: 1.73, 95% CI: 1.28–2.33, $p<0.001$), with risk persisting after adjustment (aHR: 1.49, 95% CI: 1.09–2.04, $p=0.013$). The multiplicative interaction term between PA and sleep duration was statistically significant ($p=0.021$).

CONCLUSION: As hypothesized, the combined optimization of physical activity and sleep duration significantly attenuates the MCR risk in older adults, with multiplicative interaction effects surpassing those of the individual factors. Community-based dual-component interventions targeting both behaviors should be implemented, while future studies need to identify subgroups benefiting most from such strategies.

EXPLORING THE INTERPLAY OF BODY COMPOSITION, PHYSICAL ACTIVITY, AND OPTIMISM ON SLEEP DURATION AND QUALITY IN POSTMENOPAUSAL WOMEN

TUCCELLA, C., VINCIGUERRA, M.G., MOREIRA, H.

UNIVERSITY OF LAQUILA

INTRODUCTION: Over 50% of postmenopausal women experience sleep disturbances, which negatively impact their quality of life. Poor sleep reduces physical activity (PA) and worsens body composition (BC) changes due to estrogen depletion. Maintaining a positive attitude can help manage menopause symptoms. This study analyses the relationship between BC, physical activity PA, optimism and sleep in postmenopausal women.

METHODS: The study included 20 women (59.06 ± 5.96 years) and half of the participants had been in late postmenopause. Moderate-vigorous physical activity (MVPA) and sleep parameters (TST, total sleep time; SOL, sleep onset latency; SE, sleep efficiency; SFI, sleep fragmentation index) were recorded using Actigraph GT3X+ accelerometers. The recommended levels were as follows: MVPA= 150 min/week, TST= 7 hours, SE= 85% and SFI< 5 events/hour. Fat mass (FM, %), trunk skeletal muscle mass (TSMM), and appendicular skeletal muscle mass were measured with InBody120 bioimpedance. The index of appendicular skeletal muscle mass (ASMMI) was calculated as ASMM divided by height squared. Obesity was defined as FM = 35%, and muscle mass deficit was identified with ASMMI < 5.5 kg/m². Dispositional optimism was assessed using the LOT-R scale. Data were summarized using descriptive statistics and significance was accepted as $p = 0.05$. Partial correlation coefficient were used to assess associations between variables.

RESULTS: In the sample, 95% experienced natural menopause, 85% did not use hormone therapy, and 35% used sleep-affecting medication. Nine participants were obese, and eight had low muscle condition. All women had SE = 85% and SFI < 5 events per hour, but 25% had insufficient sleep duration. Average MVPA was 243.55 minutes per week (90% were active) and LOT-R was 15.30 points. In early postmenopause, higher adiposity correlated with better SE ($r=0.75$, $p=0.02$), and more optimism correlated with longer SOL ($r=0.67$, $p=0.05$). MVPA inversely related to SE ($r=-0.76$, $p=0.02$). Significant associations ($p=0.01$), in the overall sample included SOL and LOT-R ($r=0.54$), SE and %FM ($r=0.42$), and SFI and TSMM ($r=0.56$).

CONCLUSION: The results indicate that SE and SOL is influenced by adiposity levels and optimism in early postmenopausal women. Better trunk muscle condition is linked to a higher SFI. More active women and those with longer estrogen depletion show lower SE. A replication with a more representative sample is recommended.

CONTEXTUAL INTERFERENCES IN MOTOR LEARNING OF CHILDREN AND OLDER ADULTS IN APPLIED SETTINGS – THE NOVELTY OF A TASK HYPOTHESIS

CZYŻ, S., WÓJCIK, A.M.

WROCLAW UNIVERSITY OF HEALTH AND SPORT SCIENCES

INTRODUCTION: Contextual interference (CI) (Battig, 1966) effect is claimed to enhance motor skill retention, though the general meta-analyses evinced that the beneficial effect of CI effect on retention is more conspicuous in adults and the elderly than in children (Brady, 2004; Czyż et al. 2024a, 2024b). Moreover, majority of the studies on adults and older adults were conducted in laboratory setting while studies on children in applied settings. To determine whether the presence of the CI effects in adults or lack in children is due to the age or setting issues we examined the interaction between practice schedule in childrens and older adults learning an aiming skill in applied settings.

METHODS: A total of 96 participants (48 children, mean age 11.09 ± 1.01 ; 48 older adults, mean age 72.9 ± 4.98) were randomly assigned to Blocked or Random practice schedules with either 18 or 24 repetitions per session. Participants threw beanbags towards the circular target (Ávila et al., 2012; Chiviawowsky et al., 2008) from 3m, 4m, and 5m. The study consisted of three phases: pretest, acquisition, and 24-hour retention test. Performance accuracy was analyzed using a 4-way mixed ANOVA.

RESULTS: Older adults consistently outperformed children ($p < 0.001$, $\eta^2 = 0.503$). Younger participants improved across acquisition and retention but showed no significant CI effect. In older adults, random practice led to better retention only at 5m ($p = 0.006$, $\eta^2 = 0.1098$), while performance at 3m and 4m remained stable. No significant interaction was found between CI and practice volume ($p = 0.238$).

CONCLUSION: Findings suggest that CI effects depend on task novelty and difficulty rather than age or settings alone. Based on these findings, we propose the Novelty of the Task Hypothesis, suggesting that the CI effect may depend on the relative novelty and challenge of a task for the learner. In applied settings, CI may be less effective when tasks are already well-practiced. Future studies should explore CI across diverse motor tasks and environments.

EVIDENCE OF A DOSE-RESPONSE EFFECT OF ACUTE AEROBIC EXERCISE INTENSITY ON MOTOR ADAPTATION AND LEARNING

HARROUM, N., PAGEAUX, B., NEVA, J.L.
UNIVERSITÉ DE MONTRÉAL

INTRODUCTION: In daily life, we are required to learn new motor skills and to adapt our movements to changes in our environment. This dynamic process of adjusting to changes in our environment is known as “motor adaptation” and constitutes an important category of motor learning. Studies have shown that a single session of aerobic exercise (AE) can enhance motor adaptation compared to rest. Specifically, high intensity AE can increase motor adaptation, while moderate intensity AE has been shown to both enhance motor adaptation and to have no effect. No studies have investigated the impact of low intensity AE on motor adaptation. Hence, it is still unclear how the intensity of AE influences motor adaptation.

This study aimed to investigate the dose-response effect of AE intensity on motor adaptation while controlling for other AE exercise parameters (duration, type) in young adults. We hypothesized that moderate and high AE intensity would lead to greater motor adaptation compared to rest.

METHODS: Eighty healthy young adults (18–39 years) were divided into four groups ($n=20/\text{group}$): 20 min of interval AE training at high-intensity (HIIT), moderate-intensity (MIIT), low-intensity (LIIT), or Rest (control). A visit prior to the intervention was conducted to perform an incremental cycling test to assess cardiorespiratory capacity. Heart rate reserve (HRR) was used to prescribe the AE intensity for visit 2. AE consisted of four blocks of 3-min cycling on an ergometer (LIIT, 35%HRR; MIIT, 55%HRR; HIIT, 80%HRR), interspersed with 2 min of active recovery (25%HRR). Perceptual responses (effort, muscle pain and affects) were reported during AE/Rest sessions. Participants completed a visuomotor rotation task (45°) immediately (acquisition: motor adaptation) and 24-h (retention test: motor learning) after AE/Rest. Performance was assessed using spatial (e.g., angle at peak velocity) and temporal (e.g., reaction time) metrics.

RESULTS: The results revealed a dose-response effect of AE intensity on motor adaptation and learning. HIIT and MIIT increased motor learning more than LIIT and Rest (temporal and spatial metrics). HIIT showed the greatest motor adaptation (temporal and spatial metrics), followed by MIIT, then LIIT (temporal metrics). Findings showed that the lower the AE intensity, the more positive perceptual responses (e.g., less muscle pain, lower perception of effort).

CONCLUSION: This research is the first to reveal a dose-response effect of AE intensity on motor learning. Specifically, the higher the AE intensity, the larger the improvements in motor adaptation and learning. These findings suggest that exercise intensity prescription could be a key factor in tailoring training protocols for athletes to enhance motor skills and adapt to varying dynamics in sport. Since MIIT elicited more favorable perceptual responses than HIIT, clinicians may consider MIIT as a viable alternative for individuals who may be more impacted by the negative perceptual responses associated with HIIT.

THE IMPACT OF MANIPULATING TASK CONSTRAINTS ON THE MOVEMENT VARIABILITY AND CREATIVITY IN KICKBOXING

MOHAMMADI SANJANI, F., ORTH, D., VAN DER KAMP, J.
KHARAZMI UNIVERSITY OF IRAN

INTRODUCTION: Creative actions are motor solutions that emerge within the dynamic interactions of the individual, task, and the environment (1). The emergence of creative action is associated with the sheer variety of action solutions an individual explores, that is, in the variety in coordination and control solutions (2). This study aimed to examine whether targeted manipulations of constraints during practice lead to specific changes in variability and creativity of action at the level of coordination and control.

METHODS: Thirty-four participants were randomly assigned to one of three groups to practice striking a boxing bag: control ($N=10$), distance ($N=12$), orientation ($N=12$). The distance group practiced hitting the bag from different distances with the aim to invite a broad search for different coordination solutions, while the orientation group practiced hitting the bag from different orientations at a fix distance to invite a relatively narrow but persistent search for control solutions. All groups completed pre-test and retention test, in which they were instructed to strike the bag in as many ways as possible. Wilcoxon signed-rank and Mann-Whitney U tests were used for within and between group comparisons.

RESULTS: Variability in coordination increased significantly in the distance group (Pre 2.81 ± 0.39 , Retention: 2.95 ± 0.29 ; $P=0.05$), while no significant change was observed in the orientation and control group ($P>0.05$). Manipulating orientation did not significantly alter control variability (Pre: 2.02 ± 0.57 , Retention: 2.10 ± 0.46 , $P>0.05$). Furthermore, the distance group showed higher creativity compared to orientation group ($U(12,12) = 40$, $p=0.01$).

CONCLUSION: These results suggest that manipulating task constraints can have specific consequences for variability and creativity. The distance manipulation did increase variability and creative in coordination solutions, but not in control solutions. Manipulating the orientation didn't affect variability and creative, perhaps because it requires a longer timescale to manifest itself.

EFFECT OF STROKE RATE ON MOVEMENT VARIABILITY DURING ROWING ERGOMETER IN ELITE ROWERS

GAO, Y., CHEN, X.P.

1 SPORTS SCIENCE RESEARCH INSTITUTE OF THE STATE SPORTS GENERAL ADMINISTRATION 2 BEIJING SPORT UNIVERSITY

INTRODUCTION: Rowing is a highly competitive power-endurance sport requiring coordinated movements of the legs, trunk and arms to optimize technique [1]. Over the past decades, movement variability (MV) has been used to assess coordination levels in various motor actions across different populations. It serves as an indicator of motor control, evaluating movement regularity [2]. However, limited research has explored MV during rowing at different intensities. The aims of this research were (a) to investigate the influence of different stroke rate (SR) on MV and (b) to assess the relationship between MV and performance.

METHODS: Twenty-one elite male rowers (24.3 ± 3.1 years, 192.6 ± 5.6 cm, 90.7 ± 11.5 kg) performed 90-second submaximal intensity rowing bouts at 20, 26 and 34 strokes per minute (spm) on a static rowing ergometer (Model D, Concept 2, USA). An inertial motion capture system (MVN, Xsens Technologies, Netherlands) with 17 sensors recorded the kinematic features of the head, trunk, upper and lower limbs, with an additional sensor on the handle of ergometer. Rowing performance was assessed by 2000m ergometer time. The time series from IMUs were analyzed using linear (standard deviation, SD) and non-linear (Sample entropy, SampEn) measures [3]. A one-way repeated measures ANOVA was used to assess the effects of SR on MV, with effect sizes (ES) expressed as partial eta-squared. Pearson's correlation coefficient was utilized to calculate the relationship between SampEn and performance.

RESULTS: SR significantly increased the SD of stroke power ($F_{2,60}=6.887$; $P=0.02$, $ES=0.187$) and SampEn of handle acceleration ($F_{2,60}=20.628$; $P<0.001$, $ES=0.407$), hip ($F_{2,60}=82.518$; $P<0.001$, $ES=0.733$), and knee ($F_{2,60}=124.612$; $P<0.001$, $ES=0.806$) angles. Across all SRs, hip angle had greater SampEn than knee and elbow. Greater variability in handle acceleration at 20 spm ($r=-0.626$, $p=0.002$) and 26 spm ($r=-0.581$, $P=0.006$), knee angle at 20 spm ($r=-0.531$, $P=0.013$), and elbow angle at 20 spm ($r=0.511$, $p=0.021$) correlated with better ergometer performance.

CONCLUSION: As SR increased, elite rowers exhibited reduced movement control compared to lower SR. Among rowers with better performance, greater MV led to efficiency and adaptability. Entropy measures may serve as a valuable tool for practitioners to assess the specific rowing performance.

EFFECTS OF THE FAMILIARISATION WITH A SOFT BACK EXOSKELETON ON MUSCLE COORDINATION.

FAVENNEC, A., MORNIEUX, G.1,2, FRÈRE, J.3

1 UNIVERSITÉ DE LORRAINE, DEVAH, NANCY, FRANCE; 2 UNIVERSITÉ DE LORRAINE, FACULTY OF SPORT SCIENCES, NANCY, FRANCE; 3 UNIV. GRENOBLE ALPES, CNRS, GRENOBLE INP, GIPSA LAB, 38000 GRENOBLE, FRANCE

INTRODUCTION: Back exoskeletons are wearable structures that give an assistive torque to one or multiple joints and can prevent from low back disorders during manual handling tasks [1]. But, the change in external constraints has been shown to modify the motor behaviour during familiarization to a soft back exoskeleton while performing manual handling tasks [2]. However, little is known about the likely changes in central command during familiarization. Therefore, the aim of this study was to assess the modulation of muscle synergies during a familiarization to a soft back exoskeleton with manual material handling.

METHODS: Eighteen males (21.5 ± 2.3 years, 178.3 ± 3 cm, 69.6 ± 6.2 kg) were recruited to perform 6 sessions of one hour of familiarization to the CORFOR® V2 soft back exoskeleton [2]. This protocol consisted in several manual handling and precision tasks involving trunk bending. During measurements carried out at baseline and at the end of each session, participants were asked to handle a box (8 kg; 15 cycles / min) using STOOP and SQUAT techniques. Surface electromyography (sEMG) signal was unilaterally recorded on 14 muscles of the lower limb, trunk, back and upper-limb. From sEMG linear envelopes, muscles synergies were extracted for each session through non-negative matrix factorization. The effect of the familiarization was assessed using a repeated measures ANOVA to identify any change in the number of synergies, their composition (motor module similarity) or their activation coefficients (center of activation, full width at half maximum and variance ratio).

RESULTS: Results showed that 2 synergies explained 91 ± 1.8 % of the variance for both STOOP and SQUAT tasks during the whole familiarization. For both STOOP and SQUAT, synergy 1 was activated during the downward phase while synergy 2 was activated during the upward phase. Over the familiarization, the motor modules remained similar, for both STOOP (0.91 ± 0.13) and SQUAT (0.86 ± 0.17) tasks. There was no statistical evidence of change in the muscle synergy activations across the sessions, whatever the metric analyzed, for both STOOP and SQUAT tasks.

CONCLUSION: Overall, it appears that the muscle synergies extracted were robust throughout the familiarization protocol, despite a known effect of this soft back exoskeleton on joint kinematics, perceived comfort and lumbar spine loads [2, 3]. According to previous results [4], these results suggest that the exoskeleton used in this study did not bring sufficient perturbations to change the central command.

OP-AP27 Sports Technology in Running

METABOLIC AND PERFORMANCE RESPONSES TO TWO SIMILAR TYPES OF ADVANCED FOOTWEAR DURING PROLONGED RUNNING

BELTRAMI, F., KNECHT, C., SPENGLER, C.

ETH ZURICH: EIDGENÖSSISCHE TECHNISCHE HOCHSCHULE ZÜRICH

INTRODUCTION: Advanced footwear technology (AFT) improves running economy and performance compared with previous generations of running footwear, but little is known about the effects of minute differences in running economy between different AFT models during prolonged exercise. This study compared two AFT models with similar mechanical properties but with known differences in O₂ cost of running during a prolonged run and its subsequent effect on performance.

METHODS: An initial study using intra-day comparisons (three 6-min runs in each shoe, at 16 km/h) determined that the Nike Vaporfly 3 shoes (VF) showed 1.3% better running economy compared with the On Cloudboom eco 3 shoes (EB). These differences occurred even though both models showed reasonably similar levels of energy return at the forefoot (VF 6.4 J, EB 6.0 J). For the main study, twenty-one trained runners completed two 10-km trials at marathon pace followed immediately by a 2km time-trial (TT), one wearing Nike Vaporfly 3 shoes (VF) and one in On Cloudboom Echo 3 (EB) shoes, with each trial separated by one week. During the constant runs, gas exchange, heart rate (HR) and perceived exertion and were assessed.

RESULTS: During the 10-km run, O₂ cost for the VF was 1.6 ± 2.8 % lower compared with the EB ($p = 0.012$). No differences were detected in rate of perceived exertion between shoes (VF 5.0 ± 0.8 points, EB 5.2 ± 0.9 points, $p = 0.270$). No differences between shoes were detected for rate of change over time for O₂ cost ($p = 0.627$), HR ($p = 0.657$), or perceived exertion (0.779). Runners performed the 2-km TT 1.8 ± 3.6 % faster wearing the VF ($p = 0.031$).

CONCLUSION: Subtle differences in O₂ cost between different AFT shoes are sufficient to elicit performance improvements. Gains in performance were higher than those previously estimated from gains in running economy alone, suggesting that other indirect benefits might be present beyond the direct metabolic savings. Factors other than energy return might be equally or more important in determining the running economy benefits of different AFT models.

CHANGES IN PLAYER LOAD BETWEEN VENTILATORY THRESHOLD RUNNING SPEEDS IN RECREATIONAL RUNNERS

HOU, C., SHIANG, T.Y.

NATIONAL TAIWAN NORMAL UNIVERSITY

INTRODUCTION: Player load monitoring via inertial measurement unit (IMU) in sports has been widely studied to prevent injuries, enhance training efficiency, and optimize performance [1]. The first and second ventilatory thresholds (VT1 and VT2) are valuable indicators of exercise intensity for identifying the transition between aerobic and anaerobic energy systems [2]. It has been found that varying running speeds influence player load [3]. However, the differences in player load between running speeds at ventilatory thresholds remain unclear. Therefore, the aim of this study was to monitor the changes in player load between ventilatory threshold running speeds in recreational runners.

METHODS: Twenty-nine recreational runners (10km finish time: 48.10 ± 5.87 min) performed maximal incremental running test with 3-minute stages on a treadmill (HP). An IMU (100Hz, Vicon) was placed on the runners' lower back (L3–L5) to collect triaxial acceleration data during the incremental test. The raw acceleration data were filtered at 20Hz using a low-pass Blackman filter (AcqKnowledge). The 1-minute root mean square (RMS) of the triaxial player load (PLT) were calculated. The 1-minute RMS of the single-axis player load in the anteroposterior (PLAP), mediolateral (PLML), and vertical (PLV) axes were also calculated. The percentage contribution of each axis was calculated by dividing the RMS of uniaxial player load by the RMS of triaxial player load. Participants' gas exchange data were continuously measured using a portable gas analyzer (Cortex). The 1-minute averaged gas exchange data were used to determine the VT1 and VT2 running speeds. The last-minute IMU and Cortex data from each stage of the incremental test were used for analysis. A paired-samples t-test was used to evaluate differences in player load between VT1 and VT2 speeds. The significant level was set at $p < .05$. The effect size was calculated using Cohens d.

RESULTS: The RMSPLV (VT1 speed: 4.25 ± 0.86 , VT2 speed: 4.87 ± 0.88 ; $p < .001$, $d = -1.87$), RMSPLML (VT1 speed: 1.87 ± 0.60 , VT2 speed: 2.34 ± 0.80 ; $p < .001$, $d = -1.37$), RMSPLAP (VT1 speed: 1.81 ± 0.52 , VT2 speed: 2.41 ± 0.64 ; $p < .001$, $d = -1.78$), RMSPLT (VT1 speed: 5.04 ± 0.92 , VT2 speed: 6.00 ± 0.93 ; $p < .001$, $d = -2.38$), RatioPLV (VT1 speed: 84.30 ± 6.14 , VT2 speed: 81.26 ± 7.24 ; $p < .001$, $d = 0.94$), and RatioPLAP (VT1 speed: 36.47 ± 9.06 , VT2 speed: 40.82 ± 10.42 ; $p < .001$, $d = -1.04$) changed significantly

between VT1 and VT2 speeds. However, the RatioPLML (VT1 speed: 37.06 ± 8.78 , VT2 speed: 38.56 ± 9.57 ; $p=.11$, $d=-0.31$) did not change significantly between VT1 and VT2 speeds.

CONCLUSION: The RMSPLV, RMSPLML, RMSPLAP, RMSPLT, RatioPLAP increased significantly at VT2 speed. Interestingly, the RatioPLV decreased significantly at VT2 speed. Additionally, the RatioPLML did not change significantly at VT2 running speed. The results of this study suggest that PL in anteroposterior direction may play a more influential role at VT2 speed in recreational runners.

THE IMPACT OF FOOTWEAR FOAM ON RUNNING ECONOMY AND PERCEPTUAL METRICS AT DIFFERENT TREADMILL GRADIENTS

MUZEAU, M., FLOOD, A., SAUNDERS, P., STAIANO, W., TAM, N., KEEGAN, R., RATTRAY, B.
UNIVERSITY OF CANBERRA

INTRODUCTION: Advanced Footwear Technology (AFT) encompasses multiple innovations including the increase in longitudinal bending stiffness achieved through the integration of a plate and a softer and more resilient foam within the midsole. They have been shown to improve running performance and running economy (1). While performance benefits have commonly been investigated in road running, AFT is beginning to influence footwear used in trail running. Therefore, research is needed to investigate the effect of AFT in trail running footwear. In this study, we aimed to compare the effect of traditional (TRADI) and advanced foam technologies (PROTO) on running economy and perceptual measures across flat, up and down-hill gradients.

METHODS: Fourteen well-trained athletes (78.9 ± 25.3 km/week) completed assessments on the treadmill with FLAT (0% gradient, 14 km.h⁻¹), UP (+10%, 8 km.h⁻¹) and DOWN (-10%, 14 km.h⁻¹) conditions. Two shoes (TRADI v PROTO) were randomly allocated in a counterbalanced order, with a replicate in each condition. The shoes differed in their midsole foam type but were otherwise matched. PROTO included a softer and more resilient foam than TRADI (deformation: 23.63 v 19.46 mm; energy return: 9.97 v 6.86 J). Oxygen consumption, HR, RPE and affect (pleasure and arousal) were collected and averaged for each replicate. General Linear Mixed Model were used for the statistical analysis with a significance set at 0.05.

RESULTS: Across conditions, oxygen consumption was lower in PROTO than TRADI (44.9 ± 0.6 v 45.4 ± 0.6 ml.⁻¹.kg⁻¹.min⁻¹ respectively) with a small effect size ($p=0.008$; $d=0.47$). This equates to a superior running economy in the PROTO across all the conditions of 1.1%. The interaction between condition and shoes was not significant ($p=0.050$) although the tendency that an improvement may be more pronounced in the FLAT (+2.1%) and UP (+1.0%) conditions, compared to DOWN (+0%) may inform future, larger investigations. HR was lower in PROTO compared to TRADI ($p<0.001$; 145 ± 3.5 v 146 ± 3.5 bpm respectively) with a large effect size likely explained by the consistency of the change across all participants ($d=1.19$). RPE was lower ($p=0.010$) and pleasure higher ($p=0.025$) in PROTO compared to TRADI with a medium effect size. No effect on arousal was identified ($p=0.730$).

CONCLUSION: The findings of this study suggest that a softer and more resilient foam in trail running shoes can improve running economy, reduce HR and perceived exertion and increase pleasure while running at different gradient in a well-trained athlete population.

DETERMINING THE ACCURACY AND CONCURRENT VALIDITY OF A CAMERA-BASED COMPUTER VISION SYSTEM FOR RUNNING BIOMECHANICS ANALYSIS

DASSO, M.1,2, DUTHIE, G.3, ROBERTSON, S.1, HAYCRAFT, J.1

1. VICTORIA UNIVERSITY, MELBOURNE 2. WESTERN BULLDOGS FOOTBALL CLUB, MELBOURNE 3. AUSTRALIAN CATHOLIC UNIVERSITY, STRATHFIELD

INTRODUCTION: The assessment and monitoring of running biomechanics kinematic variables are crucial for optimising physical performance outcomes and facilitating rehabilitation processes in field-based sports athletes. It is well-established that marker-based 3D motion capture systems are the gold standard for accurately evaluating these metrics within a controlled, artificial environment. However, its feasibility and high cost make this technology inaccessible to most sporting organisations for regular on-field use. Continued advancements in biomechanical measurement via the application of deep learning and computer vision have supported the development of more accessible, non-invasive, and cost-effective motion capture useful for determining sport-specific movement patterns outside laboratory settings. VueMotion is a 2D camera-based markerless system capable of generating and analysing motion kinematics during sprints. This study aims to establish the accuracy and concurrent validity of VueMotion through comparison with a VICON 3D motion capture system for measuring ground contact time, flight time, step length and frequency, and peak velocity.

METHODS: Twenty-five elite and sub-elite athletes (16 females and 9 males; 22.9 ± 5.34 years) completed four maximal linear sprinting accelerations (flying 10-metre) for a total of 100 sprints while being assessed concurrently through a VICON 3D motion analysis system and VueMotion. Sixteen reflective spherical markers (14 mm diameter) and four four-marker clusters were placed onto participants' key landmarks of the body (i.e., hips, upper leg, lower leg, and feet) and analysed using the VICON Plug-In Gait lower body model. Kinematics metrics were collected using 38 infrared VICON cameras operating at 100 Hz, and 10 ground-embedded AMTI force plates sampling at 1000 Hz, synched via VICON Nexus soft-

ware. Simultaneously, body landmarks were video tracked in 2D by VueMotion using an iPhone 11 with the camera resolution set at 4K (3840 × 2160 pixels), 60 frames per second. The data capturing zone was demarked by two sets of cones placed at 0 m and 10 m, with a cone at the 5 m mark as per VueMotion setup requirements.

RESULTS: Root-mean-square errors (RMSE) for peak velocity, ground contact time, and flight time were 0.63 m/s, 0.01 s, and 0.01 s, respectively. Step length and frequency reported an RMSE of 0.05 s and 0.18 Hz. Mean bias with 95% level of agreement showed systemic underestimation for step length (0.02 m [- 0.11; 0.07]), flight time (- 0.01 s [- 0.02; 0.01]), and peak velocity (0.54 m/s [- 1.72; 0.10]). Ground contact time and step frequency were (0.01 s [- 0.01; 0.02]), and (0.03 Hz [- 0.31; 0.38]), respectively. Pearson's correlation coefficients for all variables ranged from 0.72 to 0.91, and the interclass correlation coefficients ranged from 0.67 to 0.90.

CONCLUSION: The accuracy and concurrent validity results from this study should be considered by any end user prior to integrating the tested system in research and practice.

SLEEP ARCHITECTURE PATTERNS IN MARATHON RUNNERS DURING, PRE- AND POST COMPETITION PHASES CAPTURED BY 24/7 WEARABLE TECHNOLOGY

SARTOR, F., MARINI, S., PAPINI, G.B., FONSECA, P.

UNIVERSITY OF CHIETI-PESCARA

INTRODUCTION: The 2013 launch of the first wrist-worn optical heart rate monitor (OHRM) [1] has greatly impacted sports, wellness, and clinical applications. Alongside unobtrusive HR-based exercise workload monitoring [2], unobtrusive HR variability and body movement-based sleep and sleep architecture monitoring have reached outstanding levels of accuracy [3]. This study aimed to observe OHRM derived sleep architecture patterns in preparation and in response to a marathon.

METHODS: This study was designed to observe training and sleep patterns of 20 habitual marathon runners for 8 weeks, including pre-tapering, tapering, marathon, and post-marathon periods. Because of technical difficulties, data from 17 marathon runners (15 males, aged: 38 ± 12 y, height: 1.81 ± 0.09 m, weight: 70 ± 9 kg, VO_{2max} : 64 ± 12 ml/kg/min) were analyzed. They visited our laboratory two times for VO_{2max} and muscle fatiguability tests. During the 8-week free-living observation, runners wore the OHRM device [2,3] 24/7. This recorded photoplethysmography and tri-axial accelerometry signals at 32 Hz. Furthermore, runners kept pre- and post-training diaries where they logged their perceived muscle fatigue, pain, and overall stress and recovery.

RESULTS: Total Running Days (RuDs) recorded were $N=206$ and Resting Days (ReDs) were $N = 149$. Total rest time (TRT), the total time spent in bed with the intention to sleep, was longer after RuDs (466.2 ± 90.2 min) vs. ReDs (461.8 ± 99.1 min), $t(13)=-2.28$, $p = 0.040$. A trend towards a longer total sleep time (TST) for RuDs vs. ReD (TST: 428.8 ± 88.4 vs. 416.7 ± 92.3 min, $t(13)=-2.13$, $p = 0.053$) was also observed. No differences were found in either sleep efficiency (SE) nor wake after sleep onset (WASO) (SE: 91.89 ± 6.15 vs. 89.98 ± 8.50 ; $t(13)=0.938$, $p = 0.365$, WASO: 23.16 ± 24.89 vs. 26.46 ± 23.09 min, $t(13)=-0.328$, $p = 0.748$). The RuD vs. ReD comparison did not show significant changes in sleep architecture either. Light non-REM sleep normalized by TST ($N1/N2\%$: 62.55 ± 8.04 vs. $65.88 \pm 9.34\%$, $t(13)=-0.516$, $p = 0.615$), slow wave sleep normalized by TST ($N3\%$: 11.82 ± 5.87 vs. $11.29 \pm 6.85\%$, $t(13)=0.362$, $p = 0.723$), and finally REM sleep normalized by TST ($REM\%$: 25.62 ± 5.63 vs. $22.81 \pm 5.90\%$, $t(13)=362$, $p = 0.723$) did not differ.

CONCLUSION: Previous studies showed that the longer the race distance the greater the importance of optimal sleep for race performance [4], and that sleep architecture seemed to be affected by high-intensity exercise. The present study shows that marathon runners spent more time in bed trying to sleep after a training day and tended to sleep longer, whereas sleep architecture did not seem to be affected. These preliminary results need to be integrated with linear mixed effect analysis looking at sleep pattern variations during tapering, marathon, and post-marathon periods. Furthermore, relations between sleep architecture fatigue and recovery will be analyzed.

PHYSICAL ACTIVITY AND FITNESS LEVEL IN A DISADVANTAGED REGION IN CENTRAL EUROPE: FOCUS ON HIGH SCHOOL STUDENTS AND THEIR TEACHERS

BEREGI, E., BOGNÁR, J., KISS-TÓTH, E.

1. UNIVERSITY OF MISKOLC; 2. ESZTERHÁZY KÁROLY CATHOLIC UNIVERSITY; 3. UNIVERSITY OF MISKOLC

INTRODUCTION: Extensive research has documented the beneficial effects of physical activity on health and fitness at youth and adults. The relationship between teachers and students health-conscious behavior and physical activity is an important factor to consider. Besides teacher student relationship and teachers' role modelling, socio-economic status contributes to the development of sedentary lifestyles among the disadvantaged. While numerous studies have examined physical activity and fitness patterns among youth and adults, considerably fewer investigations have focused on teachers

and there is limited research available comparing students' and teachers' health behaviors. The purpose of the study is to demonstrate the characteristics physical activity of high school and technical school students and teachers in a disadvantaged region.

METHODS: State-maintained secondary and technical schools in the region were selected to participate in the study. A total of 834 individuals participated in the study, including 732 students (17.3 ± 1.2 of age) and 102 teachers (48.2 ± 11.4 of age). Data collection was conducted via a structured questionnaire that included socio-demographic questions, fitness self-assessment items, and the International Physical Activity Questionnaire-short form test. All data analyses were performed using IBM SPSS Statistics version 25.0 ($p < 0.05$).

RESULTS: During the week preceding the study, 24.1% of students and 28.0% of teachers reported no engagement in vigorous physical activity. On a scale of 1 to 4, the students subjective fitness was rated as close to good (2.81 ± 0.85), while teachers rated students' fitness level lower (2.06 ± 0.71), and also, their own fitness was rated as good (2.84 ± 0.79). Students' metabolic equivalent values ($ME = 2732$) was significantly higher than teachers' ($MET = 2116$). Students spent significantly more time walking and sitting ($p < 0.05$) compared to teachers. Additionally, teachers employed at technical schools and students attending high schools exhibited significantly higher durations of sedentary behavior than their counterparts in high schools and technical schools, respectively ($p < 0.05$). No significant correlations were found between students' socio-economic situation and their physical activity levels.

CONCLUSION: This study revealed that the activity levels in both students and teachers are insufficient to maintain optimal health in this disadvantaged region. Notably, there were a lot of differences between teachers and students. Teachers perceived the students' physical activity levels to be lower than the students' own assessments, while simultaneously rating their own fitness as higher, despite recording significantly lower metabolic equivalent values. These findings underscore the need for further research to elucidate the factors contributing to inadequate physical activity and to develop effective interventions tailored to both teachers and students.

ASSOCIATION BETWEEN BLOOD LEAD AND ALL-CAUSE OR CARDIOVASCULAR DISEASE MORTALITY RISK: MITIGATING EFFECTS OF PHYSICAL ACTIVITY

XIAO, H., DONG, X.S., BAI, M.Y., SUN, T.T.

BEIJING SPORT UNIVERSITY

INTRODUCTION: This study aimed to investigate: (1) the associations between physical activity (PA), blood lead (BL) and all-cause or cardiovascular disease (CVD) mortality risks, and (2) the combined effects of PA and BL on all-cause or CVD mortality risks.

METHODS: A total of 22821 participants were included from the National Health and Nutrition Examination Survey (NHANES) database from 2007-2018. PA levels were assessed by Global Physical Activity Questionnaire (GPAQ). BL were measured using inductively coupled plasma mass spectrometry. Mortality status was obtained from the National Death Index (NDI) database. Statistical analyses were performed using the Cox proportional hazards models and restricted cubic spline (RCS).

RESULTS: Compared with the sufficiently active PA group, the inactive PA group increased 88% all-cause mortality risk ($HR = 1.88$, 95% CI = 1.71 - 2.07) and 78% CVD mortality risk ($HR = 1.78$; 95% CI = 1.49 - 2.12). Compared with the minimal blood lead level (Min-BLL) group, the high blood lead level (H-BLL) groups increased 72% all-cause mortality risk ($HR = 1.72$, 95% CI = 1.41 - 2.10), and 132% CVD mortality risk ($HR = 2.32$, 95% CI = 1.53 - 3.52). When compared with the Min-BLL group, H-BLL combined with inactive ($HR = 2.45$, 95% CI = 1.99 - 3.01) or insufficiently active PA group ($HR = 1.69$, 95% CI = 1.33 - 2.17) increased 145% or 69% all-cause mortality risk, and 200% ($HR = 3.00$, 95% CI = 1.95 - 4.62) or 135% ($HR = 2.35$, 95% CI = 1.44 - 3.84) CVD mortality risk. Compared with the sufficiently active PA group, inactive PA group combined with H-BLL ($HR = 2.28$, 95% CI = 2.04 - 2.25) or M-BLL ($HR = 1.80$, 95% CI = 1.57 - 2.07) increased 128% or 80% all-cause mortality risk, and 108% ($HR = 2.08$, 95% CI = 1.70 - 2.56) or 86% ($HR = 1.86$, 95% CI = 1.46 - 2.37) CVD mortality risk. RCS analyses showed BLL ($\mu g/dL$) above 0.12 (0.47), 0.83 (1.06), or 1.18 (1.18) in inactive, insufficiently active, or sufficiently active PA groups could increase all-cause (CVD) mortality risk.

CONCLUSION: Physical inactivity or H-BLL can increase all-cause and CVD mortality risks. In addition, increasing PA can mitigate the adverse effects of H-BLL on mortality risk. For inactive or insufficiently active individuals, maintaining Min-BLL is essential to minimize the impact of lead exposure on mortality risks.

IMPACT OF RAMADAN DIURNAL INTERMITTENT FASTING ON PHYSICAL ACTIVITY AND RESTING METABOLIC RATE: A SYSTEMATIC REVIEW AND META-ANALYSIS

ALWALEEDI, A., BIN RADHYAN, F., ALJALOU, K., DERA, A., CHEN, W.

UNIVERSITY OF MICHIGAN

INTRODUCTION: Ramadan diurnal intermittent fasting (RDIF) is associated with a number of lifestyle modifications, including changes in sleep patterns, dietary habits, and physical activity (PA) [1]. An understanding of how RDIF affects PA behaviors is crucial for promoting cardiometabolic and mental health among individuals observing the fast. This systematic review and meta-analysis aimed to examine changes in resting metabolic rate (RMR) and PA levels before and during Ramadan, with a focus on PA levels, measurement instruments, and gender differences. Additionally, we explored whether changes in PA were associated with body weight changes during RDIF

METHODS: This systematic review of observational studies was conducted following PRISMA guidelines. A comprehensive search of databases, including PubMed, Scopus, Medline, and Web of Science, was performed. Studies examining PA levels and RMR before and during Ramadan were included. Subgroup analyses were performed to examine differences in PA levels (sedentary behavior, light, moderate, vigorous), measurement instruments (objective and subjective), and by gender (male and female). Meta-regression was conducted to investigate the relationship between changes in PA and body weight outcomes. Random-effects meta-analyses were conducted using R programming software

RESULTS: revealed a significant reduction in objective PA during Ramadan compared to pre-Ramadan levels (SMD: -0.346, 95% CI: -0.575 to -0.117, $p = 0.003$), with high heterogeneity ($I^2 = 83.84\%$). Sedentary behavior also increased significantly during RDIF (SMD: -0.261, 95% CI: -0.441 to -0.082, $p = 0.004$). Subgroup analyses indicated that vigorous PA (VPA) showed a significant decline (SMD: -0.445, 95% CI: -0.863 to -0.027, $p = 0.036$), while light PA (LPA) also decreased significantly (SMD: -0.263, 95% CI: -0.36 to -0.166, $p < 0.0001$). No significant changes were observed in moderate PA (MPA) (SMD: -0.022, 95% CI: -0.610 to 0.940, $p = 0.94$). Gender-specific analyses revealed no significant differences in PA changes between males and females ($p > 0.05$). Resting metabolic rate (RMR) showed a non-significant decrease during Ramadan (WMD: -38.97 kcal/day, 95% CI: -128.34 to 50.38, $p = 0.392$). Meta-regression analysis indicated that changes in PA were not significantly associated with changes in body weight post-RDIF ($p > 0.05$)

CONCLUSION: Vigorous and light-intensity activities decline significantly during Ramadan, accompanied by increased sedentary behavior. Objective measures of PA captured more pronounced reductions compared to subjective instruments. The overall decline in PA highlights the need for targeted interventions to promote active lifestyles during RDIF. These findings emphasize the importance of maintaining PA to support health outcomes during periods of fasting

THE ASSOCIATION BETWEEN THE FREQUENCY OF MODERATE PHYSICAL ACTIVITY AND PHYSICAL FITNESS AMONG AUTISTIC ADULTS AGED 40-70 YEARS

CAO, M., HOU, X., FENG, Y.

GUANGZHOU SPORT UNIVERSITY

INTRODUCTION: Autism is a neurodevelopmental condition characterized by impaired social functioning and repetitive, restricted behaviours. While research has documented compromised physical fitness and reduced physical activity levels in autistic children, data on autistic adults remain limited. We aim to explore the association between the frequency of physical activity (PA) and physical fitness in autistic adults aged 40 to 70 years.

METHODS: Using the UK Biobank database, this study included 408 autistic individuals who had been diagnosed by professional institutions. Data from the baseline were analysed. The participants were categorised into two groups: regular moderate physical activity (PA), defined as engaging in PA three or more times per week ($n=231$), and irregular PA, defined as engaging in PA two or fewer times per week ($n=167$). One instance of moderate PA was defined as "10 minutes or more of moderate physical activities, such as carrying light loads or cycling at a normal pace, excluding walking". Physical fitness outcomes included pulse rate, blood pressure, overweight/obesity, abdominal obesity, and hand grip strength [1]. A logistic regression model was employed to explore the association between irregular PA and physical fitness outcomes, sociodemographic factors adjusted.

RESULTS: Individuals in the irregular physical activity (PA) group exhibited higher pulse rates (72.58 ± 11.81 vs. 69.39 ± 11.25 , $p=0.007$), were less likely to have a pulse rate below 60 beats per minute (11% vs. 22.2%, $p=0.005$), and were more likely to be abnormally obese (54.8% vs. 42.6%, $p=0.019$). Additionally, they showed a higher incidence of weak hand grip strength in both the dominant hand (weak, normal, strong: 27.5%, 61.1%, 11.4% vs. 22.9%, 53.7%, 23.4%, $p=0.009$) and the non-dominant hand (weak, normal, strong: 43.7%, 49.7%, 6.6% vs. 33.3%, 52.8%, 13.9%, $p=0.02$). After adjusting for sociodemographic factors, irregular PA was associated with a higher pulse rate (OR=0.36, 95% CI: 0.18-0.72), abdominal obesity (OR=1.75, 95% CI: 1.13-2.71), and weaker hand grip strength in both the dominant (weak: OR=2.47, 95% CI: 1.20-6.21; normal: OR=2.13, 95% CI: 1.04-4.37) and non-dominant hands (weak: OR=2.70, 95% CI: 1.10-6.62).

CONCLUSION: Autistic adults with irregular physical activity (PA) habits exhibited reduced physical fitness, particularly in terms of abdominal obesity and hand grip strength. These findings have significant implications for the development of health promotion and educational services aimed at the autistic adult population. It is crucial to encourage more consistent participation in physical activity, as this can help mitigate the risk of chronic diseases and improve overall physical fitness.

IDENTIFYING MOVEMENT BEHAVIOUR PHENOTYPES USING A REVERSED GRAPH EMBEDDING METHOD AND EXAMINING THEIR ASSOCIATIONS WITH CARDIOMETABOLIC HEALTH BIOMARKERS

BACKES, A., MALISOUX, L.

LUXEMBOURG INSTITUTE OF HEALTH

INTRODUCTION: Numerous metrics have been developed to capture the complex and multidimensional nature of movement behaviours. However, it remains unclear which measures – or combination of measures – best describe these behaviours. A dimensionality reduction technique is needed to identify distinct movement behaviour phenotypes and evaluate their associations with cardiometabolic health.

METHODS: The present study included 1023 participants from a cross-sectional study in Luxembourg (2016-18), comprising residents aged 18-79 years with ≥ 4 valid days of accelerometry data. Movement behaviours were characterised using seven metrics: average acceleration (AA), intensity gradient (IG), minimum acceleration value for the most active 30 minutes (M0.5), interdaily stability (IS), intradaily variability (IV) and transition probabilities between inactive and active states (TP IN-to-PA, TP PA-to-IN). A discriminative dimensionality reduction tree algorithm, a reversed graph embedding method, was used to identify distinct movement behaviour phenotypes. Phenotypes located at distal branches represent extreme phenotypes, while central nodes indicate mixed phenotypes. Linear regression models tested associations between the derived tree dimensions, movement behaviours, and cardiometabolic health biomarkers, including systolic and diastolic blood pressure, fasting plasma glucose (FPG), triglycerides, high-density lipoprotein cholesterol (HDL-c), apolipoprotein B/A1 ratio, fasting insulin, and a clustered metabolic risk score (CMRS).

RESULTS: All movement behaviour metrics were significantly associated with both tree dimensions. IV and TP PA-to-IN were positively associated with tree dimension 1, while AA, IG, M0.5 and IV were positively associated with dimension 2. Conversely, AA, IG, M0.5, IS, and TP IN-to-PA as well as IV, TP IN-to-PA and TP PA-to-IN were negatively associated with dimension 1 and 2, respectively. Hence, individuals positioned in the upper right corner of the two-dimensional tree exhibited greater variability within a day, a higher probability of transitioning from active to inactive states, higher average acceleration, a broader intensity distribution and a higher minimum acceleration during their most active 30-minute period. Adjusted regression models showed that tree dimension 1 was significantly associated with FPG, triglycerides, HDL-c, the apolipoprotein B/A1 ratio, fasting insulin and CMRS. No association was found for dimension 2 after adjustment.

CONCLUSION: This study demonstrates that a reversed graph embedding method effectively identifies distinct movement behaviour phenotypes based on key accelerometry-derived metrics. The observed associations between these phenotypes and cardiometabolic health offer valuable insights into how variations in movement behaviours relate to metabolic risk. These findings provide a novel framework for phenotyping movement behaviours and emphasise the need for further research into their implications for disease prevention and health promotion.

TWENTY-FOUR WEEKS OF HIGH LOAD RESISTANCE EXERCISE DOES NOT INCREASE BONE MINERAL DENSITY IN WHEELCHAIR USERS: RESULTS OF THE BONEWHEEL STUDY

RISVANG, L., STRØM, V.1,2, VAN DIJK, J.W.3, RICE, H.1, BAUMGART, J.4, LILJEGREN, A.5, IRGENS, I.6, SUNDGOT BORGES, J.1, RAASTAD, T.1, JONVIK, K.1

NORWEGIAN SCHOOL OF SPORT SCIENCES, SUNNAAS REHABILITATION HOSP., HAN UNI OF APPLIED SCI, NORWEGIAN UNI OF TECHNOLOGY & SCI, WESTERN NORWAY UNI OF APPLIED SCI, VID SPECIALIZED UNI

INTRODUCTION: Wheelchair users (WCU) are at risk of low bone mineral density (BMD, Z-score < -1.0) due to lack of skeletal stimuli. Previous interventions like electrical stimulation, vibration and standing therapy have shown minimal to no efficacy in improving BMD in populations such as those with spinal cord injury (SCI). In contrast, resistance exercise (RE) improves regional BMD in ambulant populations, but its effects in non-ambulant individuals who primarily engage in upper body exercises are unknown. Thus, we aimed to investigate the impact of high load RE on lumbar spine (LS) and hip BMD in WCU with non-progressive impairments.

METHODS: In this multi-centre 24-wk RCT, volunteers (WC use $< 50\%$) were stratified by sex and activity level and randomly allocated to either upper body RE 3 x/wk combined with nutrition optimisation (EX, n=24), or nutrition optimisation only (CON, n=21). At pre-, mid- and post-intervention, we measured LS, femoral neck (FN) and total hip BMD with dual-energy x-ray absorptiometry, maximal strength, serum bone turnover markers and vitamin D, and conducted 3x24-hr dietary recalls. The training programme consisted of four isometric and two dynamic upper body exercises aiming to load the LS and hip. Nutrition was optimised through supplementing whey protein (3x30 g/wk), vitamin D (40-120 ug/d) and calcium (500-1500 mg/d). Linear mixed model analysis was employed with random intercept for participants and fixed effects for group, time and interaction, and potential moderating factors. Values are frequencies or estimates (95%CI).

RESULTS: Forty-five WCU participated (SCI: 49%, cerebral palsy: 27%, other: 24%; 40% female; age: 37 ± 9 y; mass: 67 ± 19 kg; BMD Z-score < -1.0 LS: 41%, FN: 83%, hip: 80%), of which 33 completed the study. EX improved more than CON in maximal isometric ($+2.0$ [0.4-3.5] kg) and 1RM OHP ($+2.9$ [1.1-4.7] kg), as well as 1RM bench press: ($+4.2$ [1.4-7.1] kg). Nutrition optimisation increased, in both groups, serum vitamin D over time ($+14$ [10-18] nmol/L), reducing the prevalence of subclinical deficiency (< 50 nmol/L; from 60% to 3%), and increased calcium intake ($+167$ [15-319] mg/d). No effects were found on LS BMD (EX n=8, CON=16; group: -0.072 [-.232 - .089] g/cm²; time: $+0.004$ [-.005 - .013] g/cm²), and similarly no effects on FN or total hip, nor the prevalence of Z-score < -1.0 (all $p > .05$). Lastly, the bone formation to resorption ratio PINP/CTX-1 increased over time in both groups ($+17$ [6 - 28]).

CONCLUSION: High load RE over 24 weeks did not improve BMD, despite a significant increase in maximal upper body strength. Further analyses will explore if strength development influences BMD, with findings presented at the conference. The positive bone formation-to-resorption ratio shift suggests the positive role of nutrition in bone health. Lastly, a longer

intervention period and/or larger sample may be necessary to observe changes in BMD in this population and warrants further investigation.

DIFFERENT ISOMETRIC EXERCISE MODALITIES INDUCE DIVERGENT ACUTE EFFECTS ON MYOCARDIAL WORK IN TRAINED HYPERTENSIVE PATIENTS WITH ISCHEMIC HEART DISEASE.

CAMINITI, G.

IRCCS: IRCCS OSPEDALE SAN RAFFAELE

INTRODUCTION: Isometric exercise effectively reduces blood pressure (BP). However, the utilization of IE in the context of the rehabilitation of patients with IHD has, thus far, been prevented by the concern that it may result in an excessive increase in myocardial oxygen consumption. In this study we aimed to investigate the hemodynamic effects produced by two different isometric exercise modalities in hypertensive patients with ischemic heart disease (IHD).

METHODS: Forty-eight stable, trained patients with hypertension and IHD were enrolled. They were randomly assigned to perform a single session of bilateral knee extension (IKE) or handgrip (IHG) or no exercise (control) with a 1:1:1 ratio. Both exercises were performed at 30% of maximal voluntary contraction and lasted three minutes. Speckle-tracking echocardiography with the assessment of myocardial work and BP measurements were performed at rest, during the exercise and after ten minutes of recovery.

RESULTS: Both exercises were well tolerated, and no side effects occurred. During the exercise: systolic BP increased significantly in the IKE group compared to IHG and control (ANOVA $p < 0.001$). LVGLS decreased significantly in IKE (-21%) compared to IHG and control (ANOVA $p = 0.002$). The global work index increased significantly in IKE (+28%) compared to IHG and control (ANOVA $p = 0.034$). Global constructive work and wasted work increased significantly in the IKE compared to IHG and control (ANOVA $p = 0.009$ and < 0.001 respectively). Global work efficiency decreased significantly in the IKE group (-8%) while remained unchanged in the IHG and controls (ANOVA $p = 0.002$). During the recovery, systolic BP dropped significantly in the IKE group compared to IHG and control (ANOVA $p = 0.022$).

CONCLUSION: We observed that myocardial work efficiency was impaired during isometric bilateral knee extension but not during handgrip. Handgrip evoked a very limited hemodynamic response. Our data suggests that in hypertensive patients with underlying IHD, performing isometric exercise with handgrip seems a viable choice in terms of hemodynamic tolerability. Future studies should clarify whether handgrip is also effective in lowering BP in these patients.

THE EFFECTS OF AQUATIC REHABILITATION EXERCISE PROGRAMS ON FALL-RELATED PHYSICAL FITNESS AND COGNITIVE FUNCTION IN AGEING ADULTS WITH PHYSICAL DISABILITY

YANG, H., LEE, Y.

SEOUL NATIONAL UNIVERSITY

INTRODUCTION: As the ageing population increases, elderly individuals with physical disabilities face higher risks of falls and cognitive decline, leading to reduced independence and quality of life. Traditional rehabilitation methods often pose mobility and accessibility challenges, limiting participation. Aquatic rehabilitation exercise provides a low-impact alternative, using buoyancy and resistance to enhance physical function, balance, and cognitive health while minimizing joint strain.

METHODS: This research, guided by the Leisure Ability Model (LAM), consists of two components. A systematic review was conducted to analyze existing research on aquatic rehabilitation interventions for ageing adults with physical disabilities, identifying key findings and limitations. An experimental intervention was implemented to assess the effects of aquatic rehabilitation exercise on fall-related physical fitness and cognitive function, measuring balance, muscle strength, flexibility, reaction time, memory, attention, and executive function. The relationship between physical and cognitive improvements was examined, along with the long-term impact on fall prevention and well-being.

RESULTS: Findings from the systematic review highlighted positive effects of aquatic rehabilitation on mobility, strength, and cognitive function but indicated a lack of research on long-term outcomes. The experimental study demonstrated significant improvements in balance, muscle strength, and cognitive function among participants engaged in aquatic rehabilitation compared to non-participants. A strong correlation between physical and cognitive enhancements was observed.

CONCLUSION: Aquatic rehabilitation exercise effectively improves fall-related physical fitness and cognitive function in elderly individuals with physical disabilities. The findings support the development of accessible, evidence-based rehabilitation programs to promote healthy ageing, fall prevention, and enhanced quality of life.

PRELIMINARY RESULTS FROM THE ADVICE PROJECT, PHASE I: THE INTERACTION BETWEEN MULTIPLE SCLEROSIS AND MENSTRUAL CYCLE PHASES ON FATIGUE, PAIN, AND STRENGTH.

MARÍN JIMÉNEZ, N., CUPEIRO-COTO, R., ANDREU-CARAVACA, L., ÁVILA-GANDÍA, V., ROMERO-PARRA, N., LÓPEZ-LIRIA, R., JACOBO, Á., RUBIO-ARIAS, J.A.

UNIVERSITY OF ALMERÍA; UNIVERSIDAD POLITÉCNICA DE MADRID; UNIVERSIDAD CATÓLICA DE MURCIA.

INTRODUCTION: Fatigue and pain are common symptoms in women with multiple sclerosis (MS), yet their relationship with the menstrual cycle phases (MCP; early follicular phase, EFP; late follicular phase, LFP; mid follicular phase, MLP) remains

unclear. This study aimed to analyze how MS and MCP interact to influence fatigue, energy perception, pain, and strength [handgrip strength (HGS) and 5 repetitions sit-to-stand test (5-STSS)].

METHODS: A comparative study was conducted as part of the Esclerosis Múltiple, Ciclo Menstrual y Actividad Física (AD-VICE) Project, involving women diagnosed with MS (n= 5) and women without MS (n= 8). Fatigue, energy, and pain were assessed using validated scales, while HGS and the 5-STSS were used to measure functionality. Phase-specific comparisons (EFP, LFP, MLP) were analyzed separately within each group (MS vs. non-MS). The three-step method (i.e. calendar, urine LH peak, and serum hormones) was used for MCP confirmation. Two-way mixed ANOVA was used to examine the interaction between MS status and MCP. Pairwise comparisons were conducted, with Cohen's d calculated for both intra-group (phase differences) and inter-group (MS vs. non-MS) effects.

RESULTS: Fatigue perception was significantly influenced by both MS status and MCP ($p < 0.05$). Women with MS reported the highest fatigue levels during the EFP compared to LFP and MLP ($p = 0.026$, $d = -1.3$). In women without MS, fatigue remained stable across phases, with no significant variations. A significant MS $\times$ MCP interaction was found ($p < 0.05$), indicating that fluctuations in fatigue were more pronounced in the MS group. Pain perception was higher in the MS group, particularly during the MLP ($p = 0.008$, $d = -1.9$). Intra-group comparisons confirmed that pain increased significantly from EFP to MLP within the MS group ($d > 1.0$). Women without MS did not show significant changes in pain across the cycle. Energy levels did not differ significantly between groups or across MCP ($p > 0.05$). Handgrip strength and 5-STSS performance remained stable across groups and MCP, with no significant effects of MS status or cycle phase ($p > 0.05$, $d < 0.3$).

CONCLUSION: These findings suggest that MS interacts with MCP, particularly affecting fatigue and pain perception. The EFP appears to be the most symptomatic period for fatigue in women with MS, while pain is exacerbated during the MLP. Despite these variations in perceived symptoms, functional performance (HGS and 5-STSS) remained unaffected across phases and groups. The large effect sizes observed reinforce the clinical significance of phase-specific symptom changes, even in a small sample. Future research should further explore hormonal and inflammatory mechanisms underlying these variations and develop personalized symptom management strategies for women with MS.

CARDIOPULMONARY EXERCISE TESTING IN ATHLETES WITH DISABILITIES: INSIGHTS FROM PERFORMANCE ANALYSIS

AKURATERE, G., KLAVINA, A.

RIGA STRADIŅŠ UNIVERSITY

INTRODUCTION: This study examines the cardiovascular and aerobic performance of athletes with disabilities from Latvia through Cardiopulmonary Exercise Testing (CPET).

METHODS: A group of 30 athletes with various disabilities including spinal cord injury, amputations, cerebral palsy, and congenital development disorders participated in CPET using either veloergometer (n= 12) or an arm ergometer (n =18). Key performance indicators such as peak oxygen uptake (VO₂peak), physical work capacity (PWC_{max}), and heart rate (HR), HR recovery were analysed in relation to athlete demographics, training habits, and sports. Athletes ranged in age from 18 to 68 years (mean=40.53±12.4), with BMI from 19 to 37 (mean = 26.43 ± 5.06). The athletes had an average of 13.52 (± 9.43) years of experience in their respective sports, with the majority (21 athletes) training 2 or more times per week. Athletes were divided into four age groups: 18-30 years (Group 1, N=6), 31-40 years (Group 2, N=8), 41-50 years (Group 3, N=8), and 50+ years (Group 4, N=8).

RESULTS: The greatest difference was found in maximum workload outcomes, with athletes aged 50+ years (Group 4) achieving significantly lower values compared to those aged 31-40 years (Group 2) (mean difference = 85.00 W, $p = 0.015$, CI 95% 16.98, 153.02). However, no statistically significant differences were found between athletes from other age groups ($p > .05$). The average aerobic threshold outcome for Group 4 was significantly lower than for Group 1 and Group 2 ($p = .039$, $p = .009$, respectively). The VO₂peak values presented significant differences between Group 2 and Group 4 indicating reductions in both absolute and relative VO₂peak for older athletes (mean difference = 981.75 mL/min, $p = 0.006$, CI95% 1704.74, 258.75 and 12.59 mL/kg/min, $p = 0.002$, CI95% respectively). Also, heart rate recovery was significantly slower for Group 4 athletes compared to Group 2 ($p < 0.05$). Furthermore, the reasons for CPET termination were analysed, with the most common being maximal effort (60%), followed by reaching the target heart rate (20%), excessive dyspnea (13.33%), and reaching maximal systolic blood pressure (6.67%).

CONCLUSION: Age related declines in both cardiovascular and aerobic performance were observed, especially in Group 4 (athletes aged 50+ years). Younger athletes demonstrated consistent performance, while VO₂peak significantly decreased with age. Most common reason for CPET termination was reaching maximal effort and target heart rate. These findings suggest the need for age-appropriate training interventions to maintain athletes' performance. Further research is needed to develop strategies to minimize the effects of aging on athletes' performance especially in athletes with disabilities.

OP-SH17 Physical Activity Promotion II

MEDIATING AND MODERATING EFFECTS OF A PARENT-BASED ELECTRONIC HEALTH (EHEALTH) INTERVENTION ON PRESCHOOLERS' PHYSICAL ACTIVITY, DIETARY BEHAVIORS, AND SLEEP

LAU, W., ZHOU, P.

HONG KONG BAPTIST UNIVERSITY

Background: Preschool children are characterized by physical inactivity, poor diet, and disturbed sleep quality, negatively impacting long-term health. Parental involvement is crucial in reversing unhealthy trend, and eHealth interventions can help engage parents by overcoming barriers like time and travel costs. Investigating the mechanisms by which parent-based eHealth interventions work and who they work for is particularly important.

Objectives: To evaluate the mediators and moderators of a parent-based eHealth intervention on preschoolers' physical activity, diet, and sleep at 12-week posttest.

Method: The mediation and moderation analyses utilized dataset from a 24-week electronic health intervention study of Chinese preschoolers aged from 3 to 6 years (N=237 parent-child dyads), which was designed as a two-arm single-blinded randomized controlled trial to improve preschoolers' physical activity, diet, and sleep. Preschoolers' PA and sleep duration and quality were objectively examined using wGT3X ActiGraph accelerometer. Data related to parents and preschoolers' eating behaviors and sleep problems were subjectively assessed using parent-reported questionnaires. The generalized estimating equation analysed the changes in preschoolers' physical activity, diet, and sleep from baseline to 12 weeks between the two groups. Significant changes in the intervention group were assessed using PROCESS macro version 4.2 to determine potential mediators and moderators on these outcomes.

Results: After 12 weeks of intervention, significant improvements were observed in children's diet, sleep, and screen time, which were associated with an increase in corresponding parenting self-efficacy. Enhancements in children's diet and sleep were mediated by authoritative parenting style, while improvements in diet were also influenced by the feeding practice of control overeating. The exploratory analysis of moderators indicated that the effectiveness of intervention on preschoolers' physical activity varied based on the children's age and the parents' BMI.

Conclusion: It is suggested that future parent-based eHealth intervention research could focus on parenting self-efficacy, parenting styles, and parenting feeding practices to enhance the effectiveness of interventions targeting preschoolers' lifestyle behaviors.

COMMUTING PHYSICAL ACTIVITY-SCHOOLS OF SORIA (CPA-SOSORIA): STUDY PROTOCOL

CALONGE PASCUAL, S., MANRIQUE-LÓPEZ, G., IZQUIERDO, J.M., GONZÁLEZ-GROSS, M.

UNIVERSIDAD DE VALLADOLID

Introduction: Physical inactivity is currently one of the major threats to public health. Childhood and adolescence are considered essential periods for developing healthy lifestyle habits. The school environment provides an ideal context to promote physically active behaviours. The 48% of physical activity guidelines could be achieved among students with active commuting to and from school. This study aims to design a project to analyze the physical activity of students during commuting and its relationship with personal, interpersonal, organizational, community, and policy dimensions.

Methods: Participants are 480 students, 480 parents, and 8 Physical Education teachers from all high schools in Soria, Spain. According to these socio-ecological dimensions: a) personal dimension, measured by the Basic Psychological Need Satisfaction in Active Commuting scale (BPNS-ACS) (1), and by the mode, frequency, distance and time of commuting to and from school survey (2) as well as accelerometer (ActiGraph wGT3X-BT), ALPHA Fitness test, health and quality of life survey (EQ-5D-Y-SL); b) interpersonal dimension, assessing the parental barriers by the safe routes to school program questionnaire (3); c) organizational dimension, by a Google Form questionnaire for PE teachers to check the didactic use of active commuting according to Spanish educational law; d) community dimension, by assessing walkability index and some socioeconomic factors of the school community, and e) policy dimension, by a Weaknesses, Threats, Strengths and Opportunities (SWOT) framework based on data collected from local educational policymakers. The protocol has been sent to the Ethical Committee of Universidad de Valladolid for approval. This Project (EDUCYL2024_05) is funded by the Consejería de Educación de la Junta de Castilla y León through the Dirección General de Innovación y Formación del Profesorado.

Results: Physical active commuting data and their relationship to basic psychological needs, academic performance, physical fitness, self-perceived health, well-being, and quality of life status of students, and also, parents, teachers, and policymakers' information will be shown by a SWOT.

Conclusions: This project aims to design a planned strategy to promote active commuting in schools as an educational and public health strategy.

GENDER DISPARITIES IN SCHOOL SPORT PARTICIPATION: BARRIERS AND IMPLICATIONS FOR LONG-TERM SPORT ENGAGEMENT

COULBECK, V., GOLLISH, S., RYAN, S., SABISTON, C.
UNIVERSITY OF TORONTO

School-based sport serves as a critical gateway to lifelong physical activity, athletic development, and future sport involvement. However, persistent disparities in participation rates and access continue to hinder engagement among girls and gender-diverse youth. This study investigates systemic barriers in schools in Ontario, Canada. This study analyzed survey data from 160 students (ages 5–18, $M = 12.12$, $SD = 3.44$ years) and 59 school leaders including school principals (21.3%) and physical education teachers (47.5%). Descriptive statistical analyses were conducted to examine gender-based differences in sport participation rates, perceived barriers, and structural limitations within school settings. Thematic analysis of qualitative responses provided insight into institutional challenges and facilitators of gender-inclusive sport environments. Based on the findings, a significant gender gap in participation was observed with 41% of girls meeting physical activity guidelines compared to 53% of boys. Moreover, just 29% of girls participated in varsity sports, despite equivalent program offerings, highlighting the existence of non-structural barriers that need to be further understood (e.g., perceived competence, social norms, and psychological deterrents). Notably, 25% of girls and 66% of gender-diverse youth reported actively avoiding physical education classes due to discomfort, anxiety, or lack of enjoyment, pointing to a misalignment between curricular physical education and students engagement needs. Structural barriers further constrain access to school-based sport as a developmental pathway. For example, 80% of school leaders reported that the school provided equal opportunities for physical activity, and less than 40% indicated active efforts to create more inclusive environments for girls. Additionally, 31% of girls cited menstruation as a direct barrier to participation, yet institutional accommodations (e.g., flexible uniform policies, period-friendly resources) remained inconsistently implemented. Limited off-hours access to gymnasiums (reported by 50% of schools) and restricted availability of sport equipment (33%) further narrowed the scope for skill development and continued participation beyond mandatory physical education. The underrepresentation of women school leaders in coaching and sport leadership roles was identified as a key barrier to program inclusivity. Furthermore, only 55% of secondary school administrators perceived gender equity in sport scheduling and resource allocation, highlighting persistent disparities shaped by institutional and cultural dynamics beyond opportunity provision. Based on these findings, recommendations for creating a more inclusive sport system will be discussed, focusing on strategies that can enhance access and engagement for all students. School sport experiences can be foundational to increased participation in physical activity across the lifespan and need to be fostered.

PREVENTION OF STRESS-ASSOCIATED CONDITIONS IN HIGHER EDUCATION STUDENTS THROUGH HEALTH-ENHANCING RECREATIONAL PHYSICAL ACTIVITY

DROZDOVSKA, S., ANDRIEIEVA, O.V., BYSHEVETS, N.G.
NATIONAL UNIVERSITY OF UKRAINE ON PHYSICAL EDUCATION AND SPORT

INTRODUCTION: Today's Ukrainian university students are exposed to military stressors for a long time. They experience significant psychological stress as a result of constant anxiety, fear for their lives and health, instability, and economic disruption caused by military operations. These factors lead to widespread stress-related states among students, including stress, anxiety, and the risk of developing post-traumatic stress disorder (PTSD).

METHODS: The study involved 125 university students. The study utilized questionnaires comprising blocks of questions designed to ascertain psychophysiological indicators (activity, mood, sleep, appetite, performance, and well-being) with the 5-point Likert scale; stress level by V. Y. Shcherbatykh; anxiety scores using the Spielberg-Hanin Inventory; and the risk of PTSD using the Mississippi Scale. To analyze the impact of different types of physical activity (PA) on stress-related states, logistic regression models were built. GLZ models were utilized. The statistical significance of the models was assessed using the Wald test.

RESULTS: The analysis indicated that adventure tourism is a statistically significant predictor ($p < 0.05$) of stress reduction, a decrease in intrusive thoughts, and mood improvement. Mental fitness was found to be the most effective means for the restoration of mental balance. The models for predicting an increase in stress tolerance revealed dependencies on the type and amount of PA. This study contributes to the extant scientific knowledge base in the field of health-enhancing recreational physical activity aimed at preventing stress-related states. The proposed approach to the use of GLZ-models in the study of students stress tolerance opens up new opportunities for analyzing the complex relationships between types of PA and psycho-emotional states.

CONCLUSION: The findings confirm prior research on the significant impact of PA on mental well-being. Studies highlight PA as a key adaptive mechanism in stress management, while the type and context of PA influence its effectiveness in alleviating stress. Predictive models developed in this study suggest that while team sports participants exhibited better performance, their high PTSD risk nullified stress-reducing effects. This may stem from competition-induced emotional strain, as elevated cortisol levels hinder psychological recovery. In contrast, mental fitness and adventure tourism groups

showed superior outcomes, aligning with research on the stress-reducing effects of less competitive, nature-based activities. Adventure tourism, in particular, fosters resilience through nature exposure, social support, and personal achievement. Despite the statistical significance of the models, further refinement is needed, particularly through larger, more diverse samples and a focus on sex-based differences. Given the unique stressors of wartime conditions, integrating non-competitive PA— such as adventure tourism and mental fitness – into student wellness programs is essential.

AN INVESTIGATION INTO THE HEALTH-PROMOTING LIFESTYLE AMONG ITALIAN INDIVIDUALS AND ITS INTERACTION WITH SOCIODEMOGRAPHIC VARIABLES AND PERSONAL CHARACTERISTICS.

STRASSOLDO DI VILLANOVA, F., MORGANTI, G., VITARELLI, M., QUARANTELLI, M., ANDRIEU, B., RUSCELLO, B., PADUA, P.
SAN RAFFAELE OPEN UNIVERSITY, ROME

INTRODUCTION: Lifestyle is shaped by sociodemographic and environmental factors (e.g., age, sex, economic conditions, education, employment, housing, social inclusion, infrastructure access) that interact with individual behaviors (e.g., diet, physical activity levels, spirituality, social engagement, and healthcare) [1]. In Italy, regional disparities exist in health systems, economic conditions, infrastructure, and employment [2]. In this context, monitoring people's lifestyles and well-being is essential for improving health interventions. Accordingly, this cross-sectional study explores the relationship between sociodemographic factors, health-promoting behaviors, and perceived well-being in Italy.

METHODS: An online survey was distributed through Google Forms to people aged 18–70, containing 12 sociodemographic items and two validated questionnaires. The Health Promoting Lifestyle Profile II assessed health-promoting behaviors (i.e., Health Responsibility HR, Interpersonal Relationships IR, Nutrition N, Physical Activity PA, Spiritual Growth SG, Stress Management SG) while the WHO-5 Well-Being Index measured perceived well-being. Descriptive statistics were reported. Independent t-tests examined sex differences in health behaviors and well-being, while ANOVA models (followed by Bonferroni post-hoc test) assessed differences among variables per sociodemographics. Pearson's *r* coefficient explored the relationships between health behaviors and well-being. Statistical significance was set at $p < 0.05$.

RESULTS: 186 individuals (mean age= 40±12years) participated: 126 women (mean age= 41±12years; height= 165±5cm; weight= 61.5±10.7 kg; BMI= 23.3±3.8 kg/m²) and 60 men (mean age= 39±12 years; height= 178±7cm; weight= 78.7±11.9kg; BMI= 23.6±3.5 kg/m²). ANOVA revealed significant differences in HR, IR, and SG scores based on sociodemographics ($F = 3.1$ to 8.73 ; $p < 0.001$ to $p = 0.037$). Post-hoc analysis shows women reported higher HR than men. Higher HR was also reported for individuals living with other adults and under 18 compared to those living alone. Regarding SG and IR, people living with under 18 scored higher values than those living alone or with other adults. Additionally, a recent improved financial status links with higher SG and IR. No significant differences were found for well-being across sociodemographics, while IR, N, and PA showed small-to-moderate positive correlations with the WHO-5 score ($R = 0.131$ to 0.620).

CONCLUSION: Findings suggest that, in Italy, factors such as sex, housing, and financial status interact with health-promoting behaviors. Notably, living with children seems to encourage focusing on aspects like health guidance, personal needs, and love. A higher income fosters well-being, as individuals feel more confident and stable, allowing for deeper relationships. Finally, behaviors such as PA and N correlate with well-being, highlighting their role in enhancing life quality.

ANALYSIS OF THE TENNIS EXPERTS' ANTICIPATORY PERFORMANCE IN GRAND SLAM FINAL MATCH (FEDERER AND DJOKOVIC, WIMBLEDON FINALS MATCH, 2019)

DIMIC, M., BUSUTTIL, N.A.
WASEDA UNIVERSITY

INTRODUCTION: During professional tennis match-play, the demands for movement efficacy increase due to the high level of technical-tactical expertise of competing athletes [1]. To gain an advantage, athletes may require increased perceptual-cognitive performance (anticipation) during rally exchanges to cope with these increased demands. Expert receivers (ball incoming) demonstrate an ability to use perceptual cues in the form of postural kinematics, such as hip and shoulder movement [2] and body movement dynamics [3], to proactively anticipate an opponent's stroke intention [4]. In addition, they exploit the same abilities as hitters (ball leaving) to disguise their strokes to cause deception [5]. Therefore, the analysis aimed to understand the anticipatory and deceptive behavior of two expert performers in-situ of grand slam tennis match-play.

METHODS: Anticipatory performance was analyzed during two sets, with a frame-by-frame video analysis using Dartfish (v7.0.20114, Dartfish, Fribourg, Switzerland). Every receiver's (ball incoming) movement response initiated pre-impact was

defined as anticipation. The response orientation corresponding to the post-impact ball direction was classified as correct, while in the opposite direction, as an incorrect anticipatory response. The disguising stroke execution intention (ball leaving) was analyzed as the hitter's stroke intentions judged for stroke direction opposite from the post-contact direction (6). To judge the stroke intentions, kinematics of trunk (hip and shoulder) rotations during shot preparation for the forehand (7) and backhand (8) were observed. We analyzed both performances, acknowledging that if disguising did not occur and execution followed previously judged intentions, the receiver's anticipatory responses were categorized as "incorrect", and the disguised stroke execution should be acknowledged as "correct".

RESULTS: Analysis data showed that both experts as receivers initiated:

(A) 98 correct anticipatory responses to hitter's 300 strokes

(B) 52 incorrect anticipatory responses to hitter's 83 disguised strokes.

By combining (A) and (B), receivers' efficiency in anticipatory movement increased from initially observed 98 correct responses (success rate 54%) to 150 (83%), showing that receivers' efficiency of the anticipatory movement responses should not be analysed without the consideration of hitters' expertise in disguising stroke performance.

CONCLUSION: The analysis suggests that future research should consider the mutual relationship between receivers' and hitters' perceptual-cognitive abilities for anticipation.

DEVELOPMENTAL TRAJECTORIES OF TALENTED TENNIS PLAYERS DURING ADOLESCENCE: A PROSPECTIVE LONGITUDINAL APPROACH

RIKKEN, K., HUIJGEN, B., HOEKSTRA, A., BROUWER, M., DEN HARTIGH, R.
UNIVERSITY OF GRONINGEN

INTRODUCTION: Talent typically emerges during adolescence (1), as athletes develop physically, psychologically and socially during this period (2). Talent development is assumed to be a complex, often non-linear and individual-specific process. Yet, longitudinal studies on junior performance during adolescence are limited (4), and many studies retrospectively analyze elite players (5). The current study aims to address this gap by prospectively examining the developmental trajectories of a broad sample of talented tennis players during adolescence, based on a continuous and objective performance measure (i.e., rating). Additionally, the relationship between performance at age 16 and preceding ages is studied. Differences between male and female players will be highlighted.

METHODS: Growth Mixture Modeling (GMM) was performed to analyze the development of performance of 755 youth tennis players (at least once ranked top-300 nationally in their age category), aged from 11.5 until 16 years (N=469 males, N=286 females). Players' individual singles rating of the national rating-system in the Netherlands was taken at half-yearly intervals. Correlations were calculated to analyze the relation between rating at age 16 and the preceding ages. Overlap percentage with preceding ages was calculated for the top 5% and the top 5 players at age 16.

RESULTS: To fit the developmental trajectories, a 4-class solution performed best for male players and a 5-class solution was best for female players. For both genders, quadratic fixed and mixture effects were included. The male class with the best performance at age 16 displayed a non-linear developmental trajectory, coming from little improvement up until age 13.5, after which performance improved rapidly. On the other hand, the female class with the best performance at age 16 showed a linear developmental trajectory throughout. For both the whole male and female sample of players, the correlation between rating at the age 16 and at preceding ages increases steadily from .60 at age 11.5 to .95 at age 15.5. The overlap percentage for the best 5% and best 5 is consistently around 15% higher for females than for males between age 11.5 to age 14.

CONCLUSION: The growth mixture models for male and female players both show diverse developmental trajectories. Performance in male players remained consistent among the classes between ages 11.5 and 13.5, after which performance diverged. This resulted in a non-linear developmental class trajectory for the best male class. Performance in female players showed no divergence point, as the best female class showed consistent linear improvement from 11.5 onwards. These findings could be related to gender-based differences in maturation. Given the linear trajectories and consistently higher overlap percentage, talent identification could be feasible at earlier ages for female compared to male players.

ADVANTAGES AND DISADVANTAGES OF LONG-HITTER SWING TECHNIQUES: A COMPARATIVE ANALYSIS OF CHINESE AND INTERNATIONAL PROFESSIONAL GOLFERS (2022-2023)

YIN, H.

SHANGHAI UNIVERSITY OF SPORT

INTRODUCTION: INTRODUCTION: As golf continues to expand and benefit from technological innovations, courses are lengthening, making tee-shot distance increasingly critical in competition. Long hitters gain advantages in club selection, greens in regulation (GIR), and putting performance. However, emphasizing distance too heavily may compromise stability and fairway accuracy, particularly if techniques from long-drive contests are applied to formal stroke play. Consequently, professionals must balance power and control, preserving both distance and consistency.

METHODS: We analyzed PGA Tour data (2022-2023) from Chinese professional players ($n=4$, representing all Chinese male players who participated in PGA Tour events during this period) and leading international professional players ($n=10$, selected based on their consistent ranking within the world's top 50 and average driving distance exceeding 310 yards). Performance metrics were analyzed using TrackMan and ShotLink systems, focusing on driving distance, accuracy, GIR, and world rankings.

RESULTS: The average driving distance for the top 10 professional players worldwide is 313.2 yards, whereas Chinese professional players average 299.0 yards, indicating a distinct advantage for international professional players in terms of driving distance. The average driving accuracy of international professional players is approximately 58.8%, while that of Chinese professional players is approximately 57.2%, both close to the tour average of approximately 59%. Despite the minor difference, an integrated analysis of overall competitive performance and world ranking suggests that driving accuracy has no direct, significant impact on ranking. The top 10 professional players worldwide generally achieve a GIR rate of approximately 70%, whereas Chinese professional players typically achieve approximately 65%, reflecting disparities in technical details and training methodologies. Top 10 professional players driving distance averages 318.8 yards, while those within the top 50 average 312.8 yards, demonstrating a positive correlation between driving distance and higher world rankings. This further confirms the importance of driving distance for overall competitive performance.

CONCLUSION: Our analysis indicates that longer driving distance tends to associate with better tournament performance and higher world rankings. Chinese professional players displayed notable differences in driving distance (14.2 yards lower) and GIR (5% lower) compared to top international professional players. Based on these findings, we recommend developing targeted training programs emphasizing strength, flexibility, and swing mechanics, supported by modern technology, to improve driving distance while maintaining consistent accuracy.

TAEKWONDO KICKING MOVEMENT QUALITY ASSESSMENT BASED ON INERTIAL MOTION CAPTURE

LIU, Z., YANG, M.Y., QIN, X.

BEIJING SPORT UNIVERSITY

INTRODUCTION: Taekwondo leg techniques demand high-speed execution and complex coordination, making their training and evaluation a long-standing focus in both teaching and research. Unlike traditional camera-based motion capture systems, inertial motion capture systems—composed of multiple IMUs—offer significant advantages, including portability and minimal dependence on environmental conditions. This study utilizes high-dimensional motion data collected through an inertial motion capture system and applies deep learning models to achieve objective recognition and quality assessment of Taekwondo leg techniques. By enabling automated action classification and scoring, this approach provides a more scientific and practical solution for Taekwondo instruction and training.

METHODS: A total of 20 participants (both professional athletes and amateur practitioners) were recruited. Each participant wore an inertial motion capture system (Noitom Perception Neuron 3) attached to key body segments (e.g., waist, thighs, ankles) while performing five types of Taekwondo kicking techniques (front kick, roundhouse kick, side kick, back kick, spinning hook kick). The raw data underwent preprocessing steps including data cleaning, windowing, and normalization. For action classification, we implemented an improved one-dimensional convolutional neural network (1D CNN) and a Transformer architecture, enhanced with techniques such as Dropout, Batch Normalization, and L2 regularization to improve model accuracy and generalization. Building on the action recognition results, we employed an autoencoder to reduce dimensionality and constructed a Gaussian Mixture Model (GMM) with the Expectation-Maximization (EM) algorithm to generate a quality assessment score. The log-likelihood values derived from the GMM were mapped to a 0–10 scoring range through a monotonically decreasing function. Expert evaluations were used as a reference for tiered comparisons, and a CNN-based regression model was developed to predict final scores for each kicking technique.

RESULTS: The 1D CNN achieved an accuracy of 93%, up from an initial 87%, while the refined Transformer model achieved a 96% accuracy rate. The automated scoring system demonstrated an approximately 85% agreement with expert-based tier assessments, indicating strong consistency between objective and subjective evaluations. Furthermore, the model exhibited stable predictive performance for different kicking techniques, with the side kick attaining a mean absolute deviation of 0.555 and a root mean square deviation of 0.645 in score prediction.

CONCLUSION: Deep learning approaches based on an inertial motion capture system can effectively recognize Taekwondo leg techniques and provide a relatively objective, interpretable quality assessment framework. This research gives valuable support for technical monitoring and scientific management in Taekwondo training, with potential applications in objective performance evaluation and intelligent training systems for other sports.

PACING PERCEPTIONS AND PREDICTION OF MARATHON PACING OUTCOME

SLATER, M., WILMOTT, A., JEWISS, M., GORDON, D.

ANGLIA RUSKIN UNIVERSITY

INTRODUCTION: Even pacing is integral to achieving optimal marathon performance and the fastest time, with runners who maintain close-to-even splits considered to possess superior pacing ability. Marathon pacing significantly influences race outcome, yet its determinants are not fully understood. This study explores how pacing and racing perceptions impact marathon performance, while adjusting for important co-variables.

METHODS: A questionnaire developed in 2021 was administered during the spring (March-May) and autumn (September-December) marathon seasons of 2022. Participants were runners who had completed their goal marathon within six weeks prior to survey completion. The survey was distributed online using JISC Online Surveys (Version 2) and promoted via social media to local, national, and international running groups. It gathered data on demographics, training habits, and pacing views (rated on a 1-5 scale). Race splits were obtained from official race websites post-race, and pacing outcome was assessed by calculating slowing (%) in the second half of the race compared to the first. After exclusions, 182 complete responses were analysed using simple and multiple regression to examine the relationship with pacing outcomes.

RESULTS: In simple regression analyses, marathon time ($P < 0.001$, Adj $R^2 = 0.22$) and pacing flexibility ($P = 0.004$, Adj $R^2 = 0.038$), positively influenced pacing outcomes. In contrast, kilometres per week ($P = 0.004$, Adj $R^2 = 0.04$), importance of marathon finishing time ($P = 0.022$, Adj $R^2 = 0.02$), and view on pacing importance to marathon performance ($P < 0.001$, Adj $R^2 = 0.11$), had negative influences. To adjust for important confounders and isolate potential true effects, a multiple regression was conducted. This model was statistically significant ($P < 0.001$), explaining 32% of the variance in pacing outcomes (Adj $R^2 = 0.32$). Within the multiple regression, finish time ($P < 0.001$, R^2 change = 0.178) and importance of marathon finishing time ($P < 0.001$, R^2 change = 0.05) emerged as positive predictors. Conversely, sex (coded as 0 for males and 1 for females; $P < 0.001$, R^2 change = 0.06) and view on pacing importance to marathon performance ($P = 0.003$, R^2 change = 0.04) were significant negative predictors. Notably, distance per week, which was significant in simple regression, was not significant in the multiple regression ($P = 0.90$, R^2 change = 0.00).

CONCLUSION: These findings suggest that runners who understand and prioritise pacing as a key element of their race strategy, rather than focusing solely on finish time, are more likely to optimise their pacing and achieve their best performance on race day. This likely intrinsically regulated approach highlights autonomy and personal mastery, enhancing an athletes ability to monitor their effort and exercise intensity during a race. These skills are crucial for effective race performance and pacing.

THE NEOHUMANIST INTERFACE: THE IMPACT OF RESIDENTS PERCEPTIONS ON URBAN COMMUNITY COHESION AT DIGITAL SPORTING EVENTS

ZI, Y.

SHANGHAI UNIVERSITY OF SPORT

Introduction: The Renaissance concept of "virtù", which emphasizes the citizens ability to shape social life, has been revitalized in Shanghai's large-scale sports events in the digital era. Sports events have evolved along with the development of social productivity, and have continued to evolve along with human civilization to meet the needs of people for sports competitions in different historical periods. Shanghai, as a world-famous sports city, has gradually formed a new form of sports competition under the development of digital technology, showing the dual characteristics of digitization and competitiveness. This study combines historical sports sociology and digital technology to explore how traditional sports events reconstructed by digital technology activate urban community cohesion.

Methods: The study mainly adopts research methods such as literature review, questionnaire survey, data analysis and expert interviews. First of all, we searched with the theme of "digital sports events", "community digital sports" and "influence", and established two factors, six topics and three factors of community cohesion that constitute residents perception. 3 factors and 10 topics that constitute community cohesion. Next, the authors attended 10 major sporting events as participant observers and distributed 1,600 questionnaires to the residents of the communities where they were held, obtaining a total of 1,434 valid samples with a validity rate of 89.63%. Finally, data were analyzed using Amos27 and SPSS27. The purpose of this study was to investigate the relationship between residents perceptions of digital sports events and community cohesion using validated factor analysis (CFA) and structural equation modeling (SEM).

Results: The study showed that community residents attending digital sports events were predominantly male 873 (60.9%), the age of the participants involved in this study was predominantly between the ages of 20 to 30 years old 985 (68.7%), and the level of education was predominantly bachelors degree and above residents 1076 (75.1%). The results showed that perceived benefits were positively related to resident participation, social interaction, and sense of community be-

longing. Whereas, perceived cost was negatively related to resident participation and positively related to social interaction and sense of community belonging.

Discussion: The study draws the following insights: (1) Perceived benefits for residents of digital sports events are necessary to generate urban community cohesion. (2) Interaction among residents participating in digital sports events and sense of community belonging are both high-frequency elements in the pathway portfolio. (3) A highly educated young population is an important antecedent for the high impact of digital sports events in the community.

RESEARCH ON THE INTEGRATION OF COMMERCE, TOURISM, CULTURE, AND SPORTS PROMOTED BY SPORT EVENTS

WANG, S., CHEN, C., XU, L.

SHANGHAI UNIVERSITY OF SPORT

INTRODUCTION: The integration of commerce, tourism, culture, and sports (CTCS) is an essential approach in the new era to meet the diverse needs of the public, unlock the potential for social consumption, optimize industrial structures, and achieve high-quality economic development. Sport events serve as a bridge to highlight the unique characteristics of CTCS integration, unleashing the powerful synergy of commerce-driven industrial development, tourism-driven urban integration, culture-driven societal enrichment, and sports-driven vitality. Therefore, in-depth exploration of successful experiences from cities across various countries and proposing optimization pathways can offer theoretical and practical insights for the sustainable economic growth.

Methods

The study primarily adopts methods such as literature review, case analysis, and field investigation. Relevant studies were retrieved from CSSCI journals in the CNKI and WOS database using the keywords "sport events" and "industrial integration" in their titles covering the past five years. A total of 308 and 344 papers were identified, respectively. More than 60 articles from core academic journals and over 10 reports and monographs were reviewed. Case studies of over 10 countries, including the United States, the United Kingdom, France, Italy, Japan, and Australia, were conducted. Additionally, interviews were carried out with more than 10 experts in the field of sport events.

RESULTS: The study reveals that the contextual drivers for promoting the integration of CTCS through sport events stem from three aspects: 1) The practical necessity of meeting peoples aspirations for a better life. 2) The national demand for driving high-quality economic development. 3) The strategic imperative of achieving the goal of a modernized and strong nation.

The research identifies four key lessons from developed countries regarding the promotion of CTCS integration through sport events: 1) Setting new benchmarks for integration with a focus on collaboration and socialization. 2) Building new platforms for integration by emphasizing quality and branding. 3) Creating new scenarios for integration by leveraging agglomeration and differentiation. 4) Fostering a new ecosystem for integration based on inclusivity and scientific approaches.

Discussion: The study suggests that advancing the integration of CTCS through sport events should focus on the following four dimensions: 1) Enhancing comprehensive planning and deployment, improving governmental governance capacity, and stimulating social actors vitality. 2) Strengthening cross-industry product linkages, reshaping the event supply system, and optimizing event portfolio design. 3) Creating holistic event experiences, enhancing spatiotemporal connections of events, and leveraging technological empowerment. 4) Promoting inclusive sharing of outcomes, addressing diverse public needs, and paying attention to event-related trends and innovations.

IOT - INNOVATION. OLYMPICS. TECHNOLOGY.

MATE, T., ANDRÁS, K.

OBUDA UNIVERSITY

INTRODUCTION: Since the appearance and widespread use of computers, we have witnessed a technological transformation in all areas, transforming the functioning of different social subsystems. Sports innovation refers to innovations and developments in the field of sport that aim to improve the performance of sports disciplines, enhance the experience of athletes and spectators, and make sports infrastructure and organisational operations more efficient (Tjønndal, 2018).

METHODS: Our research aims to answer the question: what are the main areas of innovation in ensuring the effectiveness of the Olympic Movement? In the analysis of the last Olympic cycle(s), we have processed primary and secondary sources, analysed the delivery solutions and innovation strategies of the Olympics, the relationship between successful nations in terms of sporting performance and innovation. We conducted expert interviews in the field of innovation and sport event organisation.

RESULTS: Three areas of innovation emergence were identified and analysed: (1) organisational innovation: the protection and development of the Summer Games as a brand, (2) sport innovation: the sporting competition of sports, competitiveness and future of business, (3) sport performance innovation: the central actor in all of this, the athlete.

For the Paris Summer Olympics, we identified 8 areas of change (operating model, programme, broadcast technology, opening and closing ceremonies, Athlete first, image elements, sustainability and social aspects), change drivers and innovations, drawing parallels between the 1924 and 2024 Paris Olympics. We analysed the developments in the 29 sports, grouping the innovation objectives into two main categories: enhancing sporting performance (data collection, analysis and development) and enhancing the consumer experience (transparent, scoring, broadcastability). For the 12

countries that have been in the top ten at the last four Summer Olympics, we examined the Global Innovation Index of these countries. For the Netherlands, strong growth was identified: both in sport performance and in innovation capacity.

Discussion: Examining the Olympic Movements effectiveness based on sports innovation requires a systemic approach when considering organisational culture, leadership, the global market environment and technological developments. Firstly, the relationship between the picture presented by the innovation composite indicators of each country and the evolution of the countries sport performance. Also of importance is the typical operating model of each country: the role of the state and the business world.

THE SOCIAL, COMMUNITY, AND SPORTING IMPACT OF MEDIUM AND SMALL-SIZED SPORTS EVENTS: EVIDENCE FROM THE ITALIAN NATIONAL UNIVERSITY CHAMPIONSHIPS

FALESE, L., ROSSINI, L.

UNIVERSITY OF CASSINO AND SOUTHERN LAZIO

INTRODUCTION: Medium and small-sized sports events promote community engagement, social cohesion, and local economic benefits. While large-scale events like the Olympics receive extensive attention, smaller events remain underexplored despite their socio-economic potential. This study examines the 2022 Italian National University Championships (CNU), which attracted 2500 university athletes, assessing its influence on local spectators sense of belonging, community pride, motivation to be physically active, and satisfaction.

METHODS: A structured questionnaire was administered to 221 local spectators, measuring variables such as service satisfaction, community pride, motivation to be physically active, and sense of belonging. Correlation and regression analyses identified key predictors of community connection and engagement.

RESULTS: Higher satisfaction with event services correlated with overall satisfaction ($r = 0.511$, $p < 0.01$), while excitement for competitions also positively influenced satisfaction ($r = 0.598$, $p < 0.01$). Sense of belonging was strongly associated with event satisfaction ($r = 0.551$, $p < 0.01$) and community pride ($r = 0.548$, $p < 0.01$). Attending the event as spectators motivated individuals to be more physically active, indicating a positive sporting impact. Negative experiences ($r = -0.261$, $p < 0.05$) reduced satisfaction, but the association with logistical difficulties was weak ($r = -0.091$). Regression analysis confirmed pride in the host city as a significant predictor of belonging (Coef. = 0.238, $p = 0.046$), while motivation to engage in future community events emerged as the strongest factor (Coef. = 0.592, $p = 0.000$). Security concerns also positively influenced belonging (Coef. = 0.388, $p = 0.012$), while environmental concerns had an adverse effect (Coef. = -0.446, $p = 0.009$).

Discussion and CONCLUSION: The findings of this study reinforce the idea that medium and small-scale sports events, when effectively managed, can have lasting positive social impacts, particularly in terms of community engagement, sporting impact and pride. Satisfaction with event logistics and participants perceptions of security measures enhanced personal enjoyment and level of engagement. Managing negative effects and controlling undesirable impacts, such as environmental concerns and disruptions, is crucial to maintaining benefits. Future studies should continue exploring how different types of stakeholders perceive social impacts, how strategies can be developed to maximize the positive outcomes and the role of sustainable practices in maximizing social and environmental benefits.

Our findings offer valuable insights for event organizers, policymakers, and stakeholders seeking to optimize sports events for community and social development minimizing dissatisfaction and promoting environmentally sustainable practices.

THE PHENOMENON OF ABUSE IN HUNGARIAN SPORTS THROUGH COACHES' EXPERIENCES

SZEKERES, D.1, NOVÁK, J.2, DÓCZI-VÁMOS, G.2, SOÓS, I.3

HUNGARIAN UNIVERSITY OF SPORTS SCIENCE

Diána Szekeres, János Novák, Gabriella Dóczi-Vámos, István Soós: The Phenomenon of Abuse in Hungarian Sports Through Coaches' Experiences

INTRODUCTION: The topic of child protection in the Hungarian sports world has only come into focus in recent years due to changes in the social environment and the unresolved scandals that have come to light. Since 2017 January 1st, all national sports federations in Hungary are required to implement an ethics and child protection code. In 2022, a comprehensive project titled "Child, Youth, and Professional Protection in Sports" was launched, aiming to understand Hungarian sports culture and the sports family through a multidisciplinary approach.

METHODS: The research project, which incorporates sociological, legal, pedagogical, and psychological aspects, attempted to identify the social, organizational, and individual risk factors of becoming a victim. This presentation shows the experiences of the primary data collection phase of the project, derived from a survey conducted among coaches, with a particular focus on the different forms of abuse. Responses were collected from 64 sports, at different levels of sport, from various age groups, both genders, and all counties in Hungary, resulting in the organization of responses from a total of

863 coaches. We examine the occurrence of abuse in four areas (neglect, emotional, physical, and sexual abuse (with and without contact), while also addressing certain issues that may negatively affect coaching work.

RESULTS: The survey results are presented according to the following dimensions: (1) coaches' perceptions as athletes and coaches of the occurrence of violent and abusive coaching differ, in fact, it is more subtle, (2) their knowledge of the child protection policy applicable to their sports federation as well as their organization is very low, the data show a lack of knowledge about child protection policies: 42% of respondents did not know if their sports organisation had such a policy, and 39% had no knowledge about the policies in place at the sports federations, and (3) their experiences, knowledge, and perceptions regarding problematic behaviors affecting young people range widely, with excessive phone use being the most common (81%), while various forms of abuse are also experienced by a relatively large number of coaches.

Conclusions

The findings indicate that the knowledge of Hungarian sports professionals in victimization, assistance and protection is inadequate, therefore, as the research highlights, there is an urgent need for developing abuse-prevention protocols, creating appropriate organizational cultures, and – most importantly – raising awareness and expanding knowledge of Hungarian sports professionals. The research significantly contributes to the development of the regulatory environment and the creation or updating of ethical codes and procedures for sports organizations.

OP-AP31 Team Sports VII - Talent Support and Youth Training

TOWARDS FAIR FITNESS ASSESSMENT IN SOCCER: A GRADING FRAMEWORK INTEGRATING CHRONOLOGICAL AGE AND BIOLOGICAL MATURATION STATUS IN ELITE AUSTRIAN YOUTH PLAYERS

BIRKLBAUER, J., RUDIGIER, J.1, STOLLNBERGER, D.1, DIRNBERGER, J.2, GONAUS, C.3

1: DEPARTMENT OF SPORT AND EXERCISE SCIENCE, UNIVERSITY OF SALZBURG; 2: OLYMPIC TRAINING CENTER SALZBURG; 3: DEPARTMENT OF SCIENCE, ANALYSIS AND DEVELOPMENT, AUSTRIAN FOOTBALL ASSOCIATION

INTRODUCTION: Normative reference values for fitness performance are widely used for talent identification and training monitoring in elite youth soccer. However, accurately interpreting performance metrics requires consideration of key developmental factors, particularly the relative age effect and maturation status (1). To ensure fair, individualized and developmentally appropriate fitness benchmarks for elite youth soccer players, we introduced and evaluated a 5-point scoring approach that factors in exact age and maturation, enabling consistent performance comparisons across tests and players.

METHODS: We analysed fitness test data from a sample of 2989 U13 and U14 players (12.4 ± 0.6 yrs), selected nationwide into one of 29 accredited youth development centres between 2016 and 2023. Athletes completed an annual battery of 12 fitness tests (2), with their biological age estimated using the Mirwald equation. In a previous categorical framework, norm values ranging from 0 to 5 points were calculated using SD ranges around the mean and identical norms within the same birth year. In contrast, the new approach uses the same point scale but assigns individualized norms for each birth date by accounting for the relationship between test performance and both chronological and biological age.

RESULTS: Across fitness tests, the BIC and AIC criteria identified linear regressions as the best fit for capturing the relationship between test performance and both chronological and biological age. Biological age was more strongly linked to fitness gains than chronological age with medium effects in running speed tests ($r^2 = .099-.175$; $p < .001$; $BF_{10} > 100$; 0.41-0.55 SDs per yr), CMJs and multiple-choice RT ($r^2 = .097-.105$; $p < .001$; $BF_{10} > 100$; 0.42-0.43 SDs per yr) as well as large effects in medicine ball throw ($r^2 = .479$; $p < .001$; $BF_{10} > 100$; 0.91 SDs per yr). As intended, mean scores did not differ between the two grading approaches ($d < 0.191$). However, individual-level variations were evident, with 16.4% of players exhibiting changes of 1-2 points, 1.2% of 2-3 points, and 0.2% of even 3-4 points in the ball throw.

CONCLUSION: Our results revealed a substantial fitness development in U13 and U14 elite youth soccer players in 8 out of 12 tests, which are particularly influenced by anthropometric and power changes, whereas elementary speed, coordination and flexibility hardly improved. Given that the relative age effect is most pronounced at ages 12-14, our findings highlight the importance of considering both exact age and maturation when evaluating and interpreting fitness performance metrics in this age group. By accounting for both factors and maintaining overall comparability, our revised scoring approach introduced meaningful individual-level variability, emphasizing the need for tailored fitness benchmarks to ensure fair and developmentally appropriate assessments in elite youth soccer.

DIFFERENCES IN GAME-BASED PERFORMANCE BY PLAYING POSITION IN YOUNG ELITE MALE TEAM HANDBALL PLAYERS

WAGNER, H., RADIC, V., HINZ, M.

UNIVERSITY OF SALZBURG

INTRODUCTION: In male team handball, different playing positions have specific physical demands due to their tactical roles. Backcourt players (backs) rely on physical strength for one-on-one situations and perform long-distance throws. Wing players (wings) focus on speed for fast breaks and jumping from wide angles for better throwing positions. Pivots face the most physical contact with defenders and require high aerobic capacities. Previous studies have shown that general physical performance (e.g., strength and power) and match performance (e.g., heart rate, game statistics, or position tracking data) differ across playing positions. However, game-based physical performance has not been analyzed, although this is crucial for training young elite players to reach a world-class level based on their specific positions. Consequently, the aim of this study was to analyze game-based performance in young elite male team handball players based on their playing positions.

METHODS: Forty-eight young elite male team handball players (age: 17.5 ± 1.9 years, body weight: 82.5 ± 9.9 kg, body height: 1.86 ± 0.05 m), including 23 backs, 17 wings and 8 pivots participated in the study. All players trained 7–8 sessions per week at an elite team handball academy and competed at the highest international level for their age group. To determine specific physical performance, all participants performed the team handball game-based performance test. A one-way ANOVA was used to compare the performance differences among backs, wings and pivots.

RESULTS: Significant differences between playing positions ($P < 0.05$) were found in peak oxygen uptake, heart rate, fast break and offense time, jump height during the jump shot, and body mass. Wings showed the best performance in fast break (1.78 ± 0.08 s), offense time (5.74 ± 0.19 s), jump height during the jump shot (0.39 ± 0.06 m), and peak oxygen uptake (72.4 ± 8.4 ml/kg/min). Backs performed best in ball velocity during the jump shot (25.1 ± 1.5 m/s), while pivots had the highest body weight (90.5 ± 14.1 kg).

CONCLUSION: As expected, pivots were the heaviest due to facing the most physical contact with defenders during matches. Wings were the fastest on the court and jumped the highest, while backs demonstrated the highest throwing velocities, as they frequently perform long-distance throws during games. However, the high levels of peak oxygen uptake for wings and backs (around 70 ml/kg/min) and pivots (around 60 ml/kg/min), along with no significant differences in defense time between positions, highlight the importance of both aerobic and anaerobic performance for all players to maintain an active and dynamic defense throughout the entire match. We suggest implementing a selective position-specific strength and power training program, while also incorporating a balanced position-independent high-intensity on-court training, for young elite male team handball players to reach a world-class level.

PERFORMANCE AND BODY COMPOSITION EVALUATION DURING 1 YEAR OF YOUNG ELITE FOOTBALL PLAYERS IN MALTA NATIONAL TEAM

GRIMALDI, A., PETRELLI, A., PANZETT, W., ATTARD, K., FENECH, D., FARRUGIA, E., STRAFACE, N., CIONE, E., CANNATARO, R.

UNIVERSITÀ DELLA CALABRIA

INTRODUCTION: The attention and care of youth sectors have been growing in recent years; on the other hand, especially in the younger age groups, it is important to ensure adequate support for the physiological development of the boys; there are no standardized evaluation protocols; in our work, we report the work carried out with the Maltese national team, which supervises young footballers throughout the year, even if they play and train with their club teams.

METHODS: The sprint test was performed on artificial turf using three timing gates. A target marker was positioned 3 m beyond the final timing gate. The best performance was recorded for each distance. The 30-15 Intermittent Fitness Test was conducted on artificial turf following the official protocol outlined on the test's website. Countermovement jump height, CMJ-modified reactive strength index, and multi-rebound performance were assessed using force plates. The best of two trials was recorded. For the Triple Hop Test for distance, participants executed a rapid countermovement followed by three consecutive forward hops, landing on both feet after the final jump. The jump distance was measured from the starting line to the heel of the closest foot upon landing. Bioimpedance analysis was performed with BIA101 Anniversary (Akern Srl, Florence, Italy) and an ultrasound device (BX2000, IntelMetrix, Brentwood, CA, USA) to determine the thickness of subcutaneous fat.

RESULTS: Sprint performance (10m: U15: 1.91 ± 0.09 s, U16: 1.88 ± 0.10 s, U17: 1.84 ± 0.09 s, U18: 1.84 ± 0.09 s; 30m: U15: 4.58 ± 0.23 s, U16: 4.45 ± 0.20 s, U17: 4.31 ± 0.17 s, U18: 4.33 ± 0.16 s), endurance using the 30-15 Intermittent Fitness Test (VIFT: U15: 19.56 ± 0.93 km/h, U16: 19.96 ± 0.81 km/h, U17: 19.87 ± 1.10 km/h, U18: 19.78 ± 0.86 km/h), CMJ modified reactive strength index (U15: 0.51 ± 0.08 m/s, U16: 0.51 ± 0.09 m/s, U17: 0.56 ± 0.07 m/s, U18: 0.62 ± 0.11 m/s), CMJ jump height (U15: 32.40 ± 4.73 cm, U16: 33.66 ± 4.09 cm, U17: 35.79 ± 4.04 cm, U18: 36.90 ± 5.01 cm), multi-rebound reactive strength index (U15: 1.96 ± 0.38 cm/ms, U16: 1.99 ± 0.30 cm/ms, U17: 2.29 ± 0.33 cm/ms, U18: 2.20 ± 0.37 cm/ms), triple hop test for distance (average distance: U15: 5.79 ± 0.69 m, U16: 6.06 ± 0.48 m, U17: 6.43 ± 0.37 m, U18: 6.56 ± 0.56 m), Levi Mass Index (U15: 2.28 ± 0.53 kg/m², U16: 2.60 ± 0.50 kg/m², U17: 2.76 ± 0.48 kg/m², U18: 3.04 ± 0.47 kg/m²), and phase angle (U15: $6.59 \pm 0.72^\circ$, U16: $7.04 \pm 0.76^\circ$, U17: $7.39 \pm 0.73^\circ$, U18: $7.77 \pm 0.63^\circ$).

CONCLUSION: Results revealed a consistent improvement in speed, reactive strength, and lean mass with increasing age, reflecting the combined effects of natural physical development and training adaptations. It is concluded that football training can support the physiological growth of young people, specifically due to the combination of the support of the

national team and club teams. These findings provide benchmarks for talent identification and offer insights into the progression of physical development.

THE RELATIVE AGE EFFECT IN YOUTH FEMALE ACADEMY ATHLETES: IS THERE A DIFFERENCE BETWEEN TEAM AND INDIVIDUAL SPORTS?

VELENTZA, E., MARIDAKI, M., TSOLAKIS, C., APOSTOLIDIS, N.

NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS

INTRODUCTION: Relative age effect (RAE) refers to those (dis)advantages and outcomes that result from the age differences between athletes born in the same year but different birth months [1]. Research supports that in male sport academy level RAE is present [2], however limited data are available in female sport academy level, and specific to team and individual sports, with recent research presenting the highest level of RAE risk in female preadolescent (≤ 11 years) and adolescent (12-14 years) age categories, but a moderate-to-high heterogeneity in competitive and representative level [3]. Therefore, the objective of this study was to further investigate the RAE difference between team and individual sports in female academy athletes aged 9-12 years old related to athletic performance.

METHODS: A total of 370 female academy athletes born between the years 2010 and 2013 were collected and analysed from team ($n=104$, basketball, volleyball, handball) and individual ($n=266$, gymnastics, track and field, fencing, judo, swimming) sports. The athletes were 9 ($n=160$), 10 ($n=102$), 11 ($n=94$), and 12 ($n=114$) years old. Univariate analysis was used to investigate the differences, as well as the effect sizes expressed as partial eta-squared. Speed (20m) and power (medicine ball throw 1kg, (MB1kg); jump and reach test, (JR)) assessments were analysed by birth quartiles, year of birth and type of sport.

RESULTS: The univariate analysis demonstrated significant difference for individual sports at the age of 9 years old (born 2013) in 20m ($F=3.656$, $p=.013$, $\eta^2=.023$), and specifically between Q1 ($M 3.97 \pm 0.72$) vs. Q4 ($M 4.25 \pm 0.65$, $p=.031$). There were no other differences between team and individual sports related to 20m. Related JR, one significant difference was observed between team and individual sports, and specifically at Q1 (16.75 ± 3.32 vs. 29.91 ± 1.38 , respectively, $F=13.409$, $p<.001$, $\eta^2=.028$). In MB1kg there were significant differences in individual sports at the age of 12 years old (born 2010) ($F=8.163$, $p<.001$, $\eta^2=.037$) and specifically between Q2 (349.17 ± 22.05) and Q3 (336.25 ± 26.99) vs. Q4 (453.46 ± 21.18 , $p=.002$ and $p=.002$, respectively). Further differences were found between team and individual sports at the Q2 ($F=4.324$, $p=.038$, $\eta^2=.010$; 415.45 ± 63.93 vs. 349.17 ± 81.40 , respectively) and Q3 ($F=5.627$, $p=.018$, $\eta^2=.013$; 430.00 ± 75.50 vs. 336.35 ± 85.35 , respectively).

CONCLUSION: The novel finding of this research was that academy female athletes, who participated in individual sports revealed better performance in JR test at the age of 9 and lesser performance in MB1kg at the age of 12, compared to team sports.

Moreover, at the age of 9 years old female athletes born in Q1 revealed better performances in speed compared to Q4, as well as at the age of 12 years old female athletes born in Q2 and Q3 achieved higher performances in MB1kg compared to Q4. All differences demonstrated small effect size.

STRENGTH TRAINING FREQUENCY AFFECTS EXPLOSIVE STRENGTH AND REPEATED SPRINT ABILITY BUT NOT MUSCLE GROWTH OR MAXIMAL STRENGTH IN WELL-TRAINED JUNIOR FOOTBALL PLAYERS

HAMARSLAND, H., MOEN, H., MØLMEN, K.S., RØNNESTAD, B.R.

UNIVERSITY OF INLAND NORWAY

INTRODUCTION: Athletes in team sports must carefully balance and prioritise different types of exercise training to optimise adaptation, rest and performance. Heavy strength training is an effective method for enhancing muscular strength and physical performance in team sport athletes. However, the effects of different training strength frequencies with the same weekly training volume are underexplored in this population. This study examined the effects of higher versus lower strength training frequency on muscle growth, muscle strength, and physical performance during an 11-week intervention in well-trained junior football players.

METHODS: Thirty-four well-trained male junior football players (17.5 ± 1 years) completed an 11-week lower-body heavy resistance training program. Players were randomised to a high-frequency group (HF: 32.1 ± 2.4 sessions) or a low-frequency group (LF: 15.9 ± 0.9 sessions), with both groups maintaining the same weekly strength training volume. The program consisted of nine lower-body exercises with loads ranging from 5-10 repetition maximum (RM). Vastus Lateralis muscle thickness was assessed using ultrasound, while muscular strength and performance were measured using a 1RM trap bar deadlift, counter movement jump (CMJ) on a force plate, 40-meter sprint, and 6x30-meter repeated sprint tests. Group differences were analysed using ANCOVA, adjusted for baseline differences.

RESULTS: No significant group differences were observed for 1RM trap bar deadlift (HF: $11.9 \pm 5.2\%$, LF: $12.2 \pm 10.3\%$, $p=0.959$, $ES=0.04$) or muscle thickness of the vastus lateralis (HF: $9.1 \pm 6.4\%$, LF: $6.9 \pm 7.2\%$, $p=0.345$, $ES=0.31$). However, the HF group demonstrated greater improvement in CMJ than the LF group ($9.1 \pm 13.5\%$ vs. $0.9 \pm 7.6\%$, $p=0.016$, $ES=0.75$). The 40-meter sprint time had a numerical decrease in the HF group and an increase in the LF group, resulting in a group difference (HF: $-0.47 \pm 2.1\%$, LF: $1.2 \pm 2.2\%$, $p=0.016$, $ES=0.72$). The LF group demonstrated enhanced fatigue resistance, as indicated by an improved maintenance of speed from the first to the last 30-meter sprint compared to HF (HF: $34.3 \pm 33.4\%$, LF: $-13.6 \pm 86.4\%$, $p=0.03$, $ES=0.78$).

CONCLUSION: Heavy strength training effectively increased 1RM trap bar deadlift and vastus lateralis muscle thickness, with no differences between groups. However, the different training frequencies elicited distinct responses in some performance-related outcomes. Lower-frequency training enhanced fatigue resistance, while higher frequency training improved rapid power production. These findings suggest that training frequency can be tailored to target specific training goals in well-trained male junior football players.

OP-AP30 Running III - Applied Physiology

THE PHYSIOLOGICAL DETERMINANTS OF SUCCESSFUL MIDDLE-DISTANCE RUNNING PERFORMANCE

OSBORNE, R., WANGDI, J.T., KIRBY, B.S., BLACK, M.I., VANHATALO, A., JONES, A.M.

UNIVERSITY OF EXETER

INTRODUCTION: The physiological underpinnings of successful middle distance (MD) running performance have proven challenging to determine and quantify. This is a consequence of the heavy reliance on both the mitochondrial (aerobic system) and glycolytic and high-energy phosphate (anaerobic system) contributions to energy transfer. Furthermore, most of the previous research on MD running performance has been conducted with male athletes. Consequently, we sought to investigate the physiological variables associated with male and female 1500 m running performance, with the aim of producing a mathematical model which enables the prediction of 1500 m performance.

METHODS: Twenty-one ($n = 11$ male, 1500 m personal best: 242.9 ± 5.8 s; $n = 10$ female, 1500 m personal best: 267.4 ± 7.1 s) MD athletes completed one laboratory visit and six field-based track assessments. We collected data on over seventy variables in total. During the laboratory visit, an incremental step test was conducted to determine maximal oxygen uptake ($\text{VO}_{2\text{max}}$), running economy (RE), lactate threshold (LT) and lactate turnpoint (LTP). The six field-based performance tests included: a 10 m maximal sprint speed (MSS) test; a 20 s maximal rate of lactate accumulation (VL_{max}) sprint test; and 2, 4, 6 and 12-minute time trials for estimation of critical speed and D' . The participants' 1500 m seasons best (1500SB) speed was the performance outcome. Pearson's correlation and stepwise multiple linear regression were conducted to assess the strength of the relationship between the physiological and performance outcomes with 1500SB.

RESULTS: The mean $\text{VO}_{2\text{max}}$, RE, LT and LTP were 65.5 ± 5.2 mL·kg⁻¹·min⁻¹ (male), 62.9 ± 4.8 mL·kg⁻¹·min⁻¹ (female), 221 ± 17 mL·kg⁻¹·km⁻¹, 14.5 ± 1.0 km·h⁻¹ and 16.8 ± 1.2 km·h⁻¹, respectively. CS was 4.8 ± 0.3 m·s⁻¹ and D' was 161 ± 40 m. MSS and 20 s sprint speed were 8.0 ± 0.6 m·s⁻¹ and 7.3 ± 0.5 m·s⁻¹, respectively. 20 s sprint speed had the strongest correlation with 1500SB ($r^2 = 0.76$, $P < 0.001$). The fitted regression model was: $1500\text{SB} (\text{m}\cdot\text{s}^{-1}) = .43 (20 \text{ s sprint speed}) + .144 (\text{LTP}) + 0.335$. The model explained 81.9% of variance in 1500SB ($F(2,14) = 37.11$, $P < 0.001$). Mean 20 s sprint speed ($\text{m}\cdot\text{s}^{-1}$) and LTP ($\text{km}\cdot\text{h}^{-1}$) were both significant predictors in the model (20 s sprint speed: $t = 5.88$, $P < 0.001$; LTP: $t = 4.87$, $P < 0.001$).

CONCLUSION: These findings indicate that 20 s sprint speed ($\text{m}\cdot\text{s}^{-1}$), and LTP ($\text{km}\cdot\text{h}^{-1}$) are the two most important physiological determinants of 1500 m running performance. These two variables incorporate both the aerobic and anaerobic contribution to energy transfer, highlighting that for successful MD performance, it is imperative that athletes train to improve energy transfer from all three energy systems (mitochondrial, glycolytic and high-energy phosphate).

PHYSIOLOGICAL CHANGES AT THE MODERATE-TO-HEAVY INTENSITY TRANSITION AND 5-MIN TIME-TRIAL PERFORMANCE DECLINE IN RUNNING AFTER PROLONGED CYCLING

FUK, A., VILLANOVA, S., QUAGLIAROTTI, C., FILIPAS, L., GALLO, G., GRAMAZIO, A., DELLO STRITTO, E., BAZZUCCHI, I., CONTI, A., LAMBERTS, R.P., PIACENTINI, M.F.

UNIVERSITY OF ROME 'FORO ITALICO'

INTRODUCTION: Long-distance triathlons are ultra-endurance multisport events that require sustaining high training volumes in the "moderate-to-heavy" intensity domain (MTHID)¹. Recently, the concept of durability, defined as the time of onset and magnitude of physiological decline over time during prolonged exercise, has been studied in isolated cycling and running activities². However, changes in running profiling when transitioning from prolonged cycling have yet to be studied. The aim of this study was to evaluate physiological changes while running at the MTHID after prolonged cycling and changes in performance during a 5-min time trial (TT) to better understand specific training and racing demands.

METHODS: Seven trained male triathletes (age: 36 ± 8 y, relative $\text{VO}_{2\text{max}}$: 61.7 ± 4.9 mL·kg⁻¹·min⁻¹) completed two running tests on separate days, one performed in a "fresh" (FRE) and one in "fatigued" (FAT) condition. Fatigue was induced by performing a prolonged 150-min indoor cycling at 90% of LT_1 power. The testing protocol was a submaximal incremental test on a treadmill with 5-min steps until the second lactate threshold (LT_2), followed by an outdoor all-out 5-min TT. VO_2 , respiratory exchange ratio (RER), ventilation (VE), respiratory frequency (RF), HR, BL_a and RPE were determined during the steps below (UNDER) and just above (OVER) the LT_1 and compared to the same speed in the FAT condition. In addition, distance completed during the 5-min TT were compared between the conditions. Due to the small sample size, data were analyzed with a Wilcoxon signed rank test ($p < 0.05$) and presented as median (interquartile range).

RESULTS: Differences in both the UNDER and OVER period between the FRE and FAT condition were found in VO₂ [UNDER: VO₂FRE: 45.3(42.0-46.8) vs VO₂FAT: 47.5(46.1-53.2) p=0.02; OVER: VO₂FRE 47.7(46.3-51.2) vs VO₂FAT 52.0(47.8-55.1) ml·kg⁻¹·min⁻¹; p=0.02], HR [UNDER: HRFRE 153(142-154) vs HRFAT 157(147-161); p= 0.02; OVER: HRFRE:160(150-163) vs HRFAT:163(153-168) bpm; p=0.02], BL_a [UNDER: BL_aFRE 1.6(1.5-1.7) vs BL_aFAT 2.2(2.2-2.6); p=0.02; OVER: BL_aFRE 2.1(1.9-.2.2) vs BL_aFAT 2.4(2.2-2.8) mmol·L⁻¹; p=0.02] and RER [UNDER: RERFRE 0.92(0.88-0.95) vs RERFAT 0.84 (0.83-0.87); p=0.04; OVER: RERFRE 0.92(0.90-0.96) vs RERFAT 0.87(0.84-0.89); p=0.02] Total distance covered during the 5-min TT, was less in the FAT condition [FRE:1483(1405-1538) vs FAT:1406(1374-1500) m; p=0.02].

CONCLUSION: Induced fatigued, resulted in higher VO₂ costs, HR and BL_a levels, with lower RER levels in data UNDER and OVER LT1 during a standardized submaximal test. In addition, the mean distance covered during a 5-min TT was lower in the FAT condition. These findings indicate that physiological markers change with increasing levels of accumulating fatigue, which should be considered when prescribing training and determining racing strategies in triathlons.

NEUROMUSCULAR CONTRIBUTIONS TO RUNNING STRIDE MECHANICS: ASSOCIATIONS BETWEEN STRENGTH, POWER, AND BIOMECHANICAL PARAMETERS IN WELL-TRAINED RUNNERS

GOODIN, J., PALOMARES-GONZALEZ, I., OCOYNE, C., SNYMAN, S., SAWYER, B.

POINT LOMA NAZARENE UNIVERSITY

INTRODUCTION: Modifiable stride components—ground contact time (GCT), ground reaction force (GRF), flight time (FT), and stride frequency (SF)—substantially influence running economy. Less is known about how these parameters are related to force-time characteristics of dynamic movements like the countermovement vertical jump (CMJ) or isometric tests like the isometric mid-thigh pull (IMTP). This exploratory study examined the associations between neuromuscular performance measures and running stride parameters at three individualized paces in well-trained male and female runners.

METHODS: Stride parameters were assessed via a validated 2D video app [1] as participants (N = 16, age = 34.6 ± 5.7y, height = 171.7 ± 9.4 cm, mass = 66.5 ± 11.5 kg, VO₂max = 58.8 ± 5.6 ml·kg⁻¹·min⁻¹, 10 males, 6 females) ran on a treadmill at 3 stages (warm-up, easy aerobic, and half-marathon pace, individualized based on recent race performance). On a separate day, CMJ and IMTP tests were completed on force plates.

RESULTS: MANOVA revealed a significant multivariate effect of pace (Wilks' Λ = 0.517, F(10,82) = 3.205, p < 0.001), with GCT decreasing from stage 1 to 3 (diff = -0.044, p < 0.001) and stage 2 to 3 (diff = -0.031, p = 0.0025), while relative GRF increased from stage 1 to 3 (diff = 0.3023, p = 0.0049). FT, SF, and VO did not change significantly (p > 0.06). Correlational analysis revealed that GCT positively correlated with rate of force development (RFD) (r = 0.29–0.40) and concentric impulse (r ≈ 0.28), while FT correlated with normalized peak force (PF) (r = 0.39–0.54). SF correlated inversely with force and impulse measures (up to r = -0.64), whereas VO correlated positively with force production metrics (r ≈ 0.46–0.56).

CONCLUSION: Neuromuscular contributions to running mechanics arise from the interplay between lower-limb force, impulse, and stride parameters. Force, impulse, and RFD metrics are moderately associated with reduced GCT and enhanced relative GRF, demonstrating the neuromuscular system's role in optimizing the GRF/GCT relationship. In particular, the inverse association between SF and impulse measures indicates how efficient neuromuscular function supports more economical running mechanics, though this may be confounded by athlete height, as taller runners with greater mass tend to generate larger impulse values and longer legs may influence flight times. Together, these results indicate that power, force, and impulse capacities are associated with and may influence biomechanical factors related to running economy. Future research should further delineate these relationships by employing longitudinal studies to investigate causal links between targeted strength, power, and plyometric training and subsequent changes in stride characteristics over time.

EFFECTS OF DIFFERENT SHOCK-ABSORBING MIDSOLES ON KNEE BIOMECHANICS DURING SINGLE-LEG LANDING IN RECREATIONAL RUNNERS

YUTING, L., FU, S., YU, C., NING, Y., WANG, Q.

UNIVERSITY OF TAIPEI

INTRODUCTION: Single-leg landing is a common yet challenging movement requiring appropriate knee force distribution. Footwear design can substantially influence lower-limb biomechanics by modulating impact absorption and muscular stabilization strategies [1,2]. Prior research has shown that variations in shoe cushioning and support can alter landing mechanics, affecting both injury risk and performance. However, there remains a need to systematically examine how barefoot (Bare), casual (Casual), and sports (Sports) footwear differ in their effects on knee angles, flexion moments, and vertical ground reaction force (vGRF) during single-leg landing.

METHODS: Six participants (3 males, age 24.0 ± 4.36 y; 3 females, age 23.7 ± 4.7 y), with no lower-limb injuries in the past six months, performed single-leg landings under three conditions: Bare (no shoes), Casual (shoes not meeting ≥ 50% shock absorption or ≥ 15 N/degree torsional rigidity), and Sports (meeting or exceeding these criteria). Kinematic data were recorded via a Vicon motion capture system (Vicon Motion Systems, Oxford, UK), and vGRF was measured using an AMTI force platform (AMTI, Watertown, MA, USA). A one-way repeated-measures ANOVA was used to assess differences

in knee angles ($^{\circ}$), knee flexion moments (N·m), and vGRF (N) among the three footwear conditions. Where main effects were significant, Bonferroni-corrected post hoc tests were conducted ($\alpha = 0.05$).

RESULTS: Mean $\pm$ SD values indicated that the Sports condition produced significantly higher knee angles ($62.50 \pm 17.21^{\circ}$) than the Bare condition ($57.83 \pm 15.94^{\circ}$, $p < .05$), while Casual ($60.67 \pm 17.03^{\circ}$) did not differ significantly from either. Although knee flexion moments were numerically greater in Sports ($1,722.00 \pm 1,321.60$ N·m) versus Bare (594.50 ± 157.10 N·m) and Casual ($1,288.50 \pm 1,025.00$ N·m), variability among participants led to a non-significant overall effect ($p = .06$). Vertical ground reaction forces were significantly higher in Bare ($2,015.33 \pm 452.80$ N) than in both Casual ($1,753.50 \pm 431.10$ N) and Sports ($1,741.67 \pm 536.50$ N, $p < .05$), suggesting that additional cushioning helps mitigate landing impact.

CONCLUSION: These findings demonstrate that footwear with enhanced shock absorption (Sports) can reduce impact forces and influence knee joint loading, potentially lowering the risk of landing-related injuries. While higher knee flexion moments in the Sports condition did not reach statistical significance, this trend may indicate greater muscular activation for joint stabilization [3]. Additionally, the increased knee angles observed with Sports footwear may facilitate improved force distribution across the lower limb [4]. Future research with larger samples and more diverse movement tasks is warranted to clarify how variations in shoe design can optimize both performance and injury prevention strategies.

EFFECTS OF RUNNING SPEED AND ADVANCED FOOTWEAR TECHNOLOGY ON RUNNING ECONOMY IN NATIONAL TEAM TRIATHLETES AND HIGH-LEVEL RUNNERS

BLOKKER, T., AMMANN, S., WEHRLIN, J.P., STEINER, T.

SWISS FEDERAL INSTITUTE OF SPORT MAGGLINGEN: EIDGENÖSSISCHE HOCHSCHULE FÜR SPORT

INTRODUCTION: Since its introduction in 2016, Advanced Footwear Technology (AFT) has played a crucial role in enhancing running economy (RE), contributing to recent faster times in elite running performance. While the effects of AFT on RE are increasingly well-documented, the degree of interindividual variability remains unclear. This is highly relevant for athletes looking to optimize their footwear selection. Thus, the aim of this athlete-driven applied study was twofold: first, to assess the potential benefits of AFT over standard footwear for individual athletes, and second, to determine whether a detectable difference RE exists between two AFT models.

METHODS: Eleven athletes (age 27.3 ± 6.5 years), including four national-team triathletes (2 males, 2 females) and seven high-level male runners completed a standardized treadmill protocol on two testing days to assess RE at three different running speed (RS) (stage 1, stage 2 and stage 3) while wearing a control shoe (CON) without a carbon plate and two AFT models (AFT 1 and AFT 2). The specific brand and model of each shoe was selected by the athletes. Following a 10-min warmup, the test session consisted of three 5-min running intervals (one per shoe), interspersed with a 5-min standing passive recovery (to allow for shoe change) at 12, 14, 16 km/h ($n = 4$), or 14, 16 and 18 km/h ($n = 7$) depending on sex and performance level. The shoe order was randomized and mirrored on the second day, while stage speeds were reversed in descending order. Gas exchange using the Douglas bag method and heart rate (HR) were measured in the last 60 s of each stage. Blood lactate (BLA) was measured between the stages. The data of both days were averaged for analysis.

RESULTS: A total of 21 shoe models (8 CON, 13 AFT) were tested. Regardless of shoe type, higher RS increased RE ($p = .02$). For CON, RE at stage 1 was 183.9 ± 9.2 ml/kg/km, increasing by 4.1 ± 1.2 ml/kg/km at stage 2 ($p = .002$) and by 12.2 ± 1.2 ml/kg/km at stage 3 ($p < .001$). Shoe type significantly influenced RE, with both AFT models consistently lowering RE compared to CON. Overall, AFT shoes led to a $3.5 \pm 5.4\%$ improvement ($p < .001$). Specifically, compared to CON, AFT1 reduced RE by $-3.2 \pm 0.9\%$ at stage 1, $-3.7 \pm 1.0\%$ at stage 2, and $-3.9 \pm 0.9\%$ at stage 3, while AFT2 reduced RE by $-2.7 \pm 1.1\%$, $-3.7 \pm 1.0\%$, and $-4.2 \pm 1.0\%$, respectively. No significant differences were observed between AFT models ($p = .417$) or in the interaction between shoe type and RS ($p > .05$). Individual differences accounted for 91% of the total variance in RE ($ICC = .91$). HR response aligned with RE changes, while no differences in BLA were observed between shoes.

CONCLUSION: These findings confirm previous research that increasing RS worsens RE, while AFT models enhance it. The measurable differences observed between AFT were minimal, and the lack of statistical significance suggests a uniform effect across AFT models. However, the large interindividual variability in responses highlights the necessity of a personalized approach to footwear selection.

Invited Symposium

IS-MH07 Emerging perspectives in exercise oncology: insights from exercise-induced cancer suppression to pragmatic implementation Exercise Oncology: New Insights

EXERCISE MEDICINE AS NEOADJUVANT, ADJUVANT, REHABILITATIVE AND PALLIATIVE THERAPY IN CANCER MANAGEMENT

ROBERT, N.

EDITH COWAN UNIVERSITY

Exercise has been demonstrated to be an effective medicine across the cancer spectrum from initial diagnosis through to palliative and end-of-life care. In this setting it is termed "exercise oncology". As a neoadjuvant therapy, exercise medicine is highly beneficial in preparing the patient physically and psychologically for the primary cancer treatment. Improving

physical fitness, body composition, and overall resilience positions the patient much more favorably to tolerate surgery, chemo, or radiation therapy. The most common application is exercise medicine neoadjuvant to surgery where it has been demonstrated to reduce adverse events during the operation, reduce surgical complications, reduce length of hospital stay, and facilitate recovery. When implemented adjuvant to chemotherapy or radiation therapy, exercise medicine ameliorates side-effects and is increasingly being demonstrated to enhance the effectiveness of the primary therapy through a range of mechanisms. For chemotherapy, exercise increases perfusion through the tumors delivering more chemotherapy to cancer cells. Acute and chronic exercise enhances radiation therapy effectiveness by reducing hypoxia, facilitating the oxygen enhancement effect and innate immune response. On completion of the cancer treatment exercise medicine is used extensively to rehabilitate the patient, facilitating recovery, increasing physical fitness and improving body composition while also reducing the risk of onset of other chronic diseases. In the long-term, ongoing exercise is critical for reducing the risk of cancer recurrence, by creating a more cancer suppressive environment through cytokine signaling and increased immune cell concentration and surveillance, as well as reducing risk of other diseases such as cardiovascular and metabolic that can arise due to prior cancer treatments. For patients with incurable cancer, exercise medicine has an important role through to end of life by slowing decline in physical function, quality of life, and mental health with emerging research being reported as causative extension of survival. In this presentation we will explore all these quite amazing aspects of exercise medicine in the management of patients with cancer. Medical doctors, oncologists, nurses, clinical exercise physiologists, physiotherapists, fitness professionals, patients and carers will find this presentation of interest as it will create an understanding of the critical role of exercise medicine for all people going through a cancer journey.

TOWARDS OPTIMAL DOSE AND TYPE OF EXERCISE FOR CANCER CARE: INSIGHTS FROM MOLECULAR MECHANISMS

NATALUCCI, V.

UNIVERSITY OF MILAN

To maintain cellular homeostasis, cells must reside in an optimal environment, have the capacity to sense surrounding signals, and respond to these cues precisely. In cancer, however, this balance is disrupted, and communication between healthy and malignant cells no longer conforms to normal regulatory mechanisms. Cancer progression is frequently driven by the dysregulation of multiple cellular pathways, where dysfunctions across various molecular circuits facilitate malignant transformation. Efforts to counteract these processes often impact multiple cellular pathways, highlighting the complexity of targeting cancer biology. Within this intricate landscape and in an era marked by precision oncology, cancer prevention strategies have evolved to address the multifaceted process of carcinogenesis. Recently, these strategies have broadened to integrate exercise medicine and nutritional therapy throughout the continuum of cancer care. These approaches aim to reduce cancer incidence and inhibit tumor progression by addressing metabolic and cellular vulnerabilities in cancer. Exercise requires skeletal muscle to engage in “crosstalk” with other organs through voluntary contractions. This inter-organ communication induces biomechanical and metabolic adaptations in skeletal muscle, cardiac tissue, and adipose tissue, as well as systemic changes that have shown potential to modulate tumor biology and improve clinical outcomes. Both preclinical and clinical studies show that exercise-conditioned serum, derived from human subjects pre- and post-exercise, exhibits inhibitory effects on cancer cell growth (e.g., reducing proliferation and metastatic potential) and survival (e.g., diminishing cell viability), while also increasing cell death via apoptosis and necrosis across various tumor types. These findings underscore the therapeutic promise of exercise in oncology and its role in potentially improving patient outcomes. In both acute and chronic contexts, each component of exercise—defined by the FITT-VP principle (frequency, intensity, time, type, volume, and progression)—is essential for mediating the effects. Current evidence is that a single session of moderate-to-vigorous intensity aerobic exercise can exert suppressive effects on cancer cells and lead to significant increases in circulating bioactive factors. Conversely, in structured training programs (whether short-term or chronic), training volume appears to be a key factor in modulating cancer cell inhibition and altering circulating factors, regardless of the specific mode of exercise used. However, the question remains unanswered:

HOW TO EFFECTIVELY IMPLEMENT EXERCISE AS A STRATEGY TO SUPPORT PATIENTS WITH CANCER IN THE REAL-WORLD SETTING?

AVANCINI, A.

UNIVERSITY OF VERONA

Physical activity and exercise have been proven to confer several important benefits to patients with cancer. There is an inverse relationship between physical activity and mortality, and preclinical evidence supports these findings, highlighting how exercise may slow tumor progression. Beyond the possible impact on prognosis, exercise has been confirmed to be important supportive care during the cancer journey by optimizing patients’ physical fitness, managing symptoms and treatment-related side effects, and enhancing effectiveness of other cancer treatments and quality of life. Several national and international scientific societies, including the American College of Sports Medicine, the American Cancer Society, and Exercise and Sports Science Australia, have proposed dedicated guidelines for exercise in cancer and strongly recommend avoiding inactivity and engaging in regular exercise. Despite the benefits and published guidelines, a large number of patients affected by cancer are insufficiently active. In this regard, a recent multicenter investigation conducted in Italy on 549 patients found that 92% did not reach a sufficient level of physical activity. Implementing exercise in oncology is far from simple. Patients themselves may face several obstacles in starting an exercise program, ranging from the adverse events or sequelae experienced during cancer treatment, such as fatigue, dyspnea, and loss of muscle mass, to non-health related issues, including lack of dedicated guidance from experienced experts, lack of family support and distance

from facilities. In addition, the scarce knowledge about the beneficial role of exercise and the confidence in its promotion by oncologists and healthcare professionals may negatively influence the adoption of physical activity or targeted exercise medicine among patients. In a multi-level view, even just the word cancer inspires fear among lay people, with more than half of the general population afraid of cancer more than other diseases. These cultural myths and beliefs have led patients with cancer to be stigmatized, isolated from social life, and should not perform activities such as exercise. In this presentation, we will explore all these challenging aspects, the barriers and facilitators concurring in an effective exercise implementation in the cancer context. Several stakeholders, including clinicians, exercise specialists, physiotherapists, oncologists, healthcare professionals, patients, and their caregivers, may find this presentation appealing.

OP-BM07 Neuromuscular Physiology III - Ageing

NEUROMUSCULAR DETERMINANTS FOR THE DIFFERENCES IN POWER OF THE KNEE EXTENSOR MUSCLES IN YOUNG AND OLDER ADULTS

JAMES, J., KERN, L., WRUCKE, D., KRONER, K., DOBRZYCKI, I., ZEPEDA, C., KLAMECKI, L., TOUANNAS, J., ACKLIE, P., HUNTER, S., SUNDBERG, C.

MARQUETTE UNIVERSITY

INTRODUCTION: Aging is accompanied by a progressive decline in skeletal muscle mass and function that leads to impaired mobility of older adults. Importantly, the ability to produce power is one of the strongest predictors of physical function with aging, and power declines at a greater rate than the loss in mass (~2-4%/yr vs. ~0.5-1%/yr) (1-2). These observations suggest factors such as impaired neural activation, altered intrinsic contractile properties, and/or the selective atrophy of the myosin heavy chain (MyHC) II muscle fibers may contribute to the more rapid decline in power relative to muscle mass. Thus, the aim of this study was to determine the primary factors responsible for the age-related decline in power.

METHODS: 10 young (23±3 yrs, 5 women) and 13 older adults (72±5 yrs, 7 women) performed maximal velocity contractions lifting a load that was 20% of the maximal voluntary isometric contraction to assess power of the knee extensors. Voluntary activation and contractile properties were measured with electrical stimulation. Biopsies were obtained from the vastus lateralis to assess fiber type distribution and proportional area with immunohistochemistry. Knee extensor muscle volume was quantified with MRI, and the fiber type specific volume was estimated as the product of fiber type proportional area and volume.

RESULTS: Power was ~46% lower in older (120±37W) compared to young (223±73W; $p=0.001$), while muscle volume was ~34% lower with age (1692±625 vs. 1123±302cm³; $p=0.021$). When power was normalized to muscle volume, specific power in older adults remained ~23% lower than young ($p<0.001$). Voluntary activation was near maximal in young (92±7%) and older adults (93±6%) and did not differ with age ($p=0.95$). In contrast, the involuntary electrically-evoked twitch (Q_{tw}) was ~36% lower in older (49±14Nm) compared to young (76±24Nm) and closely associated with power ($R^2=0.91$; $p<0.001$). MyHC I proportional area was greater in older adults (62±15% vs. 40±12%, $p=.001$), and MyHC II proportional area was lower with age (39±16% vs. 60±12%; $p=0.002$). The estimated volume of muscle composed of MyHC I did not differ with age ($p=0.840$), but MyHC II muscle volume was ~56% lower in older (458±242cm³) than young (1033±500cm³; $p=0.006$). Accordingly, there were strong associations between the estimated MyHC II muscle volume and both power ($R^2=0.77$; $p<0.001$) and Q_{tw} ($R^2=0.78$; $p<0.001$). In contrast, there were only weak associations with MyHC I muscle volume and both power ($R^2=0.21$; $p=0.029$) and Q_{tw} ($R^2=0.24$; $p=0.019$).

CONCLUSION: These preliminary data suggest that the greater age-related loss in power relative to muscle mass of the knee extensors is determined, at least in part, by the selective atrophy and/or loss of MyHC II fibers and that interventions should target fast fiber atrophy to help attenuate the loss of power with age.

CHANGES IN MOTOR UNIT PROPERTIES AFTER EIGHT WEEKS OF RESISTANCE TRAINING IN YOUNG AND OLDER ADULTS

CASOLO, A., SAMPIERI, A., SPINELLO, G., FRANCHI, M., PAOLI, A., MORO, T.

UNIVERSITY OF PADUA: UNIVERSITA DEGLI STUDI DI PADOVA

INTRODUCTION: Aging is associated with a progressive decline in neuromuscular function, partly due to neural alterations, particularly affecting motor unit (MU) function and properties. In contrast, resistance training can enhance muscle force production and control by partially reversing age-related neural alterations at the MU level. Previous evidences in young and older adults have shown that short-term resistance training (< 6 weeks) increases MU discharge rate (MU DR), in turn mediating the early force gains. However, the time course of MU adaptations to longer resistance training interven-

tions remains elusive. This study aimed to investigate and compare the effects of an eight-week resistance training intervention on MU properties in young (YA) and older adults (OA).

METHODS: Eleven OA (age: 71.4 ± 5.2 yr) and twelve YA (age: 23 ± 2.4 yr) participated in an 8-week dynamic and progressive resistance training protocol. Measurements were taken at baseline (T0), after 4 weeks (T4), and at the end of the intervention (T8). During these sessions, participants performed maximal (MVf) isometric knee extensions and submaximal trapezoidal ramps (35, 50, 70% MVf). Simultaneously, high-density surface EMG signals muscle were recorded from vastus lateralis muscle and decomposed offline into individual MU spike trains. Training-induced changes in MU properties, including recruitment (MU RT), derecruitment (MU DERT) thresholds and average discharge rates (MU DR), were analyzed with generalized mixed-effects models. Repeated measure correlations were performed to assess the association between changes in MU DR and MVf.

RESULTS: Preliminary results revealed that, after the training protocol, MVf increased similarly in both YA and OA (time effect, $p < 0.001$). Specifically, MVf increased by $\sim 10\%$ between T0-T4 ($p < 0.001$), by $\sim 9\%$ between T4-T8 ($p < 0.001$), and by $\sim 20\%$ between T0-T8 ($p < 0.001$). Similarly, MU DR increased after the training protocol (time effect, $p < 0.001$), but with a different time-course between OA and YA (time by group effect, $p = 0.008$). Specifically, MU DR increased between T0-T4 in both OA ($p = 0.039$) and YA ($p = 0.002$), but between T0-T8 in YA ($p < 0.001$) only. Interestingly, the initial changes (T0-T4) in MU DR were moderately associated with changes in MVf ($r_{rm} = 0.51$, 95% CI [0.126, 0.763], $p = 0.013$). Conversely, no changes were observed in normalized MU RT (% MVf) and MU DERT after the training.

CONCLUSION: Eight weeks of resistance training increased MVf in both OA and YA, with comparable MU adaptations particularly during the first four weeks of training. Notably, the observed association between changes in MU DR and MVf emphasizes the similar early (< 4 weeks) adaptability of the nervous system to resistance training in OA and YA. However, the relative contribution of neural adaptations to muscle force production may diverge between OA and YA in the subsequent weeks of training.

PERSISTENT INWARD CURRENT ALTERATIONS IN YOUNG AND OLDER ADULTS FOLLOWING BED REST AND RECOVERY

MARTINO, G., KALC, M., SARTO, F., KRAMBERGER, M., FRANCHI, M.V., NARICI, M.V., PIŠOT, R., SIMUNIC, B., HOLOBAR, A., DE VITO, G.

UNIVERSITY OF PADOVA

INTRODUCTION: Bed rest represents a well-accepted model to study the effects of prolonged periods of muscle disuse due to injury, surgery, illness, hospitalization or spaceflight. Muscle disuse is primarily associated with a reduction in muscle mass and strength and, in addition to functional alterations of the peripheral nervous system, changes in central activation have been suggested to play an important role in the loss of muscle strength. We recently showed that persistent inward current (PIC), an intrinsic motoneuron property proportional to monoaminergic neuromodulatory input, is reduced after 10 days of lower limb suspension (1). However, our previous study did not consider that the decreased maximal voluntary contraction (MVC) after disuse leads to changes in the assessed torque profiles across time points, introducing a confounding factor in estimating changes in PICs. This study aims to assess PIC changes after prolonged bed rest followed by supervised recovery in young and older adults at matched torque profiles across time points.

METHODS: Nine young (YA, age 22 ± 4) and 10 older (OA, 69 ± 3) healthy males underwent 21 (BR21) and 10 days (BR10) of bed rest, respectively, followed by 21 days of endurance training (ET). High density surface electromyography (HDsEMG) was recorded from vastus lateralis muscle during isometric triangular contractions at 20% of pre bed rest (BR0) MVC. After decomposing motor unit (MU) firing rates from HDsEMG signals, PICs were estimated via paired motor unit (MU) technique (2) as the delta frequency (Δf) of a lower threshold MU (control unit) at the time of recruitment and derecruitment of a higher threshold MU (test unit). Individual Δf differences across time points were assessed using linear mixed models.

RESULTS: A total of 234 (58 at BR0, 74 at BR21 and 102 at RT) and 373 (111, 126 and 136) MUs were successfully decomposed from HDEMg signals for YA and OA groups, respectively. From the total MU pool, we identified 251 (37 at BR0, 51 at BR21 and 70 at RT) test units in YA and 284 (82, 98 and 104) test units in OA. In YA, Δf values decreased at BR21 compared to BR0 ($p < 0.001$) and were restored after RT compared to BR21 ($p < 0.001$). Similarly, in OA Δf values were lower at BR10 compared to BR0 ($p < 0.002$) and RT ($p < 0.03$).

CONCLUSION: This is the first study assessing the neuromodulatory contribution to force generation after prolonged bed rest in young and older individuals. Remarkably, even adopting the same torque profiles for the assessment, we found changes in PIC estimates across time points. These results further highlight the important role of neuromodulation in muscle force generating capacity following muscle disuse and its recovery through physical activity.

IN VIVO AND EX VIVO SKELETAL MUSCLE CHARACTERISTICS OF THE NEW—OVER 90 YEARS OF AGE— FEMALE WORLD RECORD HOLDER IN THE 200M SPRINT: A CASE REPORT

COLOSIO, M., DOBRZYCKI, I., TEIGEN, L.E., PILOTTO, A.M., ANSALDO, M., GATTI, M., BRUSCO, C.M., PELLEGRINO, M.A., BOTTINELLI, R., FRANCHI, M.V., PORCELLI, S., SUNDBERG, C.W.

MARQUETTE UNIVERSITY

INTRODUCTION: We had the unique opportunity to test the 91-year-old female that set the W90+ world record (WRW) in the 200m sprint last year, with a time of 51.47s, which was 1.48s faster than the previous record. We aimed to characterize the in vivo and ex vivo skeletal muscle determinants underpinning her elite performance and compare them, when possible, to data in the literature.

METHODS: Knee extensor muscle architecture was evaluated with ultrasound, and force, power and fatigability assessed with dynamometry. A biopsy was obtained from the vastus lateralis to assess single fiber contractile mechanics, fiber type distribution, capillarization, and markers of denervation.

RESULTS: CSA at 50% femur length was 36.5cm², while fascicle length, pennation angle and muscle thickness were 6.7cm, 11.56°, and 1.4cm, respectively. Knee extensor MVIC was 79Nm, power output was 28W and fatigability (reduction in power during a 4-min exercise) was 43%. Single fiber absolute and size-specific force were 0.88±0.20mN and 114±11kN/m² for myosin heavy chain (MyHC) I fibers and 0.74±0.24mN and 168±16kN/m² for MyHC II fibers. VL fiber type distribution was 38% MyHC I, 49% IIa, 5% I-IIa, 5% IIa-IIx and 2% IIx. Interestingly, the MyHC I fibers (4267±2181µm²) were ~55% larger than MyHC II fibers (2752±1608µm²). Together with larger CSA, MyHC I fibers had higher capillary-fiber contacts and capillary-to-fiber ratio (4.28 and 1.67) compared to MyHC II fibers (2.68 and 1.03). Less than 1% of the fibers were positive for the denervation marker NCAM, and no fibers were positive for embryonic MyHC. In addition, no MyHC I fibers were positive for neonatal MyHC (nMyHC), while ~1% of MyHC II fibers were nMyHC positive.

CONCLUSION: The WRW's knee extensor muscle CSA, architecture, force, power and fatigability were consistent with individuals of the same age (1,2). Type I fiber absolute force was ~30% greater than young and older females, while type II fiber absolute force was higher than older females in their 70s but lower than younger females (3). She had exceptionally large type I fibers and a high percentage of type II fibers (4,5). The capillarization of the type I fibers was comparable to that of women in their 60s, but lower for the type II fibers (6). Interestingly, there was minimal evidence of denervation compared to what is expected in the ninth decade of life (7). We speculate that the WRW's exceptional performance was driven, in part, by a low prevalence of denervation and a high proportion of fast fibers, along with her remarkably large and well vascularized slow fibers. This highlights the potential effect of sprint training to promote health and youthfulness, even in very advanced age.

Invited Symposium

IS-PN06 Sex Differences in Hemodynamics and Oxygen Transport during Maximal, Supramaximal, and Time-Trial Exercises: Insights from Normalization Strategies and Thermodilution Measurements

SEX DIFFERENCES IN CARDIAC OUTPUT, LEG BLOOD FLOW, AND OXYGEN EXTRACTION AT VO₂MAX AND DURING TIME-TRIAL EXERCISE: INSIGHTS FROM THERMODILUTION-BASED MEASUREMENTS

SKATTEBO, Ø.

NORWEGIAN SCHOOL OF SPORT SCIENCES

Historically, most exercise physiology research has been conducted on males, with findings often generalized to females. However, females and males have distinct body sizes and compositions, and their cardiovascular system is scaled differently, which may impact the applicability of these results. Recent studies suggest that males and females differ in central and peripheral factors limiting maximal oxygen uptake (VO₂max), yet much remains unknown about the mechanisms behind these potential differences and their implications for performance. Understanding sex-specific differences in the cardiovascular system and the oxygen transport chain from the lungs to the muscles is critical for advancing our knowledge of sex differences in athletic performance. This lecture will present insights from cutting-edge research utilizing gold-standard catheter-based techniques, including thermodilution for precise assessment of cardiac output, stroke volume, and leg blood flow during exercise, as well as direct measurements of peripheral oxygen extraction. These

methods offer the highest precision in assessing the physiological limits to VO_2max , allowing for an in-depth comparison of the oxygen transport chain between males and females. Data from submaximal, maximal, and time-trial exercise conditions will be presented, with a special focus on how closely the maximal hemodynamic responses observed at VO_2max are sustained during prolonged, competition-like exercises (time trials). Furthermore, the lecture will address the impact of normalizing hemodynamic variables, given that males and females differ substantially in muscle mass—the primary tissue consuming oxygen during exercise. This symposium will appeal to exercise physiologists, sports scientists, clinicians, and professionals working with female athletes, providing a comprehensive view of the mechanisms underlying sex-specific performance differences.

SEX DIFFERENCES IN FUNCTIONAL RESERVE: FOCUS ON HEMODYNAMICS AND OXYGEN TRANSPORT

MARTIN-RINCON, M.

UNIVERSITY OF LAS PALMAS DE GRAN CANARIA

Understanding the limits of human performance requires examining the concept of “functional reserve,” defined as the capacity to sustain or generate additional power even at the point of exhaustion. Research on how males and females utilize this reserve during high-intensity exercise remains limited, leaving critical gaps in our understanding of the underlying mechanisms. While recent evidence suggests that physiological responses to supramaximal exercise are broadly similar between sexes when normalized for lean mass, key questions remain about the compensatory mechanisms that could offset the presumed lower anaerobic capacity in women and the superior oxygen extraction observed in females during supramaximal exercise. This presentation will characterize the hemodynamic and oxygen transport responses to repeated bouts of supramaximal exercise in men and women, exploring how sprint interval training (SIT), with or without ischemia-reperfusion episodes at exhaustion, influences the functional reserve. We will focus on hemodynamics, oxygen delivery, and muscle blood flow using state-of-the-art invasive techniques, including thermodilution for measuring cardiac output, stroke volume, and leg blood flow, as well as peripheral muscle oxygen extraction. The lecture will explore whether SIT can modify the functional reserve differently in males and females and whether the application of ischemia-reperfusion immediately post-exercise may further enhance training adaptations. Additionally, we will investigate the potential of ischemia-reperfusion as a strategy to optimize hemodynamic responses and oxygen extraction during high-intensity efforts. By examining these factors, we aim to determine if targeted interventions can enhance the functional reserve and extend performance capacity. These findings will provide exercise physiologists, sports scientists, and health professionals with a deeper understanding of how training protocols can be optimized to leverage sex-specific adaptations, potentially informing strategies to enhance both performance and recovery in male and female athletes.

SEX DIFFERENCES IN VO_2MAX AFTER NORMALIZING BLOOD VOLUME AND O_2 CARRYING CAPACITY

DIAZ-CANESTRO, C.

UNIVERSITY OF ZURICH

Maximal oxygen consumption (VO_2max), a hallmark of aerobic capacity, is associated with large mortality reductions as well as cardiometabolic benefits. Understanding the physiological determinants of sex-differences on VO_2max is a fundamental topic in exercise physiology that may have a crucial impact in the prevention of cardiovascular and metabolic diseases. Intrinsic sex differences in fundamental blood attributes have long been hypothesized to contribute to the gap in cardiorespiratory fitness between men and women. The aim of the present study was to understand whether sex differences in VO_2max can be explained by blood volume and effective hemoglobin. This lecture will present insights from state-of-the-art methods for blood normalization by using blood withdrawal and O_2 carrying capacity reduction via carbon monoxide rebreathing as well as exercise echocardiography inside a lower body negative pressure chamber (to induce hemodynamic loads characteristic of the upright position). We will present data on pulmonary, cardiac and hemodynamic variables from rest to peak incremental exercise as well as at a fixed submaximal workload in women and men prior to and after blood normalization. This symposium will address a relevant knowledge gap in our basic comprehension of cardiovascular physiology that may appeal to a broad audience including exercise physiologists, sports professionals and clinicians.

OP-AP29 Power and Strength II - Cluster Sets and Lower Limbs

CHRONIC ADAPTATIONS TO A 6-WEEK PERIODIZED CLUSTER SET FREE-WEIGHT BACK SQUAT TRAINING INTERVENTION ON MAXIMUM AND SPEED STRENGTH

HOBEIN, E., FERRAUTI, A., WIEWELHOVE, T.

RUHR UNIVERSITY BOCHUM

INTRODUCTION: Cluster set (CS) training, which incorporates intra-set rest intervals, is thought to optimize neuromuscular adaptations by sustaining higher movement velocities compared to traditional sets (TS) (Suchomel et al., 2018). While its acute effects are well-documented, research on the long-term benefits of CS training, especially within periodized programs, is limited (Haff, 2024). Understanding these chronic effects is essential for developing effective, evidence-based

training strategies to enhance athletic performance. This study investigated the effects of a 6-week periodized CS training intervention on maximum and speed strength during the free-weight back squat.

METHODS: Eighteen trained adults (8 males, 10 females) with at least one year of strength training experience (1RM: females 1.23 ± 0.15 ; males 1.64 ± 0.30 times body weight) were randomly assigned to CS or TS groups. Both groups completed 12 training sessions over six weeks, with intensities progressively increasing from 70% to 85% 1RM and set repetitions decreasing from 8 to 3. CS sessions included 30-second intra-set rest periods using several variations in CS configurations, while TS sessions used continuous repetitions with 180-seconds inter-set rests. Outcomes measured pre- and post-intervention included dynamic 1RM in the free-weight back squat, maximum isometric strength, and strength endurance. Additionally, countermovement jump (CMJ) height and barbell velocity at 70% 1RM (v_{70}) were assessed during each session.

RESULTS: Significant improvements were observed in 1RM strength (CS: $+8.5 \pm 6.2\%$; TS: $+9.7 \pm 3.8\%$; $p < 0.05$) and v_{70} (CS: $+11.1 \pm 12.6\%$; TS: $+13.9 \pm 9.7\%$; $p < 0.05$) for both groups. However, there were no significant differences in these improvements between groups, as analyzed by linear mixed-effects models (LMMs). Sex did not significantly influence outcomes, as no group $\times$ sex $\times$ time interactions were observed ($p > 0.05$). CMJ height, maximum isometric strength, and strength endurance showed no significant changes or differences between groups ($p > 0.05$).

CONCLUSION: Both CS and TS protocols are equally effective for improving maximal dynamic and speed strength over a 6-week periodized training program. Neither protocol significantly enhanced CMJ height, isometric strength, or strength endurance. Contrary to our hypothesis that CS would optimize neuromuscular adaptations by sustaining higher movement velocities, the findings indicate no significant differences between CS and TS.

CLUSTER-SET VS. TRADITIONAL-SET POSTACTIVATION POTENTIATION PROTOCOLS: IMMEDIATELY AND RECOVERY TIME EFFECTS ON LOWER-LIMB EXPLOSIVE POWER

ARABACI, M.

BURSA ULUDAG UNIVERSITY, FACULTY OF SPORT SCIENCES

INTRODUCTION: Postactivation potentiation (PAP) is a theory that a muscle contraction will increase the intensity of a second contraction that follows. Acute performance increase mostly occurs as a result of a neuro-physiological, i.e. neural stimulus, and creates physiological effects; maximum voluntary muscle contraction amount, muscle contraction speed or faster contracting motor units are activated. PAP mechanism has been studied and used for a long time in the warm-up phase before performance, especially in jumping and explosive branches. However, there is still a need for studies on this subject. The main objective of present study was to investigate immediately and recovery time effects on countermovement jump (CMJ) and reactive strength index (RSI) of cluster-set and traditional-set configuration of vertical jump exercise.

METHODS: A total of twenty-seven physically active female and male university students (mean age 19.5 ± 1.6 year, height 174.1 ± 8.9 cm, weight 65.6 ± 10.3 kg and body fat 14.9 ± 6.4 %) participated voluntarily. Subjects were randomly divided into two groups: cluster-set (CS) and traditional-set (TS) groups. Subjects completed the study in 2 testing sessions; 1st is familiarisation and 2nd is experimental sessions. During the familiarisation session, PAR-Q, height, body weight and body fat % were determined. After that, subjects performed CMJ, Drop Jump (DJ), CS: 3 set, rest 2 min/set; 1 set = 5 $\times$ 2 rep, rest 15 sec/2 rep or TS: 3 set $\times$ 10 rep; 3 min/set rest) protocol, Borg Scale, Total Quality Recovery Scale (TQR). After 24 hours, subjects participated in experimental session and performed warm-up, Pre-test (CMJ and DJ), aforementioned CS / TS, Borg Scale, Test, TQR, Post-test1, TQR and Post-test2, respectively. Artificial intelligence application My Jump 2 was used to calculate Reactive Strength Index and vertical jump distance which evaluated post-activation potentiation of low extremity muscles. Two Way ANOVA repeated measures analysis of variance test, 2 groups (CS and TS) $\times$ 4 time (Pre-test, Test, Post-test1 and Post-test2) was used to determine comparisons and differences. Bonferroni test was used for pairwise time and group comparisons.

RESULTS: The results showed not statistically significant difference between the changes of CS and TS protocols for CMJ ($F = 1.488$, $\eta_p^2 = .056$) and RSI ($F = 2.377$, $\eta_p^2 = .087$). There are no statistically significant difference of CMJ by time of CS ($F = 1.313$, $\eta_p^2 = .116$). However, there are statistically significant difference of CMJ by time of TS ($F = 3.665^*$, $\eta_p^2 = .196$; *Post_3 min vs. Post_6 min). Also, there are not statistically significant difference of RSI by time of both CS ($F = 1.115$, $\eta_p^2 = .100$) and TS ($F = 1.672$, $\eta_p^2 = .100$).

CONCLUSION: In conclusion, both CS and TS protocols have similar acute effects on vertical jump exercise-based PAP and recovery. Further research with more complex and larger studies is recommended to confirm and extend these findings.

BOX JUMPS VERSUS SQUAT JUMPS: AN ANALYSIS OF EFFECTS ON GLUTEAL FUNCTION, BONE DENSITY, AND LOWER EXTREMITY MUSCLE MASS

LEHECKA, B., EHRESMAN, B., HURST, F., KING, A., KONEN, H., MICHEL-LEMUS, R., TOPEL, M., VANRAVENHORST-BELL, H.
WICHITA STATE UNIVERSITY

INTRODUCTION: The primary aim of this study was to compare the effects of box jumps and squat jumps on gluteal strength, gluteal hypertrophy, lean muscle mass, bone density, and jump height in healthy college-aged individuals.

METHODS: Forty-eight healthy college-aged men and women (18-25 years old) were recruited for this randomized controlled trial from a university setting. Participants were assigned to box jump, squat jump, or control groups. Intervention groups participated in a 12-week plyometric training program (three workouts per week), while the control group was instructed to avoid plyometric activities. Outcome measures were assessed at baseline and week 12 using a handheld dynamometer (HHD) for gluteal strength, a tape measure for gluteal hypertrophy, dual-energy X-ray absorptiometry (DEXA) for lean muscle mass and bone density, and a Vertec device for jump height.

RESULTS: Data from thirty-four participants (11 females, 23 males) who completed data collection were used in the study. One-way ANOVAs revealed no significant difference ($p = 0.05$) between groups of males and females combined. However, females in the box jump group showed increased gluteal girth compared to females in the squat jump and control groups. Paired t-tests revealed significant increases ($p = 0.05$) in bilateral hip extension strength and jump height for both intervention groups, but not the control group. Further analysis showed sex-specific adaptations, with squat jumps leading to greater jump height increases in males and box jumps leading to greater gluteal hypertrophy in females. All males demonstrated an increase in bilateral hip extension strength. Other measured variables showed no statistically significant changes from baseline.

CONCLUSION: Box jump and squat jump interventions both effectively increased hip extension strength and vertical jump height. However, exercise selection may need to be tailored based on sex to optimize training outcomes. These findings provide valuable insights for clinicians and fitness professionals working with college-aged individuals. Incorporating box jumps and squat jumps into rehabilitation or training programs can help improve strength and functional performance. Furthermore, recognizing sex-specific adaptations has the potential to personalize plyometric exercise prescription, leading to more effective training programs and improved outcomes.

THE VOLUME OF PLYOMETRIC TRAINING INFLUENCES MEDIAL GASTROCNEMIUS STIFFNESS

PECHLIVANOS, R., AMIRIDIS, I.G., SAHINIS, C., ENOKA, R.M.

ARISTOTLE UNIVERSITY OF THESSALONIKI

INTRODUCTION: The stiffness of the muscle-tendon unit (MTU) for the plantar flexor muscles functions as an enhancement mechanism for athletic performance (1). Long-term plyometric training programs likely influences MTU stiffness of the plantar flexors (2,3). Nevertheless, the optimal training volume (sets x repetitions) to induce these adaptations remains unknown due to the significant variability of the available protocols (4). The present study aimed to assess the effect of varying plyometric training volume on the MTU of the plantar flexors.

METHODS: Four moderately trained participants (2 males, 2 females out of the 16 participants that will be recruited for the ongoing study) performed a control condition and 4 progressive training volumes of hopping exercise at 5 different sessions randomly. Based on previous studies on training volume it was defined as: Low (2 sets x 10 reps), Moderate (6 sets x 10 reps), High (10 sets x 10 reps), and Very High (14 sets x 10 reps). Before and after the training protocol, the medial gastrocnemius stiffness of the right leg was evaluated with ultrasound, during gradually increasing ramp contractions to maximal voluntary contraction (MVC) force. Vertical ground reaction forces during hopping were recorded with a force platform to calculate peak force (expressed as % of body weight) and the net force-time integral (impulse) from touch-down to takeoff. Moreover, the jumping performance of participants was assessed with drop jumps (DJ) from heights of 20 and 40 cm. Two-way ANOVA was used to examine the differences in examined variables between the different conditions.

RESULTS: The pilot results showed that medial gastrocnemius stiffness changed significantly ($p < 0.05$) only after the High and Very High training-volume conditions and was unchanged for the Low and Moderate volumes. MVC force was decreased ($p < 0.05$) only after the High and Very High training-volume conditions. DJ performance from 20 and 40 cm remained unchanged ($p > 0.05$) across all conditions. Both peak force and impulse was significantly ($p < 0.05$) decreased at the final sets of High and Very High training volume conditions.

CONCLUSION: Greater plyometric training volume increased MTU stiffness of the plantar flexors and decreased the maximal ground reaction force. Our study has important implications in the optimization of plyometric training protocols. When the primary objective of a training program is to enhance the stiffness of the muscle-tendon complex of the plantar flexors, a medium training load of hopping is insufficient to produce significant changes.

THE SCALING FACTOR BETWEEN GROUND CONTACT TIME AND JUMP HEIGHT IN DROP JUMPS: A LINEAR RELATIONSHIP AT THE INDIVIDUAL LEVEL

BOCCIA, G., SERRANÒ, S., BONELLI, B., LA TORRE, A., PAVEI, G.

UNIVERSITY OF TURIN

INTRODUCTION: The extent to which jump height scales with changes in ground contact time (GCT) remains unknown. Establishing this relationship would enable more accurate comparisons of rebounds with different GCTs. Currently, to reliably compare reactive strength index (RSI) values, it is necessary to consider only those with similar contact time parameters.

METHODS: Elite track and field athletes performed drop jumps from a 40 cm box under three distinct instructional conditions: 1) Trade-off strategy – minimizing GCT while maximizing jump height; 2) Maximizing jump height; 3) Minimizing GCT. A hierarchical linear regression model was applied, with GCT and sex (male/female) as independent variables and jump height as the dependent variable.

RESULTS: Compared to the trade-off condition, focusing on short GCT led to a 21 ms reduction in GCT ($P < 0.0001$) but also a 5.9 cm decrease in jump height ($P < 0.0001$). Conversely, prioritizing jump height increased jump height by 4.8 cm ($P < 0.0001$) but prolonged GCT by 49 ms ($P < 0.0001$). However, RSI remained unaffected by instructions ($P=0.567$). A significant main effect of GCT on jump height was observed ($\beta=0.154$; $P < 0.00001$). The full model, incorporating random and fixed effects, accounted for 94% of the variance in jump height.

CONCLUSION: At the individual level, we found a linear relationship between GCT and jump height indicating that for every 1 ms increase in GCT, jump height increases by 0.154 cm. This relationship underscores the importance of considering the GCT-jump height trade-off when assessing drop jump performance and highlights the need for evaluations across various GCT ranges rather than relying solely on one jump strategy.

NEURAL OSCILLATORY RESPONSES TO EXPERIMENTAL MUSCLE PAIN AT REST AND DURING CYCLING EXERCISE

ABOODARDA, J., ZADEH, F.Y., TINGLEY, D., HECKER, K., PROTZNER, A.

UNIVERSITY OF CALGARY

INTRODUCTION: Pain experienced during exercise acts as an inhibitory factor that can alter motor output, reduce exercise tolerance, and limit the physiological and cognitive benefits of physical activity. Despite this evidence, the brain responses that characterize exercise-induced pain remain poorly understood. The present study sought to investigate electrical brain activity measured via electroencephalography (EEG) in response to exercise-relevant experimental muscle pain at rest and during cycling exercise.

METHODS: Twenty-one healthy participants completed four experimental conditions twice, with each lasting 255 s: (i) resting (sitting) while fixating on a point (FIX), (ii) resting fixation with pain intervention (PAIN), (iii) submaximal (30% of peak power output) single-leg cycling (CYCL), and (iv) submaximal single-leg cycling while pain intervention applied to the non-exercising leg (CYCL+PAIN). Experimental pain was induced using a combination of blood flow occlusion and low-intensity electrically evoked quadriceps muscle contractions. A 32-channel EEG system was used to record brain signals throughout each condition and to determine spectral power for alpha, beta, and gamma frequency bands at four distinct brain regions, bilaterally encompassing fronto-central and centro-parietal cortices. Perceived leg pain (0-10 visual analog scale) was monitored throughout the tasks.

RESULTS: Compared to FIX and CYCL, occlusion in the non-exercising leg during the PAIN and PAIN+CYCL conditions resulted in an average pain rating of $\sim 6.52 \pm 3.9$ ($P < 0.001$). At a resting state, pain induced a significant reduction in alpha ($P < 0.001$) and beta ($P < 0.001$) power in fronto-central, and centro-parietal brain areas, while gamma suppression was only observed in fronto-central brain areas ($P < 0.001$). Changes occurred bilaterally with no observable differences between brain hemispheres. During cycling, superimposed pain did not significantly alter frequency band power compared to cycling alone.

CONCLUSION: These findings suggest that tonic experimental muscle pain is characterized by distinct frequency band modulations at rest that are not observed during cycling. Pain-induced gamma suppression is a novel finding that may suggest unique cortical processing specific to exercise-relevant muscle pain. It is plausible that a greater pain stimulus may be required to detect pain-evoked modulations during cycling. Overall, this study provides novel insights into the neural responses to muscle pain, while contributing to understanding EEG spectral analysis' utility for studying pain during exercise.

ELECTROCORTICAL ACTIVITY IN REAL-WORLD CROUCHING START OF ELITE SPRINTERS

OSHIMA, A., KAKEHATA, G., KANEKO, N., YAMASAKI, D., MASHIKI, Y., ARAKAWA, H., OKEGAWA, T., DOHATA, M., YOKOYAMA, H., NAKAZAWA, K.

THE UNIVERSITY OF TOKYO

INTRODUCTION: A quick start to an imperative tone (starting gun) following a warning tone ("set") is a crucial factor influencing sprint performance, though the neural mechanisms that support the quick start are still unclear. Previous neuroimaging studies have reported that when a response to an auditory stimulus is required, brain activity is modulated preceding that stimulus [1]. Thus, examining brain activity prior to a crouching start may help us understand a part of the neural mechanisms underlying the quick start. We aimed to investigate electrocortical activity during a crouching start using electroencephalography (EEG), which enables the examination of brain activity modulation within its limited time frame.

METHODS: Seventeen sprinters (10 males, aged 19–27 years) performed the following tasks: a starting task and a non-starting task. In the starting task, participants were instructed to position their hands and feet on the starting line and starting blocks, lift their hips in response to a warning tone, and initiate the start upon hearing an imperative tone after about 1700 ms. In the non-starting task, they positioned their hands and feet but remained relaxed without focusing on starting. After the warning tone, they were asked to lift their hips but instructed to disregard the imperative tone and avoid starting. Each task consisted of 30 trials. EEG signals were recorded using a portable EEG system with 63 electrodes. EEG prior to the imperative tone was used for source analysis. Statistical significance for differences between the two tasks in event-related spectral perturbation was tested using bootstrap statistics with false discovery rate correction. The significance level was set at $p < 0.05$.

RESULTS: Statistical analysis in the anterior cingulate cluster revealed, during the starting task, a significant increase in theta (4–8 Hz) and alpha (8–13 Hz) power during the first half of the interval between the warning and imperative tones ($p < 0.05$), while power across a broad frequency range, from theta to gamma (30–40 Hz), significantly increased during the second half of this interval ($p < 0.05$).

CONCLUSION: The anterior cingulate cortex is thought to be involved in error detection and intentional motor control [2]. An enhancement of power has been considered to characterize brain states with reduced information processing [3]. In summary, our results suggest that during a crouching start, neural processing related to these cognitive functions in the anterior cingulate cortex is reduced. This reduction in neural processing may lead to an increase in attentional resources for the imperative stimulus, potentially contributing to the quick start. The findings may serve as fundamental knowledge for enhancing performance in sports requiring a quick response.

POST-STROKE CORTICAL CONTRALESIONAL CONNECTIVITY LEADS TO RANGE OF MOTION ASYMMETRY AND AFFECTS WALKING PERFORMANCE IN STROKE SURVIVORS

V RUAS, C., CARLOS, B., LIMA, C., VAZQUEZ, P., NOGUEIRA, D., BRANDÃO, A., CASTELLANO, G.

UNIVERSITY OF CAMPINAS

INTRODUCTION: Stroke may lead to plastic structural changes within areas of the ipsilesional and contralesional hemispheres of the brain, which increase cortical interhemispheric imbalance [1]. Maximum joint range of motion (ROMmax) impairments may also occur in the paretic limb, leading to an increased ROMmax asymmetry between lower limbs and reduced motor performance in functional tasks, such as walking [2]. However, the association between post-stroke connectivity of each cortical hemisphere, hip flexion ROMmax symmetry between limbs and walking performance is poorly understood. The present study examined the specific influence of post-stroke cortical connectivity in the ipsilesional and contralesional hemispheres of the brain on hip flexion ROMmax asymmetry and walking performance in stroke survivors.

METHODS: Twenty hemiparetic chronic stroke patients (57.5 ± 14.8 yr, 26.7 ± 22.2 m post stroke) were assessed for cortical functional connectivity of the ipsilesional and contralesional general hemispheres and specific primary motor cortex (M1) areas of the brain with resting-state electroencephalography (EEG). Patients were also assessed for hip flexion active ROMmax of the paretic and non-paretic limbs and 10-m walk test, and their between-limb ROMmax asymmetry was further calculated. Relationships between changes in these variables were examined by Pearson product-moment (r), and linear and multiple regression analyses.

RESULTS: Hip flexion ROMmax asymmetry was correlated ($P < 0.05$) with cortical connectivity of the entire contralesional hemisphere ($r = 0.52$) and specific contralesional M1 ($r = 0.47$) areas of the brain, while the time to complete 10-m walk test was correlated with cortical connectivity of the contralesional M1 area only ($r = 0.51$). Cortical connectivity of the contralesional hemisphere explained ~28% of the hip flexion ROMmax asymmetry, while cortical connectivity of the contralesional M1 explained ~25% of the total time to complete the 10-m walk test ($P < 0.05$). No correlations ($P > 0.05$) between the other variables were observed.

CONCLUSION: Cortical connectivity networks seem to shift mainly to the contralesional hemisphere after stroke episodes [3], which may in turn increase lower limb ROMmax asymmetry and reduce the ability of stroke patients to perform daily tasks, such as walking.

CORTICAL CHANGES IN CHRONIC ANKLE INSTABILITY DURING DROP-LANDING: A PRELIMINARY STUDY

NANBANCHA, A., THARAWADEEPIMUK, K., SIRIPORNANICH, V.
MAHIDOL UNIVERSITY

INTRODUCTION: Chronic ankle instability (CAI), primarily occurring at the peripheral level, has been demonstrated to induce alteration at the cortical level [1]. It is evidence of both structural and functional brain adaptations associated with CAI. The impact of these changes in CAI is apparent in various functional movements [2, 3]. Similarly, studies in knee injury revealed increased activity in the frontal and parietal cortex [4]. This heightened activation within brain regions associated with motor planning and sensory processing suggested that individual with peripheral injury may rely on higher-order attentional control and somatosensory processing to compensate for the neuromechanical deficit [1]. The aim of this study was to compare cortical measures of motor planning after between people with CAI and without CAI (non-CAI).

METHODS: Ten participants (5 CAI and 5 non-CAI) aged between 20 - 40 years with right dominant side were recruited. They were informed to perform 40-50 drop-landing trials. Cortical activity during the task was record using electroencephalogram (EEG). Firstly, raw data were processed using MATLAB, with the initial contact on the force plate defined as the point where a vertical ground reaction force of 20 N was detected. Secondly, movement-related cortical potentials (MRCPs) were extracted by analyzing EEG data within a time window extending 1500 ms prior to this point. The time window was divided into three consecutive 500 ms intervals relative to movement onset: readiness potential 1 (RP1), readiness potential 2 (RP2), and the negative slope (NS). Then, EEG data corresponding to MRCPs were structured into a 30×100 matrix, representing 30 electrode positions and 100 normalized time points as percentages of the MRCP duration. Further analysis focused on EEG signals across delta, theta, alpha, and beta frequency bands. Lastly, group differences during the pre-landing phase were assessed using a two-sample t-test within the statistical non-parametric mapping (SnPM).

RESULTS: A significant difference was observed during the NS, with the CAI group demonstrating higher absolute EEG power than non-CAI group in the alpha band over Cz position ($p = 0.029$) and in the beta band over FC1 position ($p = 0.031$). However, no significant differences were identified between the groups during the RP1 and RP2.

CONCLUSION: During drop- landing, the CAI group exhibited increased both alpha power over the central brain area and beta power over the left frontal region. These observed differences in cortical activation point towards an altered neural mechanism of movement control and brain processing in individual with CAI. This suggests an adaptation of brain processes, particularly those involved in cortical motor planning, specifically for the demand of drop-landings.

SKILLED PASSING IN FOOTBALL MAY REGRESS FOLLOWING AN ANTERIOR CRUCIATE LIGAMENT INJURY AS A RESULT OF CORTICAL CHANGES: PRELIMINARY EEG EVIDENCE

PISKIN, D., COBANI, G., LEHMANN, T., BÜCHEL, D., BAUMEISTER, J.
PADERBORN UNIVERSITY

INTRODUCTION: Anterior cruciate ligament (ACL) injuries impact football players substantially, leading to performance declines and premature career endings. Emerging evidence demonstrates neurophysiological alterations in injured individuals and characterize ACL ruptures not merely as peripheral injuries but as complex conditions with neurophysiological aspects. The objective of the present study was to compare kicking performance and the associated cortical activity between injured players and their healthy counterparts. Understanding the neurophysiological implications of an ACL injury within the football context may elucidate mechanisms that impair sport-specific performance and guide practical strategies for restoring the pre-injury level of performance.

METHODS: Ten reconstructed players and 15 healthy controls performed a short-distance kicking task. Kicking biomechanics were recorded using wearable inertial measurement unit sensors and the consistency was assessed by analyzing trial-to-trial non-linear fluctuations in kicking behavior using multiscale entropy (MSE). Cortical activity was captured with a 64-electrode mobile electroencephalography (EEG) system. Kick-induced cortical patterns in posterior and frontal regions were described based on source-derived event-related spectral perturbations (ERSP). The kick-related complexity of these two regions were analyzed using MSE.

RESULTS: MSE analysis of kicking biomechanics revealed increased trial-to-to complexity in foot external rotation among injured players. ERSPs indicated significant differences in posterior alpha and frontal theta oscillations during between the groups. Furthermore, the kick-related complexity of these two regions was reduced in injured players at medium and coarse scales as indexed by MSE.

CONCLUSION: The current findings suggest behavioral changes during kicking in injured players potentially as a result of proprioceptive deficits. This may necessitate compensatory strategies at a cortical level involving augmented attentional demands at the cost of processing visuospatial information. This conflict may hinder the integration of task-relevant information across distributed networks and indicate an increased cortical load. Our study provides preliminary insights into

the neurophysiological implications of an ACL injury within the football context, proposes kicking performance as a domain to consider in practical implementations following injury and underscores the potential for prospective research.

PRE-MEAL AND POST-MEAL EXERCISE: LONG-TERM INTERVENTIONS ON 24-HOUR CONTINUOUS GLUCOSE IN YOUNG ADULTS WITH OVERWEIGHT AND OBESITY

ZHANG, X., YANG, B., HO, Y., ZHANG, Z., WU, D., QIAN, J.

PEKING UNIVERSITY

INTRODUCTION: While the optimal timing for exercise to control glucose levels remains unclear, especially regarding the long-term effects of exercise timing, this study aims to investigate the long-term effect of exercise timing in relation to meal times—specifically, pre-meal and post-meal exercise—on glucose homeostasis in young adults with overweight and obesity using continuous glucose monitoring (CGM).

METHODS: A randomized controlled study was conducted on 34 overweight and obese young adults aged 18 to 35 who underwent a 10-week intervention with different exercise timings. The pre-meal exercise group performed at least 30 minutes of moderate-intensity (65% HRmax) aerobic exercise within 60 minutes before a meal, while the post-meal exercise group performed the same within 0-90 minutes after a meal, five times a week. The exercise intervention was conducted at a smart health station with at least two supervised exercise sessions per week and three self-exercise sessions, monitored by a heart rate belt. The primary outcome was 24-hour continuous glucose levels measured via CGM (SIBIONICS), with secondary outcomes being physical and mental health indicators. Participants maintained their usual dietary habits during the intervention and wore an actiGraph 3X accelerometer to monitor physical activity levels before and after the intervention. Paired t-tests were used for within-group comparisons, and covariance analysis was used for between-group comparisons.

RESULTS: There were no significant differences in 24-hour mean glucose (98.23 ± 3.16 vs. 97.77 ± 4.22 mg/dL), mean amplitude of glucose fluctuation (MAGE, 31.87 ± 4.37 vs. 33.12 ± 6.82), coefficient of variation of glucose (CV%, $15.68 \pm 1.50\%$ vs. $16.92 \pm 3.50\%$) and continuous overall glycemic effect (CONGA, 15.37 ± 2.34 vs. 16.11 ± 3.21 mg/dL) between or within the pre-meal and post-meal exercise groups (all $p > 0.05$). However, the hypoglycemia index significantly decreased in the pre-meal exercise group ($p = 0.039$). Regarding mental health indicators, only the pre-meal exercise group showed a significant improvement in mindfulness awareness. After the intervention, both groups increased their daily moderate-intensity physical activity time and reduced their sedentary time.

CONCLUSION: A 10-week pre- or post-meal exercise intervention did not significantly affect 24-hour continuous glucose levels. Compared to post-meal exercise, pre-meal exercise may reduce the risk of hypoglycemia in young adults with overweight and obesity.

EXPLORING THE RELATIONSHIP BETWEEN EXERCISE TIME, VOLUME, FREQUENCY, CONSISTENCY, AND GLYCEMIA AFTER A 26-WEEK MHEALTH EXERCISE INTERVENTION IN INDIVIDUALS WITH TYPE 2 DIABETES IN A REAL-WORLD SETTING

LOW, J., HESKETH, K., FALKENHAIN, K., LEE, H., JUNG, M.E., SINGER, J., JONES, C.A., RUSSON, C., COCKS, M., MCMANUS, A., LITTLE, J.P.

UNIVERSITY OF CALGARY

INTRODUCTION: Exercise interventions play a pivotal role in managing type 2 diabetes (T2D), yielding significant benefits in glycemic regulation. Despite the role that exercise time, volume, frequency, and consistency play in exercise prescription for T2D interventions, research is still discrepant on what metric(s) might have a more potent effect on improving glycemic regulation. The purpose of the present study was to explore the relationship between exercise metrics (duration, volume, frequency, and consistency) and markers of glycemic regulation (HbA1c and continuous glucose monitoring (CGM) metrics including mean 24-hour glucose, glycemic variability, and eA1c) after a 26-week mHealth intervention.

METHODS: This was a secondary analysis of the MOTIVATE T2D trial (NCT04653532); an RCT investigating the feasibility of an mHealth exercise intervention. Inactive individuals with newly diagnosed (<2 years) T2D ($N = 58$) completed blood and 14-day CGM testing before (T0) and after (T1) a 26-week mHealth exercise intervention. HbA1c was assessed using a lab-based point-of-care machine (Afinion 2, Abbot Inc.). CGM analysis was performed at T0 and T1 using an online no-code webtool called Diametrics (diametrics.org). Participants were asked to wear a fitness watch during the 26-week tailored intervention, and raw exercise data from each recorded session were extracted. Exercise metrics (duration, volume, frequency, and consistency) were calculated across i) the total 26-weeks; ii) the first 13 weeks (where personalized support and changes were provided); iii) the last 13 weeks (where support was reduced) of the intervention and were compared to the CGM metrics at T1. A linear model was used to examine the predictors of mean 24-hour glucose, glycemic variability (SD, CV), HbA1c, and eA1c at T1.

RESULTS: Average duration (57 ± 36 minutes) of each exercise session significantly predicted HbA1c ($\beta = -0.23$ (0.07), $P = 0.002$), 24-hour mean glucose ($\beta = -0.03$ (0.01), $P = 0.01$), eA1c ($\beta = -0.02$ (0.01), $P = 0.01$), and glucose standard deviation

($\beta = -0.01$ (0.0), $P = 0.003$) at T1. Exercise minutes (duration) accumulated during the first 13 weeks of the intervention (2931 ± 3362 minutes) were also a significant predictor of HbA1c ($\beta = -0.001$ (0.0), $P = 0.01$), 24-hour mean glucose ($\beta = -0.002$ (0.0), $P = 0.01$), eA1c ($\beta = -0.0001$ (0.0), $P = 0.01$), and standard deviation ($\beta = -0.005$ (0.0), $P = 0.03$).

CONCLUSION: Average exercise session duration and total exercise minutes accumulated during the first 13 weeks of the intervention predicted HbA1c, mean 24-hour glucose, eA1c, and glucose standard deviation at the end of a 26-week mHealth exercise intervention. These findings suggest that accumulating more minutes (duration) of exercise is an important metric for improving glucose regulation in people with newly diagnosed type 2 diabetes, especially in the early phases of an exercise intervention.

THE EFFECTIVENESS OF A COMBINED TRAINING PROGRAM IN REDUCING ANXIETY AND DEPRESSION IN SUBJECTS WITH TYPE 2 DIABETES: A CONTROLLED STUDY

DENGUEZLI, M., ABROUGUI, M., BEN ABDELAZIZ, A., HASSINE, R., OMEZZINE, A., ZAOUALI, M.

FACULTY OF DENTAL MEDICINE OF MONASTIR

INTRODUCTION: While previous research has explored the individual effects of aerobic and resistance training on anxiety and depression in individuals with type 2 diabetes, the combined impact of these exercise modalities remains underexplored. This study examines the effectiveness of a 24-week combined aerobic and resistance training program in reducing anxiety and depression scores in this population.

METHODS: The study involved 43 inactive women aged 39 to 70 years with type 2 diabetes. Participants were assigned to a combined aerobic and resistance training ($n=31$) or a sedentary control group ($n=12$). Participants in the training group engaged in supervised combined exercise training sessions three times a week over 24 weeks. Beck Anxiety Inventory (BAI) and Beck Depression Inventory-II (BDI) were used to determine depression and anxiety scores.

RESULTS: At baseline both groups scored similarly on the BAI and BDI. After 24 weeks, the trained group showed significant reductions in anxiety scores (12 weeks: 5.96 ± 2.88 ; 24 weeks: 4.83 ± 1.42), whereas the control group exhibited increased anxiety (12 weeks: 15.25 ± 5.86 ; 24 weeks: 19.41 ± 1.08). Significant differences were observed between groups. The trained group maintained stable depression scores (12 weeks: 5.51 ± 2.71 ; 24 weeks: 5.58 ± 3.59), while the control group's scores increased (12 weeks: 15.58 ± 6.12 ; 24 weeks: 19.58 ± 0.99). Significant differences between groups were observed at 12 weeks ($p = 0.001$) and 24 weeks ($p = 0.000$).

CONCLUSION: The training program significantly reduced anxiety and stabilized depression in the trained group compared to the control group. These findings highlight the programs effectiveness in managing anxiety and depression over time.

USING ECOLOGICAL MOMENTARY ASSESSMENT TO EXPLORE ADHERENCE TO JUST-IN-TIME PROMPTS FOR INTERRUPTING SITTING AND INCREASING WALKING PACE IN PATIENTS WITH PREDIABETES AND TYPE 2 DIABETES

VETROVSKY, T., MAES, I., NOVAK, J., KUHNova, J., JANEK, M., ELAVSKY, S., STEFFL, M., CIMLER, R., KRAL, N., PFEIFEROVA, M., SEIFERT, B., YATES, T., HARRIS, T., VAN DYCK, D.

CHARLES UNIVERSITY

INTRODUCTION: Interrupting prolonged sitting and increasing physical activity (PA) are crucial for managing prediabetes and type 2 diabetes. However, achieving these behavioural changes remains challenging. The ENERGISED trial leveraged mHealth technologies to deliver occasional just-in-time prompts, suggesting either sitting interruption or increased walking pace at the right moment—when patients had been sedentary for over 30 minutes or walking for at least 5 minutes, respectively. This study, embedded within the ENERGISED trial, aimed to explore patients' self-reported adherence to these prompts using ecological momentary assessment (EMA).

METHODS: Patients from the intervention arm of the ENERGISED trial ($n = 172$), receiving just-in-time prompts suggesting sitting interruption or increased walking pace, were eligible. Fifteen minutes after a just-in-time prompt, they received an EMA survey with a 50% probability, limited to no more than once every other day. Delivered via the HealthReact app, the survey asked whether they adhered to the suggestion to interrupt sitting or increase walking pace. If not, they were asked to specify the reason, including physical and social constraints, concurrent activities, environmental context, lack of motivation, or technical limitations such as delayed prompt delivery or missed prompts. The survey also measured fatigue, stress, and pain levels on 0–10 Likert scales. Descriptive statistics and logistic mixed-effects models were used to analyse adherence and its moderators.

RESULTS: Forty-one patients (50% female; median age: 61 years; 29% prediabetes) participated for a median of 252 days (IQR 157–314). They received 2,125 sitting interruption suggestions and 1,712 walking pace suggestions, of which 949 and 729, respectively, were followed by an EMA survey. In total, 394 (42%) and 338 (46%) surveys were completed. Sitting was interrupted following 26% of relevant prompts; the most common reason for non-adherence was engagement in concurrent activities such as driving or focused work (44%). Walking pace increased in response to 28% of prompts; the primary reason for non-adherence was that walking had already ceased (39%). Higher fatigue (OR 0.983, 95% CI 0.969–0.997, $p = 0.019$) and stress (OR 0.979, 95% CI 0.961–0.997, $p = 0.026$) reduced the odds of increasing walking pace, while pain had no significant effect. Adherence to sitting interruption was not moderated by fatigue, stress, or pain. Neither sex nor age influenced adherence to either suggestion.

CONCLUSION: The effectiveness of just-in-time suggestions to reduce prolonged sitting and increase PA intensity in patients with prediabetes and type 2 diabetes is limited by inappropriate triggering—either during activities that prevent sitting interruption or due to delays causing prompts to be received after walking has ceased. Future approaches should optimise prompt timing to better target moments when patients are most receptive and able to act.

EFFECTS OF AN EXERCISE- AND NUTRITION- BASED EDUCATIONAL CAMP ON GLYCEMIC CONTROL IN ADULTS WITH TYPE 1 DIABETES: THE ACTION NON-RANDOMIZED CONTROLLED TRIAL

GATTI, A., PIRAZZI, A., GIURIATO, M., CAVALLO, C., CARNEVALE PELLINO, V., DEL BIANCO, M., PAVIA, E., BRUNATO, B., CANDIDO, R., CUM, S., ASSALONI, R., VANDONI, M.

UNIVERSITY OF PAVIA

INTRODUCTION: Maintaining glycemic control is a major challenge for people with T1D, as fluctuations increase the risk of complications and double diabetes – people with T1D with also insulin resistance, typical of T2D 1. Educational camps have shown to improve glycemic control in children with T1D, but their effectiveness in adults with T1D remains unexplored 2,3. For these reasons, this study evaluates the effectiveness of an exercise- and nutrition-based educational camp (EG) compared to usual care (UC) in adults with T1D.

METHODS: A total of 48 adults (42.4 ± 12.3 years; 21 (47.7%) women) with T1D were recruited through consecutive sampling for the ACTION study and assigned to either the EG or UC ($n = 24$ each). Glycemic control outcomes (HbA1c, GMI, Time-in, above, and below range, mean, and CV of glucose) were retrieved for the 3 months before and after the intervention. Moreover, at both time points, the IPAQ-SF and IFIS questionnaires were filled out by the participants. Intervention effects on primary and secondary endpoints were analyzed using a generalized linear mixed model for repeated measures.

RESULTS: No participants dropped out of the EG, while four dropped out from the UC. The EG showed significantly greater reductions in HbA1c, GMI, time above range, mean glucose, and SD compared to the UC ($p < 0.050$). Moreover, we found a significant increase for the time in range for the EG compared to the UC and no differences in the time below range ($p = 0.010$). However, self-reported physical activity, sedentary time, and fitness perception did not differ between groups ($p > 0.050$).

CONCLUSION: Our findings suggest that an exercise- and nutrition-based educational camp improves glycemic control in adults with T1D, potentially lowering the risk of double diabetes, as shown by the greater decrease in HbA1c and GMI. These results underscore the value of structured educational interventions. Future research should assess the long-term sustainability of these benefits and optimize program implementation in clinical care.

INTRODUCTION: Mitochondrial dysfunction and oxidative stress are associated with Parkinson disease (PD) and are intrinsic factors related to its pathogenesis. Physical activity (PA) enhances cognitive function in older adults, reduces motor deficits, promotes neuron formation, and slows age-related neuronal loss. Herein we compare the effects of two different PA programs in PD patients analyzing relevant clinical aspects and its impact on mitochondrial function.

METHODS: Patients with early-stage PD (stage H&Y II; $n=24$) were randomized into 3 groups of 8 patients. The effects of two different PA programs were compared. The first group performed basic physical training (BPT) based on strength and resistance; a second group performed BPT combined with functional exercises (BPTFE) to stimulate the specific sensorimotor pathways that are most affected in PD (proprioception-balance-coordination) together with dual task training; a third group served as control. Subjects performed 3 sessions per week for 16 weeks. Motor function, quality of life, sleep quality,

cognitive aspects, humor and overall satisfaction (CSQ-8) were evaluated. Skin fibroblasts were collected for mitochondrial analysis to explore their potential as biomarkers for PD progression.

RESULTS: The CSQ-8 results demonstrated high levels of satisfaction, with mean scores ranging from 3.4 to 4.0 indicating overall positive feedback. The application of BPT and BPTFE programs significantly improved Sit-to-stand (STS) and Timed Up and Go (TUG) test performance ($p < 0.001$). Specifically, significant improvements were observed in the STS ($p = 0.001$), with both BPT and BPTFE groups demonstrating superior performance compared to the Controls ($p < 0.003$). Similarly, the TUG test showed significant improvements ($p = 0.0042$) in both intervention groups compared to the Controls ($p = 0.0039$ and $p = 0.0028$, respectively). However, no statistically significant differences were observed in quality of life (PDQ-39, $p = 0.810$) or depressive symptoms (BDI, $p = 0.577$) across the groups. Despite the lack of statistical significance, a small to moderate reduction of discomfort was noted in the BPTFE group compared to controls for both quality of life (MD = -7.71, $r_{rb} = -0.339$) and depressive symptoms (MD = -6.57, $r_{rb} = -0.429$). Mitochondrial analyses are currently ongoing and will provide further insights into their role in PD.

CONCLUSION: These findings confirm that both BPT and BPTFE interventions effectively enhance physical function in PD patients. While clinical outcomes related to mood and quality of life did not reach statistical significance, the observed trends suggest potential benefits, warranting further investigation. These results highlight the importance of incorporating targeted PA programs into PD management.

IV-VIVO ASSESSMENT OF MUSCLE MICROSTRUCTURAL PROPERTIES IN PARKINSONS DISEASE USING QUANTITATIVE ULTRASOUND RADIOFREQUENCY TECHNIQUE

BIZET, B., TRINCHI, M., NARDELLO, F., ZIGNOLI, A., BOMBIERI, F., MONTE, A., ZAMPARO, P.
UNIVERSITÀ DI VERONA

INTRODUCTION: Parkinsons disease (PD) is the second most prevalent neurodegenerative disorder, affecting approximately 1% of individuals over 60 years [1]. Current clinical assessment tools, such as the Hoehn-Yahr Scale and the Unified Parkinsons Disease Rating Scale (UPDRS) are non-quantitative, and this could potentially lead to diagnostic errors [2].

This study investigates the potential of ultrasound Nakagami imaging to quantitatively evaluate muscle characteristics in PD patients, as previously proposed for patients with Duchene Muscle Dystrophy [3]. The aim was to determine whether Nakagami imaging can effectively reflect disease severity and thus provide a reliable, quantitative tool for monitoring disease progression.

METHODS: The study included 17 PD patients (7M/10F) and 15 healthy controls (7M/8F). Based on UPDRS Part III assessment and Hoehn-Yahr (H-Y) scale scores, PD patients were divided into an early-stage group ($H-Y \leq 2$, $n = 7$) and a late-stage group ($H-Y > 2$, $n = 10$). The International Physical Activity Questionnaire (IPAQ) was utilized to assess physical activity levels in all participants.

B-mode and Radiofrequency (RF) data were collected from the tibialis anterior (TA) and the gastrocnemius medialis (GM) on the most and the less affected limb by means of an ultrasound apparatus (ArtUs EXT-1H, Telemed UAB). B-mode data were used to investigate muscle geometrical characteristics and RF data to compute the Nakagami parameters.

RESULTS: The three groups were matched for age (69-77 years), stature (1.64-1.68 m), body mass (68-73 kg) and IPAQ scores (2231-3210). A 2-way ANOVA (group x limb) indicate no differences between limbs in all the investigated parameters; thus, only the differences between groups are reported. Significant differences in the Nakagami parameters were observed between controls and late-stage patients in GM ($p < 0.001$) and in both the superficial ($p < 0.01$) and deep ($p < 0.05$) compartments of TA. Significant differences were also observed between early-stage and late-stage patients but in GM only ($p < 0.001$). No statistical differences were found between controls and early-stage patients and no differences in muscle geometry were found among groups. Finally, a significant correlation was observed between the GM Nakagami parameter obtained from the most affected side and the Hoehn-Yahr scale ($R = 0.619$, $p = 0.01$).

CONCLUSION: Ultrasound Nakagami imaging is a promising quantitative tool for evaluating muscle characteristics in PD patients. The Nakagami parameter can distinguish the severity of the disease, providing a quantitative means to monitor the progression of Parkinson's disease. Further research is needed to validate these findings on a larger sample of patients and to explore the clinical applicability of this technique.

FORCE STABILITY AND MOTOR UNIT BEHAVIOR ARE ALTERED IN PARKINSON'S DISEASE PATIENTS DURING DUAL-TASK KNEE EXTENSION

KALC, M., MILADINOVIC, A., AJCEVIC, M., HOLOBAR, A., KRAMBERGER, M., MURKS, N., MANGANOTTI, P., PESKAR, M., MARUŠIĆ, U.

SCIENCE AND RESEARCH CENTRE KOPER

INTRODUCTION: Parkinson's disease (PD) is a neurodegenerative disorder that affects neuromuscular control, reducing mobility and quality of life. These deficits arise, in part, from altered motor unit (MU) recruitment and discharge modulation. PD patients exhibit poorer force steadiness and greater MU firing variability than healthy individuals. Additionally, PD

symptoms are often asymmetric. Dual tasking, which combines motor and cognitive demands, further challenges neuromuscular control, yet its effects on MU firing behaviour remain unclear. This study examined how dual tasking affects force steadiness and MU behaviour in PD patients compared to healthy controls.

METHODS: Fifteen PD patients (6 females, age: 63.8 ± 6.2 years, UPDRS III: 14.7 ± 6.8) and fifteen healthy participants (7 females, age: 63.7 ± 7.2 years) performed a 32-second force-tracking trapezoidal knee extension task at 30% of maximal voluntary contraction (MVC) on an isometric knee dynamometer. The tasks included a) a single visuomotor condition with trapezoidal force tracking, and b) a dual-task condition requiring concurrent serial subtraction by three from a randomly selected number. High-density surface electromyography (HDsEMG) was recorded from the vastus lateralis using 32-electrode arrays, and MU firings were extracted. Outcome measures included force steadiness (coefficient of variation, CV), tracking error rates, mean MU discharge rate (DR), recruitment threshold (RT), and derecruitment threshold (DT). Data were analysed using linear mixed-effects models in R.

RESULTS: Results showed that PD exhibited greater CV during the dual task than controls ($p = 0.03$), indicating increased force variability under cognitive load. Tracking errors were also higher in PD across both tasks ($p = 0.01$), suggesting impaired force regulation. PD showed an increase ($p = 0.01$) in DR from 8.96 pps (single-task) to 9.35 pps (dual-task), while controls showed no change. When controlling for task condition, DR was significantly lower in the single-task condition (8.73 pps) than the dual-task condition (9.22 pps, $p = 0.03$), but no differences were found in controls or in the unaffected limb of PD patients. Recruitment thresholds were lower in PD (17.2% MVC) than controls (18.3% MVC), though the difference was not significant.

CONCLUSION: These findings suggest that dual tasking influence force control in PD, increasing MU discharge rates and neuromuscular demands. The results align with previous research, confirming that PD exhibit irregular MU firing patterns and lower recruitment thresholds. Combining force steadiness measures with HDsEMG analysis appears promising for detecting early-stage motor dysfunction in PD. Future studies should explore neuromodulatory and inhibitory mechanisms and assess the potential of this methodology for tracking PD progression and optimizing rehabilitation strategies.

EFFECTS OF WALKING TRAINING ON BIOCHEMICAL LEVELS OF PEOPLE WITH PARKINSON'S DISEASE

BARBIERI, R., KALVA-FILHO, C.A., BARBIERI, F.A.

UNIVERSITY OF BOLOGNA ; SÃO PAULO STATE UNIVERSITY

INTRODUCTION: Walking training is recognized as a safe and effective exercise strategy for people with Parkinsons disease (PD), promoting improvements in functional capacity, postural control and walking through the step length and average velocity and balance, reducing the risk of falling. However, the effects of this training on the biochemical parameters of people with PD remain largely unexplored since risk factors associated with metabolic syndrome, such as dyslipidemia and impaired glucose metabolism, can contribute to the development and progression of PD. Also, alterations in serum cholesterol levels, including low total cholesterol, triglycerides, and high levels of HDL cholesterol, may be linked to the progression of PD. So, this study aimed to verify the impact of walking training on biochemical markers in people with PD.

METHODS: Sixteen people with PD (72 ± 7 yrs; height of 160 ± 10 cm; weight of 66.7 ± 16.7 Kg) were recruited for a 16-week walking training program of two sessions per week. The training program involved a 10-min warm-up (stretching), 30-min of walking and motor coordination exercises (70% walking, 30% strength/balance tasks), and a 10-min cooldown. Intensity was controlled by perceived exertion, and participants were instructed to either walk the longest distance or walk at the highest possible speed depending on the daily goal. Clinical assessments (MMSE, UPDRS-II/III) were conducted to characterize participants and functional capacity (6-minute walking test: 6MWT), and biochemical marks (HDL, LDL, VLDL, total cholesterol, glucose, total protein, Triglyceride and Nitric Oxide) assessments were performed at baseline and after 16 weeks. Paired t-tests were used to compare pre- and post-training values, and Pearson's correlation analysis was applied to examine associations between variables.

RESULTS: Sixteen weeks of walking training could significantly improve the 6MWT (Pre: 448.4 ± 71.9 m; Post: 516.6 ± 83.3 m; $p = 0.037$). Additionally, significant reductions were observed in HDL (Pre: 69.5 ± 23.5 mg/dl; Post: 24.5 ± 8.8 mg/dl; $p < 0.001$), total cholesterol (Pre: 215.6 ± 39.1 mg/dl; Post: 179.3 ± 47.9 mg/dl; $p = 0.016$), glucose (Pre: 105.7 ± 6.3 mg/dl; Post: 100.5 ± 6.5 mg/dl; $p = 0.016$), and total protein levels (Pre: 7.01 ± 0.4 g/dl; Post: 6.4 ± 0.2 g/dl; $p < 0.001$). No significant changes were detected in other biochemical markers. Additionally, improvements in 6MWT performance were positively correlated with the variations of LDL levels ($r = 0.490$; $p = 0.024$), suggesting a potential link between functional capacity and lipid profile adaptations.

CONCLUSION: Walking training can positively improve the functional capacity in people with PD, and lead to favorable changes in biochemical markers, including reductions in HDL, total cholesterol, glucose, and total protein levels. These findings suggest that walking training may not only enhance motor function but also improve metabolic parameters associated with PD progression.

IMPACT OF PARKINSON'S DISEASE SEVERITY ON SINGLE- AND DUAL-TASK TURNING PERFORMANCE: A CROSS-SECTIONAL STUDY

WELMAN, K., WATKINS, C., SAM, M.

STELLENBOSCH UNIVERSITY

INTRODUCTION: Parkinson's Disease (PD) is a progressive neurodegenerative disorder that severely impacts mobility, particularly turning movements, which are essential for daily activities. Impaired turning is linked to a higher risk of falls and reduced quality of life in individuals with PD (lwPD). While gait disturbances in PD have been extensively studied, the impact of disease severity on turning performance, especially under dual-task conditions, remains underexplored. This study aimed to compare single- and dual-task turning performance and assess the influence of PD severity on turning performance.

METHODS: Seventy individuals with mild to moderate PD (H&Y II–III; 70.9 ± 6.9 years) underwent clinical assessments (MDS-UPDRS II: 14.0 ± 7.2 AU; MDS-UPDRS III: 30.8 ± 12.7 AU; MoCA: 24.7 ± 2.6 AU). Participants performed turning tasks under single-task (ST) and cognitive-motor dual-task (DT) conditions while wearing APDM tri-axial accelerometer sensors in the "ON" medication state. Turn angle, angle variability, duration, duration variability, velocity, and velocity variability were analyzed across ST and DT conditions between mild and moderate lwPD.

RESULTS: lwPD with mild PD (H&Y II) exhibited differences in ST turn duration and velocity ($p < 0.05$) compared to those with moderate PD (H&Y III), while DT turn angle, duration, and velocity also significantly differed ($p < 0.05$). In the mild PD group, turning velocity was 11% slower during DT compared to ST ($p < 0.05$). In the moderate PD group, DT resulted in smaller turning angles, greater angle variability, slower turning velocity, and increased velocity variability compared to ST ($p < 0.05$).

CONCLUSION: Disease severity significantly impacts turning performance, particularly under dual-task conditions. As PD progresses, turning becomes more impaired, with increased variability and reduced stability. These findings highlight the importance of early identification of mobility deficits and the need for targeted interventions to mitigate fall risk and enhance mobility in individuals with PD.

AFFECTIVE EXPERIENCES FROM EXERCISE PREDICT 1-YEAR PHYSICAL ACTIVITY BEHAVIOR IN MIDDLE SCHOOL STUDENTS

PIVA, T., ZERBINI, V., RAISI, A., MENEGATTI, E., BELVEDERI MURRI, M., GRAZZI, G., MAZZONI, G., MANDINI, S.

UNIVERSITY OF FERRARA

Introduction: The transition from childhood to adolescence is a critical period for the development of physical activity (PA) behaviors, as this stage marks the beginning of a well-documented decline in PA levels that continues into adulthood. However, it remains largely unknown which determinants are most influential in this stage of life. According to the Affective-Reflective Theory (ART) of physical inactivity and exercise proposed by Brand and Ekkekakis, PA behavior is driven by both "reflective evaluations" and "affective valuation". The concept of "affective valuation" has been further refined into the construct of "affective exercise experiences", defined as a summary valenced appraisal—ranging from pleasant to unpleasant—based on an individual's lifetime associations with exercise and their corresponding affective responses. This study aims to assess the predictive power of affective exercise experiences in determining PA behavior among middle school students. The hypothesis is that attraction to exercise—the motivational outcome variable in the conceptual model proposed by Ekkekakis et al.—effectively predicts PA behavior after one year.

Methods: Data were collected as part of an annual PA monitoring project conducted in schools in Ferrara, Italy. Students completed the International Physical Activity Questionnaire for Children and Adolescents (IPAQ-A) and the Affective Exercise Experiences Questionnaire (AFFEXX). Only students with two assessments spaced one year apart were included in the study.

Results: A total of 228 middle school students (mean age = 12.62 ± 0.83 years; 135 males, 93 females) were assessed over two consecutive school years. At baseline, participants were highly physically active, engaging in an average of 21 ± 23 MET/h/week of PA, predominantly at vigorous intensity (162 ± 192 min/week), with a smaller portion performed at moderate intensity (92 ± 155 min/week). All AFFEXX domains measured at baseline were significantly correlated with PA at follow-up (r values ranging from 0.14 for energy-calmness to 0.38 for showing-off-shying away). Regression analysis indicated that attraction towards exercise significantly predicted follow-up PA ($\beta = 5.9$, $p < 0.001$). When examining the relationship between attraction and PA intensity, attraction significantly predicted vigorous PA ($\beta = 51.1$, $p = 0.002$), whereas its effect on moderate PA was not significant ($\beta = 16.2$, $p = 0.11$).

Conclusion: These findings highlight the role of affective experiences from exercise in shaping future PA behaviors, particularly in relation to vigorous-intensity activities. Understanding children's affective appraisals of exercise, their exercise environment, and their overall attraction to exercise may be crucial for promoting sustained PA engagement in youth.

KEY MOTIVATIONAL FACTORS FOR DRIVE FOR MUSCULARITY IN BODYBUILDING

JUABAN, J.1, SOÓS, I.1, MOLNÁR, G.2

1. HUNGARIAN UNIVERSITY OF SPORTS SCIENCE 2. UNIVERSITY OF WORCESTER

INTRODUCTION: The aspiration for a muscular physique has been a defining characteristic of modern fitness cultures, with bodybuilding serving as a prominent subculture centered on muscle maximisation. At the core of this community is the Drive for Muscularity (DFM), which functions as both a psychological and cultural construct. DFM reflects an individual's strong inclination to enhance muscularity in pursuit of a well-defined physique. This drive is intertwined with broader themes of masculinity, body image, personal identity, and the quest for social validation. The motivational underpinnings of DFM are multifaceted. While many individuals are driven by aspirations of self-improvement and increased self-confidence, additional influences may also play a role. Despite the increasing interest in understanding the motivations behind DFM, there is a notable paucity of research focusing on Filipino population. Integrating Self-Determination Theory (SDT) into the DFM construct provides a framework for examining the role of three fundamental psychological needs—autonomy, competence, and relatedness—in shaping individuals' motivations and behaviors in their pursuit of muscularity.

Methods: A total of 117 participants, conveniently sampled, participated in the present study. The age group ranged from 18–65, Filipino males (68.4%) and females (31.6%). The average age is 32.25 years ($SD = 9.58$). Participants were recruited from a local gym in Davao City, Philippines. The study received ethical approval from the Hungarian University of Sports Science. The Drive for Muscularity Scale (DMS) a 15-item instrument designed to assess the individuals' attitudes and behaviour in relation to their pursuit of muscularity. A 6-point Likert scale ranging from (1) never to (6) always, with higher scores indicating a greater drive for muscularity. Two reasons for utilizing DFM: 1) participant identification & 2) to evaluate the drive for muscularity of the target population and ensure generalizable results. The Motives for Physical Activity Measure Revised (MPAM-R), a 30-item questionnaire evaluates five motives for physical activity engagement. A 5-point Likert scale, where 1 represents "not true for me" and 5 signifies "very true for me". Utilizing MPAM-R facilitates an understanding of the underlying reasons influencing physical activity engagement. Descriptive statistics were employed to analyze the key motivational factors for drive for muscularity.

Results/conclusions: Participants engage in an average of 1.92 hours of workout per week ($SD = 0.89$), and exhibit varying degrees of muscularity-oriented behaviors ($M = 3.55$) and attitudes ($M = 2.75$). High scores in interest/enjoyment ($M = 4.19$), competence ($M = 4.20$), appearance ($M = 4.08$), and fitness ($M = 4.51$) suggest positive perceptions in these areas, while social engagement ($M = 2.88$) shows more variability. Grounded in SDT this research will further explore key motivational determinants such as personal goals, body image satisfaction and social media influence.

AN INVESTIGATION OF THE BIDIRECTIONAL RELATIONSHIP BETWEEN SELF-EFFICACY AND ULTRA-CYCLING PERFORMANCE: THE NORTH CAPE 4000 STUDY

GOLINELLI, V., AMATORI, S., MARCORA, S.M.

UNIPV

INTRODUCTION: Ultra-cycling is defined by its extreme length and duration (over 24 hours), along with numerous variables that impact the outcome. Among these, psychological variables are thought to play an important role. The main aim of this study was to investigate 1) the relationship between self-efficacy before the race (SEpre) and performance, and 2) the effect of race performance on SE during an unsupported ultra-cycling event known for its iconic route of over 4000 km from Rovereto to North Cape.

Method: All 350 participants to the North Cape 4000 were asked to volunteer for this observational study which included the completion of a battery of questionnaires before and after the race. The questionnaires included the Endurance Sport Self-Efficacy Scale (Anstiss et al., 2018). A preliminary study found that the items of this scale are relevant to ultra-endurance. Additional questions included goal setting, training status and other variables. Performance was evaluated in three ways: race time; goal achievement (GA, reaching vs not reaching the personal goal); and finisher status (FS, finishing vs not finishing the race within the time limit of 21 days). Pearson analyses were conducted to evaluate the correlations between SEpre and SEpost minus SEpre (ΔSE) with race time. A logistic regression was used to assess the relationship between SEpre and GA. Two-way (GA x time; FS x time) repeated-measure ANOVAs were used to assess the change in SE between pre- and post-race, and the moderating effects of GA and FS. Significance was set at $p < 0.05$ for all analyses.

RESULTS: The pre-race questionnaire was completed by 77 participants, with 63 (54 males, age 47 ± 12 years) also completing the post-race one. The SE of the participants increased significantly after the race (SEpre 76 ± 11 vs SEpost 80 ± 10 , $p = 0.001$). The ΔSE was slightly higher among those who achieved their personal goal ($n = 39$, 5.7 ± 2.7) than those who did not ($n = 24$, 2.8 ± 0.9). However, the difference is not statistically significant ($p = 0.220$). Similar results were found for the analysis with FS as the moderator (43 finishers, 20 not finishers). No significant correlations with race time were found for SEpre and for ΔSE . Logistic regression found no significant associations between SEpre and GA, and between SEpre and FS.

Conclusions

Contrary to our hypotheses, we found no associations between self-efficacy before the race and various performance measures. We also failed to find the expected moderating effects of GA and FS on the effect of participating in the race on

SE. The significant increase in SE among the participants who took part in the North Cape 4000 suggests that simply participating in this challenging event provides a mastery experience sufficient to increase SE.

Anstiss, P. A., Meijen, C., Madigan, D. J., & Marcora, S. M. (2018). Development and initial validation of the Endurance Sport Self-Efficacy Scale (ESSES). *Psychology of Sport and Exercise*, 38, 176–183.

NEED SATISFACTION AND PHYSICAL PERFORMANCE IN ADOLESCENT HANDBALL PLAYERS: AN INTERDISCIPLINARY STUDY

BUGTEN, J., HAUGEN, T., IVARSSON, A.Y., SPENCER, M., STENLING, A., SOLSTAD, B.E.

AGDER UNIVERSITY

INTRODUCTION: Research has consistently demonstrated the important role of basic need satisfaction in shaping adolescent team sport players' psychological experiences and physical efforts. Despite these insights, few studies have integrated objective physical measures with traditional self-report instruments. This study aims to bridge this gap by examining the dynamics between adolescent team sport players feelings and sport enjoyment, and their physical performance in youth team sport practices, ultimately providing interdisciplinary insights and suggestions for future research.

METHODS: The study followed two adolescent handball teams ($n = 50$) over the course of 11–12 practices across a 4-week period. Data were collected on both psychological variables such as players feelings of pleasure/displeasure and sport enjoyment, and physical performance measures such as players intensity (high-intensity events > 1.5 m/s; HIE) and workload (PlayerLoadTM) in practice. A Bayesian two-level regression analysis was employed to evaluate the relationship between basic need satisfaction and the psychological and physical outcomes.

RESULTS: The analysis indicated a good overall fit to the data ($PPp = 0.48$, 95% Confidence Interval = $[-21.17, 25.71]$). Basic need satisfaction was found to have credible positive associations with psychological outcomes (feelings of pleasure and sport enjoyment) as well as physical measures (greater PlayerLoadTM and high-intensity events > 1.5 m/s; HIE), with regression coefficients ranging between 0.82 and 0.91. These findings support the notion that need satisfaction plays a significant role in enhancing both the mental and physical aspects of adolescent handball players' performance.

DISCUSSION: The results underscore the importance of fostering basic need satisfaction in young athletes, suggesting that enhanced psychological experiences (feelings of pleasure and sport enjoyment) may be closely linked with increased physical engagement and performance (players intensity and workload in practice). By integrating objective physical measures with subjective reports, the study provides a more comprehensive understanding of how psychological factors contribute to physical athletic performance. These interdisciplinary insights highlight the potential for developing targeted interventions in youth sports programs, as well as suggesting future research to further explore the intricate balance between psychological needs and physical effort in youth sport.

COACHES AND PARENTS-INITIATED MOTIVATIONAL CLIMATE INFLUENCES WELL- AND ILL-BEING AND MOTIVATIONAL ORIENTATIONS OF YOUTH ATHLETES

VITALI, F., BISAGNO, E., PECCHINI, A., AGUELI, B., COCCO, V.M., SHAMLOO, S.E., CADAMURO, A., TRIFILETTI, E., VEZZALI, L.
UNIVERSITY OF VERONA

Motivation plays a crucial role in sport, not only in shaping athletes intentions to participate while preventing dropout and burnout (Sarrazin et al., 2002; Fraser-Thomas et al., 2008; Vitali et al., 2015), but also in influencing well- and ill-being of youth athletes (Adie et al., 2010). A prominent theoretical framework to study motivation in sport is the achievement goal theory (Nicholls, 1984). This approach ascribes importance to individual motivational dispositions, as well as to situational factors (i.e., motivational climate). In a mastery (task-involving) climate, coaches and parents emphasize improvement and effort. Conversely, in a performance (ego-involving) climate, coaches and parents foster social comparison and normative-based evaluation. Despite evidence linking motivational climate with individual motivational orientations (task and ego), its influence on well- and ill-being (i.e., concentration disruption, somatic symptoms, and worry) of youth athletes is less known. To address this gap, we carried out a study with 690 youth athletes aged 8 to 15 years old (332 girls, mean age 11.00 ± 1.53 years). We tested a mediation model with coach- and parent-initiated motivational climate (performance and mastery) as predictors, individual motivational orientations (task and ego) as mediators, and well-being and sport-related ill-being (i.e., concentration disruption, somatic symptoms, worry) as outcomes. The model was tested on the whole sample and separately for younger (aged 8–10) and older (11–15) participants. Mediation analyses were carried out in MPlus (Muthén, & Muthén, 2017) using bootstrapping (5,000 resamples, 95% CI). Results regarding the whole sample showed that coach- and parents-initiated mastery climates were associated with greater well-being, lower concentration disruption and reduced worry via task orientation. No other significant effects emerged. Results for the two subsamples generally replicated these findings, except for the indirect effects of task orientation in the relation between coach/parents-initiated mastery climate and worry the younger children sub-sample. These results highlight the role of coaches and parents in promoting well-being and reducing sport-related ill-being of youth athletes. From an application perspective, educating significant adults on fostering a mastery climate is crucial, as it not only emphasizes effort, but ultimately enhances youth athletes general well-being, thus operating as a protective factor in life.

PROSPECTIVE FALL RISK AND FUNCTIONAL PERFORMANCE IN OLDER ADULTS WITH AND WITHOUT PROBABLE COGNITIVE IMPAIRMENT FOLLOWING AN EMERGENCY DEPARTMENT PRESENTATION

STUCKENSCHNEIDER, T., HIMMELMANN, L., ZIESCHANG, T.

CARL VON OSSIETZKY UNIVERSITY

INTRODUCTION: Severe falls among older adults are a major cause of emergency department (ED) visits, often leading to reduced physical activity, functional decline, and diminished quality of life. While an ED presentation due to a severe fall is itself a significant risk factor for negative health outcomes, cognitive impairment further exacerbates the risk of recurrent falls and functional deterioration. Identifying the distinct needs of individuals with and without probable cognitive impairment (pCI) is crucial for tailoring secondary prevention strategies, such as balance and strength training.

METHODS: Participants were recruited from the SeFallED study, which follows individuals aged ≥ 60 years who presented to the ED after a severe fall but were not hospitalized. Functional (SPPB) and cognitive (MoCA) performance were assessed through home-based geriatric evaluations within four weeks of the fall, and subsequently at six and 12 months. Physical activity levels were quantified using a three-axial accelerometer (activPAL4, PAL Technologies Ltd., Glasgow, UK), worn continuously for seven days at each assessment point to record step count and sedentary time. Functional outcomes were analyzed using repeated measures ANCOVA, adjusted for age. Fall incidence was assessed via monthly telephone follow-ups and analyzed with chi-square tests.

RESULTS: After 12 months, valid data on recurrent falls were available for 126 older adults who are cognitively healthy (OACH, mean age 70.7, SD: 7.8; MoCA: 26.8, SD: 1.4) and 116 individuals with pCI (mean age 77.1, SD: 8.4; MoCA: 21.8, SD: 1.9). Recurrent falls were significantly more frequent in pCI (61/116) than in OACH (46/126; $p = 0.012$). Severe falls requiring medical attention occurred in 27 individuals with pCI, compared to 13 in OACH ($p = 0.018$). Despite these differences, functional performance (SPPB scores) and sensor-based measures of step count and sedentary time did not differ significantly between groups. Cognitive performance improved in both groups over time but remained significantly lower in pCI at all time points ($p < 0.001$), with mean scores consistently meeting MoCA criteria for pCI.

CONCLUSION: These findings highlight the elevated risk of recurrent and severe falls requiring medical attention among individuals with pCI, despite comparable functional performance to OACH. This suggests that fall risk in pCI may be influenced by cognitive-motor interactions rather than functional decline alone. Further research is needed to explore mechanisms underlying these associations and develop targeted interventions to reduce fall-related risks in this high-risk population.

SUBMAXIMAL ECCENTRIC TRAINING DURING IMMOBILIZATION DOES NOT PREVENT SERIAL SARCOMERE LOSS OR IMPAIRMENTS IN MECHANICAL FUNCTION IN OLD OR YOUNG RATS

HINKS, A., VLEMMIX, E., POWER, G.A.

UNIVERSITY OF GUELPH

INTRODUCTION: The age-related loss of muscle mass is partly driven by a reduction in serial sarcomere number (SSN), and further SSN loss occurs during immobilization. SSN is associated with optimal force and power production and muscle passive tension, thus immobilization-induced SSN loss is especially a concern for older individuals who are often subjected to forced muscle disuse with illness and injury. We previously showed that submaximal eccentric resistance training increased SSN and improved muscle mechanical function in old rats. The present study investigated whether this training could prevent the losses of SSN and function when performed intermittently during immobilization.

METHODS: 10 old (32 months) and 10 young (8 months) rats underwent unilateral casting of the plantar flexors in a shortened position for 2 weeks. Thrice weekly, casts were removed for isokinetic eccentric resistance training of the plantar flexors with a stimulation intensity corresponding to 60% of the maximum torque development. Pre- and post-training we assessed in-vivo maximum isometric torque at ankle angles corresponding to stretched and neutral muscle lengths, the passive torque-angle relationship, and isotonic power.

RESULTS: The soleus and medial gastrocnemius were harvested for SSN measurements, with the untrained leg as a control. In both old and young rats, muscles of the casted leg had smaller muscle wet weights (-20-40%, $P < 0.001$), physiological cross-sectional area (-6-20%, $P < 0.001$), and SSN (-7-29%, $P < 0.001$) than the control leg. Furthermore, maximum isometric torque (-37-46%, $P < 0.001$) and isotonic power ($\sim 70\%$, $P < 0.001$) decreased, and maximum passive torque increased ($\sim 400\%$, $P < 0.001$) from pre- to post-training for both age groups. These changes are similar in magnitude to what we observed previously with casting alone.

CONCLUSION: Thus, irrespective of age, submaximal eccentric resistance training 3 days/week during casting did not prevent the losses of muscle contractile tissue and mechanical function.

A COMPARATIVE STUDY OF BONE MINERAL DENSITY AMONG THE ELDERLY IN DIFFERENT OCCUPATIONS

XUE, J., YANG, K., YANG, Y.

HANDBALL, HOCKEY, BASEBALL AND SOFTBALL ADMINISTRATIVE CENTER OF GENERAL ADMINISTRATION OF SPORT OF CHINA

INTRODUCTION: China is becoming one of the fastest-aging countries in the world. There is sufficient evidence to show that human health will gradually decline with people aging, including a significant decrease in bone mineral density (BMD) of the elderly, and a great increase in the risk of osteoporosis in the elderly group. Different occupations have great differences in the cumulative effect of physical activity during long-term work, and the benefits of long-term physical activity during work may result in different effects on the BMD of the elderly. This study compares the BMD of the elderly in different occupations.

METHODS: Using Internet to recruit elderly people who living in Beijing. The inclusion criteria of the subjects are: 60-70 years old, able to walk and communicate normally. Inviting included subjects to accept the BMD test. Before the start of the test, they are required to finish a questionnaire. The content of the questionnaire includes: the working years, the occupation, the category of the work and the level of physical activity during the working period. Standards for grouping the level of physical activity: According to the standards published by the World Health Organization (WHO), subjects are divided into physical active groups (performing 150 minutes or more of moderate to high-intensity physical activity per week) and physical inactive group (less than 150 minutes of high-intensity physical activity per week). Using the speed of sound (SOS), bone density T score (T-score), and bone density Z score (Z-score) to judge the subjects BMD situation. The independent sample T test tests the difference between different physical active groups.

RESULTS: A total of 770 subjects (64.86 ± 2.98 yrs) were recruited for this study. There are 338 people (65.44 ± 3.03 yrs) in the physical active group and 432 people (64.92 ± 2.64 yrs) in the physical inactive group. It is found that the physical active group in SOS, T-score, Z-score were significantly higher than inactive group (4150.35 ± 197.17 vs. 3689.01 ± 189.73 , -0.71 ± 3.53 vs. -1.99 ± 0.12 , 0.27 ± 2.61 vs. -1.15 ± 0.35 , $P < 0.05$); For male, the physical active group had significant higher in SOS, T-score, Z-score than the inactive group (4155.61 ± 186.09 vs. 3687.61 ± 168.09 , -0.12 ± 0.77 vs. -1.73 ± 0.98 , 0.2 ± 0.8 vs. -1.08 ± 0.99 , $P < 0.05$); For women, the physical active group has significant higher SOS and Z-score than the inactive group (4148.20 ± 101.36 vs. 3689.57 ± 707.20 , -0.30 ± 1.07 vs. -1.2 ± 1.04 , $P < 0.05$). In the physical active group, female T-score and Z-score were significantly higher than female (-0.12 ± 0.77 vs. -0.76 ± 0.91 , 0.2 ± 0.8 vs. -0.30 ± 1.07 , $P < 0.05$).

CONCLUSION: The BMD of the elderly who are more physically active is significantly better than physically inactive during the work period. There is no significant difference in the T-score between the two groups in the female group. In summary, physical active during work helps to reduce the risk of BMD decrease, and the BMD in males is more likely to be improved by physical activity.

DOMAIN-SPECIFIC PHYSICAL ACTIVITY AND RISK OF DEMENTIA IN OLDER ADULTS: A CROSS-SECTIONAL STUDY

YAN, H.

TSINGHUA UNIVERSITY

INTRODUCTION: Dementia poses a significant public health challenge among aging populations. Early identification of dementia risk is critical for implementing preventive interventions, and physical activity (PA) has emerged as a modifiable protective factor. While total PA is associated with reduced cognitive decline, the differential effects of domain-specific PA—leisure, transportation, and household—on dementia risk remain underexplored. This study aimed to investigate associations between PA domains and dementia risk in older adults, adjusting for demographic factors.

METHODS: This cross-sectional study included 765 retirees (mean age 72.8 ± 8.5 years; 64.8% female) from Tsinghua University, Beijing, China. PA was assessed using the Physical Activity Scale for the Elderly (PASE), with scores categorized into leisure, transportation, household, and total domains. Dementia risk was classified via the Ascertain Dementia 8-item Questionnaire (AD8), with scores ≥ 2 indicating high risk. Descriptive statistics, independent t-tests, and logistic regression were conducted, adjusting for age, gender, and BMI.

RESULTS: High dementia risk was observed in 31.5% of participants ($n = 241$). Compared to the low-risk group, high-risk individuals exhibited lower total PA (96.1 ± 64.0 vs. 109.2 ± 66.7 , $p < 0.05$; Cohen's $d = 0.20$), transportation PA (25.3 ± 20.4 vs. 29.4 ± 25.3 , $p < 0.05$; Cohen's $d = 0.17$), and household PA (34.2 ± 30.7 vs. 41.5 ± 34.0 , $p < 0.01$; Cohen's $d = 0.22$). Leisure PA showed no significant difference ($p > 0.05$). In adjusted models, an increase in household PA was associated with a reduction in dementia risk (OR = 0.93, 95% CI: 0.89–0.98, $p = 0.01$). Leisure and transportation PA demonstrated no significant associations ($p > 0.05$).

CONCLUSION: Household PA was inversely associated with dementia risk in older adults, indicating the potential cognitive benefits of daily household engagement. Future longitudinal studies are needed to confirm causality, and interventions should prioritize domain-specific PA promotion, particularly household activities.

GENDER DIFFERENCE IN CROSS-SECTIONAL AREA AND FAT INFILTRATION OF THIGH MUSCLES IN OLDER POPULATION ON MRI: AN AI-BASED ANALYSIS

BIZZOZERO, S., BASSANI, T., SCONFIENZA, L.M., MESSINA, C., BONATO, M., INZAGHI, C., MARMONDI, F., CINQUE, P., BANFI, G., BORGHI, S.

IRCCS ISTITUTO ORTOPEDICO GALEAZZI, MILAN, ITALY

INTRODUCTION: Aging alters musculoskeletal structure and function, affecting muscle mass, composition, and strength, increasing the risk of falls and loss of independence in older adults. This study assessed cross-sectional area (CSA) and fat infiltration (FI) of six thigh muscles through a validated deep learning model. Gender differences and correlations between fat, muscle parameters, and age were also analysed.

METHODS: This retrospective study analysed 141 participants (67 females, 74 males) aged 50-80 years. Participant underwent MRI scans of the right thigh and dual-energy X-ray absorptiometry to determine appendicular skeletal muscle mass index (ASMMI) and body fat percentage (FAT%). A deep learning-based application was developed to automate segmentation of six thigh muscle groups on MR images.

RESULTS: Deep learning model accuracy was evaluated using the Intersection over Union (IoU) metric, with average IoU values across muscle groups ranging from 0.84 to 0.99. Mean CSA was 10,766.90 mm² (females: 8,892.61 mm², males: 12,463.90 mm²; $p < 0.001$), and the mean FI was 14.92% (females: 17.42%, males: 12.62%; $p < 0.001$). Males showed larger CSA and lower FI in all thigh muscles compared to females. Negative correlations were identified in females between FI of posterior thigh muscle groups (biceps femoris, semimembranosus, and semitendinosus) and age, while no correlations were observed between CSA, ASMMI, or FAT% and age.

CONCLUSION: These findings underscore the impact of aging on muscle composition and distribution, emphasizing the need for gender-specific assessments in older adults. Furthermore, deep learning techniques accurately quantify muscle CSA and FI, reducing analysis time and human error.

Oral Presentations

QUANTIFYING THE EXTERNAL GAME DEMANDS OF PROFESSIONAL, MALE BASKETBALL PLAYERS IN THE AUSTRALIAN NATIONAL BASKETBALL LEAGUE

GUY, J., SHIRLEY, S.1,2, SCANLAN, A.1, BARTLETT, R.1,2, BOWE, S.3, ELSWORTHY, N.1

1CENTRAL QUEENSLAND UNIVERSITY; 2CAIRNS TAIPANS BASKETBALL CLUB; 3VICTORIA UNIVERSITY OF WELLINGTON.

INTRODUCTION: While professional basketball games have been shown to impose various movements on players such as sprints, jumps, accelerations, decelerations, and changes-of-direction (I), minimal research has quantified the external game demands of players competing in the Australian National Basketball League (NBL), with no research providing such data specific to playing role and position. To address this gap, this study examined the external game demands of professional, male basketball players competing in the Australian NBL, according to playing role and position.

METHODS: Twenty-two professional, male basketball players (age: 27.0 ± 3.3 years; height: 196 ± 8.2 cm; body mass: 94.0 ± 13.9 kg) from the same club were monitored over two consecutive competitive seasons (2021–2023) using microsensor technology (ClearSky T6; Catapult Sports). Players were categorised according to playing role (starters vs. bench) and playing position (frontcourt vs. backcourt). Accumulated (total) and relative (per min) external game demands were calculated for PlayerLoad™, Inertial Movement Analysis (IMA) count, jump count, and high-intensity jump count during active playing time. External game demands were compared between playing role and position via linear mixed modelling and effect size (Cohen's d) analyses.

RESULTS: Starters experienced significantly higher accumulated PlayerLoad™ in both backcourt ($d = 1.39$ (0.90, 1.88, large effect) $p < 0.01$) and frontcourt ($d = 1.66$ (1.29, 2.04, large effect) $p < 0.01$) positional groups, as well as significantly higher accumulated IMA ($d = 1.44$ (0.95, 1.94, large effect) $p < 0.001$, and $d = 1.53$ (1.15, 1.90, moderate effect) $p < 0.001$), respectively. Considering playing position, starting frontcourt players performed more total ($d = 1.15$ (0.05, 2.23, moderate effect) $p > 0.05$) and high-intensity ($d = 1.02$ (-0.07, 2.11, moderate effect) $p > 0.05$) jumps during games compared to backcourt players; however, these differences were not significant. Opposite to accumulated external game demands, there were no significant ($p > 0.05$) differences in relative external game demands between playing roles and positions.

CONCLUSION: The current study is the first to quantify the external game demands of professional basketball players competing in the Australian NBL considering playing role and position. These findings demonstrate starters experienced greater accumulated external loads in games likely due to increased playing durations, which may highlight the need for compensatory training plans in bench players. The greater jump requirements for frontcourt players in games emphasise that position-specific training and tactical plans are warranted. In turn, the comparable external demands per minute of play across both playing roles and positions suggests all players may move at similar intensities during games.

COMPARISON OF TACTICAL TENDENCIES BETWEEN 3X3 AND 5X5 BASKETBALL: ANALYSIS OF MEN'S AND WOMEN'S WORLD CUPS

COUTINHO, T., MACEDO, V., LAMAS, L.

UNIVERSITY OF BRASILIA

INTRODUCTION: Basketball 3x3 was introduced by FIBA in 2010 [1]. Literature of tactics in this sport is limited, requiring investigations on differences to 5x5 basketball to support practice. The space creation dynamics (SCDs) - a set of offensive game action classes for creating space to score [2] - have been used to analyze basketball tactics and may support 3x3 and 5x5 comparisons. This study compared 3x3 and 5x5 basketball, women and men, analyzing the frequency and type of game actions, respective court zones used, and efficiency.

METHODS: Matches of women's (35 matches; 2118 ball possessions) and men's (41; 2316) in the 3x3 World Cup – 2023, women's (8; 1226) and men's (8; 1218) in the 5x5 World Cup – 2023 were assessed. A single researcher collected the data (Cohens Kappa result: > .90 for all variables). The following SCDs were notated: pick, screen, ball dribbled, ball not dribbled, hand-off, post-up, dime-in, spot-up, without ball and isolation. The court was divided in the zones: top (TOP), top of key (TPK), key (K), wing (W), short wing (SW), corner (C), short corner (SC), high post (HP), low post (LP). Efficiency was analyzed in points per possession (ppp). Bayesian methods were used to estimate the mean frequency of the SCDs per ball possession of each compared group (3x3W, 3x3M, 5x5W, 5x5M). Posterior distributions of means were computed from the Markov chain Monte Carlo draws. Statistical significance was considered when posterior probability of the mean difference exceeding 0 was > 0.90. Chi-square test was used to analyze differences in the use of court zones and respective SCD types ($\alpha = 0.05$).

RESULTS: Posterior means of SCDs per ball possession were: 3x3W = 1.85, 3x3M = 1.95, 5x5W = 2.56, and 5x5M = 2.47. 5x5 (W and M) had significantly more SCDs per ball possession than 3x3 (M and W) although it represented less than one SCD per possession. TOP, TPK and W, added, presented proportions between 51% - 63% of all zones used by every group to create space. Significant association was found between zones and groups ($p < 0.001$): 3x3W - TPK (29.7%); 3x3M: SW (16.3%); 5x5W: K (8.2%); 5x5M: TOP (28.3%). Pick, screen and ball dribbled, added, presented proportions of the total SCDs performed between 57% - 70% for all groups. Significant association was found between groups and SCD types performance ($p < 0.001$), presented with the respective efficiency (ppp): 3x3W: post-up(12.2%, 0.5 ppp); 3x3M: handoff(17.4%, 0.58); 5x5W: screen(28.2%, 0.6); 5x5M: pick(28.2%, 1.1).

CONCLUSION: Basketball 3x3 and 5x5 had different game actions per possession but with minimal practical impact (less than one action). Worth noting, 3x3 possession time (12") is half of 5x5 (24"). Perimeter was mostly emphasized in both sports besides specific tendencies. Groups' preferred SCDs had small ppp rates.

INVESTIGATING LOAD FLUCTUATIONS ACROSS QUARTERS IN MALE PROFESSIONAL BASKETBALL PLAYERS: IMPLICATIONS FOR GAME PERFORMANCE AND STRATEGY OPTIMIZATION

ZHANG, S., LI, M., GU, L., WANG, X.

TSINGHUA UNIVERSITY

INTRODUCTION: Tracking the dynamics of game loads across quarters is crucial for coaches; however, a significant limitation in existing research is the lack of integration between dynamic inter-period changes and positional specificity. While some studies consider player positions, they often fail to account for temporal dynamics across game periods. Conversely, research focusing on inter-period variations typically overlooks the distinction between player positions. Therefore, further investigation to bridge this gap is essential. This study aims to examine between- and within-quarter variations in physical loads during basketball games, exploring their interrelationships and considering the influence of contextual factors on the load profiles experienced by backcourt and frontcourt players.

METHODS: A total of 16 professional male basketball players (8 backcourt, 8 frontcourt) from the Chinese National Basketball League were recruited. External load was assessed using Catapult S7 devices, capturing PlayerLoad and Inertial Movement Analysis (IMA) variables. Internal load was measured using the session rating of perceived exertion (sRPE) method. Opponent quality, match outcome, and scoring margin (contextual factors) were incorporated into the analysis. Data were analyzed using linear mixed-effects models and repeated-measures correlation analyses.

RESULTS: Frontcourt players exhibited more pronounced fluctuations in sRPE ($F=3.378$; $p < 0.05$) and IMA changes of direction (COD) left ($F=4.409$; $p < 0.01$) from the first quarter to the fourth quarter. In contrast, backcourt players demonstrated more stable between-quarter changes but showed larger within-quarter load variations, including higher IMA jump medium in the first three quarters ($p < 0.01$), and greater IMA accelerations (ACC) ($p < 0.05$) and decelerations (DEC) ($p < 0.01$) in the second and fourth quarters compared to frontcourt players. Medium to large ($r = 0.41-0.62$) correlations were observed between sRPE and PlayerLoad as well as total jumps across quarters for backcourt players. For frontcourt players, sRPE showed medium to large correlations ($r = 0.45-0.72$) with PlayerLoad, IMA COD, and IMA high jumps across quarters. Backcourt players reported higher sRPE during winning games compared to losing games ($ES = 0.34$; $p < 0.05$).

CONCLUSION: The study reveals distinct game load patterns for backcourt and frontcourt basketball players, with frontcourt players experiencing greater physical and perceptual fluctuations across the game, while backcourt players exhibit more consistent between-quarter loads but larger within-quarter variations. The higher sRPE reported by backcourt players during winning games suggests the influence of contextual factors on perceptual measures. These findings un-

underscore the importance of position-specific training strategies that optimally prepare backcourt and frontcourt players for the specific game loads.

KINEMATIC VARIABLES AND MATCH OUTCOMES IN SERIE A: THE IMPACT OF ACCELERATION AND SPRINT DISTANCE

TROIANI, P., LUCADAMO, A., LATERZA, F., SAVOIA, C., BERTOLLO, M., POMPA, D.

UNIVERSITY

INTRODUCTION: The influence of kinematic variables on the outcome of the match has not been extensively investigated, especially in the Italian First Division. Our objective is to fill this gap by analyzing key performance indicators derived from tracking data, focusing on how these metrics relate to different match results (win, draw, loss). This study aims to explore how kinematic, mechanical, and metabolic parameters influence match outcomes in the Italian Serie A during the 2022/2023 and 2023/2024 seasons.

METHODS: We employed a multinomial logit model to evaluate the probability of various match outcomes based on differences in physical metrics between competing teams. The response variable included three categories: win (W), draw (D), and loss (L), with the loss serving as the reference category. Key variables analyzed were Total Distance Covered (Diff_TDC), High-intensity acceleration distance ($>3 \text{ m/s}^2$; Diff_D_H-acc), sprint distance ($> 25 \text{ km/h}$; Diff_D_VHRSR), and Metabolic Power High-Intensity (Diff_D_MPHI).

RESULTS: Our findings indicate that Diff_H-acc and Diff_VHRSR have a stronger impact on the probability of winning compared to drawing. In both leagues analyzed, these variables are significant when considering the "Win" category. However, for the "Draw" estimates, the p-values are slightly exceeded 0.05, with Diff_D_VHRSR showing an even higher value in the 2023/24 season. This suggests that while these two variables have a relatively small influence on the probability of drawing versus losing, they significantly affect the probability of winning versus losing. Specifically, for the 2022/23 season, a 10-meter increase in the difference between the distances covered at high speed by the two teams raises the probability of winning by approximately 12.45%. In the 2023/24 season, the same increase in the explanatory variable leads to a rise of about 17.89%. In contrast, the impact of Diff_D_H-acc on the probability of success is more pronounced. Based on the estimated coefficients, in the first season, a 10-meter increase results in a probability increase of more than 46%. For the 2023/24 season, the probability of winning versus losing rises by approximately 33.6%.

CONCLUSION: From an applied perspective, our results underscore the importance of high-intensity actions, particularly accelerations, in influencing match outcomes. This insight aligns with existing literature emphasizing the tactical value of aggressive pressing and rapid transitions. Coaches and performance analysts can leverage these findings to prioritize training interventions that enhance players explosive capabilities, potentially leading to improved competitive performance. By integrating advanced statistical modeling with applied performance analysis, this study contributes to a deeper understanding of the physical demands in elite soccer and their relationship to tactical success in Serie A.

TRENDS IN HIGH-INTENSITY RUNNING PERFORMANCE: A COMPARATIVE ANALYSIS OF PLAYERS IN THE FIFA WOMENS WORLD CUP

LUO, J., CUI, D., QU, Y.

CHINA INSTITUTE OF SPORTS SCIENCE

INTRODUCTION: High-intensity running (HIR) is a key performance metric in modern football. However, research on HIR in the FIFA Womens World Cup remains limited[1]. This study analyzes 2019-2023 HIR trends using 2023 FIFA Womens World Cup post-match reports and FIFA research. Findings offer scientific insights to support coaches in optimizing training programs.

METHODS: Data were sourced from the 2019 FIFA World Cup Physical Report and 2023 FIFA Post-Match Summary Reports (116 matches). The analysis focused on full-match players HIR metrics across positions: goalkeepers (GK), forwards (FW), midfielders (MF), and defenders (DF), including total distance, high-speed running (Zone 4: 19-23 km/h), sprint running (Zone 5: $>23 \text{ km/h}$), and HIR ($>19 \text{ km/h}$). Statistical analysis utilized IBM SPSS Statistics 27 for 2023 data (Kruskal-Wallis and Mann-Whitney U tests, $p < 0.05$). For 2019 data, only percentage changes were calculated due to missing variance and sample size information.

RESULTS: GK showed a 10.8% decrease in total distance (2019: 5028m; 2023: 4485m), while Zone 4 running increased by 8.3% (2019: 24m; 2023: 26m). Both Zone 5 (2019: 6m; 2023: 4m) and HIR (2019: 30m; 2023: 29m) showed minimal changes.

DF showed a 2.1% decrease in total distance (2019: 9,933m; 2023: 9,725m), while Zone 4 running decreased by 5.9% (2019: 425m; 2023: 400m). Zone 5 distance showed minimal change (2019: 164m; 2023: 161m), and HIR decreased by 4.8% (2019: 589m; 2023: 561m).

MF showed minimal change in total distance (2019: 10,717m; 2023: 10,669m), while Zone 4 running decreased by 11% (2019: 526m; 2023: 468m). Zone 5 distance declined by 24.6% (2019: 183m; 2023: 138m), and HIR decreased by 14.5% (2019: 709m; 2023: 606m).

FW showed a slight increase in total distance (2019: 10,267m; 2023: 10,286m), with Zone 4 running increasing by 2.1% (2019: 530m; 2023: 541m). Zone 5 distance increased by 18.2% (2019: 220m; 2023: 260m), and HIR rose by 6.8% (2019: 750m; 2023: 801m).

Statistical Analysis: A significant difference was observed in the total running distance across positions ($H = 420.901$, $df = 3$, $p < 0.001$). Pairwise comparisons of outfield players revealed that FW and MF had significantly greater total running distances than DF ($p < 0.001$). Regarding Zone 4 and 5, FW had significantly higher distances than MF and DF ($p < 0.001$).

CONCLUSION: The results show that FWs metrics have increased, indicating a need for higher demands for HIR. In contrast, DF and MF slightly declined or remained stable, still above 2015 levels. This trend may result from improved player performance, higher match intensity, and advancements in 2023 tracking technology[1]. As in previous studies, DF covered the shortest distances due to defensive duties, while FW led in HIR, highlighting position-specific physical demands[2]. These trends stress the need for targeted training.

OP-SH19 Identity and Gender

ARE THERE GENDER DIFFERENCES IN ACADEMIC CAREER TRAJECTORIES? AN INVESTIGATION IN ITALIAN SPORT SCIENCE SCHOOLS AND DEPARTMENTS.

PECCHINI, A., ROBAZZA, C., REGGIANI, L., SORGON, M., VITALI, F.
UNIVERSITY OF VERONA

INTRODUCTION: Women and men face different challenges in academic settings: despite women being approximately half of matriculating students in 2015, they represented only 28.8% of the total number of academics worldwide (UNESCO, 2018). The presence of gender differences in academia has been assessed through different perspectives: for example, female professors showed less risky research agendas (Santos et al., 2020) and fewer paper citations (Aiston and Jung, 2015). These inequalities are transversal to different fields and concern STEM disciplines specifically (Casad et al., 2020), such as surgery (Ferrari et al., 2022) and economics (Sarsons et al., 2021). In this study, we aim to investigate gender differences in academic career trajectories in a specific STEM field: the Italian Sport Science Schools and Departments.

Methods

All active members of 30 Italian Sport Science Schools and Departments in as many different universities were included in the study. From the data extracted from the curriculum vitae and personal websites' pages, we examined the academic career trajectories, taking into consideration the gender, the year in which the masters degree or PhD was obtained, the current position in academia, and the starting year of the actual position. The sample comprised 1,623 Sport Science academic members (674 women): 212 full professors, 482 associate professors, 314 assistant professors, and 615 temporary lecturers. Descriptive statistics, independent sample t-tests, and a fixed factor ANCOVA (gender x title) were conducted to analyze the data.

RESULTS: Descriptive analyses showed that women represented 42% of the total sample. Specifically, women comprised 51% of the assistant professors, 50% of the associate professors, and 35% of the full professors. Data from temporary lecturers were also analyzed, and women represented 32%. The Shapiro-Wilk test confirmed the normal distribution of the data ($w=.97$; $p<.001$). A title effect was present ($p<.001$, $d=.56$), meaning that having a PhD title shortened the time to reach each academic position. A gender effect was present only for associate professors: men reached this position earlier than women ($p=.013$, $d=.24$).

Discussion: Descriptive data were coherent with the so-called "pipeline effect" in achieving gender equality in academia: although the number of assistant and associate professors was similar, women remained underrepresented in leadership positions (full professors) and less likely to achieve promotion (Waljee et al., 2015), as demonstrated by gender effect found for associate professors. Temporary lecturers, in contrast, aligned with the trend of female employment in sports-related fields (CONI, 2020), as this category typically comprises temporary professors responsible for teaching practical and applied sports lecturing. These results can stimulate a debate towards increasingly equitable and gender-inclusive academic paths.

PERFORMANCE-ENHANCING DRUG ATTITUDE AND USE IN BODYBUILDERS: FOCUS ON THE PREDICTIVE ROLE OF PERSONALITY TRAITS AND IMPLICATIONS FOR REPRODUCTIVE HEALTH

DE SANTI, M., SARLO, M., BORGHETTI, M., BRANDI, G.
UNIVERSITY OF URBINO CARLO BO

INTRODUCTION: The use of performance-enhancing drugs (PEDs) is a widespread and largely underestimated phenomenon, especially in amateur sports where there are no controls. Particularly, bodybuilders often resort to doping, risking compromising their general and reproductive health. This work aims to analyze the personality traits associated with the use of PEDs and the attitude to doping, and the implications for the reproductive health of bodybuilders.

METHODS: One hundred and four bodybuilders (31.7% female, 68.3% male) were asked to fill out an anonymous questionnaire about PED use, symptoms, and concerns about fertility, contextually with three validated questionnaires on per-

sonality traits: the Performance Enhancement Attitude Scale (PEAS), the Big Three Perfectionism Scale–Short Form (BTSPS-SF), and the Ten-Item Personality Inventory (TIPI). Univariate and multivariate statistical analyses were used to find correlations between the variables.

RESULTS: The results revealed PED use in 36 bodybuilders (34.6 %), more in men (88.9 %) than in women (11.1 %). The most commonly used substances are anabolic androgenic steroids and growth hormone. In addition, males presented more symptoms, including those related to lower fertility, and had undergone tests or consulted a doctor to assess their ability to conceive. Notably, women who are concerned or have consulted a doctor about the effects of PEDs on their fertility said they do not use them. As expected, PED users had a higher attitude to doping (PEAS score). Regarding personality traits, the multiple regression analysis revealed that the attitude to doping was positively associated with narcissistic perfectionism and negatively with self-critical perfectionism.

CONCLUSIONS

This study confirms the high prevalence of doping in bodybuilding. The type of responses and gender differences suggest an underestimation of PED use, especially in females. This study confirms the danger of doping and the possible consequences that their use may have on the reproductive health of athletes. The assessment of doping attitude confirmed its predictive role in the use of these substances. In addition, although it is known in literature that perfectionism is associated with a greater attitude to doping, this study found that narcissistic perfectionism is particularly associated with it. On the contrary, self-critical perfectionism could represent a possible positive personality trait from a doping prevention perspective.

ATHLETIC IDENTITY AND SPORT INJURY: A SYSTEMATIC REVIEW AND META-AGGREGATION

ZHANG, Y., LIU, S., NOH, Y., LIU, H.

UNIVERSITY OF MALAYA

Objective: To systematically review qualitative studies on changes in athletic identity following sports injuries.

Methods: The study adhered to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA 2020) statement. Electronic searches were conducted in Web of Science, Psychology & Behavioral Sciences Collection, PubMed, SPORTDiscus, and Scopus. Manual searches included forward and backward citation tracking via Google Scholar. Quality assessment employed the Mixed Methods Appraisal Tool. Data extraction and synthesis followed the Joanna Briggs Institute (JBI) guidelines. We used the ConQual method, incorporating dependability and credibility evaluations to determine the confidence level of findings.

Results: A total of 24 studies were included. Meta-aggregation was used to synthesize findings into two overarching themes: “loss” (n = 17) and “reestablishment” (n = 7). The theme “loss” revealed that sports injuries lead to diminished athletic identity due to factors such as physical changes, absence from competition, and psychological challenges. The “reestablishment” theme showed that some athletes reconstruct their identity by engaging in roles such as coaching, volunteering, or participating in new sports.

Conclusion: Sports injuries have complex impacts on athletic identity, with some athletes facing identity loss and others successfully rebuilding their identity. Future research should focus on distinguishing between athletes and non-athletes, refining assessment tools. Practical strategies include psychological interventions, fostering multidimensional identities, and supporting post-retirement planning to aid injured athletes in identity recovery.

Oral Presentations

ESTABLISHING AUSTRALIA’S SCIENCE AND RESEARCH PRIORITIES FOR HIGH-PERFORMANCE SPORT: AN EVIDENCE-BASED APPROACH

MENASPÀ, P., BORG, N.D.

AUSTRALIAN SPORTS COMMISSION

Introduction.

The significance of sport in Australia is underscored by its contribution to national health, social cohesion, and economic prosperity. Following the Tokyo Olympic and Paralympic Games, the Australian Institute of Sport identified science and research priorities, releasing in March 2022 the national high-performance (HP) sport Research Agenda (RA2022), with updates every 4 years, aligned to summer Games cycles. The intended beneficiaries of the agenda were athletes, coaches, teams and organisations within Australia’s HP sport system. We report here on the process to develop and iterate thematic priorities for a national HP sport system.

Methods.

Priority setting was conducted using the framework outlined by the NSW Health Centre for Epidemiology and Evidence (1) and reported following the REPRISE guidelines (2). Stakeholder engagement was inclusive, with input from summer and winter Olympic, Paralympic, and Commonwealth sports. The process involved multiple phases: 1) after the Tokyo Games,

a diverse group of stakeholders generated the initial priorities; 2) a subgroup of participants (5 athletes, 5 coaches, 5 performance support practitioners, 5 researchers and 5 administrators) categorised and ranked the initial priorities to define emerging themes; 3) subject matter experts considered gaps in evidence and identified relevant sub-themes; 4) RA2022 was published in March 2022; 5) after Paris 2024, participants (including athletes, coaches) completed a survey on what science and research should focus on; 6) results were compared with RA2022 priorities, to highlight overlaps, gaps and/or discrepancies; 7) release of the updated national science and research priorities for HP sport (RA2025); 8) the next update will occur after Los Angeles 2028.

Results.

117 initial priorities were collected from 78 individuals (45% M, 31% F, 24% did not respond) from 31 organisations. Duplicated and out of scope priorities were removed, leaving 80 unique priorities. The equal representation subgroup identified four major thematic priorities: Successful Athlete, Coaching Science, Sports Performance Optimisation, and Practice Enhancement. A total of 154 participants from Paris 2024 Olympics or Paralympics responded to what science and research should focus on. All the RA2022 key themes were confirmed in RA2025. Emerging priorities include equipment and strategic insights.

Conclusion.

The RA2022 and the RA2025 update were developed with an evidence-based approach, supported by the National Institute Network Research Group and the National Sport Research Agenda Advisory Group. The process involved stakeholders likely to be affected by, or with an interest in, the research priorities. Appropriately developed and clearly communicated science and research priorities should facilitate the allocation of resources based on HP sport needs.

EXPLORING EQUESTRIAN EDUCATION THROUGH THE CONCEPT OF SPORT ECOLOGY

THORELL, G., HEDENBORG, S., SÄTRE, A., KRONBORG, M., RADMANN, A., BROMS, L., ANDERSSON, P.

KARLSTAD UNIVERSITY AND THE SWEDISH NATIONAL EQUESTRIAN CENTRES OF EXCELLENCE

INTRODUCTION: Environmental sustainability is an important issue for the sports sector. Climate change threatens the future of sports through factors such as extreme weather conditions, rising sea levels, and reduced water resources. Most sports organizations are poorly equipped to assess and manage the risks associated with climate challenges (Orr & Inoue 2018). A lack of knowledge is one of the biggest barriers to implementing sustainable initiatives in the sports sector (Cury et al. 2022). In this study, we focused on equestrian sports, which have been criticized for their environmental impact. The aim of this study is to explore the challenges and opportunities that equestrian education institutions face concerning environmental sustainability.

METHODS: This study applies the concept of Sport Ecology as a theoretical framework. Institutional theory is used to explain the factors that enable or hinder environmental adaptations. The study used a qualitative approach with two methodological strategies. First, semi-structured interviews were conducted with representatives from equestrian education institutions and organizations (15=Sweden and 18=Norway). Second, 8 workshops were carried out.

RESULTS: Overall, environmental challenges in equestrian education are perceived as being linked to economy, time, and knowledge. There is an interest in sustainability, and institutions feel they comply with legislation, yet they are aware that more can be done. Raising awareness and integrating sustainability further into daily activities is seen as necessary, as well as increasing reminders for pupils, staff, and visitors at facilities. Respondents recognize the need for stronger integration in curricula, exercises, and activities, involving pupils and staff while collaborating with stakeholders working on these issues.

Discussion: To address the challenges posed by climate change, strategic and well-planned solutions are required, with interdisciplinary collaboration playing a key role (McCullough et al. 2020). There is a growing need to enhance knowledge and implementation of sustainable practices in equestrian sports. Sport ecology provides a relevant framework for analyzing and improving how the equestrian sector can adapt to climate change and reduce its environmental impact. Fields such as sport management, sports psychology, leadership, and pedagogy offer theories and methods that can contribute to developing sustainable strategies for equestrian educations.

DEVELOPMENT AND APPLICATION OF A SERVICE QUALITY EVALUATION SYSTEM FOR SPORTS PARKS IN CHINA

XU, L., WANG, S.B., ZHENG, J.K., YIN, Z.H.

SHANGHAI UNIVERSITY OF SPORT; EAST CHINA NORMAL UNIVERSITY

INTRODUCTION: Recently, the Chinese government has issued several policies, such as the "Guiding Opinions on Promoting the Construction of Sports Parks," outlining development goals and requirements. However, issues like imbalance and inadequate growth in sports park development persist. Therefore, developing and applying a sports park service quality evaluation system to improve service quality is crucial for promoting sustainable and healthy sports park development.

METHODS: Using a mixed research method, the study proceeded as follows: 1) A review of domestic and international sources using keywords such as sports parks, service quality, and sports park service quality. 2) Interviews with 23 individuals (13 males, 10 females), including the public and experts in China, to explore the service quality model using grounded theory. 3) A survey of approximately 800 individuals (399 males, 401 females) in China across three rounds of questionnaires, leading to the development of a reliable and valid service quality evaluation system. 4) A case study in Shanghai, where field surveys, IPA (Importance-Performance Analysis), and other methods were used to survey 207 individuals (97 males, 110 females) who exercise in sports parks. Based on relevant policies and the current development status of Shanghai's sports parks, suggestions for service quality improvement were proposed.

RESULTS: 1) Based on theories like Maslow's Hierarchy of Needs, Service Quality Evaluation Theory, and New Public Service Theory, and from the public perception perspective, the sports park service quality model in China includes five dimensions: Tangibility, Reliability, Assurance, Responsiveness, and Empathy. This model covers 19 dimensions, 43 concepts, and 173 statements, such as transportation accessibility, park environment quality, public facility configuration, sports event variety, staff professionalism, park regulations, and multifunctional service integration. 2) Following strict procedures for scale development, the data from three rounds of questionnaires were analyzed using project analysis, exploratory factor analysis, and reliability and validity tests. As a result, a sports park service quality evaluation system was developed, consisting of 34 items across five dimensions: Tangibility, Reliability, Assurance, Responsiveness, and Empathy. 3) Based on the service quality indicators in the four quadrants of the IPA matrix, Shanghai sports parks should focus on improving service quality in areas such as health promotion services, sports events, sports fees, facility maintenance, facility configuration, and intelligent sports venue facilities. Resources should be allocated accordingly to enhance the overall service quality of sports parks.

CONCLUSION: Future empirical studies on sports park service quality in China should expand coverage to better align the development of sports parks with national construction, social development, and public needs.

THEORETICAL FRAMEWORK AND PRACTICAL PATHS FOR GRASSROOTS SPORTS GOVERNANCE TO BUILD RESILIENCE IN URBAN COMMUNITIES

DING, Y.

SHANGHAI UNIVERSITY OF SPORT

INTRODUCTION: In the context of rapid urbanization, urban expansion and population agglomeration, community resilience has become a key to sustainable urban development and has attracted much attention from all sectors. Community resilience refers to the ability of a community to mitigate, adapt and recover from the negative impacts of disasters. Sports facilities help residents to improve their physical fitness, and they can also switch functions at special times, such as serving as emergency shelters or material distribution points, to enhance spatial resilience. Indeed, the social capital generated by sport, the self-organizing capacity of communities fostered by sports associations, and the role of sport in enhancing the physical and mental health capital of residents are significant but not yet fully exploited in enhancing community resilience.

METHODS: This study uses a combination of case studies and interviews. Seven communities with outstanding community sports governance in two districts of Shanghai were selected as case studies to analyse their demographics, spatial characteristics and governance experiences, and primary data were collected through interviews.

RESULTS: The study has constructed a theoretical framework for grassroots sports governance to enhance community resilience, which includes four aspects: reconfiguring community spatial resilience, accumulating community social capital, enhancing residents health capital, and stimulating the vitality of participatory governance. First, sports facilities can take over the function of emergency evacuation in special times, thus reconfiguring spatial resilience. Second, grassroots sports governance promotes the deepening of residents trust relationships and the expansion of social networks through organised activities, thereby accumulating social capital. Third, regular physical activity can increase residents physiological and psychological resilience and improve health capital. Finally, sports clubs create opportunities for residents to participate in community affairs, enhance their capacity for self-organisation, and stimulate the vitality of participatory governance.

Discussion: The discussion identified three key pathways for grassroots sport governance to enhance community resilience. At the facility level, based on the spatial resilience of facilities, risk is buffered through functional transformation. At the institutional level, the integration of resources, strengthening the synergy of multiple actors and cultivating the leadership effect of community elites to enhance community resilience. In the social capital dimension, sport practices catalyse the endogenous governance order, focus on cultivating sport communities, and enhance community cohesion. In summary, grassroots sport governance is of great importance in enhancing community resilience. Future urban development should pay attention to grassroots sports governance in order to enhance community resilience.

DIFFERENTIAL IMPACT MECHANISMS OF AI RECOMMENDATIONS VERSUS SOCIAL RECOMMENDATIONS ON SPORTING GOODS CONSUMERS PURCHASE INTENTIONS: THE MODERATING ROLE OF PRODUCT TYPE

CAI, C., CHEN, L.

TONGJI UNIVERSITY; JIMEI UNIVERSITY

Introduction

This study investigates the distinct pathways through which these recommendation systems influence consumer decisions, focusing on how product type shapes their effectiveness. By contrasting AI-driven data precision with social-driven contextual resonance, this research addresses critical gaps in understanding interaction effects and contextualized adaptation strategies in recommendation systems.

Methods

Three mixed-design experiments (total N = 860; 47.1% male, 52.9% female; 55.8% exercised ≥ 4 times/month) were conducted to compare the effects of AI recommendations (e.g., biomechanical data for running shoes) and social recommendations (e.g., community preference tags for sportswear) on purchase intentions. Product type (performance/lifestyle), recommendation source (AI/social), and explainability (high: detailed rationale; low: generic claims) were experimentally manipulated. Mediation-moderation analyses were employed to examine dual pathways: goal-achievement efficacy (for AI) and social identity (for social recommendations). Data were analyzed using ANOVA, bootstrapping mediation (5,000 resamples), and moderated regression.

Results

AI recommendations significantly outperformed social recommendations for performance-oriented products ($M_{AI} = 5.81$ vs. $M_{Social} = 4.32$, $p < 0.001$), with goal-achievement efficacy mediating 41% of the effect ($\beta = 0.41$, 95% CI [0.28, 0.54]). Conversely, social recommendations enhanced adoption intentions for lifestyle products ($\Delta = +1.5$, $p = 0.002$), primarily driven by social identity ($\beta = 0.29$, CI [0.15, 0.43]). High explainability in AI recommendations reduced the performance-lifestyle adoption gap ($p = 0.017$), while social tags amplified group belongingness effects (e.g., campus running clubs). Community-based filtering (e.g., "choices of same-campus runners") further narrowed disparities, increasing lifestyle product adoption by 18% ($p = 0.009$).

Discussion

Product type critically moderates recommendation system efficacy: performance goods demand AI's data-driven precision, whereas lifestyle goods thrive on social recommendations' contextual relevance. The proposed Dual-Path Adaptation Framework emphasizes synergistic integration of AI's objective utility and social systems' subjective alignment. For AI, enhancing explainability (e.g., biomechanical insights for shoes) mitigates cognitive dissonance; for social platforms, embedding community tags (e.g., "trending in your gym") fosters identity-driven adoption. Practically, brands should deploy hybrid systems—prioritizing AI for technical products and social cues for experiential goods. Theoretically, this study advances dual-process models in recommendation systems by delineating how cognitive and affective pathways interact with product attributes. Limitations include self-reported exercise frequency and cultural homogeneity; future work should validate findings across diverse demographics and product categories.

TOWARD PRECISION TRAINING VIA PRESCRIPTIVE MODELING OF THE RATINGS OF PERCEIVED EXERTION IN PROFESSIONAL SOCCER PLAYERS: A CAUSAL MACHINE LEARNING APPROACH

VAN DEUREN, T., DECORTE, T., CATTEEUW, P., LATRÉ, S., VERDONCK, T.

UNIVERSITY OF ANTWERP, IMEC, ROYAL ANTWERP FOOTBALL CLUB

INTRODUCTION: Managing training loads in professional soccer requires balancing performance enhancement and injury prevention. Traditionally, this has been approached through predictive models that estimate internal load responses (e.g., rating of perceived exertion, RPE) based on external load parameters. While these models provide valuable insights into player workload, they fall short in offering actionable, personalized training prescriptions [1]. This study proposes a causal machine learning framework to move beyond prediction toward prescriptive modeling, optimizing training load recommendations for each player based on observed data.

METHODS: Fourteen male professional soccer players (age: 22.2 ± 4.5 years) from a Belgian Pro League club were monitored across a full competitive season, resulting in 974 recorded training and match observations. External load data—including total distance, high-speed running, accelerations, and metabolic power—were captured via 10 Hz GPS units (Catapult Optimeye S5). Internal load was assessed through sessional RPE, and additional pre-session wellness metrics (Hooper Index: sleep duration, muscle soreness, mood, fatigue, and stress) were collected daily. A total of 24 variables

were analyzed. Predictive modeling was conducted using linear regression, regression tree, XGBoost, and random forest, with variable importance assessed via SHapley Additive exPlanations (SHAP) to enhance interpretability. Prescriptive modeling was performed using a counterfactual recurrent network (CRN) to estimate individualized causal effects of training load on future RPE, allowing for targeted load recommendations.

RESULTS: XGBoost achieved the best predictive performance (RMSE: 1.262), with the total session distance emerging as the strongest predictor of RPE. While CRN had a slightly higher RMSE (1.379), it provided interpretable counterfactual insights, enabling training staff to simulate different load scenarios and anticipate individual player responses.

CONCLUSION: Our findings highlight the advantages of integrating causal machine learning into training load management in professional soccer. While traditional predictive models offer valuable estimations of RPE, they fall short in guiding individualized training decisions. By leveraging prescriptive modeling, we move toward actionable recommendations that consider the unique physiological and psychological profiles of each player. These findings align with prior research in [2] on machine learning techniques for optimizing training design and evaluation and extend the work of [1] by demonstrating how prescriptive analytics can enhance decision-making in elite sports settings. Future research should expand sample sizes and explore broader applications across various (team) sports to further validate these approaches.

DEVELOPING A DYNAMIC TIME-SERIES GOAL PREDICTION MODEL BASED ON POSITIONAL DATA: A CASE STUDY OF THE 2023 FIFA U-17 MEN'S WORLD CUP

ZHOU, R., YINGZHE, S., XIMING, S., XIAOCEN, H., ZHIMO, J., JORGE, D.C., NUNO, L.
CAPITAL UNIVERSITY OF PHYSICAL EDUCATION AND SPORTS

INTRODUCTION: Modern football goals determine outcomes, but their prediction is complex, influenced by strategies, player conditions, and in-game dynamics. Traditional models like xG rely on static data, missing tactical shifts and interactions. Advances in EPTS, OTS, and AI-driven analytics now provide high-resolution spatiotemporal data, enhancing accuracy. However, integrating dynamic and static features remains underexplored. This study develops a combined model to improve goal prediction methodologies.

METHODS: This study analyzed data from 52 matches in the 2023 U17 Men's World Cup, focusing on player positions, ball trajectories, and time-series events. Data was collected via an optical tracking system, with preprocessing and model development in MATLAB R2022b. Two feature types were extracted: dynamic features, capturing match evolution through x, y coordinates of 10 key events before a shot, and static features, including shot location, defensive pressure, and shooter posture for contextual insights. The target variable was goal occurrence (1 for goal, 0 for miss). Three deep learning models were implemented. The MLP model processed static features with two hidden layers (128 and 64 neurons, ReLU activation). The LSTM model analyzed sequential data with 30 hidden units and dropout to prevent overfitting. The LSTM+MLP hybrid model fused dynamic and static features at the mid-layer for improved prediction. All models were optimized using binary cross-entropy loss and the Adam optimizer. Data was split 80%-20% for training and testing, with oversampling to balance classes.

RESULTS: The LSTM+MLP hybrid model achieved the best performance in goal prediction, with an accuracy of 93.5%, recall of 95.7%, and precision of 89.8% on the test set, making it well-suited for real-time tactical analysis. The LSTM model excelled in extracting temporal features, achieving 91.7% accuracy and 90.1% precision. However, due to the absence of static feature support, its recall was limited to 86.5%, making it more suitable for post-match tactical review. In contrast, the MLP model, relying solely on static features, performed the weakest, with 80.4% accuracy and 71.5% recall, failing to effectively predict goal events and being applicable only to static tactical analysis tasks.

CONCLUSION: This study introduces a deep learning-based goal prediction model that leverages the strengths of LSTM and MLP to enhance goal-scoring event prediction, offering data-driven insights to support real-time tactical decision-making for coaches. The findings highlight that integrating time-series data with static tactical context significantly improves prediction accuracy. Moreover, the mid-layer feature fusion strategy employed in this study outperforms simple feature concatenation and late-stage fusion in effectively integrating dynamic and static features. Future research should focus on expanding the dataset to enhance model generalization and exploring model compression and lightweight design for real-time applications.

WILL POSITIONAL SHIFTS REPLACE FORMATIONS? A TACTICAL REVOLUTION IN FOOTBALL

TÜTÜNCÜ, O., BARTIK, Y., MEHTA, S., MEMMERT, D.
ISTANBUL GEDİK UNIVERSITY

INTRODUCTION: The modern era of football has witnessed a significant increase in various aspects of the game, including the pace of play, player mobility, tactical mobilisation strategies, positional shifts, and the total distance covered at high intensity (1, 2, 3). Moreover, in the modern game, players positions and roles are more fluid and complex than ever before. This trend has significantly reduced adherence to rigid tactical formations (4-3-3-, 4-4-2, etc.). The main aim of this study is therefore to analyze the tactical formation used to position the teams in the process leading to the goal.

METHODS: Three machine learning models have been developed to evaluate the discrimination of the formation distribution in the buildup to a goal (60second) from the general formation distribution of the match and other different formations (60minutes). A panel data analysis was conducted in order to examine how football formations transform over different time intervals (0, 1-15sec, 16-30sec, 31-45sec, 46-60sec and Mean-60min.). The Ordinary Least Squares (OLS) regression method was employed in order to model the Euclidean distances of player positions across various time intervals and to assess the impact of each interval. The dataset consists of 969,408,000 refined positional data points for analysis, derived from 306 matches played during the 2016–2017 Bundesliga season. Exclusion criteria were applied to ensure the datasets purity and homogeneity.

RESULTS: Model 1 (4-3-3) achieved 57% accuracy for 4-3-3 and 4-2-3-1 but only 29% for 4-4-2. Model 2 (4-2-3-1) demonstrated 43% accuracy across all formations. Model 3 (4-4-2) attained 29% accuracy for 4-4-2, 57% for 4-3-3, and 71% for 4-2-3-1. The 4-2-3-1 model ($R^2 = 0.824$, $F(15,160) = 66.72$, $p < .001$) explained 82.4% of the variance in Euclidean distances, with significant differences at 46–60s (coef = 1.5435, $p < .001$), 31–45s (coef = 1.4499, $p < .001$), and 16–30s (coef = 1.2211, $p < .001$), indicating tactical adjustments before a goal.

The 4-4-2 model ($R^2 = 0.786$, $F(15,160) = 45.45$, $p < .001$) accounted for 78.6% of the variance, with significant changes at 46–60s (coef = 1.4720, $p < .001$), 31–45s (coef = 1.1379, $p < .001$), and 16–30s (coef = 0.8432, $p = .001$), reflecting structural shifts as the goal moment nears.

The 4-3-3 model ($R^2 = 0.735$, $F(15,160) = 28.16$, $p < .001$) explained 73.5% of the variance, with significant differences at 16–30s (coef = 1.7846, $p < .001$) and 31–45s (coef = 1.3852, $p < .001$). The 46–60s interval (coef = 0.4642, $p = .124$) was not statistically significant.

CONCLUSION: The main findings of this study are as follows: Firstly, teams are unable to maintain their initial formation patterns during the sequences leading to a goal. Secondly, even distinct tactical formations tend to converge into similar patterns at the moment of scoring. As a result, since different formations adopt similar structural patterns in goal-scoring processes, it cannot be concluded that a specific formation provides a positive or negative advantage in offensive play.

IMPACT OF CHANGES IN SUBSTITUTION RULES ON ELITE FOOTBALL PLAYERS' PHYSICAL ACTIVITY AND TECHNICAL PERFORMANCE - ANALYSIS OF THE TOP 16 TEAMS AT THE 2022 FIFA WORLD CUP

WU, Y.

BEIJING SPORT UNIVERSITY

INTRODUCTION: The modification of the five-substitution regulation marks a pivotal evolution in modern football, with tactical substitutions serving as critical interventions that significantly influence players performance. As a competitive sport, football is defined by periods of high-intensity, intermittent and sustained exertion, which necessitates that players repeatedly complete sprints, accelerate and decelerate. This also results in players accumulating fatigue with greater ease, which subsequently leads to a decline in performance during matches.

METHODS: To investigate the impact of player substitutions on match dynamics, this study examined 1,173 match observations from 329 players representing the top 16 teams during the 2022 FIFA World Cup Qatar. A comprehensive analysis was conducted on 10 physical and technical indicators across match statuses, positional roles, and player categories. The players included were divided into three groups: (1) entire match players (EMP) ($n = 433$); (2) players who were substituted (SP) ($n = 370$); and (3) replaced players (RP) ($n = 370$), and Cronbachs $\alpha = 0.999$ and ICC = 0.997. The study did not require participant involvement or ethical approval due to the freely available and anonymized dataset.

RESULTS: The results show that defensive substitutions occurred more when leading by one goal (55.1%), while offensive substitutions occurred when trailing by one goal or in a draw (33.3% and 31.7%), and neutral substitutions occurred mainly in a draw (32.6%). SP have higher TD,HSRD,SPD,HSR and Sprints,Shots than EMP or RP($p < 0.001$).The SP of forwards, midfielders, and defenders show better TD,HSR,and Sprints ($p < 0.001$), compared to EMP or RP. EMP had significantly more passes ($p < 0.001$) than SP and RP. Forwards and midfielders who played entire match contributed more shots($p < 0.001$) than SP and RP. EMPs defensive performance in all positions ($p < 0.001$) was better than SP or RP.

CONCLUSION: The primary objective of rotation is to mitigate fatigue or modify the tactical strategy of the match, thereby facilitating the attainment of the teams predetermined objectives. The implementation of high-intensity running is a crucial element in the generation of load during soccer matches. Consequently, coaches are required to rotate players in accordance with their physical condition in order to guarantee the competitive edge of the team. In the event of a deficit in score, the implementation of an offensive substitution will serve to augment the impact of the team and accelerate the pace of the match, thereby enhancing the probability of scoring.

The result emphasizes the strategic importance of substitution timing and player categorization. The empirical evidence provides coaches with actionable insights for optimizing substitution protocols and tailoring position-specific training regimens to enhance competitive outcomes. This research contributes to the evolving understanding of modern football dynamics under revised substitution regulations.

QUANTIFYING AND COMPARING THE MATCH DEMANDS OF U17, U18, U23 AND 1ST TEAM SOCCER PLAYERS IN DIFFERENT PLAYING POSITIONS

ROBERTS, H., REED, B., BEATO, M., TODD, J., HULTON, A.
UNIVERSITY OF SURREY

INTRODUCTION: This study aimed to analyse the physical match and positional demands of youth and senior soccer players using GPS technology.

METHODS: Seventy-nine male outfield players from an English National League (5th tier) professional soccer club were included with GPS data obtained across the 2021–2022 and 2022–2023 seasons. Players were categorised into four age groups (U17, U18, U23, 1st team) and assigned to one of four positions (centre-back, full-back, central midfielder, forward). Data from 660 competitive match observations were analysed. GPS metrics included distance per minute (m/min), high-speed running per minute (HSR/m), sprint distance per minute (m/min), number of accelerations and decelerations per minute (n/min), and PlayerLoad (au). Linear mixed models (LMM) assessed differences across age groups and positions, with significance set at $p < 0.05$.

RESULTS: Age group analysis revealed significant differences in sprint distance per minute ($p = 0.031$) and PlayerLoad ($p < 0.001$), with the 1st team covering greater sprint distances than U17s (1.9 vs. 1.1 m/min, $p = 0.025$) and demonstrating higher PlayerLoad than U23s (458 vs 431 au). Positional analysis identified significant differences across all metrics ($p < 0.001$). Central midfielders covered the greatest total distance (114.4 m/min), while forwards exhibited the highest sprint distance (2.5 m/min), high speed running (7.4 m/min), and number of accelerations and decelerations per minute (2.24 / min). The full-back position recorded the highest PlayerLoad (au).

CONCLUSION: This study highlights the positional and age-related physical demands in elite youth and senior soccer, reinforcing the need for tailored training strategies to ensure smooth transitions throughout academy settings to meet the heightened demands at 1st team level. The findings can inform load management, injury prevention, and player development programs in professional soccer.

A SYSTEMATIC REVIEW OF SPACE CONTROL IN FOOTBALL

KRAMPE, L., BASSEK, M., RAABE, D., MEMMERT, D., REIN, R.
GERMAN SPORT UNIVERSITY COLOGNE

INTRODUCTION: In team sports, a team's ability to control key areas of the pitch and apply tactics to generate advantageous spatial team arrangements is crucial for success, as greater control is associated with better performance. However, various methodological approaches exist to analyse space control at the individual player or team level. This resulted in differing terminologies and interpretations of space in football, which hampers our understanding of how players and teams manage space during a match. The objectives of the review were to examine how the concept of 'space' is conceptualized, constructed and operationalised in high performance football, leading to the construction of a taxonomy with respect to the various analysis approaches and their associated findings.

METHODS: Systematic research of relevant English-language articles was performed on three databases (PubMed, IEEE Xplore and Web of Science), based on PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) guidelines. The keywords 'football' and 'soccer' were each paired with all possible combinations of the following keywords: 'space'; 'spatial'; 'region'; 'regions'; 'zone'; and 'zones'. Articles were first screened using Rayyan and then independently assessed by two reviewers with the following exclusion criteria: 'no football', 'no 11 vs. 11', 'small-sided games', 'only youth', 'only event data', 'not original/primary work', 'only visualisation', 'only eSports/simulation', and 'no pitch/player/team assignment'. The study was pre-registered with the Open Science Framework (<https://osf.io/6fxeb>).

RESULTS: In total $N = 33$ full-text articles studying space control in elite football using positional data were included. The review highlights a notable lack of methodological consistency across studies. Inconsistencies were found with respect to varying terminologies, including different terms for the same construct, and various visualisation techniques. Similar terms were used for different constructs based on a variety of approaches varying from deterministic to probabilistic models. Few studies included any sort of validation procedures and overall study quality was low.

CONCLUSION: The research provides a comprehensive overview of the various approaches to delineating the spatial positions assigned to players on the football pitch. It highlights the similarities and differences in the methodological constructs of space metrics and motion models, as well as their interpretation across different contexts. The identified issues stem from the fact that the complexity of dynamic interactions is frequently disregarded and the transfer to practical applications is often not adequately reflected in a relevant manner. This suggests that enhancing models may be accomplished through the incorporation of machine learning, while concurrently advocating for the application-oriented integration of coaching expertise.

RELATIONSHIPS BETWEEN EXTERNAL LOAD PARAMETERS AND MATCH OUTCOME IN PROFESSIONAL SOCCER PLAYERS

SANNICANDRO, I., TROTTA, N., COFANO, G.
UNIVERSITY OF FOGGIA

INTRODUCTION: Understanding soccer players' official match demands allows the training programme to be more carefully modulated. Certain characteristics such as the teams tactical disposition, the tactical attitude required by the coach and the course of the match can influence the soccer players motor load [1].

The influence of the playing position and contextual factors (e.g., home/away, opponent's standard positions, match period) on the match load has been a topic of particular attention [2] and their effects are well-reported [3]. So far, the literature has not sufficiently investigated whether the match result leads to changes in certain parameters of the players load. The aim of the study is to verify whether several parameters of the external load can be influenced by the match outcome (win, draw, loss).

METHODS: Thirty-six professional soccer players (age: 25.3 ± 4.6 years; height: 181.1 ± 3.5 cm; weight: 81.7 ± 5.4 kg) belonging to 4 different professional clubs, were randomly monitored during official matches. During the match, the players were monitored using global positioning system devices at 18.18 Hz (GPEXE® SYSTEM, EXELIO srl, Udine, Italy). Total distance covered (TD), average speed (AS), high speed running distance 14.4 – 19.8 Km/h (HSRD), very high speed running distance 19.8 – 25.2 km/h (VHSRD), sprint running distance >25.2 km/h (SRD), maximum speed (MS), maximum acceleration >2.5 m/s² (MA) and deceleration <-2.5 m/s² (MD) were measured. In addition, the distance covered at different intensity of power has been analysed: low intensity power (LIP, <20.00 W/kg), high intensity power (HIP, 20.00 - 35.00 W/kg), very high intensity power (VHIP, 35.00 - 50.00 W/kg) and maximal intensity power (MIP, > 50 W/kg) [4].

The significance level has been set to $p < 0.05$.

RESULTS: TD, AS, MS, MA, MD, LIP, HIP, VHIP and MIP haven't been influenced by the outcome of the competition. HSRD values have been significantly greater ($p < 0.001$) in the matches drawn (2236.6 ± 959.9 m) than ones won (1527.7 ± 386.1 m) and lost (1586.7 ± 577.8 m); VHSRD have been significantly greater ($p < 0.001$) in the matches drawn (469.2 ± 138.6 m) than ones won (341.1 ± 137.4 m) and lost (344.1 ± 100.8 m); SRD have been significantly greater ($p < 0.001$) in the matches drawn (126.3 ± 68.7 m) than ones won (67.8 ± 53.1 m) and lost (54.7 ± 43.6 m).

CONCLUSION: The data analysis describes a higher external load in official matches that had the result disputed until the end. Official matches have different loads in relation to their progress and outcome: the future line of research will be to design microcycles throughout the season, taking into account the external load of each match to improve the accuracy of training and recovery protocols [5].

ANTHROPOMETRICAL AND PERFORMANCE PROFILING OF FEMALE SOCCER PLAYERS IN THE BELGIAN FIRST DIVISION

VANDERPOORTEN, R., LIEVENS, M., BOONE, J., COLOSIO, A., BOURGOIS, J., STEYAERT, A., CAEN, K., KERCKHOVE, M., VERMEIRE, K.

GHENT UNIVERSITY

INTRODUCTION: Despite the growing interest in female soccer, research on the anthropometrical and physical performance profiles of female players across playing positions and levels remains limited. This study provides a benchmark for the anthropometrical and physical (aerobic and anaerobic) performance profiles of Belgian first-division female soccer players, considering different playing positions and levels.

METHODS: A group of 100 female Belgian first division soccer players (age: 22.5 ± 3.8 yr, VO_{2peak} : 50.3 ± 4.6 mL·min⁻¹·kg⁻¹) completed a test battery consisting of an anthropometrical assessment ($n = 99$), a maximal incremental running test (~aerobic performance) ($n=100$), and several sprint and jump tests (~anaerobic performance) ($n=99$). Data was collected over seven different seasons (2015-2019 and 2021-2024). Positional differences (goalkeepers (GK), central defenders (CD), fullbacks (F), midfielders (M), wingers (W) and attackers (A)) and the impact of their playing level (national vs. international) were investigated.

RESULTS: Anthropometrics: CD were on average the tallest (1.72 ± 0.04 m; 95% CI 1.71-1.74) and GK the heaviest (71.2 ± 10.3 kg; 95% CI 65.7-76.7). Aerobic testing: Except for A, GK exhibited significantly lower first lactate threshold (LT1) values compared to D ($p=0.025$) and other positions ($p < 0.001$). Similarly, their second lactate threshold (LT2) values were significantly lower than those of all other positions ($p < 0.001$) with exception of A. GK also attained a lower maximal speed during the incremental test than CD ($p=0.002$), F, M and W ($p < 0.001$). Additionally, GK demonstrated a significantly lower relative VO_{2peak} ($p < 0.05$) than F, W ($p < 0.001$), and M ($p=0.008$). Anaerobic testing: GK scored lower for 10-m sprint than W ($p = 0.021$) and A ($p=0.042$). GK were also slower on the 5 x 10-m shuttle run (SHR) than W ($p=0.027$). The sum of skin-folds showed a strong inverse relationship with VO_{2peak} ($r=-0.57$, $p < 0.001$), LT1 ($r=-0.47$, $p < 0.001$) and LT2 ($r=-0.55$, $p < 0.001$).

International players ($n=25$) had a higher absolute VO_{2peak} (3.17 ± 0.28 L·min⁻¹ vs. 3.06 ± 0.27 L·min⁻¹; $p=0.042$), higher fraction of VO_{2peak} at which LT2 occurred (88.4 ± 3.8 % vs. 86.9 ± 3.2 %; $p=0.022$), faster SHR (12.42 ± 0.26 s vs. 12.60 ± 0.39 s; $p=0.03$), higher countermovement jump with the hands on the hips (CMJ-) (31.54 ± 3.85 cm vs. 29.23 ± 3.68 cm; $p=0.026$) and a higher countermovement jump with preparatory step (CMJstep) (39.60 ± 5.26 cm vs. 37.17 ± 4.28 cm; $p=0.049$) than national players ($n=75$).

CONCLUSION: This data provides insight into the physiological characteristics required of female soccer players in the Belgian first division, establishing a benchmark for future comparison across playing levels. However, this data also shows that there are no specific physiological profiles across playing positions, although international players tend to score higher on both aerobic and anaerobic parameters compared to national players.

EXAMINATION OF THE EFFECT OF WEARING THERMAL TIGHTS ON IMMUNE RESPONSE

TOKUNAGA, K., YAMAMOTO, T., TSUNEMATSU, H., ABE, S., NAKASHIMA, S., KOMATSU, T., TANAKA, H., SHIRAIISHI, A., MICHISHITA, R., SAKU, K., UEHARA, Y.

FUKUOKA UNIVERSITY

INTRODUCTION: For athletes, maintaining daily training can be essential. Physical stress disrupts normal physiological balance or homeostasis, including the immune system, especially during high-intensity exercise. Natural killer (NK) cells, a type of immune cell, are sensitive to exercise, and a decrease in NK cell activity contributes to immune system dysfunction. Therefore, maintaining high NK cell activity after exercise is a key factor in improving long-term performance. Recently, it has been reported that maintaining deep muscle temperature with a heat-retaining function after exercise can improve performance. The aim of this study was to investigate the acute effects of wearing thermoretentive tights after high-intensity exercise on immune function.

METHODS: Thirteen healthy adult males (21-29 years of age) participated in a randomized crossover study comparing conditions with and without heat-retaining tights (prototype of Thermal Charge®, Mizuno, Japan). The exercise protocol consisted of resistance training followed by high-intensity interval training (HIIT) on a bicycle ergometer. The effects on NK cell activity and heat shock protein 60 (HSP60) were assessed at baseline, 0, 30, and 150 minutes after exercise. A two-way ANOVA was performed, and when significant interactions were observed, trend analysis was performed for each group. A significance level of $p < 0.05$ was used.

RESULTS: All 13 participants completed the exercise. The control group showed a significant decrease in blood NK cell activity from baseline to 150 minutes after high-intensity exercise. In contrast, there was no decrease in NK cell activity from baseline to 150 minutes post-exercise when wearing thermoretentive tights. In addition, a significant increase in blood heat shock protein 60 concentration was observed only when wearing thermal-keeping tights.

CONCLUSION: Wearing thermal-keeping tights prevented the decline in serum NK cell activity at 150 minutes after high-intensity exercise and increased serum HSP60 levels after exercise. The thermoretentive garments used in this study have been shown to maintain both deep and superficial muscle temperature during exercise.

Thus, it is suggested that heat retention in deep muscles may have contributed to the suppression of immune decline.

NEAR-INFRARED SPECTROSCOPY: HOW DOES EXERCISE INFLUENCE CALIBRATION AND MICROVASCULAR RESPONSIVENESS?

PARADIS-DESCHÊNES, P., BILLAUT, F.

UNIVERSITÉ DU QUÉBEC À CHICOUTIMI

INTRODUCTION: The changes in deoxyhemoglobin ([HHb]) derived from near-infrared spectroscopy (NIRS) are commonly calibrated with an arterial occlusion (AO) to examine muscle oxygenation and microvascular responsiveness. However, exercise alters hemodynamic and metabolic responses, which could affect this calibration method. This study aimed to examine the influence of exercise on AO variables.

METHODS: Thirty-six endurance-trained males (28 ± 9 years, 75.9 ± 9.4 kg, 1.78 ± 0.08 m) completed a cardiopulmonary exercise testing (CPET) and a 5-km time-trial (TT) on an ergocycle. The NIRS device (PortaMon, Artinis Medical Systems BV, The Netherlands) was installed on the distal part of the right vastus lateralis muscle to record changes in muscle oxygen parameters during AO executed before and after each test. The resting baseline (30 sec), the AO amplitude (difference between the hyperemia spike and baseline) and the reperfusion slope of tissue oxygen saturation (% StO₂, 10 sec post hyperemia spike) were evaluated. Student *t* tests were used to compare baseline, amplitude and reperfusion slope of [HHb] and TSI signals.

RESULTS: [HHb]baseline and [HHb]slope were similar pre- and post-CPET and between tests (CPET vs TT). [HHb]amplitude was higher post- vs pre-CPET ($p < 0.001$) and post-TT vs post-CPET ($p < 0.001$). Both CPET and TT increased TSIbaseline ($p = 0.005$) and decreased TSIamplitude ($p = 0.019$) and TSIslope ($p < 0.001$). TT also decreased TSIslope ($p < 0.001$). Finally, TSIbaseline was different between CPET and TT ($p = 0.023$), but TSIamplitude and TSIslope were similar.

CONCLUSION: These results suggest that CPET and TT independently impacted maximal deoxygenation, highlighting the importance of performing an AO after every type of exercise to accurately calibrate [HHb]. Furthermore, exercise altered microvascular responsiveness, but with similar effect for CPET and TT.

PREDICTION MODEL OF ENERGY METABOLISM IN CHEMICAL CORPS PERSONNEL WEARING NUCLEAR, BIOLOGICAL, AND CHEMICAL PROTECTIVE CLOTHING UNDER DIFFERENT OPERATIONAL LOADS

LIN, Y., CHENG, C., YU, C., FU, S., HSIAO, C.

UNIVERSITY OF TAIPEI

INTRODUCTION: Chemical Corps personnel wear nuclear, biological, and chemical (NBC) protective clothing along with 20 kg of equipment during operations, imposing significant physiological stress. NBC protective clothing restricts sweat evaporation and heat dissipation, increasing heat stress and metabolic burden (1). Heart rate is a widely used physiological indicator for workload prediction, while body composition factors such as body fat percentage (PBF) and body mass index (BMI) influence metabolic response (2,3). However, the extent to which these factors contribute to energy metabolism estimation remains unclear. This study aims to develop an optimized model for predicting metabolic equivalents (METs) based on physiological parameters.

METHODS: Twenty-five male military personnel (age: 25.32 ± 2.26 years; height: 170.42 ± 4.88 cm; weight: 64.9 ± 11.28 kg) participated. They performed treadmill walking/running at different loads (0 kg, 10 kg, and 20 kg) and speeds (4 km/h, 6 km/h, and 8 km/h) while wearing NBC protective clothing under controlled conditions (temperature: 25°C, humidity: 70%). METs were measured using a portable metabolic analyzer, and body composition was assessed prior to testing. Simple and multiple linear regression analyses were performed to determine the optimal METs prediction model.

RESULTS: Multiple regression analysis showed that the combination of HRRratio and PBF had the highest coefficient of determination ($R^2 = 0.867$, $p < 0.001$) for METs, with the model: $\text{METs} = 4.116 + 0.939 \times \text{HRRratio} - 0.051 \times \text{PBF}$. If PBF was unavailable, HRRratio and BMI provided a second-best model ($R^2 = 0.862$, $p < 0.001$):

$\text{METs} = 5.179 + 9.370 \times \text{HRRratio} - 0.088 \times \text{BMI}$. When no body composition data was available, HRRratio alone remained a strong predictor ($R^2 = 0.852$, $p < 0.001$):

$\text{METs} = 3.243 + 9.322 \times \text{HRRratio}$.

CONCLUSION: This study developed a predictive model for energy metabolism in personnel wearing NBC protective clothing, confirming HRRratio as a reliable predictor of METs, with or without body composition parameters. The findings align with prior research on heart rate-based energy estimation and the physiological strain of protective gear (4,5). NBC protective clothing has been shown to increase core temperature by up to 11.2°C during moderate to heavy workloads, significantly elevating energy demands (1). Environmental conditions further exacerbate metabolic burden, emphasizing the need for context-specific models (6). While this model provides accurate estimations under controlled conditions, further validation in extreme environments is necessary. Future research should explore additional physiological markers to refine the model for broader operational use.

RESEARCH ON THE CHARACTERISTICS OF COMPETITION LOAD AMONG ELITE CHINESE FEMALE COLLEGE VOLLEYBALL PLAYERS

WANG, T., CHEN, Z., ZHAO, H.Y., HAN, B., CAI, X.D., SHI, S.S.

NANJING NORMAL UNIVERSITY

INTRODUCTION: This study quantifies the competition load characteristics of elite female college volleyball players from Nanjing Normal University from the perspectives of external and internal loads. The aim of the present study is to provide theoretical and practical foundations for the scientific training and preparation of college volleyball teams.

METHODS: The K-sport IMU motion monitoring system (K-AI Track, K-sport, Italy) and FirstBeat heart rate monitoring system (FirstBeat, Garmin, Finland) were used to collect data from 12 athletes during four matches of the 2024–2025 Jiangsu Provincial High-Level College Volleyball Championship. The K-sport IMU system collected metrics such as low, medium, and high-intensity training loads, movement frequency, and jumps. The Firstbeat system monitored average heart rate, maximum heart rate, minimum heart rate.

Data are presented as mean±standard deviation, with $P < 0.05$ considered statistically significant.

RESULTS: During matches, the teams average movement load was 747.7 ± 26.7 . By position: outside hitters averaged 876.1 ± 32.8 , middle blockers 553.4 ± 25.3 , setters 813.1 ± 39.6 , opposites 948.8 ± 19.3 , and liberos 763.8 ± 28.1 . There were no significant differences among outside hitters, setters, and opposites, whether for the entire match or individual sets. However, setters, opposites, and liberos showed an increasing trend in movement load per set.

In $0.2g \leq \text{Training Load Low} \leq 0.75g$, no significant differences were observed except for middle blockers. Outside hitters, setters, and liberos showed higher intensity in the third set compared to the first two ($P < 0.05$). In $0.75g \leq \text{Training Load Medium} \leq 1.5g$, no significant differences were found among outside hitters, middle blockers, and liberos, or between

setters and opposites. In Training Load High $>1.5g$, outside hitters, middle blockers, and opposites showed no significant differences, but significant differences were observed compared to setters and liberos ($P < 0.05$).

The teams average number of jumps was 13.4 ± 0.1 . By position: outside hitters averaged 9.3 ± 0.2 , middle blockers 13.3 ± 0.6 , setters 26.9 ± 1.3 and opposites 19.5 ± 0.4 .

The teams average heart rate was 120.75 ± 16.7 bpm, maximum heart rate was 201.3 ± 5.8 bpm, and minimum heart rate was 66.3 ± 10.3 bpm. Opposites and liberos had the highest average heart rates (137.3 ± 15.6 bpm and 137.5 ± 13.6 bpm, respectively), followed by outside hitters and setters (120.9 ± 11.4 bpm and 121.2 ± 14.7 bpm). Middle blockers had the lowest average heart rate (107.9 ± 10.7 bpm).

CONCLUSION: Volleyball players experience high competition loads, requiring medium-to-high-intensity movement and Confrontation ability.

Frequent changes in direction and acceleration during matches demand excellent speed and agility.

Heart rate loads are higher during intense rallies.

Increase the monitoring of daily training and Physiological and Biochemical indicators.

Ensure that athletes physical conditioning during training camps meets or exceeds the demands of competition.

DIFFERENCES IN MINIMUM VELOCITY THRESHOLD (MVT) AMONG INTERNATIONAL LEVEL YOUTH SPRINT KAYAK ATHLETES AND ITS ROLE IN E1RM PREDICTION

KRALIK, M., KRAL, R., HADZA, R.

COMENIUS UNIVERSITY IN BRATISLAVA, FACULTY OF PHYSICAL EDUCATION AND SPORT

INTRODUCTION: The minimum velocity threshold (MVT) is one of the crucial metrics using velocity-based devices for prediction one repetition maximum (e1RM), from non-maximal loads. MVT is the mean concentric velocity (MCV) produced during the last successful repetition of a set and another way to acquire velocity for a 1RM (1). These velocities are afterwards also used for objective real-time monitoring, prescribing and adjustment of the training load and training intensity. We know, that for different exercises have different MVTs, but authors also have different recommendations for free-weight bench press 0.18 m/s-1 (2) and 0.17 m.s-1 (4), which is most widely used. Therefore, the aim of this study was to examine differences of MVT in free-weight bench press (BP) exercise in national level youth kayak athletes and the accuracy of the estimation. This exercise was chosen because its use in strength and conditioning training of kayak athletes and can affect the sport performance in sprint kayak (5).

METHODS: 14 resistance trained athletes (5 females, 9 males; 14-20 years of age) with minimum of 2 years of strength training experience were recruited for this study. All subjects performed a one-repetition maximum test (1RM) on BP with measuring their MCVs using Tendo unit. Subjects trained for last year 3 times a week and were familiar with BP. The individual MVTs were compared with general recommended MVTs and the individual 1RMs were compared with e1RM.

RESULTS: MVTs of 1RMs on free-weight bench press varied widely in athletes from 0.12 m.s-1 to 0.32 m.s-1 . The average of the MVTs in the group was 0.21 m.s-1 , with $SD=0.065 \text{ m.s-1}$. The mean value of 1RM was 54.6 kg ($SD=24.4$) vs. e1RM 57.6 kg ($SD=25.9$). Even though the two-way mixed effect model with single measures $ICC=0.98$. In one example subject was 9.98% difference in 1RM vs e1RM (90kg vs 98.7kg).

CONCLUSION: We found high differences in BP MVTs in our athletes and differences of the average in the group compared to recommended (0.21 vs 0.17). So, we suggest that more precise would be to establish MVT for each athlete individually and use it later in testing and training. With these findings we would recommend restraining international level athletes from using standard MTVs. We even found that these standards for BP were mostly performed as smith machine bench press, which is much less common type of pressing oriented exercise, and less adequate due to lower attained velocities compare to free-weight BP. The standard MVT 0.17 m.s-1 (used in various velocity-based training devices) caused not only overestimations but also underestimations in 1RMs. In later we would recommend to app developers to add possibility of entering individual MVT for each exercise to precisely evaluate e1RM and use this kind of technology for training purposes.

EFFECTS OF NEOPRENE KNEE BRACE ON LOWER-LIMB BIOMECHANICS DURING SINGLE-LEG LANDINGS

WENG, Y., HSIEH, C., TANG, C., LAI, C., FU, S.

UNIVERSITY OF TAIPEI

INTRODUCTION: Single-leg landing places considerable stress on the knee joint, potentially leading to acute or chronic injuries—particularly of the anterior cruciate ligament (ACL) [1]. Although knee braces are often used to reduce injury risk [2], their effects on inverse dynamics (joint moments, ground reaction forces) during single-leg landing remain unclear.

This study compared knee angles, knee moments, and vertical ground reaction forces (GRF) between control (no brace) and knee brace conditions in healthy adults.

METHODS: Seven participants (4 males, age 23.8 ± 3.6 y; 3 females, age 23.7 ± 4.7 y), with no lower-limb injuries in the past six months, were recruited. Each performed single-leg landings from a 30 cm platform under two conditions: (1) Control (no brace) and (2) Knee brace (a neoprene sleeve with adjustable, nonelastic straps). Knee flexion angles and moments were recorded using a Vicon system (Vicon Motion Systems, Oxford, UK), and vertical ground reaction force was measured via an AMTI force platform (Advanced Mechanical Technology, Inc., Watertown, MA, USA). Data normality was evaluated (Shapiro-Wilk), and paired-samples t-tests ($p < .05$) compared the two conditions.

RESULTS: Following the landing protocol, no significant differences were observed between the Control and Knee brace conditions in knee angle or kinetic variables ($p > .05$). For instance, the mean knee angle was $63.30 \pm 15.92^\circ$ (Control) vs. $58.35 \pm 19.39^\circ$ (Brace), and peak positive X moments averaged 1575.16 ± 1115.70 vs. 1684.68 ± 1032.68 , respectively (both $p > .05$). Similar results were found for negative X moments, Y moments, and peak vertical GRF, indicating that wearing a knee brace did not significantly alter the measured inverse dynamics parameters during single-leg landing.

CONCLUSION: Results showed no statistically significant effect of a standard neoprene knee brace on knee joint angles or kinetic parameters during single-leg landing in healthy adults. In a recent study [3], soft knee braces were found to provide only minor adjustments in lower-limb biomechanics for non-injured participants, supporting our finding that additional external support may not be essential in healthy populations. Meanwhile, another investigation [4] emphasized that compression-based brace designs had negligible impact on modulating landing forces and joint angles, suggesting that knee stability is primarily maintained by neuromuscular control rather than external bracing. In summary, a simple neoprene brace provides limited biomechanical benefit for healthy adults during single-leg landings. Future studies should use larger samples, varied landing tasks, and neuromuscular assessments to clarify protective or performance effects.

BRIDGING THE GAP: A CORRECTION FACTOR FOR VERTICAL JUMP PERFORMANCE ACROSS DEVICES

DERMO, A., DI LIBERO, T., FALESE, L., RODIO, A.

UNIVERSITY OF CASSINO: UNIVERSITA' DEGLI STUDI DI CASSINO E DEL LAZIO MERIDIONALE

INTRODUCTION: In sports science, vertical jump height is a key performance metric. In low-resource settings, cost-effective tools like the My Jump 2 (MJ) app and the G-Vert (GV) sensor are widely used. However, measurement discrepancies affect reliability. This study aimed to cross-compare MJ and GV data. Enhancing reliability in remote performance monitoring ensures consistent data collection in different environments, such as during the Covid-19 Lockdown.

METHODS: Twenty-eight male adults (age 37.6 ± 8.83 y, $p < 0.001$; BMI 24.9 ± 3.31 kg/m², $p < 0.001$) performed Squat Jumps (SJ), with data simultaneously collected via MJ and GV. The GV sensor was placed at L5, and jump execution was recorded via smartphone for MJ analysis. Statistical analyses included linear regression, intraclass correlation coefficients (ICC), and paired t-tests to assess relationships and determine adjustment factors.

RESULTS: The linear regression model found a strong correlation ($r = 0.75$, $p < 0.001$) between MJ and GV measurements, though GV overestimated jump height by an average of 12.02 ± 3.69 cm. To align MJ values with GV, a multiplication factor of 1.43 is recommended, while GV values should be adjusted by 0.71 to match MJ.

CONCLUSION: Discrepancies in vertical jump measurements between devices highlight the need for standardization in performance monitoring. The proposed correction factor allows for accurate data interpretation, particularly in remote training settings where device accessibility may vary. This approach is essential for maintaining consistent athlete evaluation and can aid in rehabilitation, strength assessment, and periodized training programs. This study provides a validated correction factor for comparing MJ and GV jump height measurements, enhancing cross-device reliability. The findings support broader applications in sports science, particularly in environments requiring remote assessments or multi-device monitoring. Future research should validate this correction factor across diverse populations and exercise conditions.

A QUALITATIVE STUDY ON DEVELOPING AN ATHLETE MONITORING SYSTEM FOR INJURY PREVENTION IN LONG TRACK SPEED SKATING

HENDRICKS, M., VERHAGEN, E., JULIAN, R., VAN DE WATER, A.T.M., EILS, E., BOLLING, C.

INSTITUT FOR SPORT SCIENCE, UNIVERSITY OF MÜNSTER

INTRODUCTION: Long-track ice speed skating (LTSK) is a physiologically demanding sport that requires careful training load management to optimise performance while preventing injuries. Athlete monitoring systems (AMS) can support this process by providing critical information to guide training and injury prevention decisions. However, using AMS for injury prevention presents challenges due to the context-dependent management of injuries. Therefore, this qualitative study explored how skaters and coaches perceive, report, and manage injury and their expectations of an AMS for this purpose. The findings aim to provide context-specific recommendations for developing an AMS in LTSK.

METHODS: This qualitative study utilised semi-structured interviews with 12 German Speed Skating Federation participants, eight skaters and four coaches. The data were analysed using thematic analysis.

RESULTS: Three main themes emerged. (1) Physical demands and limits – participants described "pushing their physical limits" as key in LTSK training, with skaters emphasising the challenge of recognising their limits for effective load management. Interviewees reported monitoring objective performance indicators (e.g., power output in cycling) and subjective feelings (e.g., lack of motivation) to assess fatigue. AMS potentially supports providing feedback on training intensity, guiding short-term adjustments, and identifying long-term trends.

(2) Understanding pain and injury – participants defined injuries as training-related physical complaints impacting subsequent sessions, with pain as the primary symptom. Pain was seen as a manageable aspect of training, distinguished from serious injury based on experiences. Individual pain assessments were used to decide on subsequent training adjustments, considering various characteristics and contextual factors.

(3) Reacting to Pain and Injury – more experienced skaters emphasised the importance of addressing symptoms early and proactively, highlighting the role of self-regulation. Participants reported adapting intensity, volume or exercises in response to pain and injury, opting for alternative or injury-specific exercises instead of complete rest to maintain fitness and minimise injury-specific load. They emphasised the importance of closely monitoring pain about these adaptations to evaluate their effectiveness and inform short-term adjustments for balanced training load management.

CONCLUSION: This study found balancing the training load with physical limits as challenging in LTSK. Pain, was seen as both manageable and inherent to training guiding training adjustments. Therefore, close pain monitoring is recommended to improve understanding of when and how to adapt training and evaluate the effectiveness of these changes, with training adaptations—rather than complete rest—being the preferred strategy for injury management. Additionally, monitoring fatigue may help skaters assess their physical limits when increasing training demands.

COMPARISON OF DIFFERENT SPRINT TRAINING SESSIONS WITH ASSISTED RUNNING: EFFECTS ON PERFORMANCE AND KINEMATICS IN 30-METER SPRINTS

SKUJYTE, A., GENITRINI, M., SILINSKAS, V., LUKONAITIENE, I., BRADAUSKIENE, K., TRINKUNAS, E., SAMOZINO, P., KAMANDULIS, S.

LITHUANIAN SPORTS UNIVERSITY

INTRODUCTION: Sprint training can be enhanced through assisted and resisted methods, which influence both sprint mechanics and overall performance. Assisted sprinting, typically involving towing mechanisms, has been studied using various towing forces, often providing constant full assistance. However, little is known about how adjusting these forces and setting specific speeds impact performance. Unlike full assistance, partial assistance reduces the towing force as the athlete approaches a certain speed, allowing for a more dynamic and adaptive sprinting experience. This method may require greater voluntary effort from the athlete, potentially leading to better training adaptations. Therefore, it was hypothesized that partial assistance sprinting would provide greater benefits compared to full assistance.

METHODS: This study compared two assisted sprint training methods: fully assisted sprinting with a constant 6 kg towing force and partially assisted sprinting, where assistance diminished once the athlete approached 0.5 m/s below their supra-maximal speed. Twenty-four male youth football players (age: 17.0 ± 1.9 years, body mass: 69.7 ± 9.9 kg, height: 1.80 ± 0.06 m) participated in the study during their offseason. Eight athletes completed the fully assisted training, eight underwent partial assistance training, and the remaining participants formed a control group.

The subjects were tested in both a 30-meter regular sprint and a 30-meter fully assisted sprint. The training program consisted of four 30-meter assisted sprints performed twice a week for a total of 10 sessions. A motorized device provided precise assistance loads, while sprint times were measured using the Witty Gate timing system. Maximal speed and 5-meter average speed were recorded by the towing device. Additionally, stride length, stride frequency, contact time, and flight time were analyzed using the OptoJump Next modular system.

RESULTS: Thirty-meter fully assisted sprint times significantly improved in both the fully and partially assisted groups ($p < 0.05$ for both). Additionally, contact times during both regular 30-meter sprinting and 30-meter fully assisted sprinting were significantly reduced ($p < 0.05$ for both). However, regular 30-meter sprint times remained unchanged.

CONCLUSION: Both fully and partially assisted sprint training methods effectively enhance 30-meter assisted sprint performance. Additionally, both methods led to a significant reduction in contact times, which may contribute to improved stride efficiency and sprint mechanics. However, longer training periods might be needed for a significant improvement in a regular 30-meter run. These results help coaches refine sprint training strategies, enabling them to adjust assistance techniques to better suit individual athletes.

REGIONAL BIOIMPEDANCE PREDICTS PERFORMANCE DURING PERIODIZED TRAINING OF TRACK AND FIELD SPRINTERS

PASINI, L., GIUDICI, S.

CITIZEN SCIENTIST

INTRODUCTION: Limited research has explored the relationship between variations in bioelectrical parameters during the full training season and the athletic performance of track and field sprinters of both genders.

METHODS: We collected longitudinal anthropometric and regional bioelectrical impedance vector analysis (BIVA) measurements of 12 female (age: 23.5 ± 3.7) and 9 male (age: 23.9 ± 5.2) sprinters, with >6 years experience and tier 3, for 9 months of periodization (T1, general conditioning; T2, specific conditioning; T3, pre-competition; T4, competition). Pearson's and Student's tests were used to evaluate the association with seasonal best (SB) time, maximal strength (flat bench, deadlift, squat), pre- vs. post- repeated-sprint training (4x4 of 80m sprints), and T1 to T4 progression. We also assessed how a specific nutritional plan (diet, $n=4$; non-diet, $n=3$) impacted performance and body composition. **RESULTS:** Between T4 and T1, independently of diet, we measured a median reduction of many skinfold (SF) sites, specifically the 7-site SF (females, -9.9% , $P=0.08$; non-dieting males, -3.7% , $P=0.07$), which was more marked in those athletes who followed the diet (7SF, -28.6% , $P=0.05$). By combining the BIVA regional values, we developed a sprinter performance index (SPI) able to discriminate between top and low SB female groups (100m, $P=0.003$; 200m, $P=0.04$). SPI/h showed direct correlation with SB ($r=-0.7$, $P=0.02$), following seasonal fluctuations in performance and arm strength. Women SB significantly correlated with several indices of lean body mass, with an important decrease in leg impedance (Z) and leg phase angle (PhA), indicative of premature performance drop (T4-T3). Male sprinters who followed the diet prolonged their peak performance, along with an increase in SPI/h between T4-T3, and improved their SB (100m: $-0.29s$, $P=0.03$; 200m: $-0.44s$, n.s.). The non-diet group experienced a progressive decline in arm Z and leg reactance (Xc) after T2, and a drop in the leg PhA (T4-T3). Arm Xc was the only discriminant between faster (100m: average 10.75s; 200m: average 21.71s) and slower (100m: average 11.54 s; 200m: average 23.57s) male sprinters (28.7Ω vs. 26.9Ω , $P=0.03$), showing a correlation with SB ($r=-0.6$). Both females and males exhibited a reduction of parallel reactance (XcP) concomitant to reaching peak performance. For female athletes, the repeated-sprint test revealed a sharp decrease in leg PhA (-3.8% , $P=0.04$), increase in arm resistance (R) and arm Xc (8.5% and 10%, respectively), and a significant rise in arm XcP (6.9%). Men only exhibited a certain drop in arm PhA (-2.7% , $P=0.07$) and arm Xc (-2.4% , $P=0.03$).

CONCLUSION: We formulated important regional BIVA criteria for coaches and nutritionists to plan macrocycles and mesocycles, especially for female athletes. Regional BIVA pinpointed essential physiological changes that would be masked if looking at whole body measurements only. Based on our data, arm Xc may explain most of the variation in performance, supporting the concept that arm fatigue and strength is a key factor in sprinting propulsion.

BLOOD LACTATE AND GLUCOSE KINETICS FOLLOWING 800-M RUNNING ARE ASSOCIATED WITH EXERCISE PERFORMANCE

INABA, T., WATANABE, T.1, VAN RASSEL, C.R.1,2, HATTA, H.1, TAKAHASHI, Y.1

<1> THE UNIVERSITY OF TOKYO, <2> UNIVERSITY OF CALGARY

INTRODUCTION: Carbohydrate is an important energy source particularly during supramaximal exercise such as 800-m running event [1]. Blood lactate and glucose concentrations ([BLa] and [BGlu], respectively) have been widely accepted as good indicators of the usage of carbohydrates by muscles. Blood lactate kinetics indicators after high-intensity running reflect closely the lactate metabolic response implemented during exercise [2], and that of variables have been shown to be correlated with 800-m performance [3, 4]. However, these reported data were measured in the laboratory and the exercise duration was shorter than the 800-m event. It has also been shown that [BGlu] increases markedly after strenuous exercise (i.e. exercise-induced hyperglycemia) [5], but the relationship between high-intensity exercise and changes in [BGlu] has not been investigated. The aim of this study was to investigate the relationship between the variables in [BLa] and [BGlu] from the kinetics following 800-m trial and that of performance.

METHODS: In this study, 6 male well-trained middle-distance runners performed an 800-m time trial (800-m TT) on the outdoor track. [BLa] and [BGlu] were collected from the fingertip before and after the trial (i.e. the rest and recovery period, respectively). Using a biexponential time function, lactate exchange ability (γ_1), lactate removal ability (γ_2), and the quantity of lactate accumulated (QLaA), which can be interpreted as the amount of produced lactate during exercise, was calculated from individual blood lactate recovery data [2, 6]. The delta (Δ) of [BGlu] was the difference between [BGlu] at rest and peak following the 800-m TT. The data are reported as mean $\pm$ standard deviation. Pearson correlation coefficients were used to determine the correlation between the variables (i.e. γ_1 , γ_2 , QLaA and Δ [Glu]) and 800-m performance. Statistical significance was set at $p < 0.05$.

RESULTS: The time of 800-m TT was 119.14 ± 4.26 (sec). $\dot{V}O_2$, $\dot{V}E$, QLaA and $\Delta[BGluc]$ were 0.149 ± 0.08 (l/min), 0.014 ± 0.08 (l/min), 683.5 ± 131.68 (mmol) and 3.1 ± 0.9 (mmol/L), respectively. Whereas No significant correlations were detected between $\dot{V}O_2$, $\dot{V}E$ and 800-m TT ($\dot{V}O_2$: $r = 0.46$, ns; $\dot{V}E$: $r = -0.51$, ns), there is a significant relationship between QLaA and 800-m TT ($r = -0.90$, $p < 0.05$). In addition, $\Delta[BGluc]$ was strongly correlated with 800-m TT ($r = -0.81$; $p < 0.05$).

CONCLUSION: These results suggested that not only [BLA] but also [BGluc] after exercise could evaluate the supramaximal exercise performance, especially QLaA and $\Delta[BGluc]$ may be more highly associated with performance than other variables. The ability to mobilize more carbohydrates and produce more lactate may have a positive impact on 800-m running performance.

COMPARING INFLUENCES OF SPIKES AND RUNNING SHOES ON LOWER EXTREMITY KINETICS AND SPRINT PERFORMANCE OF NOVICES

GERLACH, M., DE GRAAF, M.L., BOSTRÖM, K.J., WAGNER, H.
UNIVERSITY OF MÜNSTER

INTRODUCTION: Footwear is a critical factor influencing both sprint performance and injury incidence [1]. Despite evidence suggesting that injury rates increase with increasing training hours in spikes [2], there is a lack of studies quantifying this relationship. Additionally, it is not clear whether or not spikes actually enhance performance across different levels of sprinters. Specifically, novice sprinters may not benefit from wearing spikes to the same extent as experienced sprinters do, raising the question of whether they are worth wearing. Therefore, the purpose of this research is to investigate the effects of spikes versus running shoes on sprint performance and lower limb kinetics in novice sprinters.

METHODS: Eighteen novice sprinters completed six 60 m sprints, wearing either spikes or running shoes. Sprint times were measured using two pairs of double beam timing gates. Full-body kinematics were recorded using a motion capture suit and imported into the musculoskeletal model Myonardo®, which was used to estimate JCFs of the hip, knee, and ankle joints. All values were normalised to subjects body weight before being analysed through generalised linear mixed models.

RESULTS: Sprinting with spikes yielded significantly faster sprint times compared to running shoes. Results indicated a mean improvement of 1.7% in the 60 m sprint performances. Men benefited more from spikes (improvements of 2.7%) than women (improvements of 1.0%). When looking at the joint kinetics the peak knee JCFs were significantly higher when sprinting in spikes than in running shoes. This is consistent with reports of increasing injury incidence with increasing hours of training in spikes [2].

CONCLUSION: While the performance advantages of spikes were notable, novices should take into account the elevated loading associated with their use. Thus, it might be beneficial to implement their use progressively, allowing the musculoskeletal system sufficient time to adjust.

POLARIZED TRAINING FOR JUNIOR BIATHLETES, WISFUL THINKING, OR COACH-INDUCED MISMATCH TO TRAINING PLAN COMPLIANCE?

KÅRSTRÖM, A., STAUNTON, C., BJÖRKLUND, G.
SWEDISH WINTER SPORTS RESEARCH CENTER, MID SWEDEN UNIVERSITY

INTRODUCTION: Biathlon is an endurance winter sport that combines cross-country skiing and rifle marksmanship. Previous research suggests that elite-level endurance athletes typically follow a polarized training intensity distribution (TID) model ([1]). However, more recently, Burnley et al. suggested that polarized distributions are typically seen only in the prescription of session goals [2]. The actual TID executed by athletes is more likely to be a pyramidal distribution. Nevertheless, discrepancies between coach training prescription and athlete execution can lead to maladaptation of training.

Therefore, this study aimed to determine if there were any discrepancies in planned (PLAN), self-reported (REP), and executed (EXE) training intensity distribution in junior biathletes.

METHODS: Thirty junior biathletes (16 men, 14 women) were monitored over 13 months of biathlon training involving skiing and roller skiing. Training was PLAN by a coach and REP in an online diary using a 5-zone model (z1-z5) from the Swedish Biathlon Federation [3], based on each athletes maximum HR. Athletes wore heart rate monitors (Polar H10, Polar Electro OY, Finland) and GNSS devices (Vector S7, Catapult Sports, Australia) during sessions. EXE data were analyzed from when the athlete started moving to when they stopped, with heart rate and GNSS data co-analyzed in Matlab (Mathworks, Natick, U.S.). HR data were allocated to minutes in intensity zones, including a zone for data below z1 ($z0 < 55\%$ HRmax). Data representation was as a percentage of total training time. A non-parametric Friedman test detected differences in training conditions, and paired t-tests compared REP and EXE for $z0$. Significance was set at $p < 0.05$.

RESULTS: In total, $n=241$ sessions were analyzed. Average session duration was 96 ± 20 , 92 ± 22 , and 95 ± 24 min for PLAN, REP, and EXE, respectively. Significant differences were found between session duration on PLAN vs. REP and PLAN vs. EXE ($p=.007$ and $p=.024$, respectively). Mean zone distribution differed between PLAN and EXE in all five intensities ($z1=90 \pm 19\%$, $45 \pm 22\%$ respectively, $p<.001$; $z2=3 \pm 13\%$, $33 \pm 17\%$ respectively, $p<.001$; $z3=1 \pm 6\%$, $8 \pm 9\%$ respectively, $p<.001$;

$z_4=4\pm 11\%$, $5\pm 9\%$ respectively, $p<.001$; $z_5=1\pm 5\%$, $2\pm 4\%$ respectively, $p<.001$). Z0 accounted for $2\pm 7\%$ and $9\pm 5\%$ for REP and EXE, respectively ($p<.001$).

CONCLUSION: This works novel finding was that biathlon coaches plan endurance training polarized, favoring z_1 training with a low distribution of z_3 , while the HR response reveals that training is pyramidally performed. This suggests that junior biathletes struggle to maintain HR within a single intensity zone while performing different training modalities on varied terrain. A second finding was that adolescent biathletes perform a substantial part of their training with an HR response lower than what is considered beneficial for training adaptations while still being summarized in the total training volume.

DIFFERENCES IN PERFORMANCE AND PHYSIOLOGICAL VARIABLES BETWEEN ROLLER-SKIING WITH AND WITHOUT RIFLE DURING A SIMULATED BIATHLON COMPETITION.

JONSSON KÅRSTRÖM, M., HORVATH, M., ANDERSSON, E.P., LAAKSONEN, M.S.
SWEDISH WINTER SPORTS RESEARCH CENTRE, MID SWEDEN UNIVERSITY

INTRODUCTION: Biathlon combines cross country skiing and rifle marksmanship, and the athletes need to carry the rifle (mass >3.5 kg) on their back during skiing. Previous research in laboratory settings have shown that physiological variables, i.e. heart rate (HR), oxygen uptake (VO_2), ventilation (VE), breathing frequency (BF), respiratory exchange ratio (RER) and blood lactate concentration (BLa) increases when roller-skiing with rifle (WR) at submaximal workloads compared to roller-skiing without rifle (NR) (1, 2). Roller-skiing performance is also shown to decrease for WR compared to NR during laboratory testing (1). The aim of the study was to investigate the effect of rifle carriage on performance and physiological variables during a simulated biathlon roller-skiing sprint in the field.

METHODS: 20 well-trained tier 3 (3) biathletes (10 women, 10 men; age 22 ± 3 years) completed two biathlon roller-skiing sprints (women 3×2 km; men 3×2.5 km) in the field, one WR and one NR in a randomized order, separated by 30 minutes of active rest. After each lap, the athlete stopped for 30–45 s (normal shooting time) for measurement of BLa and rating of perceived exertion (RPE, 6–20). Respiratory variables and HR were measured throughout the sprints. A two-way repeated measurements ANOVA (two conditions (WR/NR) $\times$ three laps) was used to compare performance and physiological variables between conditions. During the stops, WR and NR was compared using paired samples t-test. Wilcoxon Signed Rank test was used if data was non-normally distributed. Data are presented as mean $\pm$ SD, except for RPE (presented as median (IQR)).

RESULTS: Mean roller-skiing speed for the race was 0.20 m/s slower for WR compared to NR (5.5 ± 0.5 vs. 5.7 ± 0.5 m/s, $p<0.001$). The time loss during WR was 13.5 ± 14.6 , 12.2 ± 8.7 and 16.9 ± 9.6 s for laps 1, 2, and 3, respectively. No difference between WR and NR in mean HR, VO_2 , VE, BF, RER or BLa was found for any of the skiing laps (all $p>0.05$). However, RPE, mean VO_2 , VE and BF during the second stop (simulating standing shooting) was higher for WR compared to NR (RPE 18 (I) vs 17 (I), $p = 0.008$; VO_2 40 ± 5 vs 37 ± 4 ml/kg/min, $p=0.006$; VE 99 ± 23 vs 92 ± 18 L/min, $p=0.031$; BF 52 ± 6 vs. 48 ± 4 breaths/min, $p=0.005$) with no difference in the duration of the stop ($p>0.05$).

CONCLUSION: Unlike previous laboratory studies, this field-based study demonstrates that respiratory variables, HR and BLa were similar for WR and NR during roller-skiing, despite the higher skiing speed for NR during all the three laps. However, respiratory variables and RPE were higher during the second stop for WR, which may impact shooting performance. To replicate competition demands, biathletes are advised to carry their rifle during high-intensity training sessions that include shooting.

CP-AP14 Coaching and Training in Youth Athletes

THE IMPACT OF FOOTBALL COACHES FEEDBACK ON PSYCHOLOGICAL VARIABLES AMONG YOUNG FOOTBALL PLAYERS – AN INTERVENTION STUDY

LAGESTAD, P., BERNTZEN, I.
NORD UNIVERSITY

INTRODUCTION: The purpose of this study was to examine how feedback from the coach influences young football players' experience of well-being, mastery, pleasure, satisfaction, development, joy, and motivation.

METHODS: The study used an intervention with a crossover experimental approach, where 95 boys that participated in sports clubs and specialization in football classes, participated in the same organized training session with the same coach in every session – one without feedback and one with feedback from the coach, answering a questionnaire after

each training session. Wilcoxon nonparametric tests were used to examine differences between the training session without and the session with feedback among players at the two groups at each variable.

RESULTS: Analyzing all players, the results showed that when feedback was given, it led to a significant increase in mastery, the experience of being seen by the coach, and motivation, compared to the same training session when they did not receive feedback. Furthermore, analyzing only players who participated in sports studies with a specialization in football, the results showed that giving feedback led to a significant increase in well-being, pleasure, satisfaction, and development. Finally, analyzing only players who participated in sports teams and did not specialize in football in sports programs, showed that when feedback was given, it led to a significant increase in the experience of development, the experience of being noticed by the coach, and motivation, compared to the same training session when they did not receive feedback.

CONCLUSION: The findings suggest that football coaches' feedback has a positive outcome for several psychological factors of young players, and especially players that participate in football classes at school experience positive outcomes from coaches' feedback. The findings of the study highlight the importance of football coaches' feedback.

PHYSICAL SUPERIORITY IN FOOTBALL. AN ANALYSIS OF THE SYSTEMATIC DEVELOPMENT OF CONDITIONAL ABILITIES AND THEIR CHALLENGES IN AUSTRIAS FOOTBALL YOUTH ACADEMIES

MADERBACHER, A.

GRAZER ATHLETIKSPORT KLUB 1902

INTRODUCTION: This study analyzes the systematic development of physical abilities in Austrian youth football. It highlights the use of training methods and resources as well as the challenges that influence the transition from youth to professional levels. The results provide valuable insights into the prioritization of conditional abilities and identify technical and organizational barriers that could hinder the development of future national players.

METHODS: Through a quantitative survey conducted among all 15 sports science heads responsible for the Austrian football academies certified by the Austrian Football Association (as of February 2024), both the significance and the organizational aspects of implementing strength, speed, and endurance training in training operations were queried. A total of 60% of all distributed questionnaires were included in the actual analysis (9 out of 15 sports science directors).

The same survey was also sent to the heads of sports science at the newly established youth performance centers (NLZ) for the 2023/24 season. However, due to the low response rate (22.2%), they were excluded from further analyses due to the lack of representativeness.

RESULTS: The results showed, among other things, a very high or high acceptance and prioritization of strength and speed training in the weekly training operations, but less priority was given to inclusive endurance training. A negative opinion of the sports science directors was detected regarding the permeability between youth and professional levels. The greatest performance differentiating factor between academy players and players from the professional level was identified as technical and tactical skills, which could also explain the below-average permeability in the clubs.

CONCLUSION: The results of the present study highlight the strengths of the Austrian academy system in physical preparation, but also reveal weaknesses that could hinder the development of future national players. To enhance the permeability and quality of youth training, the following measures should be prioritized:

1. Optimization of training scheduling: Coordination of morning strength training and football training on the same day
2. Promotion of running technique: Early and structured integration of running technique sessions for ages 10–14.
3. Focus on aerobic endurance: Increased integration of aerobic training session
4. Systematics integration of youth and professional divisions
5. Personnel and infrastructure resources: Strengthening scientific and medical departments through targeted investments

RESEARCH ON JUNIOR COACHING IN SPEED SKATING COMPETITION

ISHINO, E., YAMAGUCHI, K.

UNIVERSITY OF TSUKUBA

INTRODUCTION: Various athlete development programs have been announced for the coaching of junior athletes, and their importance has been highlighted by being implemented in many countries and competitions. In speed skating, the strong countries of the Netherlands and Canada have established their own athlete development programs (1) (2), which indicate training hours and goals according to the age of the athletes. Development programs for speed skating have also been proposed in Japan, but it is unclear what kind of coaching coaches actually provide. Therefore, the purpose of this study was to clarify the actual situation of coaching junior speed skaters in Japan and to help improve Japan's competitive performance.

METHODS: A questionnaire survey was conducted targeting coaches involved in speed skating teams for elementary, junior high, and high school students in each prefecture, asking about the purpose of coaching and the importance of on-ice training content.

RESULTS: Comparisons between the three groups were made by dividing the instructors into the three counties of elementary school students, junior high school students, and high school students according to the target group of instruction.

When looking at the goals of the three groups by subject of instruction, significant differences were found in items such as "enjoying skating" ($p=0.016$), "competing in international competitions" ($p<0.001$), and "self-development through skating" ($p=0.002$).

Importance of ice training, the items that showed significant differences were "course positioning" ($p=0.005$).

CONCLUSION: Coaching objectives were generally consistent with the indicators of strong countries in all age groups. However, elementary school students tended to seek "winning the competition" more than junior high school students, indicating that the objectives of elementary school coaches need to be carefully monitored to avoid placing excessive emphasis on competition.

Regarding the importance of ice training, a study on the track and speed of middle and long distance events in international competitions reported that the track position increases the skating distance and also affects the record (3). This is thought to be the result of strategic skating instruction being given to high school students who are becoming increasingly specialized. Given the above, in order to improve Japan's competitiveness, it is necessary to provide clear indicators for coaching methods and seek a common understanding of future directions.

THE EFFECT OF BIOLOGICAL AGE ON SELECTED COMPONENTS OF GAME PERFORMANCE IN YOUTH FOOTBALL PLAYERS

GROBAR, M.

CHARLES UNIVERSITY

INTRODUCTION: Biological maturation significantly impacts the physical performance of youth soccer players. This study aimed to investigate the influence of biological age on selected performance factors—including anthropometric characteristics, speed, agility, explosive power, and football-specific skills—among players at different stages of maturation.

METHODS: A total of 72 youth soccer players (aged 11–15) were divided into three groups based on their biological age, as determined by the TW-3 method using a DXA hand scan: accelerated (AKC, $n = 10$), on-time (ONT, $n = 45$), and delayed (DEL, $n = 17$). Eighteen variables were collected for each participant, including decimal age, biological age, height, weight, body fat percentage, sprint times (over 10 m and 20 m), agility tests (Illinois and DBF agility), jump performance (CMJ jump height and CMJ_Fpeak), football-specific skills (LPST passing and DBF dribbling tests), and coach evaluations of game and training performance. One-way ANOVAs with Bonferroni-adjusted LSD post-hoc comparisons were used to identify group differences. Additionally, Pearson and Spearman correlation analyses were conducted to explore the relationships among the variables.

RESULTS: While chronological age did not differ significantly between groups, the AKC group demonstrated a significantly higher biological age (15.49 ± 0.93 years) compared to the ONT (13.15 ± 1.19 years) and DEL groups (11.64 ± 1.02 years; $p < 0.001$, $\eta^2_p = 0.52$). In addition, AKC athletes were taller and heavier, with lower body fat percentages than their counterparts ($p < 0.001$). Performance assessments revealed that the AKC group achieved faster sprint times over 10 m and 20 m ($p < 0.001$) and superior agility in both the Illinois ($p = 0.003$) and DBF agility tests ($p = 0.007$). Moreover, AKC athletes demonstrated greater countermovement jump height and peak force ($p < 0.001$), although no significant differences were found when peak force was normalized by body weight. No group differences were observed in football-specific skills (LPST, DBF dribbling), endurance tests, or head coach evaluations.

Biological age was very strongly positively correlated with key anthropometric measures, including body height ($r = 0.850$, $p < 0.001$) and body weight ($r = 0.876$, $p < 0.001$), and significantly negatively correlated with body fat percentage ($r = -0.598$, $p < 0.001$), indicating that higher biological maturity was associated with a leaner body composition. In performance tests, higher biological age was linked to faster sprint times over 10 m ($r = -0.440$, $p < 0.001$) and 20 m ($r = -0.550$, $p < 0.001$), as well as better performance in the Illinois agility test ($r = -0.596$, $p < 0.001$). Additionally, biological age was positively correlated with countermovement jump performance, as indicated by associations with CMJ jump height ($r = 0.587$, $p < 0.001$) and peak force ($r = 0.835$, $p < 0.001$). Furthermore, higher body fat percentage was significantly associated with poorer performance in sprint and jump tests (e.g., $r = 0.520$ with 10 m sprint time and $r = -0.631$ with CMJ jump height; $p < 0.001$). Game and training performance ratings provided by the head coach were also strongly interrelated ($r = 0.941$, $p < 0.001$).

CONCLUSION: The findings indicate that biological maturation is a critical determinant of physical performance in youth football players. Players with accelerated maturation not only exhibit favorable anthropometric characteristics but also demonstrate enhanced speed, agility, and explosive power. These results underscore the importance of considering biological age in training programs and talent identification processes. Tailoring training to account for maturational differences may optimize performance development and enhance long-term athletic potential.

EXTERNAL TRAINING LOAD AND RATING OF PERCEIVED EXERTION COMPARISON BETWEEN TENNIS DRILLS IN ELITE JUNIOR TENNIS PLAYERS

TÓTH, P., CSÁKI, I., NÉGYESI, J., DOBOS, K., ÖKRÖS, CS.

HUNGARIAN UNIVERSITY OF SPORTS SCIENCE

INTRODUCTION: Professional and elite junior tennis players' competitions are often closely scheduled, leaving coaches with limited time to focus on developing technical, tactical, and physical skills. As a result, coaches tend to prioritize integrated on-court training sessions where technical and tactical training, along with match-specific conditioning, can coincide. To ensure players receive the most specific training load relative to the match, monitoring both the external and internal training loads of individual training exercises is necessary. Therefore, our study aimed to compare the external training load of various tennis drills with the rating of perceived exertion (RPE) in elite junior tennis players.

METHODS: Sixteen junior male tennis players (age: 16.0 ± 1.1 years; height: 179.2 ± 9.9 cm; mass: 67.0 ± 10.4 kg) from the same club participated in the study, performing seven types of tennis drills. To determine the external training load, seven parameters were measured in relative values using portable micro-sensors (Catapult Vector S7, Catapult Sports, Melbourne, Australia) at a sampling frequency of 10 Hz for the GNSS and 100 Hz for the tri-axial accelerometers. We also assessed the players' RPE using Borgs CR-10 scale after each drill. Differences between the tennis drills were analyzed using the nonparametric Kruskal-Wallis test with planned Bonferroni correction for post-hoc analyses. The significance level was set at $p < 0.05$.

RESULTS: There was a significant main effect for seven load parameters with the post-hoc analyses revealing difference in the Player Load/min variable between the 2-on-1 open and 2-on-1 net play ($U = 46.000$; $Z = -3.091$; $p = 0.002$; $r = 0.77$), as well as between the Recovery/Defensive and Accuracy ($U = 53.000$; $Z = -2.827$; $p = 0.005$; $r = 0.71$) drills. In the IMA Acceleration High/min variable, a significant difference was also found between the 2-on-1 open and 2-on-1 net play ($U = 35.500$; $Z = -3.487$; $p < 0.001$; $r = 0.87$), and between the Recovery/Defensive and Accuracy ($U = 24.000$; $Z = -3.920$; $p < 0.001$; $r = 0.98$) exercises. Additionally, there was a significant difference in the RPE between the 2-on-1 open and 2-on-1 net play ($U = 53.000$; $Z = -2.897$; $p = 0.004$; $r = 0.72$), and between the Open pattern and Closed technical ($U = 10.500$; $Z = -4.585$; $p < 0.001$; $r = 1.15$) tennis drills.

CONCLUSION: Overall, the results indicate that the defensive situation and shot accuracy types of tennis exercises are the most intense in terms of external training load, as the players performed more accelerations during these drills. In terms of RPE, the closed drills with coach feeding were found to be the most intense. Based on the load values of the tennis drill types obtained here, coaches can more objectively periodize the players preparation for a specific tournament.

IDENTIFICATION OF KEY PERFORMANCE INDICATORS TO DEVELOP A PERFORMANCE DIAGNOSTICS FRAMEWORK FOR BREAKING

FREITAG, N., LINDNER, S.A., NEHER, A., KELLER, T., LEGERLOTZ, K., BOEHLKE, N.

OLYMPIC TRAINING CENTRE BERLIN

INTRODUCTION: With breaking entering the Olympic stage, training science has increasingly focused on its physiological and biomechanical aspects. While most studies address injury prevalence, research on key performance indicators remains limited. This study assessed anthropometric and performance-relevant characteristics across different performance levels in German breakers, using a comprehensive diagnostic approach to identify key performance indicators for developing a performance testing framework.

METHODS: A total of 74 breaking athletes (females: $n = 21$; males: $n = 53$ males) participated. Anthropometric measures included height (standing/seated), body mass, limb lengths, age, and breaking experience. Performance tests comprised countermovement jump (CMJ), drop jump (DJ), grip strength, isometric mid-thigh pull (IMTP), pull-ups, T-agility test, and Y-Balance test (YBT). Based on national qualification status, athletes were categorized as elite (females: $n = 6$; males: $n = 7$), youth (females: $n = 10$; males: $n = 29$), or recreational (females: $n = 5$; males: $n = 16$).

RESULTS: Due to the non-normal data distribution, a Kruskal-Wallis test was used for group comparisons, considering sex differences. Elite breakers had significantly more breaking experience than youth (13.2 ± 5.0 yrs vs. 8.5 ± 4.8 yrs; $p = 0.013$) and recreational athletes (8.4 ± 4.4 yrs; $p = 0.025$). They were also shorter than recreational athletes (167.6 ± 6.2 cm vs. 173.7 ± 10.0 cm; $p = 0.041$) and had a lower seated height (88.6 ± 3.4 cm vs. 91.7 ± 6.1 cm; $p = 0.04$). No significant differences were observed in body mass, limb lengths, CMJ, IMTP, T-agility test, pull-ups and grip strength. However, elite breakers showed significantly shorter ground contact time in the drop jump (179.5 ± 29.7 ms) than youth athletes (251.8 ± 88.4 ms; $p = 0.03$), though the difference was not significant compared to recreational athletes (225.8 ± 70.4 ms). Sex-specific differences in balance were identified in males ($p = 0.049$) but not in females: elite male breakers performed significantly better compared to youth and recreational breakers in YBT upper extremity and lower extremity (right leg).

CONCLUSION: Our findings suggest that elite breakers of both sexes primarily differ from their less experienced counterparts in training history, anthropometric characteristics, and in performance during reactive jumps, while YBT performance differed in males only. However, most of the applied conventional athletic tests did not identify differences between groups, indicating that those may have limited validity in capturing the specific demands of breaking. Unlike traditional sports, breaking integrates physiological performance with artistic expression, requiring complex movement patterns, creativity, and rhythmic coordination. Given the lack of training science concepts for this competitive sport and a dance genre, future research should focus on developing breaking-specific diagnostic tools that integrate both physiological and artistic performance factors.

THE EFFECT OF ACUTE MULTIPLE SET COMPLEX TRAINING WITH DIFFERENT INTENSITIES ON JUMP PERFORMANCE IN TRAINED WOMEN

SÖNMEZ, Ç., KÖSE, G., AYTAÇ, T., KIN ISLER, A.

GRADUATE SCHOOL OF HEALTH SCIENCES

INTRODUCTION: Contrast training (CT) involves resistance exercises of maximal or high intensity before performing a lighter resistance plyometric movement with similar biomechanical properties. The aim of this study was to investigate the effect of different intensities of acute multiset CT on jump performance in trained women

METHODS: Fourteen volunteer woman athletes (age= 25.2 ± 5.2 years) with a regular menstrual cycle (26.1 ± 1.8 days) and experience in strength and plyometric training (3.79 ± 1.57 years) were randomised to 2 different intensities (90% 1RM - 65% 1RM) at the same time of day (15:30-17:00 h), with 48 hours interval, during the late follicular phase of their menstrual cycle (days 7-12). CT was performed in three sets, consisting of three repetitions of back squat exercise at the specified intensity, followed by three Counter Movement Jump (CMJ) as an explosive exercise. Participants performed 2 CMJ before CT, and the acute effect of 2 different intensities of CT on jump performance was assessed with CMJ tests repeated at the 1st and 3rd minutes after 3 sets of CT. Data were analysed using a 2x3 (intensity x time) repeated measures two-way ANOVA

RESULTS: ANOVA analysis showed that the effect of intensity ($F(1,13) = 3.230$, $p = 0.096$, $\eta^2 = 0.199$) and the interaction between intensity and time ($F(2,12) = 1.088$, $p = 0.344$, $\eta^2 = 0.077$) were not statistically significant. However, the effect of time on jump performance was statistically significant ($F(2,12) = 4.638$, $p = 0.024$, $\eta^2 = 0.263$). The jump height was lower than the reference value at 1 min after the CT ($p = 0.027$), whereas at 3rd mins, it was similar with the reference value ($p = 0.282$)

CONCLUSION: The study found no significant difference in the jump performance of woman athletes after CT, regardless of the intensity

IMPACT OF EXHAUSTIVE EXERCISE WITH A HIGH ECCENTRIC COMPONENT ON STRENGTH, SPRINT PERFORMANCE, AND MUSCLE PAIN IN YOUNG MEN AND WOMEN

DE NIGRIS, E., HERNANDEZ-BELMONTE, A.2, GARCIA-PEREZ, G.1, GARCIA-GONZALEZ, E.1, GALVAN-ALVAREZ, V.1,3, MARTINEZ-CANTON, M.1, VAL BISPO, D.1, GIL-RODRIGUEZ, G.1, ALMEIDA-RAMOS, F.1, MARTIN-RINCON, M.1, CALBET, J.A.L.1,4,5

1 IUIBS AND ULPGC, SPAIN 2 UNIV. MURCIA, SPAIN 3 UNIV. FERNANDO PESSOA CANARIAS, SPAIN 4 SCHOOL OF KINESIOLOGY, UBC, CANADA

INTRODUCTION: Muscle fatigue and soreness often occur after high-intensity exercise, particularly when eccentric contractions are involved. Women (W) show lower fatigability in low-intensity isometric tasks, but this advantage fades at higher intensities. In dynamic contractions, W fatigue less than men (M), yet may experience greater power loss in high-load eccentric tasks. Pedalling cadence influences muscle fiber recruitment, yet its impact on performance and fatigue across sexes remains unclear. W may exhibit less muscle pain and recover faster due to oestrogen effects. This study examines sex-based differences in muscle strength, pain perception and sprinting capacity across different cadences during recovery before and after a fatiguing protocol with a strong eccentric component (FP). We hypothesise that M will experience greater muscle pain, while W will exhibit a reduced loss in strength and sprint performance.

METHODS: Eighteen young active participants (9M/9W) completed a familiarisation and DXA evaluation. Pre-testing included 1RM (bench press (BP) & squat (SQ)), sprint capacity test (SpC) (6x6s sprints, 24s recovery at 80 and 110rpm) and two 30s Wingate (WG) with 20s occlusion in between, 5 min between tests. The automated constant leg pressure device (CLPD) and a visual analogue scale assessed pain. The FP included 5 sets of BP (105% 1RM, eccentric-only) & SQ to failure (5 sets: 80-60% 1RM), 120 drop jumps, and repeated cycling sprints. Post-testing was performed 24h (pain and strength) and 48h (pain, strength and SpC) after FP.

RESULTS: Muscle pain increased at 24-48h post-exercise, more in W than M, particularly in chest and legs ($p < .05$). In both sexes 1RM-strength declined (SQ: 16.3% at 24h, 12.1% at 48h; BP: 22.7% at 24h, 18.8% at 48h). M had higher baseline PPO and MPO (+11 and 9.8%) in Watts/kg-leg lean mass (W/kg-LLM) during the SpC than W ($p < .05$). At 48h, PPO (7.2%) and MPO (5.7%) were reduced ($p > 0.05$), regardless of sex. At baseline, PPO during WG1 was higher in men ($p = .047$), with a performance loss of 42% in WG2 ($P < .001$). At 48h, PPO in WG1 was decreased by 2.5% in M and 9.4% in W, while in WG2, it increased 9.2% in M and decreased 2.1% in W. This led to a PPO drop only in W (6.7%, Time $\times$ Sex interaction $P = .072$). This trend disappeared when adjusting for baseline fitness (1RM/LLM, PPO/LLM, MPO/LLM) as covariates. Higher pedalling cadence (110rpm) resulted in superior MPO compared to 80rpm ($\sim 6.2\%$, $p = .006$).

CONCLUSION: Both sexes showed significant declines in strength and SpC after a FP, with W reporting greater muscle pain and a larger WG performance loss, likely due to a lower anaerobic capacity per unit of muscle at baseline. Higher cadence allowed for a greater MPO pre- and post- FP. These findings suggest that sex-specific muscle traits influence recovery patterns, warranting further research into underlying physiological mechanisms.

GREATER TRAINING LOADS DO NOT EQUATE TO SUPERIOR PERFORMANCE: RETHINKING WORKLOAD AND ADAPTATION IN RODENT MODELS

SILVA, A., MACÁRIO, A., DE MORAES, C.
UNIVERSITY OF SAO PAULO

INTRODUCTION: Despite the well-established use of progressive training overload (PTO) and total load (TL), training monitoring and other training principles are often overlooked in animal model research, creating a gap in understanding their potential impact on performance outcomes and translational effects. This study investigates whether greater training loads equate to superior performance while also considering training monitoring metrics such as Training Monotony (TM) and internal TL.

METHODS: 70-day-old male Sprague-Dawley rats were assigned to 3 groups: Sedentary (SED, n=10), Continuous Training (CTR, n=13), or Interval Training (ITR, n=9). All animals underwent a 1-week treadmill familiarization. CTR and ITR trained 3x/week for 4 weeks. External TL was set at 34,200 arbitrary units (AU) for CTR and 16,950 AU for ITR. PTO was applied biweekly with a 22% and 18% AU increment for CTR and 15% and 13% AU increment for ITR. Running sessions: CTR—40 min at low-intensity; ITR—18 min (3 cycles of 2-min moderate-intensity + 4-min low-intensity recovery). Performance was assessed post-familiarization (week 0), at week 2, and at week 4, using external work (EW), calculated in Joules [2]. Training monitoring was conducted via lactate-based TRIMP (TRIMPLac) for internal TL at weeks 1 and 3. TM remained constant at 1.24 AU in both training groups [3]. The statistical analysis was performed using a mixed linear model to assess time and group effects on EW and TRIMPLac. The time×group interaction was explored via post hoc comparisons (Bonferroni correction). The effect size was estimated using Cohen's d. Statistical significance was set at $p < 0.05$.

RESULTS: CTR and ITR groups improved EW compared to the baseline and the SED group. A significant main effect of time was observed ($B=12.84$, 95% CI: 9.21–16.47, $p < 0.001$); indicating an overall enhancement in performance. Post hoc comparisons confirmed significant improvements in performance for CTR ($\Delta=23.6\%$, $p < 0.001$) and ITR ($\Delta=19.8\%$, $p < 0.001$) from baseline to post-intervention. The effect size for training was large (CTR: $d=1.74$; ITR: $d=1.61$), reinforcing the efficacy of the interventions. No significant EW difference was found between CTR and ITR ($\Delta=3.8\%$, $p=0.289$), despite external TL in CTR being more than double that of ITR. While TM remained equivalent across groups, TRIMPLac did not differ between CTR and ITR at week 1; however, at week 3, CTR exhibited significantly higher TRIMPLac than ITR ($p < 0.001$).

CONCLUSION: Higher training loads do not necessarily translate into superior performance outcomes. Training adaptations in rodent models are not solely determined by absolute external TL, and might be influenced by additional physiological and methodological factors such as TM and TRIMPLac. These implications highlight the relevance of our research and its potential to shape future studies in the field.

EFFECTS OF DIFFERENT INTER-SET REST DURATIONS ON MUSCLE TONE, STIFFNESS, AND RELAXATION TIME IN ISOINERTIAL BICEPS CURL EXERCISE: A PRELIMINARY STUDY

TROVATO, B., ROGGIO, F., SORTINO, M., MUSUMECI, G.
UNIVERSITY OF CATANIA

INTRODUCTION: Rests interval between resistance training sets is fundamental for performance and recovery. This area of research was already explored for traditional resistance training methods, however its impact on muscle mechanical properties, like tone, stiffness, and relaxation time, still needs more investigation in isoinertial training. The aim of this preliminary study is to investigate how different inter-set rest durations, 60 seconds and 120 seconds, influence these mechanical parameters, e.g. muscle tone, stiffness and relaxation, in an isoinertial biceps curl exercise.

METHODS: A total of 24 physically active males, aged between 18 and 30, were enrolled in this study and randomly assigned to two groups, each performing three sets of ten maximal effort repetitions of isoinertial biceps curls. One group rested for 60 second between set, while the other rested for 120 seconds between sets. Muscle mechanical properties, tone, stiffness, and relaxation time, were assessed with the MyotonPro device (Myoton AS, Tallinn, Estonia) at four time points: baseline (T0), after the first set (T1), after the second set (T2), and after the third set (T3). The statistical analysis was performed using Python (v. 3.11) and a two-way repeated measures ANOVA with the Tukey HSD post-hoc test was used to analyze the differences between groups.

RESULTS: The two-way ANOVA revealed that the group factor had a significant effect on stiffness ($p = 0.004$), and relaxation ($p = 0.005$), while muscle tone was not significant ($p = 0.179$). The Tukey HSD post-hoc tests revealed that stiffness was significantly higher in the 60 sec group compared to the 120 sec group ($p = 0.003$), and relaxation time was significantly lower in the 60 sec group compared to the 120 sec group ($p = 0.004$).

CONCLUSION: This preliminary study indicate that 60 seconds inter-set rest durations may lead to increased muscle stiffness and reduced relaxation time compared to 120 seconds rest periods during isoinertial biceps curl training. These findings suggest potential differences in the response of the mechanical properties of the muscle regarding the rest time between sets; however, they should be interpreted with caution considering the small sample size. Further researches with larger cohorts and additional physiological assessments are needed to confirm these effects and better understand the implications for isoinertial training optimization.

EFFECTS OF DYNAMIC OR STATIC STRETCHING PERFORMED BEFORE RESISTANCE TRAINING ON TRAINING PERFORMANCE AND STRENGTH GAINS ACROSS 8 WEEKS IN UNTRAINED MEN

FERREIRA-JÚNIOR, J.B.1, SANTINI, R.1, CHAVES, S.F.N.2, VIEIRA, C.A.3

1 FEDERAL INSTITUTE OF SUDESTE OF MINAS GERAIS, CAMPUS RIO POMBA, MG, BRAZIL. 2 FEDERAL UNIVERSITY OF VIÇOSA, VIÇOSA, MG, BRAZIL 3 FEDERAL UNIVERSITY OF GOIÁS, GOIANIA, GO, BRAZIL.

INTRODUCTION: Stretching exercises are often performed before resistance exercise (RE). While static stretching (SS) has been shown to temporarily reduce muscle performance, a recent study suggests that neither SS nor dynamic stretching (DS) performed before RE impairs strength gains in untrained young men (1). Other studies also reported similar strength gains regardless of pre-exercise stretching (2,3). However, no study has examined the chronic effects of SS and DS before RE using a within-between subjects' design. This approach allows for direct comparisons while reducing inter-individual variability, such as genetic and neuromuscular differences. Additionally, the impact of SS and DS on training performance throughout a training period remains unclear, which could help explain the chronic effects of stretching before RE. Thus, it was investigated the chronic effects of DS and SS performed before resistance training on training performance and strength gains over 8 weeks in untrained young men.

METHODS: Twenty-six untrained young men (21.4 ± 2.4 yrs, 72.7 ± 14.9 kg, 179 ± 1 cm) were randomly assigned to one of three groups using a unilateral crossover design: (1) Control group (no training), (2) SS group ($n=13$), where one leg performed 80 s of SS before RE, and (3) DS group ($n=13$), where one leg performed 80 s of DS before RE. In both SS and DS groups, the contralateral leg served as a control (no stretching before RE). The RT protocol consisted of 4 sets of 8-12 repetition maximum (RM) knee flexion exercises, performed twice per week for 8 weeks, with at least 48 h between sessions. Unilateral knee flexor maximal isometric strength (MIS) was measured pre- and post-training. Training volume (repetitions $\times$ load) was recorded in sessions 1, 8, and 16. The control group was used to estimate the Minimal Detectable Change (MDC) for MIS measurements (8.3 kg). MIS data were analyzed using ANCOVA (group $\times$ leg) with pre-training values as covariates, and training load was analyzed using a three-way repeated measures ANOVA (group $\times$ leg $\times$ session) with Tukey's post hoc test ($p < 0.05$).

RESULTS: A significant leg $\times$ group interaction ($p=0.043$) showed a higher training volume in the DS leg (1397 [1595; 1199] kg) compared to its control leg (1296 [1073; 1520] kg, $p=0.047$), with no other differences ($p > 0.05$). Strength gains exceeded the MDC for both SS and DS groups, but no significant group $\times$ leg ($p=0.93$), group ($p=0.19$), or leg effect ($p=0.64$) was found for MIS.

CONCLUSION: Performing 80 s of either SS or DS before resistance training sessions did not affect training-induced muscle strength adaptations in untrained young men, despite a small increase in training volume in the DS group.

FACTORS INFLUENCING STRENGTH AND HYPERTROPHY IN TRAINED COHORTS: A RETROSPECTIVE AND EXPLORATORY ANALYSIS

DE SOUZA, E., ENES, A.2, WADHI, T.3, BARAKAT, C.1, BARRETTI, D.4, SOUZA-JUNIOR, T.P.2, LIBARDI, C.A.5, UGRINOWITSCH, C.4

THE UNIVERSITY OF TAMPA

INTRODUCTION: Determining the resistance-training (RT) variables associated with muscle strength and hypertrophy gains in trained cohorts has challenged the Exercise Science field. Several literature appraisals have been published on the topic, but the large variability between and within RT protocols and muscle strength and hypertrophy assessments hinders the precision of the estimates. A retrospective analysis of multiple studies from the same research group may provide clearer insights into RT-induced strength and hypertrophy gains due to greater standardization in training and assessment procedures. This study conducted secondary statistical analyses of randomized controlled trials (RCTs) to identify key RT variables influencing these adaptations

METHODS: This retrospective study encompassed muscle strength and hypertrophy data from five published RCTs (1,2,3,4,5) and one unpublished study. One hundred seventy-six resistance-trained individuals (146 males and 30 females; 23.7 ± 4.1 years, 4.44 ± 3.06 years of training experience) were analyzed. The following variables from each study were used to determine their impact on muscle strength and hypertrophy gains after RT interventions: one-repetition maximum (1RM): body mass (BM) ratio (1RM:BM) at baseline (2.11 ± 0.54 a.u.), training duration (TD) (9.96 ± 2.00 weeks), pre-intervention weekly set number (PSN) (16.09 ± 8.03 weeks), weekly set number performed during the study (SPS) (19.17 ± 9.40), and total number of sets performed during the study (TSS) (199.7 ± 116.8). Data were obtained from two distinct laboratories using different devices. Then, data were transformed into standard units (i.e., z-values) using each assessment mean and standard deviation. Therefore, the estimates should be interpreted based on standard deviation units (SDUs) from the mean. Linear mixed models were used to determine the variables impacting muscle strength and hypertrophy gains, with variables modeled as continuous variables. The Minimal Detectable Change (MDC) of standard units was calculated using the standard formula $MDC = 1.96 \times SEM \times \sqrt{2}$.

RESULTS: Muscle Strength: The 1RM:BM ratio at baseline (0.58 SDUs, $p < 0.001$) and PSN (0.02 SDUs, $p = 0.03$) were significant. However, only the 1RM:BM estimate surpassed the MDC (0.20 SDUs). Muscle Hypertrophy: TD (-0.39 SDUs, $p = 0.046$), TSS (0.01 SDUs, $p = 0.035$) were significant. Nevertheless, only the TD surpassed the MDC (0.21 SDUs).

CONCLUSION: While some parameters were statistically significant, the estimates did not surpass the MDC, indicating that their effects may not be practically meaningful. Notably, the 1RM:BM ratio at baseline exceeded the MDC for strength gains, suggesting its potential relevance in trained individuals. Additionally, the negative estimate for TD exceeded the MDC for muscle size, suggesting a potential diminishing return.

EFFECT OF FLYWHEEL SQUAT TRAINING LOAD MAGNITUDE ON SPRINT, AGILITY, AND JUMP PERFORMANCE ADAPTATIONS

SPUDIC, D., ŠARABON, N., PORI, P., STROJNIK, V., ŠTIRN, I.

UNIVERSITY OF LJUBLJANA, FACULTY OF SPORT

INTRODUCTION: Neuromuscular adaptations are known to be velocity-specific [1]. However, research confirming this assumption for flywheel (FW) resistance training is limited. The specificity of FW loading complicates its quantification. The force-velocity-power (FvP) profiling method has been previously suggested as a way to individually determine the magnitude of FW load [2]. Therefore, the aim of our study was to evaluate differences in adaptations in sprinting, agility, and jumping performance following FW squat resistance training under low and high loading conditions, as well as to assess delayed onset muscle soreness (DOMS), fatigue, and well-being responses over time.

METHODS: Physical education students were randomly assigned to two training groups and a control group. The training groups engaged in 8 weeks of FW squat resistance training, 2-3 times per week. Load magnitudes for training groups were defined based on FvP profiles obtained during FW squats prior to the intervention. The low-load group (LL; $n = 16$) trained at the peak power FW-load, while the high-load group (HL; $n = 18$) used a load corresponding to 70% of peak power FW-load condition. The control group ($n = 13$) did not undergo any training. Pre- and post-intervention FW squat mechanical variables were assessed at peak power and 70% peak power FW-load magnitudes for both groups to assess load specific training adaptations. Additionally, various physical performance tests were conducted, including sprints with 5-, 10-, 20-, and 30-meter split times, agility T-test, and squat jump (SJ), counter-movement jump (CMJ), and drop jump (DJ). Before each session, participants reported leg muscle DOMS, fatigue, and well-being.

RESULTS: Paired samples t-test showed that both training groups improved significantly in most FW squat-related mechanical variables, including concentric and eccentric force, velocity, and power across both peak power load and 70% peak power load testing conditions. Both training groups demonstrated enhanced CMJ and agility performance, while SJ improved only in the HL group, and DJ and 10-m sprint time only in the LL group. DOMS (from 3.6 to 1.6) and overall fatigue (from 4.2 to 2.2) decreased while reported well-being increased (from 8.1 to 9.4) from the first to the last session. Analysis of covariance revealed no differences in adaptations over time between the two training groups ($p > 0.05$).

CONCLUSION: FW squat resistance training proved to be an effective modality for enhancing both concentric and eccentric leg strength and power during squatting. Additionally, it led to improvements in SJ, CMJ, DJ, agility, and sprint acceleration performance in athlete students. Interestingly, the FW training load did not affect discomfort, and no load-specific adaptations were observed. These findings suggest that similar performance enhancements can be expected regardless of the selected FW load following 22 sessions of FW squat resistance training.

SLEEP DURATION DOES NOT AFFECT RESISTANCE TRAINING-INDUCED STRENGTH GAINS

CARY, P., CANOY, L., SANZO, K., DIMICELI, S., MUNDOK, E., RAUCCI, J., YAMEEN, N., SEUNATH, D., CLARK, L., SHINE, T., SMALL, J., KOUREMENOS, K., ALIAS, T., UGRINOWITSCH, C., DE SOUZA, E.O.

THE UNIVERSITY OF TAMPA

INTRODUCTION: It is advocated that sleep duration may affect resistance training-induced strength gains. Theoretically, short-sleepers (i.e., < 360 min per night) should have lower strength gains than regular-sleepers (> 360 min per night). On the other hand, evidence suggests that a higher training volume (i.e., number of sets) may mitigate the negative effects of a short sleeping pattern on strength gains. Thus, our study aimed to determine if total sleep time, number of awake periods during the night, and differences in RT volume may affect RT-induced strength gains.

METHODS: Twenty-five untrained college students (20 females and 5 males) volunteered to participate in the study (mean $\pm$ standard deviation [SD]—age: 20.0 ± 2.0 years, body mass: 61.6 ± 18.9 kg). Total sleep time (TST) and wake after sleep onset (WASO) were assessed over seven days at pre-training via wrist-worn actigraphy. The one-repetition maximum (1RM) load was assessed using a leg extension pin-loaded machine (Body-Solid; DLEC-SF, Forest Park, IL) at pre- and post-training by researchers blinded to sleep patterns. Classification of participants into short- and regular-sleepers was performed non-randomly at post-training for blinding purposes (i.e., a non-randomized controlled trial). Participants' lower limbs were randomly assigned to low- and high-RT volume conditions (1 set vs. 3 sets per exercise [leg press and knee extension], respectively—i.e., within-subject design) and trained for eight weeks, twice a week, under the supervision of researchers blinded to sleep patterns. General linear models were used to compare changes in muscle strength from pre- to post-training and delta change in muscle strength between the low- and high-RT volume limbs.

RESULTS: Means and SD for TST and WASO were 442.0 ± 63.4 min and 32.3 ± 2.32 times per night, respectively. As our sample had only 3 short and 22 regular sleepers, TST and WASO were modeled as covariates instead of a fixed effect. Covariates TST and WASO did not change the interpretation of our findings, and they were removed from the statistical models. Both the lower-volume and the high-volume limbs presented significant increase in the 1RM values from pre- to post-training (Low volume: Pre: 75.20 ± 23.47 and Post: 91.43 ± 27.98 kg; $p=0.038$; High volume: Pre: 74.80 ± 22.57 and Post: 94.29 ± 26.57 kg; $p=0.01$, respectively). The comparison of the delta changes in muscle strength between the low- and high-volume limbs showed no difference between short- and regular-sleepers ($p=0.32$).

CONCLUSION: College students with no previous experience in RT demonstrate sleep patterns that do not appear to affect RT-induced strength gains. Additionally, a higher training volume does not seem to have positive effects on maximum strength for this cohort.

CP-AP22 Basketball

LANE AGILITY TEST DISCRIMINATES CHANGE-OF-DIRECTION SPEED BETWEEN PLAYING STANDARDS AND POSITIONS IN BASKETBALL PLAYERS

STOJANOVIC, E., RADOVANOVIC, D.

UNIVERSITY OF KRAGUJEVAC

INTRODUCTION: Although the Lane Agility Test (LAT) has been widely used for assessing change-of-direction speed in basketball, its ability to evaluate and discriminate players competing at different standards and positions is unknown [1]. The aim of this study was to compare change-of-direction speed in male basketball players according to playing standards and positions determined using the LAT.

METHODS: This study adopted a cross-sectional, descriptive research design, where data collected from highly trained adolescent basketball players ($n = 53$; age: 17.3 ± 1.0 years; height: 185.0 ± 7.8 cm; body mass: 78.3 ± 10.7 kg) and participants in the 2024 NBA Draft Combine ($n = 77$; age: 21.4 ± 1.6 years; height: 198.9 ± 8.7 cm; body mass: 96.2 ± 9.9 kg) were grouped and compared based on playing standards and positions (backcourt: $n = 54$; age: 19.1 ± 2.5 years; height: 184.9 ± 7.0 cm; body mass: 79.4 ± 10.1 kg; frontcourt: $n = 76$; age: 20.1 ± 2.4 years; height: 199.1 ± 9.0 cm; body mass: 95.7 ± 11.4 kg). Generalized linear model was performed on the LAT values, while using playing standard and position as predictors.

RESULTS: According to the generalized linear model, both predictors, playing standard ($p = 0.046$, Wald $\chi^2 = 3.977$) and playing position ($p = 0.001$, Wald $\chi^2 = 10.783$), had a significant main effect on the time in the LAT. Data collected at the NBA Draft Combine (compared to highly trained adolescents) and from backcourt positions (compared to frontcourt) accounted for -0.389 seconds (95% CI: -0.682 to -0.097) and -0.533 seconds (95% CI: -0.860 to -0.206) faster LAT times, respectively.

CONCLUSION: Our findings suggest basketball researchers and practitioners may use the LAT to confidently assess and discriminate change-of-direction speed between male players competing at different standards and positions.

INTERNAL TRAINING LOAD IN COLLEGIATE WOMEN'S BASKETBALL: DESCRIPTIVE ANALYSIS OF THE EFFECT OF A CONGESTED TWO-WEEK MICROCYCLE

MEHTA, P., SMALL, J., SEUNATH, D., ANDERSEN, J.

THE UNIVERSITY OF TAMPA

INTRODUCTION: Basketball requires high-intensity efforts across various parameters. Collegiate seasons often expose players to congested schedules with multiple games per week. Internal training load (ITL) reflects physiological stress experienced by the players during practices and games [1]. Investigating the impact of differing game schedules such as a 3-game week vs. 2-game week could provide insight on variation of ITL. ITL distribution between practice and games could further assist planning to optimize players' readiness for games [1]. While external training load has been studied well, we are unaware of research on ITL using modified summated heart rate zones (SHRZ) in collegiate women's basketball. SHRZ quantifies ITL by accounting for time spent at different heart rate intensities [2]. Our aim was to examine how a congested two-week microcycle affects ITL distribution between practices and games and the overall weekly demands in collegiate women's basketball.

METHODS: A two-week microcycle with three games and three practices in week 1 (W1), and two games and four practices in week 2 (W2) was monitored. Players who played ≥ 10 live minutes in each game of the microcycle were included. Four players with mean age 22.75 ± 0.5 years and mean height 180.97 ± 8.89 cm met the criteria. Catapult S7 sensors (indoor mode) and Openfield Console 3.13.0 captured heart rates which were exported in 1-minute epochs into Microsoft

Excel. SHRZ involves calculating heart rate bands in 2.5% increments of maximum heart rate (HRmax) (starting from 50% HRmax), assigning each band a weighting factor which was multiplied by the time spent in that band and finally summed to get absolute SHRZ (aSHRZ) in arbitrary units (AU) (2). HRmax for each player was the maximum heart rate observed from preseason to the end of the microcycle. We identified that 7 observations were missing for 3 players. The mean of the data from the remaining days in the microcycle was used for imputation. Descriptive statistics were calculated using Jamovi 2.6.17.

RESULTS: The mean aSHRZ for W1 (3-game week) was 247 ± 110 AU and W2 (2-game week) was 217 ± 86 AU. W1 practices averaged 185 ± 47.2 AU and games averaged 308 ± 121 AU. W2 had practices averaging at 201 ± 69.7 and games at 297 ± 83.1 AU. The total aSHRZ for W1 was 106% of W2. Practices and games were 37.5% and 62.5% of the total aSHRZ in W1. In W2, practices were 57.52% whereas games were at 42.48% of the total aSHRZ.

CONCLUSION: Our study found a slightly higher overall ITL during the 3-game week compared to the 2-game week consistent with previous literature (1). While games had a higher mean aSHRZ than practices in both weeks we observed that the practices in the 2-game week exhibited a higher total aSHRZ than the games. This suggests that strategic scheduling could be implemented to manage ITL, recovery and may improve performance.

CHANGE OF DIRECTION SPEED, SPEED AND CHANGE OF DIRECTION DEFICIT VARIATIONS IN YOUNG BASKETBALL PLAYERS: SEX AND MATURATION COMPARISON

KIN ISLER, A., SALDIRDAK, C., KOSE, M.G.

HACETTEPE UNIVERSITY FACULTY OF SPORT SCIENCES

INTRODUCTION: Change of direction speed (CODS) which has a very important role in basketball performance, is a complex and multidirectional skill that involves planned decelerations and accelerations in different directions¹. On the other hand, change of direction deficit (CODD) is the additional time that one directional change requires when compared to pure linear sprint over an equivalent distance¹. It is also known that for young athletes both sex and maturation are two important factors that affect performance variables throughout growth². Hence the purpose of this study was to determine CODS, speed and CODD variations in young basketball players according to sex and maturation.

METHODS: A total of 181 young basketball players (Females: n=97, Males: n=84) with at least two years of basketball experience constituted the sample of this study. Participants were classified into three groups based on their biological maturation levels determined by their distance from the peak height velocity (PHV) periods as pre-PHV (n=59), circa-PHV (n=46) and post-PHV (n=76). Each participant performed two Y-drill tests (planned) for determination of CODS to both left and right sides and two 10-m sprint tests for determination of speed in random order. CODD was calculated as the difference between best COD performance and 10-m sprint time. To determine the variations in CODS, speed and CODD according to sex and maturation a 2x3 (sex x maturation) two-way ANOVA was applied with Scheffe's post hoc analysis.

RESULTS: Results indicated significant sex ($p=.000$) and maturation effect ($p=.000$) with no significant sex x maturation interaction ($p=.159$) in CODS. Males had faster COD than females and post-PHV was the fastest compared to the other maturation groups. Similarly, in 10-m speed there was significant sex ($p=.000$) and maturation ($p=.000$) effect, while sex x maturation interaction was not significant ($p=.425$). Again males were faster than females and post-PHV group was the fastest compared to other groups. Finally, in CODD no significant sex and maturation effects were found together with sex x maturation interaction ($p>.05$).

CONCLUSION: The findings of this study indicated that sex and biological maturation resulted in significant variations in CODS and speed, whereas these two variables did not affect CODD.

EFFECTS OF KETTLEBELL TRAINING VS. PLYOMETRIC TRAINING ON JUMPING PERFORMANCE IN VOLLEYBALL AND BASKETBALL ATHLETES

KOCH, L., BRANDT, T., HERBER, M., OHLENDORF, D., SCHMIDT, A.

UNIVERSITY OF THE BUNDESWEHR MUNICH

INTRODUCTION: Kettlebell training is a well-established method to increase strength and power and appears to be a promising approach for improving jumping performance in athletes across various sports such as basketball or volleyball. However, there are no studies investigating the effectiveness of kettlebell training compared to conventional plyometric jump training in experienced basketball and volleyball athletes.

METHODS: Forty-nine volleyball and basketball athletes (age: 23 ± 5.2 years) with a minimum of 1 year of training experience, were assigned to one of three groups: a control group (CtrG), a kettlebell training group (KbG), and a plyometric training group (PlyG). Over a 6-week intervention period, KbG and PlyG trained twice per week for 25 minutes under supervision of a coach, with a minimum of 48 hours of rest between sessions. The CtrG was instructed to adhere to their habitual training schedule throughout the intervention period. All participants attended a pre- and post-test. During the test sessions, vertical jump height was assessed using the countermovement jump (CMJ), squat jump (SJ), and drop jump (DJ). Additionally, the reactive strength index (RSI) was determined for the DJ, and maximal force was measured in the

mid-thigh pull (MTP). All tests were conducted on a dual force plate and analyzed via TEMPLO™ software (Contemplas, Kempten, Germany).

RESULTS: Thirty-eight participants completed the study (CtrG: N = 12, KbG: N = 16, PlyG: N = 10). The KbG showed significant improvements in vertical jump height, with increases of 3.9% in the CMJ ($p = .039$), 9.5% in the SJ ($p = .001$), and an 11.1% in the DJ ($p = .002$). The RSI improved significantly by 13.3% ($p = .002$) and maximal force in the MTP by 9.9% ($p = .002$) in the KbG. In the PlyG, maximal force in the MTP improved significantly by 14.6% ($p = .002$). No significant differences were found between pre- and post-test results within the CtrG for any outcome.

CONCLUSION: This study indicated that even as little as 6 weeks of kettlebell training could significantly improve measures of jumping performance and strength in experienced volleyball and basketball athletes. While both plyometric and kettlebell training aimed to develop the ability to rapidly apply force, the improvements in kettlebell training could have benefited from the novelty of the training stimulus, providing additional adaptive potential. In conclusion, kettlebell training could be a valuable alternative to plyometric training, potentially reducing monotony and altering the mechanical stress on joints, tendons, and ligaments through exercise variation, making it an accessible and convenient training method for strength and conditioning professionals.

HIGH-RISK MOVEMENT LEADING TO ANKLE SPRAIN INJURY IN CONTACT TEAM SPORTS: A SYSTEMATIC REVIEW OF VIDEO ANALYSIS STUDIES

BALDAUF, L., WILKE, J.

UNIVERSITÄT BAYREUTH

INTRODUCTION: Ankle sprains count among the most common musculoskeletal injuries, particularly affecting athletes in team sports. Although a plethora of studies have investigated epidemiological aspects, preventive measures, and rehabilitative treatments, the movements leading to injury have not yet been identified. Video-based analyses of injuries sustained during match play enable the extraction of specific data on situational variables. This systematic review summarized the prevalence of different movement patterns performed during the moment of ankle sprain injury in contact team sport athletes.

METHODS: A systematic literature search was conducted using PubMed, Web of Science, SPOLIT, and Google Scholar. We included video analysis studies investigating the movement patterns performed by contact team sport athletes sustaining an ankle sprain. Risk of bias was assessed by means of the QA-SIVAS scale. Meta-analysis of prevalence was used to pool the proportions of the following movement patterns: landing, change of direction (COD), running, shuffle, and step/lunge.

RESULTS: The literature search returned seven eligible studies, collectively examining a total of 534 injuries (480 males, 54 females). Risk of bias was low to moderate, with an average QA-SIVAS score of 71% (range: 50 to 83%). Direct injuries (65%, 95% CI 54-76%, $p < .001$, $I^2 = 80\%$) were more frequent than indirect (22%, 95% CI 14-31%, $p = .01$, $I^2 = 69\%$), and non-contact ankle sprain injuries (15%, 95% CI 10-22%, $p = .01$, $I^2 = 63\%$). The most frequent movement pattern during injury was landing (32%, 95% CI 21-45%, $p < .001$, $I^2 = 86\%$), followed by running (24%, 95% CI 13-36%, $p < .001$, $I^2 = 82\%$), step/lunge (19%, 95% CI 5-38%, $p < .001$, $I^2 = 95$), COD (6%, 95% CI 2-10%, $p = .08$, $I^2 = 55\%$) and shuffle (3%, 95% CI 0-10%, $p < .001$, $I^2 = 79\%$).

CONCLUSION: Jump landing and running are the main high-risk movements associated with ankle sprain injuries. Although most traumas are caused by direct physical contact, athletes, coaches, and therapists should be aware of this finding when designing exercise programs. Additional research investigating specific populations (e.g., recreational vs. professional athletes, youth vs. adult athletes, males vs. females) or sports (e.g., team vs. individual) is warranted.

DYNAMIC POSTURAL STABILITY STRATEGIES IN FEMALE ATHLETES DURING CONSECUTIVE LATERAL LANDINGS WITH DUAL-TASK

CHANG, C., HUNG, M., YU, C., LIN, J.

NATIONAL TAIWAN UNIVERSITY OF SPORT

INTRODUCTION: Anterior cruciate ligament (ACL) injury is one of the most common sports injuries. Movements such as directional changes, jumping, and landing increase the risk of ACL injuries [1]. Dual-task interventions may interfere with landing strategies, potentially elevating the risk of injury. In complex sports environments, athletes must perform rapid movements while maintaining postural stability, often simultaneously engaging in multiple tasks such as running, passing, and dribbling, which reflect the demands of dynamic balance and dual-task performance [2]. Therefore, designing movement tasks that closely mimic real sports scenarios can provide deeper insights into dynamic postural stability strategies and injury mechanisms during lateral landings. This study aims to investigate athletes' dynamic postural stability strategies using continuous lateral jumping combined with a dual-task.

METHODS: The study recruited eight healthy female collegiate athletes. Participants performed four consecutive single-leg lateral jumps, with the jump distance set at 140% of hip width. For the dual-task condition, participants held a wireless handgrip dynamometer with their dominant hand, maintaining 30% of their maximal grip strength. In the non-dual-task, the handgrip dynamometer was not used. Data from the final landing and the subsequent three seconds were analyzed. The primary analyses focused on postural stability parameters and joint kinematics. A paired-sample t-test was used to compare postural stability indicators between the dual-task (DT) and non-dual-task (NDT).

RESULTS: This study revealed that during landing, the hip abduction angle ($p = .021$) and knee varus angular velocity ($p = .001$) were significantly lower in the DT condition compared to the NDT. Furthermore, the medial-lateral stability index (MLSI) ($p = .003$) and hip adduction angular velocity at the lowest squat position ($p = .033$) were significantly higher in the DT than NDT.

CONCLUSION: The results of this study indicate that under the DT, the MLSI index increased, hip abduction showed less angle at initial landing, and hip adduction angular velocity was greater at the lowest squat position. This study found that athletes exhibited poorer dynamic stability and movement control under DT, increasing their risk of lower limb injuries [3]. Moreover, the slower knee varus angular velocity may represent a compensatory landing strategy in response to the reduced hip abduction angle [1]. In summary, DT may affect athletes landing strategies and lower limb control [4]. Future training programs could incorporate DT exercises to enhance postural stability and athletic performance while reducing the risk of lower limb injuries.

PHYSICAL DEMANDS ON ELITE SPANISH MALE AND FEMALE FOOTBALL REFEREES DURING COMPETITION

MARTÍN-SÁNCHEZ, M.

UNIVERSIDAD EUROPEA DE MADRID

INTRODUCTION: In football, professional referees represent the highest authority during a match. They must move in all directions on the field to ensure optimal positioning and the enforcement of the laws of the game (Weston et al., 2012). Football is a team sport that requires a high level of physical fitness (Castagna et al., 2007), involving continuous accelerations, decelerations, changes of direction, and other high-intensity actions performed by professional football players (Oliva-Lozano et al., 2021).

Previous studies on professional football referees have shown significant gender differences, particularly in higher speed thresholds. Female referees generally exhibited lower aerobic fitness levels and performance compared to their male counterparts.

The objective of this research was to analyze and compare the physical demands of professional male and female field referees during official matches in terms of distance covered and speed.

METHODS: The study sample consisted of 17 female referees (age: 29.05 ± 5.24 years; height: 163.88 ± 6.77 cm; weight: 54.03 ± 5.19 kg) and 19 male referees (age: 38.25 ± 4.14 years; height: 182.1 ± 4.73 cm; weight: 74.63 ± 5.89 kg), all of Spanish nationality, officiating in the Spanish Womens First Division. Male referees trained an average of five sessions per week, while female referees trained four sessions (including strength, endurance, and speed exercises). They typically officiated one midweek match and another on the weekend. As an inclusion criterion, referees had to be free of injuries.

Data were collected from 409 matches during the 2020-2021 season (male matches: 223; female matches: 186). Matches took place in different football stadiums with similar dimensions according to FIFA requirements (110x70 meters). The physical demands of female referees were monitored using WIMU PROTM (RealTrack System SL, Almería, Spain). All devices were activated 30 minutes before data collection to acquire satellite signals and synchronize the GPS clock with the atomic clock of the satellite.

Referees performed a standardized 15-minute warm-up before the match. However, these data were excluded, and only the data collected during the first and second halves were considered for analysis.

RESULTS: Female referees showed significantly lower values than male referees in total distance covered (-451.11 m; ES = 0.56; $p < 0.05$), explosive distance (-102.92 m; ES = 0.42; $p < 0.05$), high-speed breaking distance (-55.29 m; ES = 0.57; $p < 0.05$), total sprints (-4.96 actions; ES = 1.08; $p < 0.05$), sprint distance (-112.35 m; ES = 1.16; $p < 0.05$), high-speed running actions (-10.25 actions; $p < 0.05$), high-speed running distance (-206.58 m; ES = 1.01; $p < 0.05$), and maximum speed (-2.24 km/h; ES = 1.00; $p < 0.05$).

CONCLUSION: The main finding was that Spanish male referees in mens football matches experienced higher physical demands than female referees in womens football matches in terms of both distance covered and speed.

Conventional Print Poster Presentations

EFFECTS OF DAYTIME ENDURANCE EXERCISE UNDER HOT ENVIRONMENT ON SLEEP IN ENDURANCE ATHLETES

TOMOTAKA, N., MATSUDO, H., MAEOKA, Y., TOMIISHI, C., GOTO, K.

RITSUMEIKAN UNIVERSITY

INTRODUCTION: Athletes are often required to perform intensive training sessions under hot environment. Exercise under hot environment increases physiological stress due to elevated core temperature and dehydration (Silva et al. 2019). Therefore, recovery process becomes more important following the exercise under hot environment. Although several types of the post-exercise recovery strategies are proposed, sleep is indispensable to promote recovery of exercise capacity (John et al. 2017). While the effects of exercise on sleep have been well documented, how endurance exercise

under hot environment affects sleep quality remains unclear. The aim of the present study was to clarify the effect of endurance exercise under hot environment on sleep quality, nocturnal body temperature and autonomic nerve activity.

METHODS: Ten endurance male athletes (20±1 years, 169.8±5.7 cm, 61.2±7.3 kg, VO₂max 56.1±4.9 ml/kg/min) performed 60 min of endurance exercise at two different conditions, (1) hot condition (HOT : 35°C, 50%RH), (2) control condition (CON : 20°C, 50%RH). After completing the exercise, sleep variables (evaluated by EEG), skin temperature and heart rate variability (HRV) were measured during sleep.

RESULTS: Total sleep time (TST), sleep efficiency (SE) and time of slow wave sleep (N3) were significantly greater in HOT (TST: 411.3±15.6; SE: 97.1±3.7%; N3: 107.7±31.0 min) compared with CON (TST: 389.8±34.6; SE: 92.3±8.1%; N3: 93.6±20.6 min, p<0.05 for each variable). The changes in skin temperature during initial 180 min after the sleep onset did not differ significantly between conditions. When comparing autonomic nerve activity parameters (evaluated by HRV) during sleep, no significant differences were observed between conditions for HF, LF/HF, SDNN, RMSSD, or pNN50 during sleep. However, NN50 was significantly lower in the HOT (127.5±39.2) compared with CON (138.0±30.4, p<0.05).

CONCLUSION: Our findings indicate that endurance exercise under hot environment improved sleep quality compared with the same exercise under thermoneutral environment in endurance athletes. However, changes in body temperature and autonomic nerve activity during sleep did not account for improved sleep quality following the exercise under hot environment.

PHYSIOLOGICAL DIFFERENCES DURING AN INCREMENTAL TREADMILL TEST ACCORDING TO THE PERFORMANCE LEVEL IN LONG-DISTANCE RUNNERS

ALDA-BLANCO, A., RODRÍGUEZ-BARBERO, S., MUÑOZ DE LA CRUZ, V., VALERO, F., GONZÁLEZ-MOHÍNO, F.
UNIVERSIDAD DE CASTILLA LA MANCHA

INTRODUCTION: Performance in long-distance events is influenced by several key physiological factors, including maximum oxygen uptake (VO₂max), running economy (RE), and the percentage of VO₂max at which the aerobic and anaerobic thresholds occurred [1]. Previous studies found differences in aspects such as the percentage of VO₂max where lactate threshold occurs between different level runners [2]. Therefore, this intervention aimed to analyze physiological differences between performance levels to better understand their influences on key performance parameters in long-distance runners.

METHODS: Thirty-four male and 22 female runners were categorized into two groups based on the 50th percentile of WA scores from 5 km to half-marathon events. Group 1 included runners with 965.18 ± 67.14 points for females and 933.06 ± 40.82 points for males. Group 2 averaged 652.55 ± 134.15 points for females and 737.41 ± 109.88 points for males.

A maximal graded exercise test on a treadmill (HP Cosmos Pulsar, Germany) was performed, starting at 10 km·h⁻¹ for females and 12 km·h⁻¹ for males, increasing by 1 km·h⁻¹ per minute until exhaustion and at 1% of inclination. Respiratory variables were measured with a gas analyzer (CPX Ultima MedGraphics, United States), and heart rate (HR) was recorded using a Polar H10 monitor. Ventilatory thresholds (VT1, VT2), VO₂max, and maximal aerobic speed (MAS) were determined. Independent t-tests were conducted separately for males and females to compare performance groups.

RESULTS: At the VT1, significant differences between groups were found in speed (p<0.001), %MAS where VT1 occurs (p=0.019), HR (p=0.01), and RPE (p=0.016) for male participants. In contrast, for female participants, there were only significant differences between groups in the speed (p=0.008).

At the VT2, significant differences between groups were observed in speed (p=0.022) and HR (p=0.03) for male participants. For female participants, there were significant differences in speed (p<0.001) and VO₂ (ml/kg/min) (p=0.018).

CONCLUSION: Male and female runners with higher performance levels demonstrated higher absolute speeds at both VT1 and VT2, as well as a higher %MAS where VT1 occurs only in male runners. Additionally, HR and RPE were significantly higher in males with a higher performance level, which may be attributed to their ability to sustain greater relative intensity over the same duration. These findings highlight the importance of stratifying athletes by performance level when analyzing physiological responses.

NEUROMUSCULAR FACTORS IN TRAIL RUNNING: A SYSTEMATIC SCOPING REVIEW.

MUÑOZ DE LA CRUZ, V., VALERO, F., GONZÁLEZ-MOHÍNO, F., ALDA-BLANCO, A., RODRÍGUEZ-BARBERO, S., GONZÁLEZ-RAVÉ, J.M.

UNIVERSITY OF CASTILLA-LA MANCHA - TOLEDO CAMPUS: UNIVERSIDAD DE CASTILLA-LA MANCHA

INTRODUCTION: Trail running has emerged as a growing trend in endurance sports and has seen significant professionalization among many athletes (1). As with other endurance sports, neuromuscular factors play a crucial role in performance (2). However, most reviews in the scientific literature address physiological topics and injuries, leaving a gap in the knowledge regarding neuromuscular factors. Therefore, the purpose of this scoping review was to identify which neuromuscular factors have been studied, the types of interventions that have been conducted, and the populations that have been analyzed.

METHODS: A systematic search was conducted on PubMed, Web of Science, and Dimensions databases composing "trail running" AND "strength" OR "resistance" OR "neuromuscular" OR "lower limb" as keywords. Two reviewers screened the articles for eligibility according to the inclusion criteria. The articles that did not include trail athletes were excluded and PEDro scale was used to check article's quality.

RESULTS: Eighty-four records were retrieved during an initial search with a total of 38 finally included. Most of the studies had a pre-post design (44.73%), followed by cross-over studies (26.31%), comparative (10.53%), correlational (10.53%), and longitudinal case studies (7.89%). The main topic was to analyze the effect of different trail running distances, slopes, and sex on neuromuscular fatigue. Maximal voluntary and evoked contractions of lower limb muscles were measured in most of the studies (73.68%). Electromyography (21.05%), leg stiffness (15.79%), jump performance (13.16%), muscle soreness questionnaires (10.53%), and levels of creatine kinase (5.26%) were also evaluated. Moreover, fewer than half of the studies included female participants, and while some focused on amateur or high-level/elite athletes, the majority involved well-trained and experienced individuals.

CONCLUSION: The effects of trail running fatigue on neuromuscular factors have been widely studied across different distances, sexes, and athletic levels. Similarly, the impact of neuromuscular and biomechanical factors on performance, although to a lesser extent, has also been examined. However, there is a lack of knowledge regarding the impact of strength training on trail running performance, as well as a general need for further research involving female populations.

CONTINUOUS AND INTERMITTENT RUNNING CAUSE SIMILAR IMPAIRMENTS IN MAXIMUM FORCE-GENERATING CAPACITY BUT DIFFER IN CENTRAL, PERIPHERAL, AND PERCEIVED FATIGABILITY OVER A SIX-HOUR RECOVERY PERIOD

ZAGATTO, A., MENDONÇA, P.T.1, GOODALL, S.2, DUTRA, Y.M.1

ISÃO PAULO STATE UNIVERSITY, BAURU, BRAZIL; 2NORTHUMBRIA UNIVERSITY, UK

INTRODUCTION: Fatigue is known to be task-dependent, with exercise characteristics determining the dynamics of central and peripheral mechanisms, as well as magnitude of perceived fatigability [1,2]. In locomotor efforts, fatigue processes related to exercise intensity and training type have been extensively studied [3,4], likely due to their key role in conditioning and rehabilitation routines. However, despite its widespread practice, the task dependency of fatigue during running remains a rather under-researched topic. Therefore, this study aimed to provide a comprehensive evaluation of knee-extensor neuromuscular function and perceived fatigability following distinct running exercises at well-defined levels of metabolic stress.

METHODS: Twelve recreationally trained runners (VO_2max : 52.2 ± 6.9 mL/kg/min, training volume: 23.3 ± 6.5 km/week) completed a 8.1 ± 0.6 km run under three different conditions: (i) continuously for 40 minutes at a velocity corresponding to the respiratory compensation point (vRCP; CONT100%RCP), intermittently at (ii) 30% above vRCP (HIIT30%RCP; 10×3 -min intervals), and (iii) 50% above vRCP (HIIT50%RCP). Voluntary and evoked knee-extensor contractions were assessed before and up to six hours after exercise to quantify mechanisms of fatigue. Additionally, ratings of global fatigue, leg pain, and mood state were recorded.

RESULTS: Peak force and voluntary activation of the knee extensors remained reduced for at least six hours after exercise (main effects of time $p < 0.01$), while contractile function was impaired for up to two hours (main effects of time, $p = 0.01$). Greater impairments in the central nervous systems ability to transmit electrical signals to the vastus lateralis (i.e., reductions in RMSVL/M-waveamp) were observed after CONT100%RCP compared to both HIIT30%RCP and HIIT50%RCP (main effects of time $p = 0.03$). In contrast, greater impairments in contractile function (i.e., reductions in potentiated peak force evoked by the single stimulus) were observed after HIIT50%RCP compared to CONT100%RCP (main effect of training type, $p < 0.05$). Additionally, leg pain, perceived fatigue, and mood disturbance were significantly greater after HIIT50%RCP compared to CONT100%RCP (main effects of training type, $p < 0.05$).

CONCLUSION: Our findings highlight the task dependency of fatigue in running, demonstrating that six hours post-exercise, a continuous run at a velocity corresponding to the respiratory compensation point primarily impaired central

nervous system muscle activation capacity, whereas a high-intensity interval run at 50% above vRCP led to greater impairments in contractile function and perceived fatigability.

COMPARISON OF THE LOWER LIMB MUSCLE ACTIVITY DURING A DOWNHILL RUN AND THE SUBSEQUENT MUSCLE DAMAGE IN TRAIL VERSUS ROAD RUNNERS.

HODY, S., ABRAN, G., VANDENBROECK, B., SCHLEICH, F., SCHWARTZ, C.

UNIVERSITY OF LIEGE

INTRODUCTION: Downhill running (DR) sections, a common component of off-road racing, can lead to exercise-induced muscle damage (EIMD) due to the greater eccentric work of some lower limb muscles. Repeated exposure to eccentric work is known to reduce or prevent EIMD. Running patterns may change during prolonged DR but the relationship between these adaptations and the EIMD has not been fully understood. Therefore, this study aimed to compare the running patterns during a 30min DR test and the magnitude of EIMD between trail and road runners.

METHODS: Recreational male trail runners (TR; n=22; 23.8 ± 3.7 yrs) and road runners (RR; n=21; 30.5 ± 8.8 yrs) underwent a treadmill VO₂max test to determine their maximal aerobic speed (MAS). They then performed a 30min DR protocol at 90% MAS (-15% gradient). Spatiotemporal parameters (using a 3D motion system) were measured during DR, coupled with surface electromyography recordings. Plasma creatine kinase (CK) and delayed-onset muscle soreness (DOMS) were measured before, 24h and 48h after DR. Squat jump (SJ) performance was assessed before, immediately and 24h after exercise.

RESULTS: The VO₂max values of the TR and RR groups were 55.9 ± 5.3 and 52.5 ± 6 mlO₂/min.kg, respectively. The increase in plasma CK activity was significantly higher in RR group at 24h (1306 ± 630 UI/l) and 48h (852 ± 553 UI/l) post-exercise compared to TR group (772 ± 540 UI/l; 382 ± 151 UI/l; respectively). Similarly, the RR experienced higher muscle soreness of the knee extensors at 24 and 48h post-exercise (5 ± 2.4 and 4.5 ± 2.2 a.u) than the TR (3.6 ± 2.3; 3.7 ± 2.4 a.u). SJ performance decreased immediately and 24h after DR only in the RR group (-8.7 ± 7.6 and -7.3 ± 5.4%). While no significant differences in stride frequency, swing and stance times were found between groups, the duration of the stance phase significantly increased from the beginning to the end of the run (2.3 ± 4.2%). Muscle activity of lower limbs did not differ between groups but significant changes were found over time. Muscle activity increased for the biceps femoris, rectus femoris, vastus lateralis and medialis during the stance phase whereas the gastrocnemius lateralis and medialis showed a decreased activation from the start to the end of DR.

CONCLUSION: As expected, the RR showed greater changes in EIMD indirect markers than the TR after DR but no difference in muscle activity was found between groups. Further correlation analysis between running patterns and subsequent EIMD may help to better understand the relationship between these parameters.

THE REPRODUCIBILITY OF SKIN THERMAL RADIATION VARIATIONS DURING REPEATED CONTINUOUS AND INTERMITTENT RUNNING EXERCISE MEASURED WITH AI-ASSISTED INFRARED THERMOGRAPHY

WEBER, V., ANDRÉS LÓPEZ, D., OCHMANN, D.T., ZENTGRAF, S., NÄGELE, M., NEUBERGER, E., SCHÖMER, E., SIMON, P., HILLEN, B.

INSTITUT FÜR SPORTWISSENSCHAFTEN JOHANNES GUTENBERG-UNIVERSITÄT MAINZ

INTRODUCTION: AI-assisted Infrared Thermography allows automatic time-series analysis of skin thermal radiation (T_{sr}) non-invasively and contact-free during exercise. T_{sr} variations during exercise are closely related to acute physiological response [1]. However, the reproducibility of T_{sr} variation during repeated exercise has not been sufficiently investigated. Hence, this study investigated the reproducibility of T_{sr} variations both within and between individuals across continuous and intermittent running bouts in endurance-trained individuals.

METHODS: Eleven young endurance-trained individuals (24.8±2.4 years; maximal oxygen uptake: 50.5±6.8 mL/min/kg; Physical Activity-Rating ≥ 6) completed three running protocols with a duration of 46 minutes each. The similar average external load was based on individual anaerobic threshold (IAT) measured via lactate measurement during cardiopulmonary exercise testing. Each session consisted of a warm-up (10 min), followed by either 36 min of continuous (T1), continuous-intermittent (T2), or intermittent-continuous (T3) running. A high-resolution thermal camera, positioned perpendicular to the lower leg, captured images at 30 Hz. Deep neural network-based segmentation was applied to objectively perform reproducible region of interest extraction and T_{sr} time-series analysis. The relative consistency of measurements within and between individuals was analyzed by two-way mixed-effects intra-class correlation analysis and the differences between exercise sessions were tested with repeated measures analysis of variance (rmANOVA; significance level: p < .05).

RESULTS: The interindividual intra-class correlation analysis revealed good consistency for the relative T_{sr} variations for all three exercise bouts (ICC = 0.75-0.76) comparable to oxygen consumption (ICC: 0.64-0.77) and heart rate (ICC: 0.65-0.76). The intraindividual reproducibility showed good to excellent consistency (ICC ≥ 0.75) for warm-up, intermittent-phase, and recovery, again comparable to oxygen consumption and heart rate. Additionally, there were no significant differences for the relative T_{sr} between the three running sessions at any time point according to the results of the rmANOVA [F (1.77,17.74) = 3.352, p = 0.056].

CONCLUSION: The study results indicate that time-series of Tsr variations during running are reproducible for endurance-trained individuals. Furthermore, the intraindividual comparison showed promising results regarding consistency in Tsr variation independent of day, daytime, and preload. These exploratory findings advance the field considering analysis and design of studies investigating thermography to detect individual cardiovascular and thermoregulatory long-term adaptation.

PHYSIOLOGICAL RESPONSES AND PERCEIVED EXERTION OF THREE HIGH-INTENSITY INTERVAL TRAINING PROTOCOLS IN LONG-DISTANCE RUNNERS.

ESCAJAL, B., CASTILLO, M., MAGALLANES, C.

INSTITUTO SUPERIOR DE EDUCACIÓN FÍSICA - UNIVERSIDAD DE LA REPÚBLICA DE URUGUAY. GRUPO DE INVESTIGACIÓN DEPORTE Y RENDIMIENTO.

INTRODUCTION: HIIT is commonly used in the training regimens of long-distance athletes. However, there is a wide variety of training protocols exist, each with different load components (volume, intensity, rest duration, etc.). Furthermore, there is a notable scarcity of well-controlled studies, leaving many unanswered questions regarding the most effective training types for optimizing specific adaptations in endurance athletes. This study aims to analyze and compare the acute responses of oxygen consumption (VO₂/kg), heart rate (HR) and Rating of Perceived Exertion (RPE) in three HIIT protocols with different interval durations.

METHODS: A study involved 20 highly trained adult long-distance athletes (10 men and 10 women), comparing gas exchange (MetaMax 3B Cortex), HR (Polar H10), and RPE (Borg Scale 1-10) across three different HIIT protocols: 1200m (long), 400m (medium), and 100m (short). All protocols were equated for volume (6000m), and rest time was standardized to a work/rest ratio of 1:1. The running intensity prescribed for all athletes was the maximum they could maintain throughout all repetitions. The study aimed to simulate a real-world training scenario on an official 400-meter track using portable equipment. Data were analyzed using RStudio. Two Linear Mixed Models (LMMs) were applied: one with VO₂/kg and another with HR as dependent variables. Fixed effects included protocol and time (within-subjects design), with random effects were structured to account for variability in protocol effects across individual subjects. Pairwise comparisons and R² values were calculated for both models. RPE was assessed via the Kruskal-Wallis test, supplemented by post hoc Dunn tests for pairwise comparisons.

RESULTS: The results indicate that the protocols have distinct effects on VO₂/kg and HR. The models revealed significant differences in VO₂/kg between protocols: medium (-5.68 vs long, $p < 0.001$) and short (-7.45 vs long, $p < 0.001$), with no significant difference between medium and short ($p = 0.44$). Fixed effects, including time and protocol, accounted for R² = 0.095, while random effects explained R² = 0.385. Similar effects were observed for HR; however, no significant differences were found between the protocols when directly compared. The Kruskal-Wallis test showed significant differences ($\chi^2 = 8.9575$, $p = 0.011$) in RPE across the three protocols, primarily between the short and long protocols, with the former perceived as less strenuous by the subjects.

CONCLUSION: Based on the findings, the long interval protocol results in significantly higher VO₂/kg values during the running phases compared to the medium and short protocols, with no significant differences between the latter two. In terms of perceived exertion, the short interval protocol elicited the lowest ratings. The study underscores the importance of performing intervals lasting between 3 and 5 minutes to stimulate athletes for a longer period in zones close to VO₂max.

ACUTE RESPONSES TO TWO INDIVIDUALIZED AEROBIC INTERVAL TRAINING PROTOCOLS WITH DIFFERENT INTENSITY OF EFFORT BASED ON A PREVIOUS RUNNING TEST

LENS-VALES, A., VARELA-SANZ, A., FARIÑAS-RODRÍGUEZ, J., OVIES-GUTIÉRREZ, F., NINE, I., RIAL-VÁZQUEZ, J., IGLESIAS-SOLER, E.

UNIVERSITY OF A CORUÑA

INTRODUCTION: Aerobic interval training (AIT) consists of repeated bouts of high-intensity exercise (i.e., work intervals longer than 60 s) interspersed with pauses (i.e., rest intervals), allowing for a greater accumulation of exercise volume at a targeted intensity (i.e., above 90% of VO₂max) within a single training session (Sánchez-Otero et al., 2022; Varela-Sanz et al., 2023). Scientific evidence traditionally recommends work intervals lasting 2–3 minutes, performed at maximal aerobic speed (MAS), with a work-to-rest ratio (w:r) of 1:1 and a total accumulated exercise volume of at least 15 minutes to develop aerobic power (Sánchez-Otero et al., 2022; Varela-Sanz et al., 2023). To our knowledge, no studies have explored individualized interval durations based on a time-to-exhaustion running test (Tlim) at MAS. This study aimed to examine the acute responses to two individualized AIT protocols with different intensities of effort based on the individual Tlim.

METHODS: Ten Sports Science students completed a maximal running test to determine MAS and VO₂max. After 72 hours, 20–30 m maximal sprinting speed was assessed. Participants Tlim at MAS was then determined. After 72 hours, they randomly performed two AIT sessions at MAS, each accumulating 15 minutes but differing in intensity of effort based on Tlim: AIT30 (work intervals lasting 30% of Tlim) and AIT75 (work intervals lasting 75% of Tlim). A 30-m sprint force-velocity profile was recorded before (pre) and after (post) both AIT sessions. Rating of perceived exertion (RPE) was recorded after each work interval and for the entire session. Heart rate (HR) was monitored throughout all sessions.

RESULTS: Exercise tolerance during work intervals was higher in AIT30 than in AIT75. RPE and HR for the entire session were similar between both AIT sessions. Sprinting speed performance differed between pre- and post-measurements, indicating a post-activation performance enhancement (PAPE) response following the AIT protocols.

CONCLUSION: AIT protocols performed at MAS with a w:r of 1:1, but differing in intensity of effort based on individual Tlim, provide an effective approach for prescribing individualized training loads. Both shorter and longer work intervals appear to be well tolerated when total exercise volume is equated. Interval length partially modulates acute responses to AIT. Future longitudinal studies are needed to optimize dose-response relationships and maximize adaptations in both the short and long term.

EFFECTS OF A BODY-MASS SUPPORT SYSTEM ON SPATIOTEMPORAL PARAMETERS DURING (SUPRA-)MAXIMAL TREADMILL SPRINTING

KLEIN, J., FRÖHLICH, B., OEPPERT, T., SCHAPSHRÖER, M., ABEL, T.

GERMAN SPORT UNIVERSITY COLOGNE

INTRODUCTION: Maximum sprinting speed (MSS) is constrained by the ability to generate sufficient mass-specific vertical forces within short ground contact times(tc), leading to an inverse relationship between tc and sprinting speed [1]. 'Assisted' sprinting has been proposed as a promising method to increase MSS, with traditional methods relying on horizontal towing forces. Conversely, body-mass support systems (BMSS) offer a unique 'vertical assistance' approach, that reduce vertical force demands during stance [2]. While BMSS has been explored in low-speed running, its effects on maximal and supramaximal sprinting remain poorly understood. Therefore, this study examined the impact of a novel BMSS on spatiotemporal parameters during high-speed treadmill sprinting.

METHODS: Seven male (100m PR: 10.84 ± 0.56 s) and 11 female (100m PR: 12.49 ± 0.70 s) trained sprinters participated. The study consisted of two testing sessions separated by 72 hours. During the first visit, athletes performed three maximal 70 m sprints on an indoor athletic track. MSS, defined as the highest velocity over two consecutive steps, was measured via a laser device. During the second visit, athletes completed two treadmill sprints for each of the three conditions in the following order: a) unassisted at 100% MSS (FREE), b) assisted at 100% MSS (ASSIST) c) assisted at 105% MSS (ASSIST-SUPRA). A motorized treadmill was accelerated within 5 s to the individually selected velocity and this velocity was maintained for a period of 3 s (peak velocity phase) before decelerating. Vertical assistance, corresponding to a 10% reduction in body mass during upright standing, was applied using a custom-built BMSS (LEVER UP, Lever Movement, Boulder, USA). Spatiotemporal parameters - including step length (SL), step frequency (SF), tc, and flight time (ta) - were measured via photoelectric cells during the peak velocity phase. A one-way RM ANOVA was conducted to assess differences between the three conditions, followed by Bonferroni-corrected post-hoc tests.

RESULTS: Multivariate analysis revealed statistically significant differences across conditions for all spatiotemporal parameters ($p < 0.001$) with large effect sizes (part. $\eta^2 = [0.14, 0.89]$). In ASSIST-SUPRA, participants exhibited significantly greater SL ($p < 0.01$) and SF ($p < 0.001$), alongside reduced tc ($p < 0.001$) while ta remained unchanged compared to FREE and ASSIST. No significant differences in SL and SF were observed between FREE and ASSIST. However, ASSIST altered step time distribution, reducing tc ($p < 0.001$) and increasing ta ($p < 0.01$).

CONCLUSION: Unlike horizontal towing devices, which primarily increase velocity by lengthening SL through extended ta [3], this study observed a combination of supramaximal speed and reduced tc. These findings highlight the potential advantages of BMSS as a training tool to possibly enhance MSS, warranting further investigation in applied sprint training.

HEART RATE VARIABILITY (DFA A1) AS A FATIGUE MARKER: DIFFERENTIAL RESPONSES TO LIGHT, MODERATE, AND HIGH-INTENSITY TRAINING WITH MATCHED WORKLOADS

DE BEUKELAAR, T., MÜLLER-JABUSCH, Y., OLIESLAGERS, A., DE MAESENEER, J., SEYNAEVE, M.

KU LEUVEN

INTRODUCTION: Training improves performance through progressive overload, delicately balancing stress and recovery. Hence, an objective fatigue-recovery marker would greatly benefit athletes seeking to sustainably improve performance. Interestingly, a non-linear heart rate variability (HRV) index (DFA a1) holds promise as a marker of exercise intensity as well as one's physiological status of fatigue during endurance training. Specifically, DFA a1 has gained attention for its potential to demarcate intensity thresholds as its value decreases with increasing intensity and hereby correlates with aerobic and anaerobic thresholds. Moreover, it could be applied to monitor fatigue as it shows suppressed values during prolonged exercises. However, responsiveness of DFA a1 to training sessions of different intensities with identical workload remains unexplored.

METHODS: Eighteen participants (18-35yrs, BMI<25, ≥ 5 h endurance training/week) performed three training sessions (light, moderate, high-intensity) separated by at least one week. Training sessions were matched for workload (joules) by adapting training time, calculated using the formula $E=P \times \Delta t$. The high-intensity training was done first and determined the duration of the light and moderate training. The order of the light and moderate training was randomized and was performed as a continuous training at the first and second lactate threshold (i.e. LT1 and LT2) power, respectively, based on the subject's individual maximal incremental exercise test results. The initial high-intensity training followed a 10x1-minute high-intensity interval protocol at 110% VO_2max power alternated with 1 minute rest at 80% LT1 power. Each training started and ended with a standardized 10-min warming-up (WU) and 10-min cooling-down (CD) at LT1 power. Mean DFA a1 and HR were calculated during the final two minutes of WU and CD to assess intensity-specific physiological changes.

RESULTS: Mean differences in DFA a1 and HR (beats/min) values between the last two minutes of WU vs. CD were 0.051 (± 0.160), $p=0.66$ and 6.50 (± 3.67) beats/min, $p=0.27$ for light-intensity, 0.285 (± 0.140), $p=0.006$ and 8.28 (± 3.48) beats/min, $p=0.14$ for moderate-intensity, and 0.321 (± 0.222), $p=0.009$ and 9.39 (± 5.71) beats/min, $p=0.11$ for HIIT. Repeated measures ANOVA of DFA a1 during WU vs. CD revealed significant differences for light vs. moderate (0.234, $p<0.001$) and light vs. HIIT (0.269, $p<0.001$). However, no significant difference was observed for moderate vs. HIIT (0.035, $p=0.486$). Importantly, HR values obtained during WU vs. CD were not significantly different across training intensities, indicating that DFA a1 seems to be a more sensitive marker of acute fatigue.

CONCLUSION: The responsiveness of DFA a1 to training intensity, especially compared to unchanged HR values, highlights its potential as a sensitive marker of fatigue. This responsiveness suggests DFA a1 could serve as a practical tool for monitoring physiological stress and personalizing exercise and recovery programs.

EFFECTS OF BREATHING HYPEROXIC GAS DURING HIGH-INTENSITY INTERVAL EXERCISE ON POST-EXERCISE MRNA RESPONSES IN EQUINE SKELETAL MUSCLE

MUKAI, K., EBISUDA, Y., SUGIYAMA, F., YOSHIDA, T., MIYATA, H.

EQUINE RESEARCH INSTITUTE, JAPAN RACING ASSOCIATION

INTRODUCTION: High-intensity interval training (HIIT) in hyperoxia is proposed to enhance exercise performance and aerobic capacity, but its potential efficacy and underlying mechanisms remain unclear. Therefore, the aim of this study was to determine the effect of breathing hyperoxic gas during HIIT on post-exercise mRNA responses in equine skeletal muscle.

METHODS: In a randomized crossover study design, seven trained Thoroughbred horses (3 geldings and 4 mares) performed four work-matched treadmill exercise protocols: 1) moderate-intensity continuous exercise in normoxia (fraction of inspired oxygen $\text{FIO}_2 = 0.21$, 6 min at 70% VO_2max ; N-MICT), 2) high-intensity interval exercise in normoxia ($\text{FIO}_2 = 0.21$, 6×30 s at 100% VO_2max with 30 s recovery; N-HIIT), 3) moderate-intensity continuous exercise in hyperoxia ($\text{FIO}_2 = 0.30$, 6 min at 70% VO_2max ; H-MICT), and 4) high-intensity interval exercise in hyperoxia ($\text{FIO}_2 = 0.30$, 6×30 s at 100% VO_2max with 30 s recovery; H-HIIT). Arterial blood samples were collected during exercise to measure blood gases and plasma lactate concentrations. Biopsy samples from the middle gluteal muscle were collected pre-exercise and 4 hours post-exercise for real-time PCR analysis of gene expression. Data are expressed as mean $\pm$ standard error (SE), and the effects of time, protocol and their interaction (time $\times$ protocol) were analyzed using mixed models ($P < 0.05$).

RESULTS: At the end of exercise, arterial O_2 saturation (SaO_2) was higher in H-MICT ($95.6 \pm 0.1\%$), H-HIIT ($95.1 \pm 0.2\%$) and N-MICT ($92.4 \pm 0.7\%$) compared to N-HIIT ($86.5 \pm 1.6\%$) ($P < 0.001$). Plasma lactate concentrations were higher in N-HIIT (23.6 ± 2.6 mmol/L) and H-HIIT (19.5 ± 2.6 mmol/L) compared to N-MICT (9.5 ± 2.1 mmol/L) and H-MICT (12.0 ± 2.5 mmol/L) ($P = 0.001$). After 4 hours of exercise, HIF-1 α mRNA increased 4.6-fold in N-HIIT ($P = 0.046$), VEGF mRNA increased 2.0-fold in H-HIIT ($P = 0.032$), and HSP70 mRNA increased 6.2-fold in N-HIIT ($P = 0.001$) and 2.9-fold in H-HIIT ($P = 0.036$). PGC-1 α mRNA increased by 4.2- to 5.4-fold ($P < 0.001$ to $P = 0.0033$), and PDK4 mRNA increased by 7.9- to 10.1-fold ($P < 0.001$ to $P = 0.019$) in all groups.

CONCLUSION: Plasma lactate concentration was unaffected by FIO₂, whereas SaO₂ was maintained during HIIT when breathing hyperoxic gas. These results suggest that H-HIIT can enhance whole-body O₂ delivery to skeletal muscle, which may reduce cellular adaptation to hypoxia but enhance angiogenic responses. However, H-HIIT had no additional effects on heat shock response, mitochondrial biogenesis, or lipid metabolism compared to N-HIIT.

RELIABILITY AND VALIDITY OF THE ILLINOIS AGILITY TEST AND THE T-AGILITY TEST AMONG CHINESE CHILDREN

HONGJUN, Y.1,2, SONGMEI, L., PU, S.3, XIN, C.4, YANMEI, L.

1 TSINGHUA UNIVERSITY; 2 BEIJING NORMAL UNIVERSITY; 3 BAOTOU KUN DISTRICT TUANJIE STREET NO.1 PRIMARY SCHOOL; 4 BAOGANG HOSPITAL OF INNERMONGOLIA

INTRODUCTION: Agility is an individual's ability to maintain and control body posture while running and changing direction quickly[1]. During childhood, routine play activities often involve speed, twists, and turns, making this period particularly sensitive for agility development[2]. The Illinois Agility Test and the T-Agility Test have been validated in adults and athletes[3], yet their reliability and validity in Chinese children remain underexplored. This study aims to evaluate the test-retest reliability and validity of the Illinois Agility Test and the T-Agility Test in Chinese children.

METHODS: For test-retest reliability, 90 participants (41 males and 49 females; age: 11.6 ± 0.6 years; height: 148.3 ± 7.9 cm; weight: 43.1 ± 12.6 kg; BMI: 19.4 ± 4.6) completed the Illinois and T-Agility Tests twice, with a two-week interval between assessments. To assess validity, 189 participants (86 males and 103 females; age: 11.6 ± 0.5 years; height: 148.9 ± 7.7 cm; weight: 42.4 ± 11.3 kg; BMI: 18.9 ± 4.0) were evaluated using both agility tests alongside the 20-meter dash and the standing long jump (SLJ). Data were analyzed using Spearman correlation. Significance was set at $p < 0.05$.

RESULTS: The intraclass correlation coefficient (ICC) for test-retest reliability of the Illinois Agility Test was 0.778 ($p < 0.001$), while the ICC for the T-Agility Test was 0.771 ($p < 0.001$). For validity, the Spearman correlation coefficients between the 20-meter dash and the Illinois and T-Agility Tests were 0.540 ($p < 0.001$) and 0.581 ($p < 0.001$), respectively. The Spearman correlation coefficients between the SLJ and the Illinois and T-Agility Tests were -0.611 ($p < 0.001$) and -0.537 ($p < 0.001$), respectively.

CONCLUSION: This study demonstrates that both the Illinois Agility Test and the T-Agility Test are reliable and valid measures of agility in children. Among Chinese children, the Illinois Agility Test exhibits superior reliability and validity compared to the T-Agility Test.

THE EVIDENCE-BASED FORCE VECTOR THEORY OF TRAINING SPECIFICITY

XINZHE, X., LIN, J., LI, W.

BEIJING SPORT UNIVERSITY

INTRODUCTION: The force-vector theory of training specificity indicates that the similarity between movement patterns and force-vector specificity of training exercises and the target movement will likely result in the greatest transfer of the practiced skills and physical abilities to the intended sports skill performance [1]. Thus, performing training exercises predominantly in the plane in which the target motor performance task is also executed is more effective compared with training during which training exercises and the target movements are done in different planes of movement [2]. Therefore, compared to vertical jump, the horizontal jump may be shown greater correlations with horizontal movements (e.g., sprint and change of direction).

METHODS: Thirty-six male college players well-trained background were recruited in this study. All subjects performed 30 m sprint, 505 COD, CMJ, and sprint bounding for three trials in random order. The 2-3 min rest interval was allowed between trials and 5 m interval between tests. For the CMJ test, participants rapidly moved down to the knee joint angle of 90° and then immediately and vertically jump as high as they can, the jump height was assessed using force platform. For the sprint bounding test, participants started with a 5 m sprint and completed a 5-step forward jump, the jump distance was measured using a tape. For the 30 m sprint test, two pairs of time gate were placed at the 0 m and 30 m line, respectively, and participants started behind 30 cm of the 0 m line with the two-point position. For 505 COD, the time gate was placed at the 10 m line, the participants started with a two-point position 30 cm behind the 0 m line, and immediately sprint back to the 10 m line after reached the 15 m line. The correlation analysis was examined using Pearson's (parametric data) or Spearman's (non-parametric data) correlations.

RESULTS: The CMJ height, 30m sprint time, sprint bounding distance, and CODD were normally distributed ($p > 0.05$). The CMJ height was significantly correlated ($p < 0.05$) with 30 m sprint time, CODD and sprint bounding distance, with moderate magnitude of correlations (30m: $r = 0.34$; CODD: $r = 0.31$; sprint bounding distance: $r = 0.38$). Significant correlations were also observed between sprint bounding distance and 30 m sprint time ($r = 0.54$) and CODD ($r = 0.62$), with large magnitude of correlation.

CONCLUSION: Compared to vertical jump height, the sprint bounding jump distance showed greater correlations with horizontal movement performance, thus supporting the force-vector theory of training specificity.

THE EFFECTS OF LADDER DRILLS AND HURDLE JUMPS ON AGILITY AMONG CHINESE CHILDREN : A RANDOMIZED CONTROL TRIAL

LIN, S.2, YU, H.1, SUN, P.3, CUI, X.4, LIN, Y.

1 BEIJING NORMAL UNIVERSITY; 2 TSINGHUA UNIVERSITY; 3 BAOTOU TUANJIE STREET PRIMARY NO.1 SCHOOL; 4 BAOGANGHOSPITAL OF INNERMONGOLIA

INTRODUCTION: Agility is a crucial component of physical fitness that enables children to maintain and control correct body positioning while responding to multidirectional speed and changes in movement direction[1]. Childhood is a critical period for developing agility, which involves speed, twists, and rapid directional changes[2]. However, despite its importance, the effects of different training methods on agility in children have not been thoroughly investigated[3]. Therefore, this study aimed to examine the effects of ladder drill (LD) and hurdle jump (HJ) training on agility performance among Chinese children.

METHODS: A total of 99 participants (39 males and 60 females; age: 11.44 ± 0.57 years; height: 148.35 ± 7.28 cm; weight: 42.26 ± 12.31 kg; BMI: 18.99 ± 4.56) were randomly assigned to one of three groups: the ladder drill (LD) group (n = 33), the hurdle jump (HJ) group (n = 33), and the control (C) group (n = 33). The LD and HJ groups underwent six weeks of training, performing their respective exercises three times per week. In contrast, the control group attended regular physical education classes three times per week without participating in ladder drills or hurdle jump exercises. Agility performance was assessed using T-Test and the Illinois Agility Test the before and after the intervention. Data were analyzed using one-way ANOVA and paired t-tests. Significance was set at $p < 0.05$.

RESULTS: After six weeks of agility training, significant improvements in agility performance were observed in both the LD and HJ groups. In the T-Agility Test, the HJ group demonstrated the largest improvement (12.33% improvement; pre-test: 15.32 s, post-test: 13.43 s, $t = 9.13$, $p < 0.001$), followed by the LD group (6.66% improvement; pre-test: 14.87 s, post-test: 13.88 s, $t = 7.27$, $p < 0.001$). The control group exhibited only a moderate improvement (3.86% improvement; pre-test: 14.75 s, post-test: 14.18 s, $t = 3.18$, $p < 0.01$). Similarly, for the Illinois Agility Test, the HJ group exhibited the greatest improvement (6.67% improvement; pre-test: 22.35 s, post-test: 20.86 s, $t = 8.64$, $p < 0.001$), followed by the LD group (4.52% improvement; pre-test: 22.53 s, post-test: 21.50 s, $t = 4.52$, $p < 0.001$), while the control group showed no significant change (2.97% improvement; pre-test: 22.22 s, post-test: 21.56 s, $t = 1.44$, $p = 0.08$).

CONCLUSION: Both ladder drill and hurdle jump training significantly enhanced agility in Chinese children. However, hurdle jump training proved to be more effective in improving agility compared to ladder drills. These findings suggest that hurdle jump exercises should be considered a more efficient method for agility development in children.

THE EFFECT OF APPROACH MOMENTUM ON HORIZONTAL DECELERATION PERFORMANCE

LI, W., LIN, J.

BEIJING SPORT UNIVERSITY

INTRODUCTION: Deceleration is fundamental to multi-directional team sports match play performance (2-3) and thereby the need to assess the horizontal deceleration ability of athletes to provide insights into training programs and player development. Notably, the objective of horizontal deceleration is to reduce the bodies momentum, which is determined by approach velocity and body mass. Theoretically, an athlete attempting to decelerate from a greater approach momentum may require a longer duration and distance over which to stop, to reduce their horizontal velocity to zero, compared to lower approach momentums. This is likely on account of a greater number of foot contacts required to generate sufficient braking impulse to reduce the horizontal momentum. However, this hypothesis has not been examined in previous studies.

METHODS: Eighty male university athletes were recruited in the present study. During the acceleration-deceleration test, all participants were instructed to reduce the horizontal velocity to zero as quickly as possible following a 15 m linear sprint. Following deceleration, all participants were required to backpedal to the deceleration line to determine the ending position of deceleration. All participants were instructed not to decelerate until passing the 15 m line, and the 15 m completion time of any trial that was 5 % greater than the individual best sprint time was discarded, and subsequently another trial was performed following 2-3 min recovery. The completion time of the 15 m sprint was recorded using the aforementioned timing gates and the velocity-time-distance profile was collected using a radar device, which was positioned 5 m behind the starting line with a height of 90 cm and sampling at 47 Hz. Three successful trials were collected for each participant. The instantaneous deceleration during the deceleration phase was determined using the following Equation (linear adjacent method): $\text{Deceleration (m/s}^2\text{)} = (V_f - V_i) / (T_f - T_i)$. The correlative analyses were examined using Pearson's (parametric data) or Spearman's (non-parametric data) correlations. Within-session reliability was examined using intra-class correlation coefficients (ICC) and coefficients of variation (CV %).

RESULTS: Mean and peak deceleration had very high agreement between consecutive trials (ICC = 0.79-0.88), while time to stop showed poor reliability. Lower peak approach momentum was significantly and moderately correlated with greater mean deceleration ($p = -0.354$, $p = 0.001$) and greater peak deceleration ($p = -0.323$, $p = 0.001$).

CONCLUSION: Horizontal deceleration performance is determined by the magnitude of approach momentum; thus, caution is advised when classifying players as faster or slower deceleration performers, as direct comparisons using mean/peak deceleration may lead to erroneous conclusions regarding deceleration ability.

ASSOCIATION BETWEEN CHANGES IN SELF-REPORTED QUESTIONNAIRES AND COUNTERMOVEMENT JUMP PERFORMANCE FOLLOWING A FATIGUING AEROBIC PROTOCOL

KROEZE, M., MICHELI, L.2, GROSSI, T.2, IMPERIO, M.2, BRINK, M.1, CAIMMI, A.2, GASTREGHINI, E.M.2, LUCERTINI, F.2, FERRI MARINI, C.1

1 UNIVERSITY OF GRONINGEN, UNIVERSITY MEDICAL CENTER GRONINGEN; 2 UNIVERSITY OF URBINO CARLO BO

INTRODUCTION: Athletes' self-report measures (ASRM) are commonly used as indicators of fatigue status and training predisposition [1]; however, the sensibility of these questionnaires to detect changes in performance and fatigue status has not yet been investigated. This study aims to explore if ASRMs are sensitive to changes in fatigue status and if they can be used to predict changes in performance after an exhaustive aerobic exercise.

METHODS: Nine healthy adults (6 females, 24.7 ± 2.7 yrs and 3 males, 28.7 ± 2.6 yrs [mean $\pm$ SD]) performed 9 testing sessions: i) a maximal incremental test to determine peak power output (POpeak); ii) eight identical testing sessions consisting of ASRM (total quality of recovery questionnaires on 6 to 20 [TQR6-20] and 0 to 10 [TQR0-10], 8-item short recovery and stress scale [SRSS], and an adapted 0 [not ready] to 10 [completely ready to perform physical exercise] readiness scale [RS] [2]) followed by three counter-movement jumps (CMJ), both performed before and after a constant-load exercise to task-failure at 70% of POpeak. For each individual, Spearman's correlation coefficients (ρ) were calculated to assess the correlation between the changes (i.e., the differences Δ) between pre and post exercise values) of all ASRM and CMJ performance indicators (i.e., best jump height and peak power [3]). Then, one-sample t-tests or the Kolmogorov-Smirnov tests were used to assess if the individual ρ between the several Δ ASRM and Δ CMJ were different from 0. α was set at 5%.

RESULTS: Δ SRSS items (i.e., mental performance capability, emotional balance, overall recovery, muscular stress, lack of activation, and negative emotional state), Δ TQR6-20, and Δ RS were not associated (i.e., ρ not significantly different from 0) with Δ CMJ jump height. However, the correlations between Δ SRSS of two items (i.e., physical performance capability [$\rho = 0.027 \pm 0.372$; $p = 0.065$] and overall stress [$\rho = -0.299 \pm 0.433$; $p = 0.072$]), Δ TQR0-10 ($\rho = 0.101 \pm 0.372$; $p = 0.088$), and Δ RS ($\rho = 0.280 \pm 0.439$; $p = 0.092$) and CMJ jump height showed a trend towards significance (i.e., $p < 0.1$). Likewise, Δ SRSS items and Δ TQR (0-10 and 6-20) were not associated with Δ CMJ peak power; however, the Δ RS ($\rho = 0.281 \pm 0.351$) was associated ($p = 0.043$) with Δ CMJ peak power.

CONCLUSION: In conclusion, most of the commonly used indicators of readiness and fatigue were not associated with CMJ jump height and peak power, and solely RS correlated with CMJ peak power. This points out the potential superiority of a simple and specific readiness scale in predicting neuromuscular fatigue-related performance changes compared to non-specific physical or mental fatigue ASRMs.

EFFECTS OF COMPRESSION SLEEVES ON MUSCLE FATIGUE FOLLOWING ECCENTRIC CONTRACTION

ISHIYAMA, K., NAKAO, G., NARA, G., ADACHI, R., KOZAWA, K., SEKIGUCHI, K., FUKUYO, C., TANIGUCHI, K.

SAPPORO MEDICAL UNIVERSITY

INTRODUCTION: Compression garments are widely used in sports to reduce fatigue and improve performance. Previous research suggests that external compression during exercise may reduce muscle stress [1] and fatigue [2] and improve exercise performance. Although a few reports have examined the fatigue-reducing effects of external compression on muscle strength, or performed frequency analysis using electromyography, the effects of external compression on exercise-induced muscle fatigue remain unclear. Therefore, in this study, we aimed to investigate the effects of compression garments on post-exercise muscle fatigue, focusing on eccentric contractions, where muscles experience high mechanical stress.

METHODS: This study included six healthy young male subjects. A compression sleeve was worn by the study participants covering the entire lower leg during exercise. Maximum voluntary contraction (MVC) torque and mean power frequency (MPF) were measured before and after exercise. The assessment included five sets of 10 maximal eccentric ankle plantar flexion exercises performed in a seated position with 80° hip and 0° knee flexion using a dynamometer (Biodex system 4), with a 30-second rest period between sets. After recording measurements on one leg, the same procedure was conducted on the contralateral leg following a 15-minute recovery period. Rates of change in MVC torque and MPF were calculated by dividing the difference between pre- and post-task measurements by the pre-task value. A repeated-measures two-way ANOVA was conducted to assess both MVC torque and MPF, with compression garment use status (with or without compression) and time as factors. Each change in rate was analyzed using a paired t-test, with statistical significance set at $p = 0.05$.

RESULTS: The time factor showed a significant effect on MVC torque ($p < 0.05$), but no significant effect of the compression garment use status or the time $\times$ compression garment use interaction was observed. In contrast, a significant effect of compression garment use status on MPF ($p < 0.05$) was noted, but no significant effect of time or time $\times$ compression garment use interaction was observed. The change in rate of MVC torque was significantly lower among participants wearing the sleeve than those not wearing it (wearing: -7.55% , not wearing: -15.95% , $p < 0.05$). Additionally, the change

in rate of MPF was significantly lower among those wearing the sleeve compared to those not wearing it (wearing: + 1.20%, not wearing: - 7.62%, $p < 0.05$).

CONCLUSION: External compression of the lower leg reduced neuromuscular fatigue during eccentric contractions, as indicated by the lower change in rates of MVC torque and MPF. These findings suggest that compression sleeves can help maintain muscle performance during activities involving eccentric contractions, particularly in the lower extremities

EVALUATING FAST STRETCH-SHORTENING CYCLE FATIGUE USING A NOVEL 30-SECOND REPEATED JUMP TEST

STEWART, R., GREEVY, J., TIMMONS, J., DUPAN, S.

UNIVERSITY COLLEGE DUBLIN

INTRODUCTION: Rebound jumping performance is widely used to assess fast stretch shortening cycle (FSSC) mechanics in athletes, as it plays a crucial role in sprinting, jumping and changing direction [1]. Athletes' FSSC capacity is often referred to as reactive strength (RS). While practitioners typically evaluate maximal FSSC and RS capacity using short duration tests with fewer than 10 ground contacts [2], tests with higher number of ground contacts provide an opportunity to assess both maximal FSSC and the impact of fatigue on FSSC. This approach may more accurately reflect the demands of sporting activities. This study aims to investigate changes in FSSC performance during a continuous 30 second rebound jumping test.

METHODS: Thirty elite male soccer players (21.10 ± 1.61 years; height 181.01 ± 6.45 cm) completed a 30-second repeated jumping trial (30RJT). Participants were instructed to jump maximally while minimising ground contact time (CT) and maximising jump height (JH). Three-dimensional force data were collected at 2000 Hz using four floor-integrated force plates (AMTI BP400600, Massachusetts). Performance was evaluated using the Reactive Strength Index (RSI), calculated as JH divided by CT, along with peak force (PF) and time to peak force (TTPF) during the first and last 10 jumps of the test. A one-sample t-test was used to determine whether the relative changes in performance metrics were significantly different from zero.

RESULTS: Participants completed 46 ± 3 jumps during the test. For the first 10 jumps, averages for RSI, JH and CT were 1.70 ± 0.12 , 27.91 ± 1.62 cm, and 166.70 ± 8.04 ms respectively. Average ground contact time ranged from 127.6 ms to 222.3 ms for the first 10 jumps, and 138.7 ms to 229.9 ms for the last 10. Comparisons between the first and last 10 jumps showed a drop of $13.80 \pm 8.66\%$ for the RSI ($p < 0.001$), increase in CT of $4.82 \pm 3.74\%$ ($p < 0.001$), and drop in JH of $8.11 \pm 7.49\%$ ($p < 0.001$). Investigating the force traces in more detail, PF dropped by $6.91 \pm 5.46\%$ ($p < 0.001$), while the change in TTPF was not significant (increase of $1.21 \pm 12.38\%$, $p = 0.601$).

CONCLUSION: The 30 second jump induced fatigue, evidenced by significant decreases in RSI, JH and PF. Despite the fatigue, participants were able to sustain CTs under 250 ms, ensuring we tested the FSSC. Changes in RSI were predominantly due to changes in JH. Changes in TTPF were highly variable between participants and should not be used to assess fatigue in RS and FSSC performance.

EVALUATING WALKING SPEED AND HEART RATE RESPONSE AS INDICATORS OF ASSESSMENT QUALITY OF THE SIX MINUTE WALKING TEST

ŠMITE, Z., PAHIRKO, L., FEDULOV, A., IVANOVA, I., PLAKANE, L., SOKOLOVSKA, J.

UNIVERSITY OF LATVIA

INTRODUCTION: The six minute walking test (6MWT) is a cost-effective and easy to administer submaximal test used to evaluate functional capacity and estimate aerobic fitness in both clinical and healthy populations [1]. However, because it is self-paced, test intensity can vary significantly between individuals, ranging from moderate to vigorous, potentially affecting the reliability of the maximum walking distance achieved during the test [2][3]. This variation raises concerns about whether test outcomes accurately reflect an individual's functional capacity in a healthy population or are largely influenced by motivation. This study aimed to evaluate whether walking speed and heart rate measures can help assess the quality of each individual's test results by identifying the impact of motivation on performance.

METHODS: Seventy overweight participants (84.1 ± 11.9 kg; 170.6 ± 9.0 cm; BMI: 28.8 ± 2.3 kg/m²) performed the 6MWT on a 20 m indoor track. Participants were instructed to walk as fast as possible to cover the greatest distance in six minutes.

Time updates were provided every minute without additional encouragement. HR was recorded using a Polar H10 chest strap, and lap counts and time were tracked with a Polar Pacer Pro watch. Pearson correlation was used to analyze the relationship between average relative HR expressed as a percentage of predicted max HR ($220 - \text{age}$) and maximum walking distance. Hierarchical agglomerative clustering using Wards minimum variance linkage method and Euclidean distance was applied to classify participants based on their average walking speed and average relative HR. Group comparisons were conducted using ANOVA or the Kruskal-Wallis test, depending on normality (Shapiro-Wilk test), with appropriate post hoc tests applied when significant differences were detected.

RESULTS: A moderate positive correlation was observed between average relative HR and maximum walking distance ($r=0.36$, $p=0.002$). Based on average walking speed and average relative HR, four distinct clusters were identified: Slow-LowHR ($n=11$), and Slow-ModerateHR ($n=19$), Fast-ModerateHR ($n=9$), Fast-HighHR ($n=31$). Significant differences in average walking speed were observed between all groups except Slow-LowHR (1.66 ± 0.09 m/s) and Slow-ModerateHR (1.74 ± 0.12 m/s) as well as Fast-ModerateHR (2.01 ± 0.09 m/s) and Fast-HighHR (1.93 ± 0.15 m/s). Average relative HR differed significantly between all groups (Slow-LowHR: 64.2 ± 2.4 %HRmax, Slow-ModerateHR: 74.4 ± 3.4 %HRmax, Fast-ModerateHR: 70.7 ± 5.0 %HRmax, Fast-HighHR: 84.4 ± 3.6 %HRmax), except between Slow-ModerateHR and Fast-ModerateHR.

CONCLUSION: In the 6MWT, evaluating the interaction between walking speed and heart rate response can support interpretation and help identify individuals whose slow pace and low HR may indicate low motivation, suggesting that their results could be unreliable and a repeat assessment may be needed.

LONGITUDINAL MONITORING OF INTERNAL LOAD IN AN ELITE ATHLETE: A SINGLE-CASE STUDY TOWARDS THE PARIS OLYMPIC GAMES

NAKAMURA, M., SHIMISU, J., TAKEBAYASHI, Y.

JAPAN INSTITUTE OF SPORTS SCIENCES

INTRODUCTION: Monitoring training load is essential for understanding individual responses to training, managing fatigue, optimizing recovery, and minimizing the risk of nonfunctional overreaching and injury. Training load is typically classified into internal load (IL) and external load (EL) (1). Despite the importance of these monitoring methods, standardized methods for longitudinal evaluation remain limited. This study aimed to explore an effective condition assessment framework for optimizing elite athlete performance using a single-case experimental design (SCED) in preparation for the Paris Olympic Games.

METHODS: A single elite athlete was monitored over one year, tracking daily sleep parameters, lowest heart rate (HR), and heart rate variability (HRV), which were measured using the OURA Ring (Our Health, Oulu, Finland). Subjective data, including subjective fatigue and training load indicators such as session rating of perceived exertion (sRPE), calculated as training time $\times$ RPE, were collected via AthletesPort developed by JISS, while both subjective and objective data were managed using a centralized tool (2). Preparedness was estimated using a fitness-fatigue mathematical model incorporating sRPE (3). Tau-U was employed to compare various indices during the training and tapering phases. Effect sizes (ES) were classified as follows: 0.80–1.00 (very large change), 0.60–0.80 (large change), 0.20–0.60 (moderate change), and 0.00–0.20 (small change) (4). The Bayesian hierarchical piecewise regression model (BHPRM) with AR1 was employed to assess athlete-specific indicators and evaluate daily condition fluctuations in the year before the Paris Olympic Games.

RESULTS: A comparison of changes in resting HRV between the training and tapering phases of hypoxic training at 2,000 m, conducted three times a year, showed that resting HRV increased significantly from the first training to the tapering phase ($ES = 0.71$), with moderate increases in the second ($ES = 0.27$) and third ($ES = 0.43$). Based on BHPRM estimation, preparedness, calculated using a 5-day moving average, differed significantly between the training and tapering phases within the three weeks before each race (level difference: 0.26 [95% CI: 0.09 – 0.41], slope difference: 0.09 [95% CI: 0.03 – 0.16]). Both the level and slope improved during tapering, with significant between-race variability in the training phase slope (0.05, [95% CI: 0.02 – 0.10]).

CONCLUSION: Monitoring daily IL demonstrated its potential for assessing training adaptation and competition readiness in elite athletes. Furthermore, the results of the present study suggested that IL data collection and SCED-based statistical analysis may be useful for tracking intra-individual conditions in athletes.

THE EFFECTS OF VISUAL BLUR ON GAIT ALTERATIONS: ADAPTIVE AND COMPENSATORY MECHANISMS IN ATHLETES

CHANG, C., ZHOU, Z., LIN, J.

NATIONAL TAIWAN UNIVERSITY OF SPORT

INTRODUCTION: Refractive error is one of the most prevalent eye disorders worldwide, occurring when light fails to focus accurately on the retina, thereby reducing visual clarity [1]. The visual system plays a vital role in dynamic tasks, and visual

blur can significantly impair athletic performance. Despite the importance of vision in sports, few studies in sports biomechanics have explored how blurred vision affects motor tasks. This study aims to address this gap by examining lower limb joint kinematics and foot plantar pressure characteristics during slow running under varying degrees of refractive error.

METHODS: This study recruited 5 male collegiate athletes. Blurred vision was induced by wearing lenses with different diopters (D) to simulate three visual conditions: myopia (-3D), full correction (0D), and hyperopia (+3D). Participants performed a 15-second slow run at a speed of 6 km/h. The gait parameters, lower limb joint angles, and foot plantar pressure during the stance and swing phases were analyzed. One-way ANOVA repeated measures was used to compare kinematic and kinetic differences among the three visual conditions.

RESULTS: The results revealed no significant differences in foot plantar pressure, gait parameters, or joint angles among the visual conditions. However, descriptive statistics revealed some noteworthy trends. Full-foot pressure during the stance phase showed higher in the -3D and +3D conditions compared to 0D. Specifically, midfoot and heel pressures were higher in both the -3D and +3D conditions compared to 0D, with midfoot pressure increasing by 3.29% (-3D) and 5.05% (+3D), and heel pressure increasing by 12.53% (-3D) and 11.8% (+3D), respectively. During the swing phase, participants exhibited greater hip and knee flexion and increased ankle abduction in the -3D and +3D conditions. Additionally, gait analysis showed that the -3D condition demonstrated a wider step width compared to the other two conditions.

CONCLUSION: The findings suggest that blurred vision reduces athletes environmental perception, prompting them to adopt more stable gait strategies, such as increased hip and knee flexion and greater ankle abduction during the swing phase to improve swing foot safety and center of mass adjustment. Moreover, blurred vision (-3D and +3D) resulted in increased midfoot and heel pressures during the stance phase. Under the -3D condition, athletes compensated by increasing step width, thereby enhancing balance support [2]. Although these compensatory strategies help mitigate the effects of visual blur on motor control, they may also increase the mechanical load on the hip and knee joints, which potentially affecting gait patterns and athletic performance over time. Therefore, it is recommended to fully correct refractive errors to ensure clear visual feedback and reduce the need for compensatory gait adjustments.

THE EFFECTS OF DIFFERENT ATHLETIC TAPES ON DYNAMIC POSTURAL CONTROL AND JOINT MOVEMENT PATTERNS DURING DUAL TASKS LANDING TASKS

LIN, J., CHUNG, Y.C.

NATIONAL TAIWAN UNIVERSITY OF SPORT

INTRODUCTION: Lateral ankle sprains are the most common lower limb injury and influence athletes in the long term. Athletic taping plays a role in providing reinjury. In addition to conventional rigid white tape, a novel taping material known as dynamic tape offers high elasticity. Nonetheless, its efficacy in safeguarding the ankle joint remains unexamined. To investigate the benefits of different taping methods on dynamic posture stability at drop jump tasks during divided attention.

METHODS: Recruited thirty male college-level Class A athletes and divided them into CAI and healthy groups based on the Cumberland Ankle Instability Tool (CAIT). The test item is a drop jump test and a divided attention task using different athletic taping methods. The taping methods involve no tape, dynamic tape, and white athletic tape. Used motion capture and force plates were collect during the landing. Statistical analysis was using two-way mixed design ANOVA.

RESULTS: The intervention of this study found that AT and DT effectively reduced ankle plantarflexion. Moreover, DT is beneficial in reducing the center of pressure (CoP) sway area during the landing phase for athletes with ankle instability.

CONCLUSION: The study found that athletes with CAI face ongoing risks of sprains due to biomechanical issues like reduced dorsiflexion and excessive plantarflexion. This leads to altered joint energy absorption and increased knee joint stress. CAI athletes also show impaired postural stability with greater sway areas of CoP and center of mass, heightening the risk of injury. Taping interventions (AT and DT) effectively reduce ankle plantarflexion, with DT showing additional benefits like improved ankle range of motion and enhanced dynamic postural stability, crucial for injury prevention in CAI athletes.

RELATIONSHIP BETWEEN ULTRASOUND IMAGING AND STANDARD APPROACHES IN ASSESSING DIAPHRAGM FUNCTIONALITY

RAMPICHINI, S., BORRELLI, M., DORIA, C., LIMONTA, E., MOTALLI, A., LONGO, S., CORATELLA, G., CÈ, E., ESPOSITO, F.

UNIVERSITÀ DEGLI STUDI DI MILANO

INTRODUCTION: Diaphragm is the primary inspiratory muscle involved in quiet and deep breathing. Like other skeletal muscles, it undergoes functional and structural adaptations in response to training procedures or diseases. The former can be comprehensively evaluated through the integration of different measurements, including spirometry, maximal inspiratory and expiratory pressure (MIP and MEP, respectively) and maximal voluntary ventilation (MVV). An additional indicator of diaphragm functionality can be obtained by ultrasound imaging (US) by quantifying the amplitude of diaphragm excursion during voluntary breathing. US can also provide evaluations of structural adaptations. Neuromuscular evaluations further complement functional assessments by measuring the compound motor action potential (CMAP) of the diaphragm during phrenic nerve stimulation (PNS). The relationship between US-derived measurements and functional or structural indicators has been scarcely investigated. Moreover, no studies have assessed the feasibility of US meas-

urement during PNS. Therefore, this study aims to explore correlations between US and pulmonary function variables and to evaluate the feasibility of a combined US and PNS technique for the assessment of diaphragmatic function.

METHODS: Twenty-seven healthy students (17 male; age: 23 ± 5 yr; body mass: 72 ± 11 kg; stature: 1.7 ± 0.1 m, mean $\pm$ standard deviation, SD) participated to the study. Pulmonary function was assessed via Forced vital capacity (FVC), vital capacity (VC), MVV, MIP and MEP. The amplitude of diaphragm excursion was evaluated through US during voluntary deep breathing (AmpDB) and PNS (AmpPNS). Simultaneously, CMAP was recorded. A Pearson's product moment correlation coefficient determined the correlation between US-derived variables and CMAP and with the outcomes of the standard pulmonary test.

RESULTS: AmpDB correlated with MVV ($r=0.45$; $p<0.05$) and MIP ($r=0.38$; $p=0.048$). AmpPNS showed a slight correlation with only CMAP ($r = 0.37$; $p=0.05$) while its correlations with FVC and VC were near to significant values ($p=0.07$ and $p=0.08$, respectively).

CONCLUSION: US imaging proved to be a convincing indicator to evaluate diaphragm function changes. Moreover, the simultaneous acquisition of US and PNS proved novel insights into the mechanical counterpart of the diaphragm electrical excitation.

VASCULAR AND CARDIORESPIRATORY ADAPTATIONS TO A 4-WEEK BLOOD FLOW RESTRICTED COUPLED WITH HIGH-INTENSITY INTERVAL TRAINING (HIIT) PROGRAM

GERNIGON, M., DESANLIS, J., COLIN, A., COTTIN, F., GORDON, D.

UNIVERSITÉ PARIS-SACLAY

INTRODUCTION: Blood Flow Restriction (BFR) interventions using occlusion pressures between 40-80% of individual limb occlusion pressure (LOP) have been shown to improve cardiovascular function and maximal oxygen uptake (VO_{2max}) [1] more effectively than training without BFR. Additionally, HIIT has been promoted as a time efficient method for increasing VO_{2max} [2]. The aim of the present study was to examine the effect of 4-weeks of HIIT cycling under localized BFR on submaximal and maximal cardiorespiratory and vascular responses.

METHODS: Twenty-five participants (11 females, 16 males; 19 ± 7 yo; 175 ± 8 cm; 67 ± 8 kg) were randomly assigned into one of the three groups: (G1) HIIT+20 mmHg of blood occlusion (SHAM), (G2) HIIT+40% LOP, and (G3) HIIT+60% LOP. The training program lasted 4-weeks, with 4 to 7 cycling bouts of 90s HIIT+BFR performed at 90% of VO_{2max} , interspersed with 2 min unoccluded recovery. During all training intervals, both thighs were occluded. Pre- and post- training intervention, participants completed an incremental step to volitional exhaustion for determination of VO_{2max} , Gas Exchange Threshold (GET), Respiratory Compensation Point (RCP), Q_{max} and Tissue Saturation Index (TSI). Additionally, they completed a pre- and post- submaximal cycling trial of 10 min at baseline (BL; i.e., 50W for females, 100W for men), 6 min at moderate (MOD=BL+50% (GET – BL)), 10 min at BL, and 6 min at heavy (HEV=GET+20% (RCP – GET)) intensities.

RESULTS: Maximal aerobic power (MAP) improved significantly across all groups ($p<.001$; $\eta^2=0.11$) but not for VO_{2max} among any of the groups ($p>0.05$). A significant rightward shift of GET ($p<0.001$) and RCP ($p<0.001$) against workload were observed but with no differences among any of the groups. Q_{max} ($p=0.13$, $r=-0.335$) and TSI_{max} ($p=0.54$) remained unchanged after the training period. All groups showed a sub-maximal heart rate response ($p<0.001$) only in the BL, but with no differences among any of the groups. G3 exhibited a reduced VO_2 and VCO_2 in both MOD bouts ($p<0.001$). In HEV, a lower VO_2 ($p=0.004$) was observed with no differences across all groups.

CONCLUSION: While all groups showed increased MAP, 4 weeks of BFR+HIIT did not enhance maximal cardiovascular adaptations, suggesting peripheral adaptations highlighted by delayed GET and RCP. Submaximal results indicate HIIT+60% LOP may be more efficient probably due to increased blood pooling and metabolite accumulation. A longer BFR training might demonstrate benefits for maximal cardiovascular and cardiorespiratory adaptations, highlighting the potential of combining HIIT+BFR.

A NOVEL EQUATION FOR PREDICTING WALKING-INDUCED ENERGY CONSUMPTION IN MALE COLLEGE STUDENTS

LIANG, C., WANG, L., MAO, Y., LI, L., YU, M., SU, H.

1 GUANGXI UNIVERSITY; 2 BEIJING SPORT UNIVERSITY

INTRODUCTION: As health awareness continues to rise among college students, walking has emerged as a popular form of exercise due to its simplicity, cost-effectiveness, and efficiency in promoting fitness. Accurate measurement of walking energy expenditure (EE) is crucial in ensuring exercise safety and optimizing health outcomes. However, traditional methods for assessing EE, which often rely on complex and expensive equipment, pose significant barriers to widespread and timely public assessment. This study aims to develop a convenient and precise method for estimating walking EE among Chinese male college students, utilizing straightforward parameters to predict consumption across various speeds. This will provide college students with a practical self-monitoring tool, promoting scientifically-based fitness practices.

METHODS: 60 healthy male Chinese college students (21.12 ± 1.28 years) were recruited for this study. Under rigorously controlled conditions, including the testing environment, workload, rest intervals, and dietary intake, a crossover experimental design was adopted. Participants were engaged in 30-minute treadmill walking exercises at inclinations of 0° , with speeds of 4.8 km/h, 6.4 km/h, and 8.1 km/h. A 7-day washout period was imposed between each speed test to ensure the absence of residual effects. EE was measured through respiratory gas analysis utilizing a MetaLyzer 3B ana-

lyzer (Germany) and heart rate monitoring with a Polar device (Finland). Subsequently, partial correlation analysis and multiple regression were performed on the collected data to formulate a regression equation linking EE with pertinent physical parameters. To further validate the equations precision, an identical experimental protocol was applied to an additional cohort of 20 healthy male college students. Their measured data were rigorously compared with the predicted values derived from the regression equation, using a paired t-test.

RESULTS: EE per minute during 30-minute walking was significantly correlated with walking pace and heart rate ($P < 0.01$), and moderate correlations with BMI, height, and body weight ($P < 0.05$). Stepwise multiple regression analysis yielded an EE prediction model: $EE \text{ (kcal/min)} = -8.453 + 1.030 \times \text{pace (km/h)} - 0.023 \times \text{BMI (kg/m}^2\text{)} + 0.032 \times \text{heart rate (bpm)} + 0.080 \times \text{body weight (kg)}$. There were no significant differences between the predicted values of the formula and the measurements of the external validation sample at the three walking speeds ($P_{4.8} = 0.255$, $P_{6.4} = 0.470$, $P_{8.1} = 0.353$).

CONCLUSION: This study developed a precise EE prediction model for male college students during walking, incorporating four readily measurable parameters: walking speed, BMI, heart rate, and body weight. The validated formula provides a reliable and practical tool for quantifying walking-related EE in this population.

MOTOR CONTROL, COGNITION, AND HORMONAL LEVEL DURING THE MENSTRUATION PHASE IN HIGHLY TRAINED FEMALE ATHLETES

TEULIER, C.1,2, CASTANIER, C.1,2, BONNIGAL, J.1,2,5, BUISSON, C.4, DURON, E.6, FAVORY, E.5, ZIMMERMANN, M.8, AMIOT, V.8, COLLOMP, K.1,2,3,4, OLIVIER, A.5

IFCE, CADRE NOIR, SAUMUR, FRANCE. 6. HÔPITAL BROUSSE, AP-HP, VILLEJUIF, FRANCE. 7. EQUIPE INSERM MOODS-CESP, VILLEJUIF, FRANCE. 8. MÉDECINE DU SPORT, CHU ORLÉANS, ORLÉANS, FRANCE.

INTRODUCTION: Around 50% of female athletes use hormonal contraception (Martin et al., 2018). However, it is currently unknown if fluctuations in sex hormones either during the normal menstrual cycle (NMC) or during combined oral contraceptive intake (COC) influence motor or cognitive performance in female athletes.

METHODS: Therefore, we tested 22 trained female athletes 3 times: 14 with NMC (tested during the early follicular phase vs. follicular phase vs. luteal phase) and 8 with COC (tested during no hormonal intake vs 1st week of intake vs 3rd week of intake). Estradiol (E2) and testosterone (T) levels were assessed, as well as cognitive performance (tests on spatial cognition, memory, and reaction times) and motor performance (countermovement jump and grip test).

RESULTS: Motor and cognitive performances were stable across the menstrual cycle for both groups of participants ($ps > .05$). A group effect was found for some performances (higher grip strength for the COC group; greater memory span for the COC group, $ps < .05$). No correlations were found between neither hormonal concentration in E2 or T and motor or cognitive performance, nor between the variation in hormonal concentration and performance ($ps > .05$).

CONCLUSION: As previously described in the literature (Smith et al., 2024), there is no obvious variations in either motor or cognitive performance across the menstrual cycle in trained athletes. Moreover, fluctuations of E2 and T, which are supposed to impact performance, are not related to the performance of highly trained athletes. More studies are necessary to understand if a high dose of training might overcome the usual impact of sex hormones on performance.

ASSOCIATION BETWEEN MAXIMAL LOWER BODY STRENGTH AND BALANCE PERFORMANCE IN GRASSROOTS SPORTS ATHLETES

CUHALOVŠ, R., PLAKANE, L., SMITE, Z.
UNIVERSITY OF LATVIA

INTRODUCTION: Postural balance plays a crucial role in minimizing injury risk during both daily life and sports activities, with research showing that individuals who exhibit greater postural sway are more prone to injuries [1]. Maintaining balance requires significant neuromuscular contributions from the trunk, hip, ankle, and foot, as the neuromuscular system must execute rapid and coordinated minor adjustments in muscular activity to preserve balance [2,3]. Previous studies have demonstrated a link between ankle and hip strength and balance performance [1,2,3]. This study aimed to evaluate the association between lower body maximal strength, balance performance, and asymmetries.

METHODS: Twenty grassroots sports athletes (mean±SD; 71.3±12.5 kg; 175.2±7.9 cm; BMI: 23.2±3.4 kg/m²) participated in a cross-sectional study. The test protocol included the isometric mid-thigh pull (IMTP), seated isometric plantarflexion (PF), and a single-leg balance test, which were performed on force plate (Musclelab, Ergotest Innovation AS, Norway). All assessments were performed unilaterally on both sides with three trials conducted per test. Maximal force was obtained from the strength tests, with the best trial selected for further analysis. Center of pressure (CoP) displacement as the primary variable, was obtained from single-leg balance test. Average CoP displacement values across the three trials were

used for further analysis. Statistical analyses included Pearson or Spearman correlation coefficients depending on normality (Shapiro-Wilk test), to evaluate the relationship between strength and balance variables. The Wilcoxon signed-rank test, followed by Bonferroni correction, was used to detect significant differences in asymmetry magnitude across tests. Cohen's Kappa coefficient was used to assess agreement in asymmetry direction between tests.

RESULTS: There were no significant correlations between single-leg balance test variables and IMTP or PF ($p > 0.05$). IMTP asymmetry magnitude is significantly lower than asymmetry calculated from single-leg balance test variables area, mean CoP length and SD CoP length ($p = 0.003$). Single-leg balance test variables have poor to moderate ($\text{Kappa} = -0.10$ – 0.60), and poor to fair ($\text{Kappa} = -0.10$ – 0.29) agreement levels with IMTP and PF, respectively, determining direction of asymmetry.

CONCLUSION: Maximal isometric strength of the hip, knee extensors, and plantarflexors was not associated with balance performance, suggesting that maximal strength may not be a key factor in maintaining balance. However, single-leg balance asymmetry more closely aligns with the direction of hip and knee extensor strength asymmetry.

CP-BM02 Motor Learning and Motor Control I

IDENTIFYING EARLY LEARNING STAGES IN THREE-BALL CASCADE JUGGLING

WU, Y., LIU, Y.T.

NATIONAL TAIWAN NORMAL UNIVERSITY

INTRODUCTION: Motor skill learning is an individual process. Individual constraints such as body size and prior experiences contribute to motor performances as well as the progress of skill learning. Early identification of the result of these constraints allows adaptive guidance at an early stage. 3-ball cascade juggling is a complex yet attainable novel task to study motor learning. Prior research has often observed different progress rates among learners reflecting different stages of juggling development. Different functions have been used to model long-term learning performance. This study examined athletes from different sports backgrounds learning 3-ball cascade juggling and categorized them into different learning stages based on different models.

METHODS: 16 college athletes with no prior experience with 3-ball juggling, 8 each from open- (O) and closed-skill (C) sports, participated in learning to do so. After a brief instruction session and the pre-test (PRE), participants practiced 15 min 3-ball juggling for 4 days, followed by a post-test (POST) on day 5. Based on the POST performance of 6 catches or more, participants were identified as in progression (P) or beginning (B) stages. The accelerated exponential (AEXP) and linear function (LN) fit the daily average catches of 4 practice days. The 2-way mixed-design ANOVA was used to examine differences in PRE-POST performance between O and C, as well as differences in R^2 between AEXP and LN within P and B. Additional independent t-tests were performed to compare the rate of change of AEXP and LN between P and B.

RESULTS: For the number of successful catches, no significant differences were observed between the PRE and POST ($p = .20$), between O and C ($p = .26$), or in their interaction ($p = .27$). However, in the analysis of model fit, a significant interaction was found between function type and learning stages ($p < .05$). Post-hoc analysis indicated that AEXP R^2 value (0.98) were significantly higher than LN (0.85, $p = .002$) for P. No significant difference was observed between AEXP and LN in B. The rate of change was significantly higher for both the AEXP ($p = .03$) and LN ($p = .002$) for P compared to B.

CONCLUSION: The results suggest that sports background did not contribute significantly to learning to 3-ball juggling in 4 days. The P group demonstrated rapid improvement, with the AEXP providing a better fit for their performance curves. The B group did not show significant differences in model fit between AEXP and LN, and their rates of change were significantly lower than that of the P group, indicating a slower progression over the practice. This suggests that the B group may require additional instructional support. The findings indicate that early-stage learning 3-ball juggling can be categorized based on the average number of successful catches, and the model-fitting results further support this classification.

ECRONY: AN INNOVATIVE MOTOR LEARNING TOOL FOR TEACHING THE BIOMECHANICS OF WALKING

FOGLIATA, A., AMBRETTI, A., TARDINI, S.

UNIVERSITY OF CAMPANIA LUIGI VANVITELLI

INTRODUCTION: Walking is a fundamental motor pattern that integrates complex biomechanical and neurological systems, whose efficiency is crucial for the development of advanced motor gestures such as running and its variations in sports and physical activities. Although it may seem like a simple coordination task, walking is, in fact, a multifaceted and systemic process that requires a deep biomechanical understanding to be effectively taught and optimized. This study aims to present and analyze eCrony, an innovative educational tool based on the Sincrony educational framework, designed to support students in sports science in comprehending human walking.

METHODS: eCrony innovatively emphasizes proprioceptive and kinesthetic awareness as primary tools for motor comprehension. Using an experimental approach that differentiates between the causes and visible effects of movement, it

equips learners with the knowledge needed to enhance their correction and teaching abilities. The tool, structured into four didactically progressive levels, introduces the concept of the "vacuum" as a theoretical framework to understand the influence of external forces like gravity and inertia on visible motor gestures. eCrony also guides students through the activation sequence of the main muscle groups involved in walking, using interactive modules, video demonstrations, and practical exercises. These combine proprioceptive feedback with theoretical knowledge. Additionally, this tool introduces advanced biomechanical concepts, such as the Grocco model (2008), which defines the basic segmental unit of movement as consisting of two joint segments and one motor muscle.

RESULTS: The educational path provided by eCrony aims to stimulate learning by developing advanced observational skills essential for identifying errors and inefficiencies in motor gestures, particularly walking. The eCrony prototype transforms the traditional study of the gait cycle into an in-depth theoretical and practical analysis of walking as a transitional foundation for more advanced motor activities, such as running and jumping, which are fundamental to many sports.

CONCLUSION: The expected outcomes from using this digital tool include improved observation and correction skills in walking for future sports science educators. Furthermore, eCrony, with its apparent simplicity, incorporates several innovative principles for motor education that could inspire new possibilities for teaching movement.

BACKWARDS WALKING IN A THERAPEUTIC CONTEXT: A SCOPING REVIEW

RADEBE, V., LATEGAN, L.

STELLENBOSCH UNIVERSITY

INTRODUCTION: Walking is used by physical therapists as both a technique for rehabilitation and as a measure of success to treat a number of conditions and diseases. The ability to walk in multiple directions including backward is an imperative for activities of daily living and survival. Retro walking is not simply the reverse of forward walking and with the changes in the direction there are changes to the joint kinematics occurring at the ankle, knee, and hip. The main aim of the study was to determine the therapeutic benefits of backward walking and provide guidelines for physical therapists.

METHODS: The research design used was a scoping review. The sources of the scoping review included both randomised and non-randomised controlled trials which utilised "retro walking and/or backward walking". The search of published literature was completed using databases. The sources of the research were published before 1 November 2024 which utilised backward walking in a physical rehabilitation context. The studies included in the literature review included adults (above 18 years old) both male and female. The articles that met the inclusion criteria were analysed by means of the data extraction form. From the articles that were analysed, the results were drawn up. Six articles were included and analysed to address the research question.

RESULTS: A total of six studies met the inclusion criteria and were subsequently analyzed. Two of these studies specifically investigated the effects of backward walking interventions on patients diagnosed with knee osteoarthritis, assessing parameters such as pain reduction, joint function, and biomechanical adaptations. Three studies focused on the application of retro walking as a rehabilitative strategy for individuals recovering from stroke, examining its impact on gait mechanics, balance restoration, and neuromuscular activation. The remaining study explored the influence of retro walking on individuals with general and abdominal obesity, evaluating changes in body composition and metabolic parameters.

CONCLUSION: Backward walking is a valuable rehabilitative tool in physical therapy, offering significant therapeutic benefits for individuals physical rehabilitation for neuromuscular skeletal, neurological and chronic conditions. Backward walking is utilized to restore functional mobility, enhance proprioception, and improve neuromuscular control in individuals with neuromuscular skeletal conditions such as knee osteoarthritis. Additionally, it plays a critical role in neurological rehabilitation, aiding stroke survivors by promoting balance, gait symmetry, and lower limb coordination. Its application in chronic disease management, particularly in individuals with obesity in reduction in waist circumference further highlights its role in improving functional capacity and overall physical health. Backward walking is a cost effective, easy to administer tool that should be utilized in conjunction to traditional therapy.

EVALUATING THE IMPACT OF PASSIVE EXOSKELETON ON MAXIMAL ISOMETRIC STRENGTH, PERCEIVED WORKLOAD AND COMFORT IN MANUAL MATERIAL HANDLING

BULLO, V., GOBBO, S., FAVRO, F., DORO, B., PAVAN, D., BORTOLETTO, A., BERGAMO, M., BERGAMIN, M.

UNIVERSITY OF PADOVA

INTRODUCTION: Work-related musculoskeletal disorders (WMSDs) are the most common work-related health problem in the European Union, with an increasing trend from 27 EU countries (Eurostat data) between 2007 and 2020 (from 54.2% to 60.1%). In recent years, exoskeletons have been developed to aid manual workers, wearable devices that stabilize and support the locomotor system of the human body. Studies have tested the effectiveness of passive back-support exoskeletons during simulated load-handling tasks (Schmalz et al., 2022), but the effect on maximal strength has not yet been investigated under standardized conditions. The aim of this study was to determine whether the use of a passive exoskeleton supporting the lower body can improve the user physical performance during a maximal strength isometric lifting task. Additionally, we sought to investigate the comfort and wearability of the device.

METHODS: The exoskeleton used for this study was the Paexo Back model produced by Ottobock SE & Co. KGaA (Duderstadt, Germany), designed to aid in lifting by supporting the lower back. 34 healthy male workers (age: 30 ± 11 years old) participated in this study. Stature and weight were measured and handgrip strength was tested on the dominant side. Each participant performed general and specific warm-up, afterward, they performed three trials of isometric

maximal deadlift pulls with and without wearing the exoskeleton, in a randomized order, with 90 seconds of rest between each attempt. Then, the participants completed a questionnaire on the wearability and comfort of the exoskeleton prepared for this study.

RESULTS: The mean strength performance without using the exoskeleton was 135.5 ± 31.2 kg, and 144.9 ± 32.1 kg with the device, with a mean difference between the two conditions (Δ exo) of 9.4 ± 16.5 kg. The range for Δ exo was -27.9-55.1 kg. The paired t-test revealed a significant difference between the two conditions (t-score = 3.3246, p-value = 0.0022, fig. 4), with an effect size of 0.56 (95% confidence interval of 0.20-0.92). There was a weak correlation between Δ exo and stature (Pearson's $r = 0.35$, p-value = 0.045). From the comfort questionnaire, strength support was the highest scored item, while dressing autonomy received the lowest scores.

CONCLUSION: The exoskeleton was effective in improving isometric strength and was perceived as providing good support, although wearability remains a barrier.

THE EFFECT OF OBSTACLE APPEARANCE TIMING ON DECELERATION BEHAVIOR DURING WALKING

TATSUYA, H., ISSEI, O., SHOJI, K., SUSUMU, I., TOMOYUKI, M., KEN, N.

OSAKA UNIVERSITY

INTRODUCTION: Sudden deceleration during change of direction (CoD) may increase the risk of non-contact anterior cruciate ligament (ACL) injury. Sudden CoD is typically experienced when athletes are required to avoid obstacles, such as opponents, in team sports. Although studies have focused on risk-elevated lower limb kinematics and kinetics during unanticipated CoD, it is still unknown whether the timing of obstacle appearance affects the deceleration behavior during subsequent CoD. This lab-controlled study aimed to investigate whether the timing of obstacle appearance during walking affects the distribution of deceleration amount in the subsequent first and second steps.

METHODS: Fourteen healthy adults were asked to walk on the 5.5 m platform at 100 bpm cadence. If the visual obstacle (black circle with a 25-cm radius) appeared on the platform in front of them, they were instructed to change their walking direction toward left or right to avoid the obstacle. The positions of the torso marker cluster and the toe markers were collected (360 Hz). 80 trials with obstacle appearance and 20 trials without obstacle appearance were performed randomly to avoid anticipation of obstacle appearance. In the obstacle appearance trials, a custom MATLAB script was used to control the timing of the obstacle appearance so that it appeared randomly and evenly from the beginning to the end of the swing phase. The timing of obstacle appearance was quantified as the percentage of the swing phase from toe-off (0%) to heel contact (HC, 100%). The negative peaks of torso marker cluster's acceleration at the first and the second HC after obstacle appearance were analyzed. The percentage of the first HC deceleration (%1stHCD) relative to the sum of the first and the second HC deceleration was calculated as an outcome measure of deceleration behavior. In addition, the body momentum at the obstacle appearance (BM@ob) was calculated as the torso marker cluster velocity times the participants body mass. Both %1stHCD and BM@ob were grouped into five bins at every 20% interval in the timing of the obstacle appearance, and a Mann-Whitney U test was conducted between these timing groups.

RESULTS: 1022 trials were included. %1stHCD was smaller when the obstacle appeared in the earliest (0—20%) or the latest (80—100%) swing phase compared to the middle (20—80%) swing phase. When the obstacle appeared in the latest (80—100%) swing phase, BM@ob became the greatest among all swing phases. All p-values were < .005.

CONCLUSION: When an obstacle appeared in the latest swing phase, the %1stHCD was smaller despite the greatest body momentum. This suggests that the latest obstacle appearance did not allow sufficient preparation time for the subsequent stance limb (the first HC) to decelerate body velocity effectively, resulting in a reduced %1stHCD. Insufficient preparation time for sudden deceleration could also increase the load on the second stance limb, consequently leading to improper deceleration function on the first limb.

RELATIONSHIP BETWEEN PERCEPTION THRESHOLD OF LEFT-RIGHT SPEED DIFFERENCES AND LOCOMOTOR ADAPTATION IN SPLIT-BELT TREADMILL WALKING

HAMADA, T., KITAMURA, M., KAMIBAYASHI, K.

DOSHISHA UNIVERSITY

INTRODUCTION: Humans can adjust their walking patterns in response to various environments. A split-belt treadmill has been utilized to study locomotor adaptation. When healthy individuals are exposed to a perturbation where the walking speeds differ between the right and left legs, their walking patterns become asymmetrical but gradually approach symmetry over several minutes¹). For locomotor adaptation, the perception of left-right speed differences is considered important to recognize asymmetric movements as errors and correct them²). However, the relationship between the ability to perceive left-right speed differences and the ability to modify asymmetric movement during walking remains unclear. Therefore, this study aimed to investigate the relationship between changes in walking patterns due to locomotor adaptation on a split-belt treadmill and the ability to perceive left-right speed differences.

METHODS: Eighteen healthy adults performed two types of walking tasks to evaluate perception threshold for left-right speed differences and locomotor adaptation ability during split-belt walking. To evaluate the perception threshold for speed difference, the treadmill belt speed on one side was increased from 1.0 m/s to 1.4 m/s over 40 s while the participants were walking at 1.0 m/s. They were instructed to press a button when they perceived the speed difference and to indicate which side had the increased speed. Six trials were randomly conducted under three conditions: left-belt speed increase (4 trials), right-belt speed increase (1 trial), and no speed change (1 trial). The perception threshold was calculated

as left-right speed difference at the time of button press during the trials where the left-belt speed was increased. The walking task to evaluate locomotor adaptation ability consisted of three periods: Baseline period (both belts at 1 m/s for 2 min), Adaptation period (right: 1 m/s, left: 1.5 m/s for 10 min), and Washout period (both belts at 1 m/s for 5 min). To assess adaptation ability, step length symmetry was evaluated. Pearson correlation coefficients were calculated between the perception threshold and step length symmetry for specific phases of the Adaptation and Washout periods: 0-10 s, and 30-s intervals up to 240 s.

RESULTS: In the first 240 s of the Adaptation period, significant negative correlations were observed between the perception threshold and step length symmetry. Specifically, the most prominent correlation was observed between 30 and 60 s.

CONCLUSION: The results suggest that the ability to perceive left-right speed differences is related to the ability to adapt during split-belt walking. Individuals who can perceive small speed difference between the left and right belts are likely to rapidly adjust asymmetric walking movements into more symmetric walking patterns.

IDENTIFYING THE FACTORS THAT INFLUENCE CYCLING SKILLS ON CONVENTIONAL AND ELECTRIC BICYCLES IN YOUNG AND OLDER ADULTS

DEROOST, F., LEPLAE, J., DE GROOTE, F., ORBAN DE XIVRY, J.J.

KU LEUVEN: KATHOLIEKE UNIVERSITEIT LEUVEN

INTRODUCTION: Cycling is a widely practiced and sustainable activity offering substantial health benefits across all age groups. In recent years, more older adults have continued cycling at a later age, particularly on electric bicycles. However, older adults are more involved in cycling accidents compared to other age categories, especially when riding electric bicycles (1). These accidents often occur without the involvement of other road users, suggesting that reduced cycling skills in older adults is a contributing factor (2). This study aims to investigate whether balance strategies differ between younger and older adults when riding conventional and electric bikes.

METHODS: A group of young (20-35 y/o) and older adults (60-75 y/o) completed a cycling track on both a conventional and an electric bicycle while cycling at their preferred pace and at 50% of this pace. The cycling track consisted of several tasks related to real-life traffic situations (e.g. cycling through a narrow lane, mount and dismount the bicycle, shoulder checking). Wireless inertial measurement units (IMUs) were attached to the bicycle's handlebar, frame and the cyclists. This data was used to compute the steering angle and the bike roll angle. Bike stability while cycling was quantified using the standard deviation of the bike roll angle and the steering rate, which is the rate of change of the steering angle over time.

RESULTS: We will investigate the effects of bike type (conventional vs electrical bike), age group (old vs young adults), and cycling speed (self-selected vs. slow speed) on bike stability. We hypothesize that (1) cycling at lower speeds will lead to higher standard deviations in both steering rate and bike roll angle. (2) We also expect older adults to exhibit higher standard deviations in steering rate and bike roll angle compared to younger participants while completing the cycling track. (3) Furthermore, we anticipate greater standard deviations in steering rate and bike roll angle when riding an electric bike compared to a conventional bike at lower speeds. (4) Finally, we predict that the differences in bike stability will be mainly observed in more challenging tasks, such as shoulder checking, compared to easier tasks like cycling in a narrow line.

CONCLUSION: The findings will provide insights into the aspects contributing to balance difficulties while cycling, with implications for developing targeted interventions to reduce cycling-related accidents, particularly among older adults.

ACUTE EFFECT OF VIRTUAL REALITY EXERGAME TRAINING ON SPEED-ACCURACY TRADE-OFF

GROSPRETRE, S., RUFFINO, C.1, JOURNOT, P.1, MARUSIC, U.3,4, WOLLESEN, B.5

1: C3S LABORATORY; 2: INSTITUT UNIVERSITAIRE DE FRANCE ; 3: ZRS KOPER; 4: ALMA MATER EUROPAEA UNIVERSITY; 5: GERMAN SPORTS UNIVERSITY COLOGNE

INTRODUCTION: The duration of arm-reaching movements depends on target distance and size, as modeled by Fitts in 1954 through a linear relationship between target difficulty and movement duration (1). Thus, increasing execution speed compromises accuracy and vice versa. Both elite sports performance and daily tasks rely on managing this speed-accuracy trade-off. This study aimed to examine how a virtual reality (VR) exergame can improve this motor competence.

METHODS: Twelve healthy young participants (23.4 years old, 4 females) completed three sessions on separate days in a random order to assess the effects of three VR interventions: control condition (CONT), accuracy-focused (ACC), and speed-focused (SPE). The control condition consisted of a neutral immersive VR video. ACC and SPE involved playing the VR rhythm game "Beat Saber" (Beat Games, Prague), where players cut approaching cubes with two virtual sabers. In ACC, cubes were at minimum size, cutting tolerance was reduced, and speed was moderate. In SPE, cube size and dis-

play speed were maximized, while cutting tolerance increased. Each intervention (CONT, ACC, SPE) lasted 15 minutes. Before and immediately after each session, participants performed a Fitts' pointing task with their right arm, targeting four difficulty levels (determined by Fitts formula) on a large vertical touchscreen (120 × 70 cm). Standing participants extended their arm to touch targets in four directions: UP, DOWN, RIGHT, and LEFT. Throughout the experiment, variation of electromyographic (EMG RMS) activity of 5 shoulder muscles and three-dimensional hand acceleration were recorded.

RESULTS: CONT induced no changes in pointing times or muscle activations. In RIGHT and LEFT pointing, SPE reduced pointing time for the largest target (low difficulty), increasing Fitts' slope ($P < 0.001$). Conversely, ACC reduced pointing time for the smallest targets (high difficulty), decreasing Fitts' slope ($P < 0.001$). UP pointing remained unaffected. For DOWN pointing, SPE increased pointing time in difficult targets ($P = 0.011$), whereas ACC reduced pointing time in easier targets ($P = 0.006$). Muscle activation strategies and deceleration patterns varied between ACC and SPE. Arm accelerometry confirmed that the game used primarily involves horizontal and downward movements.

CONCLUSION: VR exergaming acutely modifies motor strategies by adjusting the speed-accuracy trade-off, as reflected in changes to Fitts' slope. These effects are intervention-dependent: accuracy training improved precise targeting, while speed training enhanced performance on simpler tasks. However, the speed-focused session impaired accuracy in downward movements. Actimetry data suggest that these effects are direction-specific and linked to the training, as no significant impact was observed in the less trained movement direction (UP).

CP-BM06 Gait

DIFFERENCES IN GAIT CHARACTERISTICS, STRENGTH AND BALANCE BETWEEN MALES WITH AND WITHOUT TYPE 2 DIABETES

BIRGISDÓTTIR, S., GISLADÓTTIR, T., PETROVIC, M.

UNIVERSITY OF ICELAND, SCHOOL OF EDUCATION, RESEARCH CENTER FOR SPORT AND HEALTH SCIENCES

INTRODUCTION: The prevalence of type 2 diabetes (T2D) is increasing, placing a burden on both individuals and healthcare systems. T2D accounts for approximately 90% of all diabetes cases, making it a priority for improved prevention and management. T2D is associated with various pathological complications, including those affecting the neuromuscular system. Previous research suggests that individuals with T2D often exhibit slower walking speeds, altered gait patterns, decreased muscle strength and impaired mobility compared to non-diabetic individuals. The aim of this study was to examine how strength, balance, ankle range of motion and step length are associated with self-selected walking speed (SS) and maximum walking speed (MS) among males with T2D.

METHODS: This cross-sectional study included 18 males diagnosed with T2D (age 62.5 ± 10.6 , body height 177.1 ± 5.4 cm, body weight 94.7 ± 16.7 kg), recruited from the Department of Endocrinology at the University Hospital, Reykjavik, Iceland and 10 non-diabetic males, (age 67.6 ± 3.3 , body height 182.3 ± 6.8 cm, body weight 98.8 ± 11.1 kg), recruited via convenience sampling. Walking speed was assessed at SS and MS by walking between two gates placed 10 meters apart. Balance was measured using a 15-second single-leg stand on VALD ForceDecks. Maximum voluntary contraction (MVC) of plantar flexors was tested using VALD ForceFrame and MVC of knee extensors using VALD DynaMo. Step length and ankle range of motion during walking were analyzed using video recordings of treadmill walking and Dartfish software. Independent samples t-tests in Jamovi software were used to compare SS, MS, strength, balance, ankle range of motion and step length between males with and without T2D. The significance level was set at $\alpha = 0.05$ and effect sizes were reported using Cohen's d.

RESULTS: Males with T2D had significantly lower MS ($p = 0.012$, $d = -1.11$) and knee extensor strength ($p = 0.006$, $d = -1.27$), compared to non-diabetic males. Mean values suggested that males with T2D had lower SS, shorter step-length, slightly lower ankle angles at toe-off and heel strike at SS and MS (except for a slightly higher angle at toe-off during MS), greater center-of-pressure range during single leg stance and lower plantar flexor strength compared to males without T2D. However, these differences were not statistically significant.

CONCLUSION: Results of this ongoing study indicate differences in physical performance of males with and without T2D in Iceland, with significant reductions in MS and knee extensor strength in people with T2D. These findings highlight the potential impact of T2D on strength and mobility, emphasizing the importance of screening for functional limitations and implementing targeted interventions to improve the quality of life in individuals with T2D.

LONGITUDINAL CHANGES IN STRIKE ANGLE SYMMETRY IN ACLR PATIENTS' GAIT MEASURED BY SMART SHOES

YUKI, U., ISSEI, O., SHOJI, K., MUTSUMI, S., AKIRA, T., KEN, N.

KEIO UNIVERSITY

INTRODUCTION: Gait asymmetry after anterior cruciate ligament reconstruction (ACLR) is frequently reported, potentially raising the risk of re-injury and posttraumatic knee osteoarthritis (KO). Conventional assessment methods focus on the

sagittal-plane knee angles and moments, which are key parameters influenced by ACLR, but require complex equipment such as optical motion capture and force plates.

With advancements in wearable sensor technology, gait analysis has become widely accessible in recent years. We have developed shoes with embedded sensors (smart shoes), which are more comfortable to wear and easy to calculate gait parameters based on foot movements. We hypothesised that ACLR-related asymmetry could be detected in the sagittal-plane foot movement measured by smart shoes, and observed the symmetry of the strike angle (the angle between the ground and the foot in the sagittal plane at initial ground contact) during the postoperative rehabilitation period. This study aimed to quantify strike angle symmetry in ACLR patients from 2 to 6 months post-surgery, comparing them with healthy controls to identify changes over time. We hypothesized that early postoperative asymmetry would decrease, approaching healthy levels by 6 months.

METHODS: Eight ACLR patients and 12 healthy participants wore smart shoes and walked on a treadmill at 4 km/h for 3 minutes. ACLR patients executed this task at 2, 3, 4, and 6 months postoperatively. Three-dimensional foot acceleration and angular velocity data (200 Hz) during walking were measured by smart shoes, and processed with gait analysis software ORPHE ANALYTICS to calculate the strike angle for each step. The symmetry index (SI) of the strike angle was computed for each participant. The effect of postoperative time (2, 3, 4 and 6 months) on the SI was tested by one-way ANOVA ($\alpha = 0.05$). The SI of each postoperative time was compared to the SI of healthy participants using Wilcoxon rank sum test with significance level $\alpha = 0.05/4$.

RESULTS: A significant main effect of postoperative time on SI was identified ($p = 0.021$). The SI decreased as postoperative time progressed (2 months: $22.19 \pm 13.09\%$, 3 months: $14.03 \pm 8.09\%$, 4 months: $10.50 \pm 5.00\%$, 6 months: $9.61 \pm 4.58\%$). While at 2 months, ACLR patients had a significantly larger SI than healthy participants ($6.57 \pm 5.95\%$; $p = 0.0015$), no significant differences emerged at 3 ($p = 0.047$), 4 ($p = 0.115$) or 6 months ($p = 0.208$) compared to healthy controls.

CONCLUSION: We quantified the change in gait symmetry over time in ACLR patients by gait analysis with smart shoes. The symmetry of the strike angle changed over time, and no statistically significant difference was observed already at 3 months postoperatively, indicating that the ACLR patients may have reacquired a level of symmetry like that of the healthy controls. Although strike angle symmetry alone may not be sufficient to assess the symmetry of kinetics inducing KOA, it may lead to the development of a new screening modality that is versatile in clinical practice.

COMPARATIVE ANALYSIS OF IN-SHOE KINETICS DURING LOADED RUNNING AND WALKING USING TWO MILITARY FOOTWEAR TYPES

HOGAN, J.A.1,2, BUNCLARK, H.2, PICKESS, H.2, BYRNE, C.2, RICE, H.3, BROWN, P.4, FALLOWFIELD, J.L.1, ALLSOPP, A.J.1, DIXON, S.J.2

1 ENVIRONMENTAL MEDICINE AND SCIENCES, INSTITUTE OF NAVAL MEDICINE. 2 PUBLIC HEALTH AND SPORT SCIENCES, UNIVERSITY OF EXETER MEDICAL SCHOOL, FACULTY OF HEALTH AND LIFE SCIENCES, UNIVERSITY OF EXETER, UK. 3 NORWEGIAN SCHOOL OF SPORT SCIENCES. 4 DEFENCE SCIENCE AND TECHNOLOGY, UNITED KINGDOM MINISTRY OF DEFENCE

INTRODUCTION: Wireless insoles offer a field-viable alternative to traditional, laboratory-based force plate measurements, enabling ecological assessment of mechanical loading during physical activity. While foot-ground and shoe-ground interactions are well studied [1,2] in-shoe plantar forces remain poorly characterised. This study examined kinetic parameters associated with lower limb injury aetiologies, [3,4] using force-measuring insoles. We aimed to characterise in-shoe loading profiles of military relevant ambulation to enhance understanding of in-shoe loading dynamics.

METHODS: Seven members of the United Kingdom armed forces (age: 20.6 ± 3.5 years, body mass: 81.2 ± 6.2 kg, height: 1.80 ± 0.04 m, shoe sizes 9-13) walked ($1.5 \text{ m}\cdot\text{s}^{-1}$) and ran ($3.6 \text{ m}\cdot\text{s}^{-1}$) along a 10-m runway with a designated foot-strike target. Trials were performed whilst wearing military-issue boots (BOOT) and military-issue training shoes (SHOE) under body-worn loading conditions: 0 kg, 20 kg, and 40 kg during walking and 0 kg and 20 kg during running. Force data were recorded wirelessly at 200 Hz using proprietary software. Data analyses included initial impact peak (iGRF), propulsive force (pGRF), loading rate (LR), impulse (IMP) and stance time (ST). Differences between footwear types, loading states and modes of locomotion were assessed using paired sample t-tests ($p < 0.05$).

RESULTS: Increased load significantly increased: iGRF, 1.19 ± 0.15 [0 kg], 1.46 ± 0.17 [20 kg], 1.75 ± 0.16 [40 kg] times BW; pGRF, 1.16 ± 0.14 [0 kg], 1.43 ± 0.15 [20 kg], 1.62 ± 0.20 [40 kg] times BW; IMP, 452.3 ± 48.4 [0 kg], 556.1 ± 54.1 [20 kg], 663.7 ± 71.7 [40 kg] $\text{N}\cdot\text{s}^{-1}$; LR, 7.7 ± 0.8 [0 kg], 11.1 ± 1.8 [20 kg], 13.5 ± 2.5 [40 kg] $\text{BW}\cdot\text{s}^{-1}$ and ST, 0.70 ± 0.02 [0 kg], 0.71 ± 0.3 [20 kg] and 0.72 ± 0.03 [40 kg] seconds ($p < 0.05$). Compared with walking, running increased iGRF, pGRF, IMP and LR and decreased ST ($p < 0.05$). During walking trials, iGRF was higher ($p = 0.01$), ST shorter ($p = 0.02$) and LR higher ($p < 0.005$) in the SHOE vs the BOOT condition. During running trials, LR was significantly higher in the BOOT vs SHOE condition ($p = 0.02$).

CONCLUSION: This study quantified injury-relevant in-shoe kinetics during walking and running in two standard issue military footwear types. Load carriage increased kinetic parameters associated with injury aetiology. Training shoes were associated with higher loading rates and iGRFs across walking trials compared with boots. This study has demonstrated the utility of in-shoe force measuring insoles, which can be used in field studies to quantify walking and running kinetics. Future work will assess how in-shoe kinetic differences influence the mechanical loading of the lower limbs and their potential impact on injury risk.

EFFECTS OF DUAL-TASKING ON DYNAMIC GAIT STABILITY DURING WALK-TO-STAIR DESCENT TRANSITION

ZHAO, G., QU, F., YANG, Z., LIANG, C.

1 GUANGXI UNIVERSITY; 2 BEIJING SPORT UNIVERSITY; 3 BEIJING INSTITUTE OF FASHION TECHNOLOGY

INTRODUCTION: Stair descent is an activity of daily living with the potential for falls. Performing level walking before stair descent should bring additional challenges. The effects of a concurrent cognitive or manual dual-task condition on dynamic gait stability (DGS) during the stair descent transition remain uncertain. COM–COP Inclination Angle (IA) can comprehensively assess DGS as it considers both center of mass (COM) and center of pressure (COP) [1]. This study aimed to investigate the effects of dual-task conditions on DGS during walk-to-stair descent transition.

METHODS: Twenty healthy young male participants performed five-step staircase descent tests under three conditions: (1) single task (ST, descend stairs only); (2) cognitive dual-task (CT, descend stairs while subtracting serial sevens from a three-digit number); and (3) manual dual-task (MT, descend stairs while carrying a glass of water weighing 500g in their right hand). Participants were instructed to perform level walking on the 5-meter walkway followed by stair descent in a step-over-step manner at a self-selected comfortable speed to the bottom and continued their walk for 5 meters. A 14-camera motion capture system (Qualisys AB, 200Hz) and two force plates (Kistler, 1000Hz) were used to obtain the kinematic and kinetic data. Data from level walking to stair descent transition were obtained from stance phases of lead leg (foot contacting the first step down on the staircase) and trail leg (foot contacting the top step of the staircase) and used to calculate IA in the sagittal and frontal plane. Two-way RM ANOVAs were performed. Significant ANOVAs were followed up with Bonferroni post-hoc procedures. Alpha level was set at 0.05.

RESULTS: In the sagittal plane, the CT condition showed increased time-averaged anterior IA during single leg stance of lead leg (ST: -0.8 ± 0.8 , CT: -1.2 ± 0.8 , MT: -0.7 ± 0.6 °, $P < 0.001$), but the MT condition showed increased time-averaged posterior IA during single leg stance of trail leg (ST: 2.1 ± 1.6 , CT: 2.0 ± 1.2 , MT: 2.6 ± 1.4 °, $P < 0.001$). The MT condition showed decreased ranges of IA (ST: 17.1 ± 1.5 , CT: 16.9 ± 1.5 , MT: 16.4 ± 1.5 °, $P = 0.021$) and anterior IA at contralateral-heel-strike (CHS) (ST: -7.6 ± 1.3 , CT: -7.6 ± 1.3 , MT: -6.9 ± 1.1 °, $P < 0.001$) for both lead and trail legs. In the frontal plane, ranges of IA for both lead and trail legs increased during CT, but decreased during MT (ST: 1.9 ± 0.4 , CT: 2.1 ± 0.5 , MT: 1.8 ± 0.4 °, $P < 0.001$). Medial IA at CHS for trail leg increased during CT, but decreased during MT (ST: 4.8 ± 0.9 , CT: 5.2 ± 0.9 , MT: 4.6 ± 0.9 °, $P < 0.001$).

CONCLUSION: The results of the current study suggest that during walk-to-stair descent transition, performing a cognitive task results in decreased DGS, especially in the frontal plane. However, performing a manual task improves gait stability. The unconscious alteration in IA might be key to avoiding hazards and preventing falls.

PREDICTION OF GROUND REACTION FORCES BY KINEMATIC VARIABLES DURING GAIT: BASED ON OPTIMIZED ARTIFICIAL NEURAL NETWORK ALGORITHM

JEHEON, M., JINSEOK, L., SUNGMIN, K., JINTAEK, L.

KOREA NATIONAL UNIVERSITY OF EDUCATION

INTRODUCTION: Gait is a fundamental daily movement involving alternating single- and double-leg stances that propel the body forward. Ground reaction forces (GRF) provide critical biomechanical insights for diagnosing disorders and monitoring rehabilitation. However, conventional force plates face practical limitations, including fixed positioning and high costs. This study explores an alternative approach to predict GRF by integrating center of mass (COM) coordinates from infrared motion capture and accelerometer (ACC) data from wearable sensors using artificial neural networks (ANN). The study evaluates the reliability and accuracy of GRF predictions using ANN integrating COM and ACC data, aiming to develop a cost-effective, versatile alternative to force plates.

METHODS: Eighty university students (52 males, 28 females) participated. Data were collected using 18 infrared cameras, two force plates, and wearable inertial measurement units (IMU) recording at 100 Hz, 1,000 Hz, and 100 Hz, respectively. Reflective markers were placed at 72 anatomical landmarks. Participants performed 20 gait trials on a 10-meter walkway, ensuring force plate contact. Kinematic data were processed with Visual3D, using 6 Hz and 20 Hz low-pass filters for marker trajectories and GRF/ACC data, respectively. GRFs were normalized to body mass, and time-normalized to 100 data points per stance phase. A feedforward neural network (FNN) with two hidden layers (500 units each, ReLU activation) predicted GRF. Bayesian optimization determined hyperparameters. Input data included time-normalized COM and ACC variables; outputs were GRF components. Metrics included Pearson correlation (r), root mean square error (RMSE), and normalized RMSE (NRMSE).

RESULTS: Using COM data alone, GRF predictions achieved highest accuracy in the medial-lateral direction ($r = 0.963$, RMSE = 0.088 N/kg). Using ACC data, the anterior-posterior direction showed the highest correlation ($r = 0.941$), while the medial-lateral direction exhibited the lowest error (RMSE = 0.123 N/kg). Combining COM and ACC data improved accuracy across all directions, with medial-lateral GRF achieving $r = 0.979$ and NRMSE = 6.07%. Anterior-posterior and vertical GRF predictions also showed significant error reductions.

CONCLUSION: The integration of COM and ACC data enhances GRF prediction accuracy, particularly in the medial-lateral direction. This approach offers a viable, cost-effective alternative to force plates, with applications in gait analysis, rehabilitation, and performance optimization. Future studies should refine ANN models and incorporate additional sensor data to improve vertical GRF predictions further.

VALIDITY AND RELIABILITY OF INERTIAL MEASUREMENT UNITS FOR ASSESSING LOWER EXTREMITY JOINT COORDINATION AND VARIABILITY IN GAIT AMONG COMMUNITY-DWELLING OLDER ADULTS

YIN, L., WANG, L.

SHANGHAI UNIVERSITY OF SPORT

INTRODUCTION: Joint coordination and variability are key indicators for assessing fall risk in older adults. As a convenient tool, it is crucial to determine whether IMUs can accurately measure these parameters for effective fall risk evaluation. This study aimed to assess the validity and reliability of inertial measurement units (IMUs) in measuring lower extremity joint coordination and variability in gait among community-dwelling older adults.

METHODS: Forty-five older adults participated in the study. Lower extremity joint angles during walking at preferred speeds were simultaneously measured using IMUs and an optical motion capture (OMC) system. The modified vector coding technique was applied to calculate coupling angles (CA) and coordination variability (CAV) for four joint coupling pairs: hip flexion/extension-knee flexion/extension (HXKX) and hip flexion/extension-ankle dorsiflexion/plantarflexion (HXAX). The Coefficient of Multiple Correlation (CMC) was used to assess waveform consistency, and systematic error (SE) was calculated to quantify deviations. Pearson's correlation coefficient (r) and root mean square error (RMSE) were used to evaluate CAV. Additionally, the 1-dimensional statistical parametric mapping (1d-SPM) method was employed to compare differences in joint coordination during validity analysis.

RESULTS: IMUs demonstrated excellent validity in measuring lower extremity joint coordination waveforms both before (HXKX: CMC = 0.936, SE = 24.8°; HXAX: CMC = 0.921, SE = 33.9°) and after offset correction (HXKX: CMC = 0.949, SE = 19.5°; HXAX: CMC = 0.942, SE = 28.8°). The reliability of IMUs was confirmed with within-rater assessments (HXKX: CMC = 0.959, SE = 27.4°; HXAX: CMC = 0.927, SE = 35.7°) and across-rater assessments (HXKX: CMC = 0.970, SE = 23.8°; HXAX: CMC = 0.950, SE = 29.2°). Statistical parametric mapping (SPM) revealed significant differences in joint coordination during specific gait intervals for both HXKX (8.9–9.8%, 13.8–18.3%, 30.7–33.8%, 58.9–62.3%, and 89.8–93.7%) and HXAX (13.0–21.8%, 42.9–48.3%, 75.6–79.3%, and 89.9–98.0%) coupling pairs. Regarding CAV results, IMUs showed strong performance, with Pearson correlation coefficients ($r > 0.7$) and low deviations (RMSE values $< 5^\circ$) during validity and reliability analysis.

CONCLUSION: IMUs demonstrate high validity and reliability in measuring hip flexion/extension-knee flexion/extension and hip flexion/extension-ankle dorsiflexion/plantarflexion coordination and variability in community-dwelling older adults. These findings suggest that IMUs are a reliable and accurate tool for gait analysis in the context of fall risk assessment.

STEP COUNTING AND GAIT SPEED ESTIMATION USING ARM-BASED WEARABLE ACCELEROMETRY: A PROOF OF CONCEPT FOR A CUSTOM ALGORITHM

SIEBOLD, E., SCHWEIZER, T., GILGEN-AMMANN, R., LIZARRIBAR CARRILLO, Y.

SWISS FEDERAL INSTITUTE OF SPORT MAGGLINGEN

INTRODUCTION: Step count estimation using wearable accelerometers is widely applied in commercial settings, with accuracy depending on both device placement (e.g., wrist, hip) and the algorithm used (1, 2). However, algorithms tailored for upper-arm acceleration data remain rare. As part of a broader gait abnormality recognition system, we developed an acceleration-based algorithm for upper-arm data to measure walking cadence and peak foot strike acceleration (pFSA). This study serves as a proof of concept for step count and average walking speed (AWS) estimations of our self-developed algorithm.

METHODS: Ten participants each completed two 420-meter walking trials on a flat surface while manually counting their steps. Both walking trials were self-paced: one at a leisurely pace and one at a fast pace. Acceleration data (52 Hz) was collected using a Polar Verity Sense device worn on the upper arm. Step count and pFSA were estimated using our algorithm. We evaluated algorithm performance using Pearson correlation, mean step difference, and mean absolute percent error (MAPE) between estimated and manually counted steps. A random forest regression was performed to predict AWS using participant height, weight, pFSA, and cadence.

RESULTS: All participants ($f = 4$, $m = 6$; height = 173.5 ± 9.5 cm; weight = 72.9 ± 11.5 kg) successfully completed both trials with a mean AWS of 5.7 ± 0.7 km/h. Manually counted and estimated steps showed a strong correlation ($r = 0.95$), with the algorithm slightly overestimating step count by 6.8 steps (503.4 ± 41.5 vs. 510.2 ± 42.4) and a MAPE of 2.2%. The random forest regression for predicting AWS resulted in a R^2 of 0.91 (MAPE = 3.1%), with cadence (importance = 0.68) and pFSA (0.17) contributing most to reducing model uncertainty.

CONCLUSION: Our acceleration-based algorithm demonstrated high accuracy in step count estimation, with a MAPE of 2.2%. In comparison, recently tested open-source wrist-based accelerometry algorithms reported a MAPE of 19% or higher under similar conditions (1). The R^2 of 0.91 in the random forest regression suggests strong predictive potential for gait speed estimation, highlighting applications in gait analysis and load monitoring. Future research should explore the generalizability of these findings across different populations and conditions.

A COMPARATIVE ANALYSIS OF ISO-INERTIAL ECCENTRIC-OVERLOAD (YOYO) RESISTANCE EXERCISE AND ALPINE SKIING BIOMECHANICS

COSTA, I., CUNIBERTI, G., TROPEA, P., PELLEGRINI, B., BORTOLAN, L.

UNIVERSITY OF VERONA

INTRODUCTION: Alpine skiing requires strength, power, and neuromuscular control due to its complex biomechanics and intense eccentric muscle contractions, particularly in the lower body. Effective training is crucial for performance optimization and injury prevention. Iso-inertial, eccentric-overload resistance training, especially using YoYo devices, has been explored for its benefits in skiing.

This study compares kinematics, kinetics, and muscle activation patterns between YoYo training and alpine skiing data from the literature, highlighting biomechanical similarities and potential applications for sport-specific training.

METHODS: Six moderately trained subjects performed three 20-second trials, executing lower limb flexion-extension movements to simulate skiing. Trials took place on an inertial system (YoYo, Hance, Sweden) with ski bindings. Joint angles were estimated using an Xsens system (Movella). Forces exerted were measured via four load cells (Fyearfly, 200 kg) mounted between the ski bindings and YoYo, two per side-one front, one rear. EMG sensors (MiniWave, Cometa) recorded muscular activation of the Vastus Lateralis (VL), Biceps Femoris (BF), Gastrocnemius Medialis (GM), and Tibialis Anterior (TA) bilaterally.

Data were processed, cycle-averaged based on minimum knee flexion, and compared with literature. Left and right side data were averaged due to movement symmetry.

RESULTS: Trunk flexion ranged from $20^\circ \pm 20^\circ$ to $53^\circ \pm 11^\circ$, hip flexion from $24^\circ \pm 11^\circ$ to $86^\circ \pm 22^\circ$, knee flexion from $14^\circ \pm 4^\circ$ to $53^\circ \pm 7^\circ$, and ankle dorsiflexion from $6^\circ \pm 2^\circ$ to $18^\circ \pm 5^\circ$. Considering forces, the anterior force varied between 0.3 ± 0.08 BW and 1 ± 0.21 BW, the posterior force between 0.2 ± 0.08 BW and 0.6 ± 0.15 BW, while the total force ranged from 0.5 ± 0.05 BW to 1.6 ± 0.32 BW. VL showed a peak activation at around 52% of the cycle, BF at 76%, GM at 90%, and TA at 42%.

CONCLUSION: Greater trunk flexion ROM was observed. Hip and knee flexion angles were lower than outdoor data, while ankle dorsiflexion was comparable [1]. Max vertical forces were slightly lower, while min vertical forces were higher than outdoor [2]. TA showed a similar activation pattern with a peak slightly earlier. BF showed peak activation only during knee extension. Since no VL and GM data were available, activation was compared with synergistic muscles. VL showed a similar pattern to VM, while GM was comparable to GL [3].

The exercise can be used in training as muscle activations resemble outdoor activities, and ground reaction forces are comparable. Proper technique is crucial, as there is a tendency for lower hip and knee angles and increased trunk flexion, which may raise injury concerns.

Further investigations are ongoing to compare indoor and outdoor data using a similar setup.

3D PEDALLING ANALYSIS AT DIFFERENT INTENSITIES AND SLOPES IN COMPETITIVE YOUNG OFF-ROAD CYCLISTS: PRELIMINARY RESULTS

VICARI, D., GIUSTINO, V., SCARDINA, G., CANZONE, A., ZANGLA, D., LAKICEVIC, N., ZENTI, L., SCROFANI, G., SEDITA, A., BATTAGLIA, G., BIANCO, A.

UNIVERSITY OF VERONA

INTRODUCTION: Cross-country races feature a mix of steep ascents, where the cyclists must generate high power to tackle the slopes, and descents, where the cyclists' performance depends on their riding skills. To optimize the cyclist's efficiency, the bike fitting is performed with the aim of improving performance [1]. Although bike fitting is often performed on a cycling simulator without simulating various slopes, they can influence the cyclist's pedalling. The aim of this study was to evaluate the three-dimensional kinematics at different pedalling intensities and slopes in young competitive cyclists.

METHODS: Eleven off-road cyclists were recruited. Each cyclist was assessed on own bike after a bike fitting. In the first test session, each cyclist performed an incremental test with a 15 W per minute increase until exhaustion. During the test, a gas analyzer (Cortex; MetaLyzer 3B) was used to assess the $\dot{V}O_{2max}$. In the second test session (48 h later), each cyclist performed 4 trials of 2 minutes at different intensities (65%, 75%, 85%, 95% of the $\dot{V}O_{2max}$) and the bike set at a 0° slope with a 3-minute rest between trials. Subsequently, the same 4 trials were repeated with a 10° slope. For the kinematic analysis, a 3D motion capture system composed of multiple cameras positioned around the cyclist (Cycling 3DMA, STT Systems), who wore markers in certain anatomical points, was used [2]. For statistical analysis, the following parameters

were considered: mean ankle flexion angle at 90° (AFA), mean knee flexion angle at 180° (KFA), mean hip flexion angle (HFA), vertical hip oscillations (VHO), mean shoulder flexion angle (SFA).

RESULTS: At 90°, AFA decreased between: the trials at 65% and 95% and at 0°slope ($p=0.001$), the trials at 65% and 95% at 10°slope ($p<0.001$). At 180°, KFA increased between: the trials at 65% and 75% and at a 0°slope ($p=0.049$), the trials at 65% and 75% at 10°slope ($p=0.029$). Additionally, there was a significant decrease between the trial at 65% at 0°slope and the trial at 65% at 10°slope ($p=0.035$). There were no VHO in the flat trials, but between the slope trials from 65% to 85% ($p=0.025$). A significant decrease in SFA was observed both on flat trial (between 65% and 95%, $p=0.003$) and on slopes ($p=0.001$), with no differences between flat and slope conditions.

CONCLUSION: Since slope influences the pedalling kinematics and considering that cyclists generate power during ascents in cross-country races, we suggest that coaches and cycling biomechanics perform bike fitting using slopes that simulate at least a 10° slope to best reproduce racing conditions.

EFFECTS OF CADENCE, LEVELS OF ASSISTANCE, AND THEIR INTERACTION ON OXYGEN UPTAKE WHILE RIDING AN E-BIKE. WHAT'S THE ROLE OF FREE CHOSEN CADENCE?

TODESCO, B., DECET, M., PELLEGRINI, B., BORTOLAN, L.

UNIVERSITÀ DEGLI STUDI DI VERONA

INTRODUCTION: PURPOSE: While it is known that the electric motor provides some power, reducing the overall effort required by the cyclist [1-2], and the cadence affects the oxygen uptake in the common muscular bike [3], it is not known if, using an e-bike, the oxygen uptake is influenced by assistance, the RPMs and their interaction. This study aimed to evaluate the effects of different levels of assistance at different pedaling cadences (RPM) on oxygen uptake while riding a city e-bike.

METHODS: Fourteen (8 male, 6 female) active subjects (age 27 ± 3.4 years), were tested at three different RPMs (60 – 90 and free choice: FCC), and three different levels of assistance (no assistance A0, the lowest A1 and the highest A3) in random order. The tests were performed using a city e-bike on a bike trainer, where an external power corresponding to the anaerobic threshold previously determined for each subject (4 mmol/L : $2.6 \pm 0.5 \text{ W/kg}$) was set. Averaged oxygen uptake (VO_2) values of the last 30" of each 5-minute trial were analyzed using a two-way ANOVA followed by a post hoc test (Bonferroni).

RESULTS: VO_2 is influenced both by the cadence ($P<0.01$) and the level of assistance ($P<0.01$), but not by their interaction ($P>0.05$). As expected, A3 shows lower values compared with A1 and A0, with a difference of 10 ml/min/kg and 23 ml/min/kg respectively. The cadence shows higher VO_2 values at 90RPMs compared with 60RPMs and FCC with a difference of 5.98 ml/min/kg ($P=0.02$) and 4.78 ml/min/kg ($P=0.03$) respectively. Interestingly, there are no significant differences in VO_2 between FCC ($80 \pm 10 \text{ RPMs}$) and 60 RPMs ($P=1.00$).

CONCLUSION: in this study, as expected, we can see the effect of motor assistance on VO_2 uptake with lower consumption at the highest assistance. Moreover, we observe that the behavior of VO_2 relative to cadence is similar to that studied on a conventional muscular bike: the higher the cadence at the same power output, the greater the oxygen consumption [3]. Last, as we didn't expect, the VO_2 at FCC is very close to VO_2 at 60 RPMs. Therefore, we can assume that the cadence chosen by the subjects is probably the optimal balance that combines the metabolic and muscular efforts as in the conventional bike. However, in this case, the effect of RPM on oxygen consumption may also be influenced by the properties of the electric motor of the bike, which was found to provide more power at lower RPMs. From a practical point of view, we could, therefore, suggest developing engines based on FCC cadences to ensure also the best efficiency.

BIOMECHANICS OF BACKSTROKE START IN ELITE SWIMMERS: EXAMINING THE EFFECTS OF POSTURE, DYNAMIC BALANCE AND VERTICAL JUMP PERFORMANCE

COSKUN, E., CENGİZ, S., SAHİN, S., GÜNAY, E.

İSTANBUL GEDİK UNIVERSITY

INTRODUCTION: In swimming competitions, the start phase has a high impact on competitive performance. The postural, motor and biomechanical aspects of this phase, which have only been studied to a limited extent, especially in the backstroke, are critical for understanding start performance. The aim of this study was to investigate the relationship between kinematic parameters of the backstroke start performance of swimmers and dynamic balance, vertical jump and postural values.

METHODS: Elite male ($n=7$) backstroke swimmers with a mean FINA score of $716 (\pm 22.25)$ were included in the study. The study consisted of 4 sessions. In the first session, 2 sessions of start trials were performed to adaptation to the start platform where the start measurement would be performed. The data from the trials were used to optimize the placement of the start systems. In the second session, kinematic parameters related to start performance were evaluated and the swimmers performed three repetitions of the supine start using the supine start platform. The kinematic parameters of the

start performance were recorded using stabilized GoPro10 Cam System and DACTRONICS HS-200 Start System and the images were analyzed using Kinovea 0.9.5 motion analysis program. In the third session, the dynamic balance (DB) performance was evaluated with the TecnoBody PK200 device and the vertical jump (VJ) measurements were evaluated with the Microgate Witty Wireless Training Timer. In the fourth session, a postural analysis of the athletes was performed using Apece Posture Analysis Pro Plus 8.2.6 and the New York Posture Assessment (NYPA) method. The statistical analysis of the study was carried out using Pearson Correlation analysis with SPSS 25.0 package program.

RESULTS: There was a significant negative correlation between supine hip height (HH) and NYPA scores ($p=-0.790$). Similarly, a significant negative correlation was found between NYPA scores and flight time (FT) ($p=-0.792$). A significant positive correlation was found between front hip angle (FPT) and water entry distance (ED) ($p=0.805$). However, no significant correlation was observed between start kinematic parameters and VJ, DB.

CONCLUSION: In the supine ascent mechanics, the static posture HH was found to be an important parameter influencing the FT, and the degree of FPT was also found to be a value that strongly influenced the FT. Swimmers who have the advantage of postural adaptation required by the start performance show better start performance. There is no direct relationship between DB and VJ performance and start velocity (SV), vertical (VV) and horizontal velocity (HV), HH, FD, block time (BT), FT, ED, hand entry angle (HEA) kinematic parameters. We believe that the mechanical difficulty of the starting position highlights the contribution of postural factors more than motor factors.

ANALYSIS OF SWIMMING PARAMETERS DURING THE PERFORMANCE OF DIFFERENT BREATHING PATTERNS: A CASE STUDY OF AN AMATEUR TRIATHLETE

BORGES DOS SANTOS, K., GONÇALVES, L.L., RODACKI, C.L.N.

UNIVERSIDADE TECNOLÓGICA FEDERAL DO PARANÁ

INTRODUCTION: Triathlon is a sport composed of the sequential modalities of swimming, cycling and running, which individually contribute to the final race result (1). Swimming, as it is performed in open water, requires athletes to frequently execute front-lateral breathing for orientation purposes (2). However, performing this movement causes an elevation of the torso and head, which generates greater water resistance (3). Thus, front-lateral breathing can influence the kinetic and kinematic factors of swimming performance. The objective of this study was to analyze the force production, stroke length, and stroke frequency of an amateur triathlete while executing different breathing patterns.

METHODS: The study participant was a male amateur triathlete (24 years old, 1,79m, 73kg). Peak force was measured through a 30-second maximum effort test using a tethered swimming protocol, with alternating execution of lateral and front-lateral breathing every four strokes. The kinematic swimming parameters, stroke length (SL) and stroke rate (SR), were measured through video recording of a 100-meter performance in a previously calibrated space.

RESULTS: The average peak force during front-lateral breathing and in the absence of breathing was similar (approximately 140N), while force production during lateral breathing was slightly higher (147N). SL was relatively higher and SR was lower during the stroke cycle with front-lateral breathing (1.81 m and 40 cycles/min, respectively) compared to lateral breathing (1.72 m and 42 cycles/min) and the absence of breathing (1.62 m and 43 cycles/min).

CONCLUSION: Although force production was similar among the breathing patterns (justified as a maximum test performance), SL was greater during the stroke cycle with front-lateral breathing. This likely occurred because more time was required for its execution, resulting in a lower SR. The study objectively demonstrates the influence of breathing patterns on swimming performance. It is suggested that training strategies be adopted to minimize the need for front-lateral breathing during the swimming stage of triathlon races.

COMPARISON OF BUTTERFLY SWIMMING SPEED BETWEEN SEXES USING STATISTICAL PARAMETRIC MAPPING

PINTO, M., NEIVA, H., BARBOSA, T., MARINHO, D., MORAIS, J.

UNIVERSITY OF BEIRA INTERIOR

INTRODUCTION: The main objective of sports science is to identify, develop and refine strategies to improve performance [1]. In competitive swimming, given its time-based nature, researchers and coaches focus on understanding how to improve swimming speed [2]. Traditionally, swimming speed is measured as an average value (i.e., a discrete variable with no time dimension) [3]. However, this approach only provides insights into the entire stroke cycle or the average of a combination of stroke cycles. This study aims to compare swimming speed in the butterfly stroke between sexes using Statistical Parametric Mapping (SPM).

METHODS: Ten competitive swimmers (5 males, 5 females) who regularly participate in national and international competitions were analyzed. The male swimmers (18.8 $\pm$ 3.2 years, 77.6 $\pm$ 12.0 Kg of body mass, 187.2 $\pm$ 8.3 cm of height, 189.0 $\pm$ 8.3 cm of arm span and 605.8 $\pm$ 69.2 of WAPS) and female swimmers (18.3 $\pm$ 3.1 years, 73.1 $\pm$ 7.3 Kg of body mass, 179.2 $\pm$ 5.5 cm of height, 181.6 $\pm$ 5.7 cm of arm span and 525.7 $\pm$ 112.4 of WAPS) performed three all-out 25 m butterfly trials with a push-off start and a 10-min recovery interval. The fastest trial and the average of the three-stroke

cycles were analyzed. The mechanical device (SpeedRT, APlab, Rome, Italy) was used to measure velocity, with a string attached to the swimmer's waist. A GoPro Hero 7 (San Mateo, CA, USA) filmed the swimmers in the sagittal plane to identify hand entry and exit from the water.

RESULTS: Male swimmers were significantly faster than female swimmers throughout the entire stroke cycle. SPM revealed significant differences ($t = 3.456$, $p < 0.001$) between the sexes, throughout the entire stroke cycle.

CONCLUSION: SPM analysis revealed significant sex differences throughout the entire stroke cycle in butterfly swimming, which traditional methods might miss. This continuous approach offers deeper insights into biomechanical variations, aiding in optimizing training and performance in competitive swimming.

CP-BM09 Upper Limb Biomechanics

TECHNICAL, ANTHROPOMETRIC AND NEUROMUSCULAR ASSOCIATIONS WITH BALL RELEASE SPEED IN ELITE AND EMERGING FEMALE CRICKET FAST-BOWLERS

WATSFORD, M., LANG, T.1, FARHART, P.2, LAMBERT, G.2, PICKERING RODRIGUEZ, E.1

1. UNIVERSITY OF TECHNOLOGY SYDNEY; 2. CRICKET NSW

INTRODUCTION: Fast bowlers play a critical role in cricket, with effective bowlers greatly contributing to team success. The rapid growth of women's cricket means that research into performance is in its infancy however the available information suggests there may be anthropometrical, neuromuscular or technical differences between sexes. Using an exploratory research design this study explored these factors with respect to ball release speed in elite and emerging female fast-bowlers.

METHODS: 3D motion analysis and ground reaction force assessment quantified the bowling action and ball release speed of 34 elite and pathways female fast-bowlers (17.6 ± 3.5 years). Anthropometry measures of height, mass, leg length and bowling arm length were assessed, as were neuromuscular measures of 20m sprint, countermovement jump (CMJ), isometric mid-thigh pull (IMTP) and unilateral sub-maximal stiffness. Correlation analyses were undertaken to identify associations between ball release speed and the measured variables.

RESULTS: Ball release speed exhibited associations with anthropometrical measures of stature ($r=0.529$), body mass ($r=0.469$) and mean leg length ($r=0.576$). Ball release speed was associated with front leg knee flexion at front foot contact (FFC) ($r=-0.350$) and horizontal and resultant ground reaction force at FFC ($r=-0.511$, $r=0.687$ respectively). Neuromuscular measures of CMJ power ($r=0.443$), IMTP peak ($r=0.518$) and net force ($r=0.491$), front ($r=0.342$) and back leg absolute stiffness ($r=0.397$), and back leg relative stiffness ($r=0.397$) all revealed associations with ball release speed.

CONCLUSION: The associations between ball release speed and strong, powerful and long legs may inform the methodologies of future studies. The current cohort revealed relationships between ball release speed and certain biomechanical measures at FFC, whereby less front knee flexion, higher levels of braking force and higher overall ground reaction force at FFC were associated with faster bowling speeds. Future research could focus on FFC during bowling given it's apparent relevance. The general lack of associations between ball release speed and kinematic and kinetic factors at other parts of the bowling action may be due to the wide age range and physical maturation of the participants. Alternatively, data from discrete timepoints may not reflect the individualised nature of cricket bowling technique and there may be scope for other types of analysis such as functional data analysis to examine the entire action. The current findings provide insights into new relationships with ball release speed in female fast-bowlers that require validation by future confirmatory research.

KINEMATIC ANALYSES OF FASTPITCH SOFTBALL PITCHES

HSU, Y., LIU, Y.

NATIONAL TAIWAN NORMAL UNIVERSITY

INTRODUCTION: Fastballs(FB) and changeups(CU) are fastpitch softball's most commonly used pitch types. Studies have shown that the speed range for FB is 85-95 km/h and 60-75 km/h for CU. CU typically has greater torso flexion and lateral flexion at ball release, while FB relies more on the linear movement of the torso to increase ball speed [1]. The individual differences between pitchers can often be observed by examining the changes in the kinematics of the limbs over the

pitching movement. This study examined the 3-D kinematic parameters of fastpitch softball pitchers throwing fastballs and changeups to provide recommendations for individually targeted training strategies.

METHODS: 4 collegiate division I womens softball pitchers threw 10 FB and CU each. The pitch speed was recorded with a speed gun. 5 strikes of each pitch type were selected for analysis. 2 high-speed cameras and Simi Motion software captured the 3-D kinematics of the pitchers head, wrist, elbow, shoulder, hip, knee, and ankle on the throwing side from the stride foot off the ground to the ball leaving the hand. A camera behind the net captured the ball's position as it passed the home plate, which is used as the basis for determining a strike. The independent sample t-test was used for each pitcher between the 2 pitch types; a significant level was set at $\alpha=.05$.

RESULTS: The results of the independent sample t-test of the 4 pitchers were all significant ($p<.05$), but only 2 reached 85 km/h ball speed in FB. For the kinematics, the maximum absolute velocity of the hips of all but one qualified FB pitcher was significantly different between the 2 pitch types ($p<.05$). The exception pitcher, however, found a significant difference in changes in elbow joint angles between pitch types ($p<.05$) and no other pitchers did. In addition, the absolute speed of the wrist at the time of the ball release was significantly different between the pitch types ($p<.05$) except for one pitcher of FB speed under 85 km/h.

CONCLUSION: The association between absolute hip velocity and pitch speed in most pitchers supports the relation between the FB and the linear movement of the torso. 2 pitchers did not reach 80 km/h in FB pitches. Post-hoc examination indicated that a lower absolute hip velocity may have contributed to the low pitch speed. One pitcher who met the FB standard did not differentiate in absolute hip velocity between pitch types but was the only one with a difference in the amount of elbow angle change between pitch types. Although the upper limbs' movement may also generate faster pitch speed, the smaller mass of the upper limbs is prone to injury. Strengthening torso acceleration should be a primary way to improve pitch speed. The analysis of the kinematics of pitcher movement is an important basis for coach-player training programs, and future research should consider the stability of pitching for different pitching types.

BIOMECHANICAL ANALYSIS OF SHOTPUT PERFORMANCE IN ELITE PARALYMPIC ATHLETES

RUSSOMANNO, T., BENTO DA SILVA, S., QUINTELLA, J.V.I., COSTA, R.H., MÁXIMO, A.G.A., SABINO, A.J., MISUTA, M.S., LOURENÇO, T.F.

TECHNICAL UNIVERSITY OF MUNICH / SPORTS SCIENCE DEPARTMENT, BRAZILIAN PARALYMPIC COMMITTEE/ UNIVERSITY OF BRASILIA

INTRODUCTION: This study aims to correlate biomechanical implement release variables with implement distance (performance) in elite Paralympic shot put.

METHODS: Six athletes (A1–A6) from different functional classes (F11, F12, F42, F57, F55) participated in the research conducted at the Paralympic Center in São Paulo in preparation for the Paris 2024 Games. A total of 36 throws were analyzed using data captured by two synchronized SONY FDR-AX40 cameras (120 Hz), the 3D data was obtained through standard calibration and reconstruction methods. The analyzed variables included the release angle in the XZ and XY planes (RAXz; RAXy), release height (RH), distance from the sector limit (DSL), scalar velocity (SV), and its components (Vx, Vy, Vz).

RESULTS: Results show significant differences across functional classes, for standing athletes (F11, F12, F42), phase times from T1 to T5 were also analyzed. Spearmans correlation analysis revealed distinct patterns for each athlete. For A1, a moderate positive correlation was found between distance from the sector limit (DSL) and throw distance (TD) ($r=0.522$; $p=0.288$), and between scalar velocity (SV) and TD ($r=0.829$; $p=0.058$). The T3-T4 phase showed a positive correlation ($r=0.478$; $p=0.338$), while the T4-T5 phase showed a negative correlation ($r=-0.432$; $p=0.392$). For A2, there was a strong positive correlation between release height (RH) and TD ($r=0.696$; $p=0.125$) and between SV and TD ($r=0.771$; $p=0.103$). The T2-T3 phase had the highest correlation with TD ($r=0.794$; $p=0.059$). For A3, the relationship between SV and TD was statistically significant ($r=0.812$; $p=0.0499$), while DSL had a strong negative correlation ($r=-0.754$; $p=0.084$). For seated athletes (F57, F55), A4 showed a strong positive correlation between TD and DSL ($r=0.794$; $p=0.059$) and between RH and TD ($r=0.627$; $p=0.183$), while SV had a moderate positive correlation ($r=0.464$; $p=0.354$). In A5, the release angle (RAXz) had a strong negative correlation with TD ($r=-0.829$; $p=0.058$), suggesting that higher angles may reduce distance. SV had a moderate positive correlation ($r=0.580$; $p=0.228$), while RH had a negative correlation ($r=-0.609$; $p=0.200$). For A6, RH had a significant negative correlation with TD ($r=-0.956$; $p=0.0029$), while DSL had a strong positive correlation ($r=0.779$; $p=0.068$) and SV a moderate negative correlation ($r=-0.725$; $p=0.103$).

CONCLUSION: The correlations between variables and distance highlight the complex interplay of factors influencing performance in Paralympic shot put. The findings indicate that different variables influence throwing distance (TD) depending on the athlete and their technique, suggesting the need for individualized adjustments to maximize performance in Paralympic shot put.

KINETIC AND KINEMATIC ANALYSIS OF TENNIS SERVE: INFLUENCE OF LOWER LIMB STRENGTH ON SERVE VELOCITY

ÖLMEZ, C., YÜCELİSOY, B., SAR, H.

ORDU UNIVERSITY

INTRODUCTION: The tennis serve is a complex motor action requiring precise coordination of various body segments. Effective force transmission from the ground to the ball is essential for maximizing serve performance. Lower limb strength may be a critical factor influencing serve speed. This study investigates the effects of countermovement jump performance and isokinetic knee strength on serve speed in elite tennis players.

METHODS: Thirteen elite-level competitive tennis players voluntarily participated in the study. The data collection process was completed in two phases. In the first phase, the athletes lower limb strength and power profiles were analyzed by assessing their isokinetic knee flexion (FLX) and extension (EXT) strength, along with their countermovement jump performance. In the second phase, their serve speeds were measured. Serve speed assessments were conducted using the flat serve technique, and athletes were instructed to exert maximal effort during each trial. If a serve was unsuccessful, it was repeated; however, participants were required to execute the serve in a first-serve manner (high-speed execution). Serve speed was measured using a handheld radar device (Bushnell 101911, USA). Countermovement jump performance was evaluated with an electronic jumping mat (Microgate Witty, USA). Isokinetic knee strength measurements were performed concentrically at angular velocities of 60°/s, 180°/s, and 240°/s using a Humac NORM isokinetic dynamometer (CSMI, Stoughton, MA).

RESULTS: The analysis revealed a highly significant relationship between serve speed and countermovement jump performance ($r=0.745$, $p<0.01$). Additionally, serve speed exhibited moderate to strong correlations with peak knee FLX torque at various angular velocities: at 60°/s in the non-dominant limb ($r=0.652$, $p<0.05$), at 180°/s in both the dominant and non-dominant limbs ($r=0.597$; $r=0.582$, $p<0.05$), and at 240°/s in the dominant ($r=0.712$, $p<0.01$) and non-dominant ($r=0.670$, $p<0.05$) limbs. The relationships between serve speed and other isokinetic torques were not significant ($p>0.05$).

CONCLUSION: Lower limb strength plays a crucial role in generating higher serve speeds in tennis. The results of this study demonstrate that torque production at higher angular velocities exhibits a stronger relationship with serve speed, suggesting that the ability to generate rapid force in the lower limbs contributes significantly to serve performance. This finding underscores the importance of not only maximal strength but also the rate of force development in optimizing tennis serve mechanics.

Given these results, training interventions that emphasize explosive power development may be particularly beneficial for tennis players. Incorporating plyometric exercises alongside submaximal resistance training with lighter loads performed at high velocity could enhance both lower limb strength and neuromuscular efficiency. Such training strategies may improve the rapid force application needed for an effective and high-speed serve.

EXPLORATION OF ANTAGONISTIC RELATIONSHIP BETWEEN BARBELL HIGH-HANG MUSCLE SNATCH AND KIPPING BAR MUSCLE-UP BASED ON MACHINE LEARNING ALGORITHMS

XU, Y., GU, Y.

NINGBO UNIVERSITY

INTRODUCTION: The kipping bar muscle-up constitutes a multifaceted, multi-joint maneuver that significantly augments upper-body explosiveness and neuromuscular synergy, yet demands intricately honed technique and entails notable injury risks. To elevate acquisition efficacy without escalating training volume, a posture-oriented approach designates the high-hang power snatch as a plausible antagonist. By analyzing biomechanical trajectories via machine learning, this study seeks to quantify their antagonistic nexus and refine training methodologies.

METHODS: Eight males (21.2 ± 1.2 yrs, 175.6 ± 2.2 cm, 70.3 ± 6.6 kg), able to perform ≥ 5 kipping bar muscle-ups and a ≥ 60 kg snatch 1RM, participated. Over six test days, bar muscle-ups or snatches (20–60 kg) were alternated in five sets of three reps, with two-day intervals. Warm-up involved brief cycling and stretching; main tests used five sets $\times$ 3 reps and three-minute rests. Xsens and Gymaware captured displacement, velocity, angles, force, power, and work. Paired t-tests (Jamovi, $\alpha=0.05$) compared temporal and kinematic data, while SPM1D analyzed time-series. DTW examined reversed snatch data for antagonistic joint motion; Python scripts executed SPM1D and DTW.

RESULTS: Barbell displacement during snatches markedly surpassed body COM displacement in kipping muscle-ups ($p<0.001$), with no significant difference in total movement time ($p>0.05$). Although the 20 kg snatch required less time than muscle-ups ($p<0.05$), peak power and relative force showed no significant discrepancy ($p>0.05$). Notably, the 40 kg snatch produced the highest velocity (3.05 ± 0.08 m/s), power (3201.03 ± 1061.52 J/s), and relative force (14.84 ± 2.86 N/kg), closely paralleling muscle-ups. While muscle-ups had the largest shoulder range (e.g., frontal plane $26.53\pm3.59^\circ$ – $122.25\pm0.94^\circ$), the 60 kg snatch exceeded other loads ($16.63\pm1.14^\circ$ – $140.51\pm3.97^\circ$). Elbow motion at 40 kg most resembled muscle-ups. SPM1D revealed minimal time-series discrepancies in velocity and power. DTW analysis indicated a 63.18% reduction in distance for the 30 kg snatch upon sequence reversal, underscoring reversed kinematic patterns that better align with the muscle-up profile.

CONCLUSION: The results revealed that the barbell high-hang power snatch exhibits an antagonistic relationship with the kipping bar muscle-up in specific degrees of freedom—namely shoulder abduction-adduction, rotation, flexion-extension, and elbow rotation. Notably, a 40 kg snatch (61.5% 1RM) produced the highest peak velocity, peak power, and relative force, closely approximating the muscle-up profile. By contrast, 20 kg and 30 kg snatches (30.8% and 46.2% 1RM) demonstrated the strongest antagonistic joint kinematics per DTW analysis, suggesting lighter loads may be preferable for

technique training or injury prevention. Overall, to boost explosive strength, loads near 60% 1RM are advisable; while to refine muscle-up technique or accommodate joint limitations, lighter loads constitute a safer, more effective antagonistic alternative.

AN INVESTIGATION OF UPPER LIMB ELECTROMYOGRAPHIC PERFORMANCE IN BACKHAND DRIVES AMONG MALE BADMINTON PLAYERS OF DIFFERENT SKILL LEVELS

KUO, Y., CHEN, K., TANG, W.

NATION TAIWAN SPORT UNIVERSITY

INTRODUCTION: The backhand drive is a crucial mid-court technique in badminton, playing a key role in matches. The core of this technique lies in accurately and consistently returning the shuttle to the opponent's court while maintaining a degree of control over the match's tempo. By precisely managing the shuttle's trajectory, height, and speed, players can strategically time their returns to disrupt the opponent's attack and reestablish their own rhythm. Compared to other strokes such as serves and smashes, biomechanical research on the backhand stroke in badminton remains relatively limited, as most previous studies have primarily focused on other aspects of the match. This study is to compare the racket head speed and upper limb muscle activation in backhand drive technique among male badminton players of different skill levels.

METHODS: Twenty-four male badminton players, divided into twelve from the elite group and twelve from the sub-elite group. All participants were right-handed, there were no upper limb muscle, skeletal, or nerve injuries in the past six months. Surface electromyography (sEMG) was used to collect activation characteristics of nine muscle groups on the right side (first dorsal interosseous, thenar eminence, extensor carpi ulnaris, flexor carpi ulnaris, biceps brachii, triceps brachii, anterior deltoid, posterior deltoid, and pectoralis major) at a sampling frequency of 2000 Hz. A 3D motion analysis system, sampling at 250 Hz, was synchronized for motion segmentation. The Shapiro-Wilk test was used to determine the normality distribution. For normally distributed data, independent sample t-tests were used; for non-normally distributed data, the Mann-Whitney U test was applied. Statistical significance was set at $\alpha = .05$.

RESULTS: The racket head speed during the impact moment showed no significant difference between groups. Analysis of the percentage of upper limb muscle activation in different phases revealed that during the backswing phase, the peak and mean electromyographic activation levels of the biceps brachii and pectoralis major were significantly lower in the elite group compared to the recreational group ($p < .05$), while no significant differences were observed in the other muscle groups.

CONCLUSION: Elite players exhibit lower activation of the biceps brachii and posterior deltoid muscles during the backswing phase, allowing for a controlled utilization of antagonist muscles and resulting in a smoother and more precise stroke execution. Coaches are advised to closely observe the activation patterns of the shoulder and elbow muscle groups while emphasizing wrist and finger stability to further enhance the effectiveness of return strokes.

IMPACT OF MOVEMENT DURATION ON TENNIS FOREHAND PRECISION: A KINEMATIC PERSPECTIVE.

BOTTURA, R., FERRANDO, V., PLACIDILLI, F., RUGGERI, P., FAELLI, E., BISIO, A.

UNIVERSITA DEGLI STUDI DI VERONA

INTRODUCTION: In sports like tennis, an athlete's technique is a key factor in determining their success. To improve technical skills, it is essential to understand the biomechanical characteristics of each movement in the sport. In tennis, the forehand is the most commonly used groundstroke during a match (1). This study aimed to analyze the relationship between the duration of the forehand stroke and shot precision.

METHODS: Sixteen skilled tennis players of both sex (11 males, 5 females; age: 14.88 ± 2.06 years, height: 1.71 ± 0.10 m, weight: 59.13 ± 11.59 kg, Italian National Class: 3.11 ± 0.43) were evaluated before and after six weeks of routine training during a non-competitive phase. The test involved performing 15 forehands with maximal acceleration from a standing position. Each forehand was video recorded for subsequent analysis of movement duration using Kinovea software, and precision was recorded by marking whether the ball landed in or out of the court. Total movement duration was divided into two phases for analysis: the backswing to impact (initial phase) and the impact to follow-through (final phase).

RESULTS: The results indicate a significant reduction in total movement duration (PRE: 814.69 ± 67.68 ms; POST: 715.59 ± 42.97 ms; $t(15) = 6.641$, $p < 0.001$, Cohens $d = 1.66$), suggesting improved efficiency. However, no significant differences were observed in precision (PRE: 9.13 ± 2.19 balls in; POST: 10.00 ± 2.66 balls in; $t(15) = -1.431$, $p = 0.173$). A significant negative correlation was found between precision and the final phase of the movement ($r = -0.40$, $p = 0.023$), highlighting the importance of efficient technique in improving shot precision. Additionally, a linear regression model including the initial and final phases as predictors showed that the latter significantly explains the variability in precision ($\beta = -0.027$, $p = 0.025$). Nevertheless, the model accounts for only 19.6% of this variability ($R^2 = 0.196$), indicating that other factors also play a significant role.

CONCLUSION: These findings suggest that optimizing specific phases of movement, particularly the second phase, may enhance tennis forehand performance. While improvements in movement duration were evident, their direct impact on shot precision remains influenced by other factors, such as technical and strategic adjustments. Further studies are recommended to explore these dynamics in detail.

THE EFFECTS OF MOTOR IMAGERY TRAINING ON THE ACCURACY OF THE FOREHAND TENNIS PERFORMANCE

BISIO, A., MULLER BOTTURA, R., PLACIDILLI, F., RUGGERI, P., FAELLI, E., FERRANDO, V.

UNIVERSITY OF GENOA

INTRODUCTION: Motor imagery (MI) is the mental rehearsal of a movement without any overt motor output. Scientific literature provided successful examples of the application of MI as tool for enhancing motor performance particularly in sports contexts. For instance, positive hints about the use of MI in sports came from studies on tennis serve performance (1,2). In tennis, together with tennis serve, another fundamental stroke that could benefit from MI training is the forehand. The aim of this study is to test whether MI can enhance the forehand performance accuracy of young tennis athletes when applied during corrective exercises for the forehand technique.

METHODS: Sixteen young tennis players (14.88 ± 2.06 years, 11 males, 5 females) from the Italian national category (2.7 – 4.0) participated in a six-week training program (12 sessions). Eight of them were assigned to the motor imagery training group (MIT), where they practiced MI combined with two corrective exercises for the forehand technique. During training, they stood on the court in the loading position for the forehand and were instructed to kinesthetically imagine executing a forehand stroke before physically performing it with corrective exercises (6 reps x 2 exercises). The control group (CONTR, eight participants) performed only the corrective exercises without MI. Before and immediately after the training period, the stroke's performance was monitored using the Baseline Vision system in two tests: 20-forehand (starting from the loading position) and 5-minute (during which the highest number of forehands must be executed, thus inducing fatigability) tests. The percentage of balls within and outside the designated area in the opponent's field (BALLS IN, BALLS OUT) was monitored together with rate of perceived exertion, fatigability with a visual analogue scale and heart rate.

RESULTS: Statistical analysis in the 20-forehand test revealed that, from PRE to POST, the MIT group showed a significant decrease in BALLS OUT compared to the CONTR group ($p=0.03$). Additionally, in POST, BALLS IN and BALL OUT of MIT were significantly higher and lower, respectively, than those of CONTR ($p=0.015$). In the final minute of the 5-minute test, BALLS IN was significantly higher in the MIT group than in the CONTR group ($p=0.01$), while BALLS OUT was significantly lower ($p=0.01$).

CONCLUSION: This study suggests that incorporating kinesthetic MI into corrective exercises for forehand training in young tennis players enhances accuracy in both training-like and match-like conditions, suggesting coaches to include it in the athletes' training routine.

KINEMATIC DIFFERENCES BETWEEN THREE FOREHAND OPEN-STANCE STROKE TRAJECTORIES IN TENNIS

JUNYAN, X., YIXIONG, C., SANJUN, Y., XINYI, W., JINTAO, Z.

CHINA UNIVERSITY OF MINING & TECHNOLOGY-BEIJING

INTRODUCTION: This study applied kinematic principles to investigate the movement characteristics of body joints in tennis players during forehand shots with different trajectories.

METHODS: Ten male tennis players with an ITF level of 4 or higher, all right-handed and employing an open stance technique for forehand shots, were recruited. The study selected three forehand shot trajectories: baseline straight, baseline diagonal, and midcourt diagonal. For each trajectory, 50 balls were grouped into one set. Only shots landing within the target area were deemed valid, and data from at least 20 successful in-zone shots per set were recorded and collected. Two high-definition cameras captured three-dimensional (3D) video of the forehand motions. The Fastmove-3D AI motion capture system extracted and synthesized the X, Y, Z coordinates of five right-side joints (elbow, shoulder, hip, knee, ankle). A Butterworth low-pass filter was applied to the 3D coordinates of the markers. Kinematic parameters were calculated, and the forehand motion was divided into four key frames: A. body rotation, B. backswing, C. ball impact, and D. follow-through. Repeated-measures ANOVA was used to analyze differences across shot types and subjects, focusing on resultant angles, angular velocities, and angular accelerations of the five joints ($P < 0.05$).

RESULTS: 1) For midcourt diagonal shots, the right elbow exhibited significantly higher resultant angles in key frames A and B compared to baseline diagonal and straight shots ($P < 0.05$). The right hip showed significantly higher resultant angular velocity in frame C and higher angular acceleration in frame D ($P < 0.05$).

2) Baseline straight shots demonstrated significantly greater angular velocity in the right elbow (frame B) and right shoulder/ankle (frame C) compared to other shot types ($P < 0.03$), while the right hip exhibited lower angular acceleration in frame C ($P < 0.05$).

CONCLUSION: 1) Midcourt diagonal shots demand faster hip rotation during impact to better wrap around the ball and prevent out-of-bounds trajectories.

2) Baseline straight shots require increased upper limb engagement (e.g., shoulder acceleration) to counteract incoming ball spin while maintaining hip stability.

3) The shoulder and elbow joints generate peak resultant angular velocities, accelerations, and angles during forehand strokes, rendering them high-risk injury zones. Coaches should develop targeted training programs to optimize joint force sequencing and improve kinematic patterns in tennis forehand techniques.

DIFFERENT PHYSICAL ACTIVITIES CAN INFLUENCE THE MECHANIC AND NEUROMUSCULAR BEHAVIOR DURING A REACTION TIME TASK: A PILOT STUDY

PETRIGNA, L., AMATO, A., AMORIM, P.R.S., MUSUMECI, G.

UNIVERSITY OF CATANIA; FEDERAL UNIVERSITY OF VIÇOSA

INTRODUCTION: A growing number of people prefer gym instead of sports practice. In the long term, the practice of activities in which there is a lack of a decision-making process associated with rapid whole-body movement could influence physical performance. The study aim was to investigate the differences in a time reaction task (TRT) between a sportive, a sedentary, and a gym user group.

METHODS: A total of 80 participants were recruited. Only 18 participants met the eligibility criteria and presented a complete EMG data set. The control group (CG) (3 females, 3 males, 24 ± 2.1 years, 171.5 ± 9.8 cm, 75.7 ± 19 kg) was composed of sedentary people. The sports group (SG) (6 men, 21.8 ± 2.3 years, 178.7 ± 5.2 cm, 73.1 ± 6.7 kg) was composed of people practicing soccer or basketball. The gym group (GG) (2 females, 4 males, 21.2 ± 1.5 years, 171 ± 6.9 cm, 67.5 ± 8.6 kg) was composed of gym users. For the SG and GG, the participants had to perform at least 360 min/week. All groups performed a TRT in which they had to react to a stimulus with a jump for 3 times. Was recorded the time between the stimulus and the jump. Furthermore, s-EMG was recorded for the tibialis anterior (TA) and gastrocnemius lateralis (GL) during the task. A maximal voluntary contraction was recorded before the time reaction task to normalize data (MVC%). Data were analyzed with the Friedman and the Durbin-Conover comparison to detect differences between the groups. The Spearman correlation analysis was used to detect the correlation between body fat percentage (%F) and the variables studied.

RESULTS: No significant statistical differences were detected between the CG (mean (m) 0.54 ± 0.08 s), the SG (m 0.5 ± 0.13 s) and the GG (m 0.56 ± 0.08 s), and between the SG and GG. A significant difference was detected between the TA of the CG (m 3.93 ± 1.61 MVC%) and the SG (m 1.43 ± 0.13 MVC%) ($p=0.004$) and between the SG and the GG (m 2.08 ± 0.6 MVC%) ($p=0.034$). No significant difference was detected between CG and GG, and among GL and CG (m 8.20 ± 5.23 MVC%) and the SG (m 5.76 ± 3.39 MVC%), between CG and GG (m 9.96 ± 5.23 MVC%), and between SG and GG. After the correlation analysis, no significant difference was detected in most of the variables. Was found correlation between the % of activation of the TA and the %F, total (correlation coefficient (CC) 0.585; $p=0.011$), of the right (CC 0.622; $p=0.006$) and of the left leg (CC 0.621; $p=0.006$). This was also confirmed by the regression model built with % tibial activation as the dependent and total and limb fat as independent variables.

CONCLUSION: The results show a less active TA and GL for the SG but a better performance in the TRT. Was verified that practicing a sport increases the quality of neuromuscular action, suggesting sporting activity as a more effective tool for agility. These preliminary findings could be important as the current generation of gym-goers gets older, in some everyday tasks. Future studies should consider these findings in older adults from a retrospective point of view.

THE EFFECTS OF LOADS AND FATIGUE LEVELS ON MUSCLE ACTIVATION AND GROUND REACTION FORCE DURING THE REAR-FOOT-ELEVATED SPLIT SQUAT

KAIFANG, L., ZHILI, C., CHAO, B., YONGMING, L.

CHENGDU SPORT UNIVERSITY;1, SHANGHAI SPORT UNIVERSITY;2

INTRODUCTION: The Rear-foot-elevated split squat (RFESS) is a typical unilateral exercise[1, 2]. Previous studies have shown that the RFESS not only equally improve strength levels but also have superior effects on enhancing change of direction and single-leg jumping performance compared to the back squat, [3-5]. Identifying the change of muscle activation and ground reaction force distribution is important in needs analysis of the RFESS. Knowledge of that can be used to guide the design of the resistance training program. However, there is currently a lack of research on the muscle activation and GRF of the RFESS under different loads and fatigue levels. Therefore, the purpose of this study is to explore the changes in muscle activation and GRF of RFESSs with the changes of loads and fatigue levels.

METHODS: 19 male college athletes (RFESS 1RM: left leg, 103.06 ± 13.3 kg; right leg, 103.61 ± 13.15 kg) attended five experimental sessions. During the session 1 and 2, anthropometric data (height, weight) were collected, and the participants were familiarized with the testing procedures. In the testing session 3 and 4, the 1RM of RFESS was tested, followed by randomized testing of 75% 1RM fatigue-to-failure and different loads (40%, 50%, 60%, 70%, 80%, 90% 1RM). surface electromyographic (EMG), kinetic and three-dimensional kinematic data were collected during the tests. Two-factor repeated measures ANOVA was used to determine differences of GRF, GRF ratio, and average surface electromyographic

(AEMG) % between different loads and fatigue level (initial, middle, and final stages of fatigue to failure set) on the lead and rear foot. The overall alpha level was set at $p \leq 0.05$.

RESULTS: The GRF (GRF) of the front leg during the RFESS significantly increased from 40% to 90% 1RM ($p = 0.001$) and was consistently higher than that of the back leg ($p = 0.001$). The AEMG% of the vastus lateralis of the front leg was the highest, followed by the vastus lateralis of the rear leg, gluteus maximus of the front leg, and biceps femoris of the front leg. the proportion of GRF on the rear leg decreased as the load increased. The ratio of GRF between the front and rear legs was approximately 8:2. As the fatigue level up, the AEMG% of the main muscles of both the front and rear legs showed no significant changes across the initial, middle, and final stages of fatigue to failure set ($p > 0.05$). the GRF of the front leg showed an increasing trend across the initial, middle, and final stages. The GRF in the initial stage was significantly lower than that in the middle stage ($p = 0.003$) and final stage ($p = 0.001$), while there was no significant difference between the middle and final stages ($p = 0.19$).

CONCLUSION: Muscle Activation and GRF are affected by loads and fatigue levels during the RFESS. The front leg is the main force contributor (80%), and the loads and fatigue level have little effect on the contribution of the front legs to the force during RFESS exercises.

COMPARING LANDING STABILITY ACROSS DROP LANDINGS, DROP JUMPS, AND COUNTERMOVEMENT JUMPS

GREEN, A., SZELES, K.T.

UNIVERSITY OF JOHANNESBURG

INTRODUCTION: Landing requires athletes to attenuate ground reaction forces in three planes while establishing postural stability. Various jump or landing tasks are employed to monitor performance and injury risks. These include the Drop Landings (DL); Drop Jumps (DJ) and Countermovement Jumps (CMJ). Moreover, landing stability can be quantified using Dynamic Postural Stability Indices (DPSI) and Time to Stabilisation (TTS). The study purpose was to evaluate the stability indices of landing phases across the various landing conditions.

METHODS: 20 female recreational athletes (age: 23.4 ± 2.87 years; mass: 62.85 ± 10.28 kg; height: 1.69 ± 0.08 m) volunteered to complete 40cm DL, 40cm DJ and CMJ in a randomised order. All kinetics were recorded using two Bertec force plates at 1000Hz. Force tracings were analysed in MatLab, where stability metrics (APSI, MLSI, VSI, DPSI and TTS) were calculated. One-way ANOVA with appropriate post-hoc tests were conducted with significance at $p < 0.05$.

RESULTS: Stability indices showed differences across all three landings and directional components ($p < 0.001$). Higher APSI were recorded for DL (0.059 ± 0.013) compared to DJ (0.027 ± 0.025) and CMJ (0.019 ± 0.013) and a lower MLSI in DL (0.023 ± 0.01) compared to CMJ (0.032 ± 0.015). VSI and DPSI were the lowest in DL (0.265 ± 0.068 ; 0.273 ± 0.07) compared to DJ (0.578 ± 0.175 ; 0.564 ± 0.148) and CMJ (0.514 ± 0.136 ; 0.516 ± 0.136). Finally, no TTS differences were observed across the landings (DL: 1.50 ± 0.27 s; DJ: 1.52 ± 0.35 s; CMJ: 1.40 ± 0.28 s).

CONCLUSION: Stability differences were noted across the various conditions, with the DL reporting the most differences with DJ and CMJ. It's apparent that DJ and CMJ are more dynamic movements and more variable in terms of joint movements (1). Furthermore, studies have shown that cognitive load can negatively impact knee joint stability during landing tasks (2), showing that dual-task conditions can significantly increase peak GRF. This may translate into the findings of the current study, where VSI and DPSI are significantly larger in DJ and CMJ compared to DL. Additionally, DJ and CMJ require more reactive landings compared to DL. APSI in DL may indicate a greater joint excursion as most of the force attenuation occurs in the AP and vertical planes. Specific to the vertical stability (VSI & DPSI) differences might be attributed to the landing heights, leading to greater joint flexion angles and higher GRF (3).

In conclusion, Landing stability may be determined by the dynamics of the jump or preceding events. Additionally, postural stability might be affected by the landing height and kinematic strategies used to attenuate force.

GROUND REACTION FORCE ASYMMETRIES AND PERFORMANCE DURING DIFFERENT VERTICAL JUMPS MODALITIES IN YOUNG RHYTHMIC GYMNASTS

DI GIMINIANI, R., MARINELLI, S., PASSACANTANDO, E., FARINA, F., LA GRECA, S.

UNIVERSITY OF LAQUILA

INTRODUCTION: Rhythmic gymnastics (RG) is characterized by unilateral jump exercises that may accentuate dominance, determining asymmetries and increase injury risks. The purpose of this study was to investigate lower limb asymmetries by recording vertical ground-reaction force-time profiles during squat jump, counter movement jump, and drop jump in young RG athletes.

METHODS: Young rhythmic gymnasts (N=15; Age: 12.15 ± 2.26 years; Stature: 148.89 ± 14.31 cm; Body Mass: 39.02 ± 12.26 kg; BMI: 17.11 ± 2.65 Kg/m²), performed SJ, CMJ and DJ in a random order on a dual force platform that recorded the vGRF-time profile in the preferred or non-preferred limb. Three trials were conducted for each jump, and the jump with the highest flight time was selected for analysis. The values of the vGRF-time profiles in distinct jump phases for each leg were

retained for analysis: in the SJ, the highest vGRF values were analysed during the propulsion and landing phases; in the CMJ, the highest values were analysed during the counter movement, propulsion, and final landing; and in the DJ, the highest vGRF values were analysed during the braking, propulsion, and final landing phases. Other performance variables, such as flight time, jump height, and power propulsion, were also analysed.

RESULTS: The intra-class correlation coefficient (ICC) of the measurements ranged from 0.87 to 0.98 (95% confidence limit= 0.65-0.99). The flight time measured during the CMJ was significantly higher than that of DJ (451.21 ± 27.62 vs. 410.07 ± 35.29 ms; $p < 0.001$) and SJ (451.21 ± 27.6 vs. 419.1 ± 26.57 ms; $p < 0.001$). The jump height was higher in DJ than in SJ (22.65 ± 4.61 vs. 21.55 ± 2.67 cm; $p < 0.001$) and in CMJ than in SJ (25.02 ± 3.02 vs. 21.55 ± 2.67 cm; $p < 0.01$). Similarly, the power propulsion yielded higher values in DJ (2682.81 ± 938.01 watt) and CMJ (2454.74 ± 599.54 watt) when the values were compared to those of SJ (1988.48 ± 479.35 watt) ($p < 0.01$).

During the braking phase of DJ, the non-preferred limb displayed higher vGRF values compared to the preferred limb ($\Delta = 40\%$, $p < 0.01$). In contrast, the preferred limb showed higher vGRF values than the non-preferred limb during the propulsion phase ($\Delta = 45\%$, $p < 0.05$). During the SJ and CMJ, the differences between preferred and non-preferred limb did not show significant values in any phase of the jumps (Δ ranged from 7 to 15%; $p > 0.05$).

CONCLUSION: The observed asymmetries in the vGRF-time profile during DJ highlight the distinctive characteristics of RGs performance requirements. The neuromuscular patterns may be the result of the sustained similarity of training volume and task-specific to the technical demands in which rhythmic gymnasts are involved. Through compensative training protocols focused on the high-impact phases like DJ and landing, it may be possible to improve the long-term technical development of young gymnasts, optimize performance, and reduce injury risk.

INFLUENCE OF TEACHING STRATEGIES ON BIOMECHANICAL CONTROL AND ATHLETIC PERFORMANCE IN ADOLESCENTS: COMPARISON OF INTERNAL AND EXTERNAL FOCUS

GRAVINO, G., FOGLIATA, A., MAZZELLA, M., AMBRETTI, A.

UNIVERSITÀ DEGLI STUDI DELLA CAMPANIA LUIGI VANVITELLI

INTRODUCTION: Optimising motor learning and physical performance in adolescents is very important for the biomechanical learning of the sporting gesture. This study therefore examined the impact of two differential teaching strategies with respect to attentional focus: the first based on internal focus (FI), oriented towards the understanding of the causes of movement by the Sincrony methodology, the second with external focus (FE), focused on the visible effects of the athletic gesture. The aim was to identify which approach favours better motor control and long-term performance maintenance.

METHODS: 196 competitive adolescents (mean age: 15.2 ± 0.8 years) were recruited and randomly divided into two groups (FI and FE). Athletes participated in a standardised 8-week training programme focused on biomechanically relevant exercises, including vertical jumps (Squat Jump and Countermovement Jump) and flat bench presses protocolized by Sincrony methodology. Performance was measured with the ChronoJump Bosco system for explosive power and a digital dynamometer for maximum force in push-ups. Evaluations were conducted at three time points: baseline (T0), post-intervention (T1) and 12-week follow-up (T2).

RESULTS: Results showed significant improvements in jump height ($+9.3\%$ FI, $+8.3\%$ FE) and maximal strength ($+14.6\%$ FI, $+13.8\%$ FE) at T1 in both groups. However, the internal focus showed a greater ability to maintain improvements over time, with a minimal decrease in maximal strength at T2 (-1.1% FI vs. -2.2% FE). The FI approach favoured a more stable biomechanical control in static exercises such as the flat bench, highlighting a superior cognitive involvement in understanding the dynamics of the gesture.

CONCLUSION: The study emphasises the role of internal focus in improving movement biomechanics, in line with the Sincrony methodology, particularly in static exercises. This approach has been shown to promote more stable motor learning and greater persistence of improvements. The integration of specific biomechanical instructions may be an effective strategy to optimise athletic performance in young athletes. Future studies could further investigate the effectiveness of internal focus in complex, high-load biomechanical contexts.

VARIABILITY OF MEAN PROPULSIVE VELOCITY IN BACK SQUAT DURING THE MENSTRUAL CYCLE IN FEMALE RUGBY PLAYERS: PRELIMINARY RESULTS

PÉREZ CEPÁ, D., ARMADA-CORTES, E., SAN JUAN, A.F.

UNIVERSIDAD POLITÉCNICA DE MADRID

INTRODUCTION: The menstrual cycle (MC) is being studied as one of the possible causes of variation in sports performance in female athletes. Numerous variables are affected by it, both at a physiological (Kissow et al., Sports Medicine, 2022) and biomechanical level (Montalvo et al., Journal of athletic training, 2019). One of the theories related to this possible variation in performance is the cyclic fluctuation of female sex hormones, such as estrogens and progesterone (Draper et al., Scientific reports, 2018). The aim of this research is to determine whether the different phases of the menstrual cycle influence the mean-propulsive-velocity (MPV), and the power developed in the back squat exercise in female rugby players.

METHODS: Ten female rugby players (age: 25.3 ± 3.2 years; height: 167.3 ± 4.2 cm; weight: 68.0 ± 13.6 kg) performed a back squat test to measure, through a linear encoder, the MPV (m/s) in the three phases of the MC. It was considered the early follicular phase (days 1 to 8), late follicular phase (days 9 to 12) and luteal phase (days 14 to 28), estimated through

calendar and ovulation strips. An incremental power test (Maté-Muñoz et al., J Int Soc Sports Nutr, 2018) was performed in the first late follicular phase to ascertain the load at which the following speed tests would be conducted (i.e., maximal power developed). If the external load remains the same, an increase in MPV will mean an increase in sports performance in resistance training. Therefore, the measurement of this value can be significant for evaluating the athlete. Differences between the values of the three phases of the MC were analyzed using a repeated measures analysis of variance (ANOVA) via SPSS Statics. The statistical threshold was set at $p < 0.05$.

RESULTS: Statistically significant differences in MPV are observed between the early follicular phase (0.533 ± 0.031 m/s) and the late follicular phase (0.596 ± 0.040 m/s); ($p < 0.001$, IIC 95% -0.091, -0.035) with a high effect size: $F(2) = 21.554$, $p < 0.001$, $d = 0.84$, $\beta - 1 = 1$; calculated throw Cohen's d. Although the differences are significant, there is a large inter-subject variability.

Power and velocity have a directly proportional relationship, so the observed changes in MPV are also shown in power values. The difference in power (w) between late follicular phase and early follicular phase was 11%, while between the late follicular phase and luteal phase was 5.3%.

CONCLUSION: These preliminary data seem to indicate that MPV, related to sports performance, might be higher during the late follicular phase, just before ovulation, while the lowest data appear during the menstruation phase. Moreover, it would be relevant to include an objective MPV measure to control the athlete's performance during the sport season, and during the rehabilitation and return to play process.

THE INFLUENCE OF EXTERNAL ATTENTIONAL FOCUS ON SINGLE-LEG DROP JUMP ASYMMETRY

LAI, M., HO, I.M.K., LUK, J.T.C., XU, J.Q.

TECHNOLOGICAL AND HIGHER EDUCATION INSTITUTE OF HONG KONG

INTRODUCTION: Inter-limb asymmetry (IA) refers to the differences between limbs in function or performance, which has implications for sports performance and injury risk. While some studies indicate that IA negatively affects activities like jumping and sprinting, findings remain mixed due to the task-specific nature of IA. External attentional focus (EAF) such as an overhead goal (OG), was shown to promote automatic motor control, significantly enhancing the vertical rebound jump performance. This study investigated the effects of OG on single-leg drop jump (SLDJ) asymmetry, aiming to determine if OG can reduce IA while maintaining consistency in the asymmetry direction.

METHODS: Sixteen recreational overhead sports athletes performed SLDJs from a 20cm-platform under non-overhead goal (NOG) and OG conditions as repeated measures. In the OG condition, the subjects were required to grasp the OG after the single-leg vertical rebound jump at the peak of jump height (JH) and land with the same instructed leg. Ground contact time (GCT), JH, and reactive strength index (RSI) were measured using the mobile device with the app My Jump2.

RESULTS: The results of the paired T-test revealed no significant difference ($p > 0.05$) between NOG and OG conditions in all measured metrics and no significant difference ($p > 0.05$) in the IA of SLDJ, with the magnitude of IA deemed small effect size. GCT asymmetry showed "substantial" agreement (Kappa = 0.63), while RSI and JH asymmetry showed "fair" agreement (Kappa = 0.25) between conditions.

CONCLUSION: The lack of significant differences may be due to task complexity, athletic level, and jumping capacity in relation to the nature of IA. Moreover, the specific requirement of the OG condition, where the arms are required to reach a fixed goal, limits the joint range of motion and restricts the coordination patterns of muscle synergies across one or more joints, which might affect the magnitudes of asymmetry. The following key messages should be considered for practitioners when evaluating IA with EAF. It is essential to exercise diligence in selecting tasks that align with the athletes sport-specific contexts and physical capabilities, as exercise demands beyond the athletes current level may obscure accurate performance metrics. This study suggests that adding an overhead target does not lead to a positive impact on SLDJ asymmetry.

COMPARING THE LOWER LIMB JOINT KINETICS AND KINEMATICS BETWEEN SINGLE-LEG DROP LANDING AND DROP LANDING WITH 90-DEGREE ANTI-CLOCKWISE TURN

HO, I., HO, C.W., YEUNG, L.M., LUK, J.T.C.

TECHNOLOGICAL AND HIGHER EDUCATION INSTITUTE OF HONG KONG

INTRODUCTION: Single-leg landing is highly demanding in both individual and team sports whereas, athletes may suffer from lower limb injuries such as knee pain and injuries when performing this motor skill improperly. When the single-leg hop and land is incorporated with an anti-clockwise turn during the flight phase, it may increase the demand on knee control in the frontal plane such as the hip abduction/adduction and knee valgus/varus position as it potentially increases the horizontal moment of inertial during landing.

METHODS: A total of 12 male healthy active individuals participated in the single-leg drop landing conditions (all performed 3 trials of the vertical drop landing (VDL) and drop-landing with a 90-degree anti-clockwise turn (90ACDL) with their dominant leg on a 30-cm platform). The joint kinetic such as the vertical ground reaction force (vGRF) was measured by the force plate (ATMI, sampling rate at 1000 Hz) meanwhile the joint angles including the knee flexion, hip adduction, and knee valgus (peak and mean during landing phase as well as the peak and mean values at the time point of highest vGRF value) were observed using the inertial measurement unit (IMU sensors, APDM Opal, sampling rate at 128 Hz).

RESULTS: Paired sample t-tests showed no significant difference ($p>0.05$) in the comparison of all metrics between the VDL and 90ACDL conditions. Only the peak knee valgus angles of the 90ACDL were apparently shown to be larger than the VDL with marginal significance ($p=0.09$) while the magnitude-based decision (MBD) showed a likely increase (standardized change in mean = 0.50) in the peak knee valgus angles.

CONCLUSION: Paired sample t-tests showed no significant difference ($p>0.05$) in the comparison of all metrics between the VDL and 90ACDL conditions. Only the peak knee valgus angles of the 90ACDL were apparently shown to be larger than the VDL with marginal significance ($p=0.09$) while the magnitude-based decision (MBD) showed a likely increase (standardized change in mean = 0.50) in the peak knee valgus angles.

ARE WE THERE YET?: A SYSTEMATIC REVIEW AND META-ANALYSIS OF MARKERLESS MOTION CAPTURE FOR LOWER LIMB ASSESSMENT DURING JUMPING TASKS

OGURA, A., FLORIO, E., DENNISON, L., PSARAKIS, M., WILEMAN, T.
UNIVERSITY OF TSUKUBA

INTRODUCTION: Accurate measurement of lower-limb biomechanics is crucial for rehabilitation monitoring, performance assessment, and return-to-sport decisions. Although marker-based motion capture and force plates are the accepted gold standards for kinematic and kinetic measurements, their cost, complexity, and laboratory requirements constrain widespread field-based use. Markerless motion capture (MMC) which uses computer vision and AI-driven pose estimation has the potential to deliver biomechanical insights in more accessible settings. This systematic review and meta-analysis evaluated the validity, reliability, and real-world applicability of MMC for assessing lower-limb kinematics, kinetics, and performance during jumping tasks.

METHODS: A systematic literature search of four databases (EBSCOhost, PubMed, Web of Science, Scopus) identified studies involving (1) jumping tasks, (2) MMC compared with marker-based or force-plate gold standards, (3) lower-limb kinematic/kinetic/performance measures, and (4) validity or reliability outcomes. The methodological quality of included studies was appraised using the COSMIN risk-of-bias checklist. A meta-analysis of root mean square error (RMSE) for key kinematic variables was conducted using a random-effects model.

RESULTS: Of 478 identified records, 12 met the inclusion criteria, and 6 contributed data to the meta-analysis. Overall methodological quality was rated "doubtful," indicating uncertainty regarding risk of bias. MMC performance varied across measurement planes, with sagittal plane measurements showing RMSE exceeding 5° at all lower limb joints. While some studies reported lower RMSE, wide Bland-Altman limits of agreement ($>10^\circ$) and high minimal detectable change values raised concerns about detecting clinically meaningful changes. Frontal-plane kinematics showed better accuracy (RMSE $\sim 5^\circ$), though discrete events remained variable. Kinetic validation studies were limited in number and scope, with mixed findings regarding force and joint moment accuracy. Jump height emerged as the most robust measure, showing minimal bias and higher reliability.

CONCLUSION: Markerless motion capture shows potential for field-based assessments, particularly for jump height measurements and frontal-plane movements, but current limitations in sagittal plane precision restrict its use in clinical decision-making. Performance notably varied with hardware configurations and processing methods, with higher accuracy often achieved through multiple cameras and specialised setups that may limit practical implementation. Future research requires standardised reporting of error metrics, systematic evaluation of minimum camera requirements, model training protocols, and environmental constraints to establish whether MMC can serve as a viable alternative to traditional laboratory methods.

CP-BM15 Fatigue

EFFECTS OF EXPERIMENTALLY INDUCED FATIGUE ON MOTOR LEARNING: A SCOPING REVIEW

GHAFAARI GOUSHE, B.1,2, YOUSSEF, L.1,2, MANGIN, T.1,2, ARVISAIS, D.3, NEVA, J.1,2, PAGEAUX, B.1,2
1 ÉCOLE DE KINÉSIOLOGIE ET DES SCIENCES DE L'ACTIVITÉ PHYSIQUE, UNIVERSITÉ DE MONTRÉAL, MONTRÉAL, CANADA 2
CENTRE DE RECHERCHE DE L'INSTITUT UNIVERSITAIRE DE GÉRIATRIE DE MONTRÉAL, MONTRÉAL, CANADA 3 DIRECTION DES
BIBLIOTHÈQUES, ÉCOLE DE KINÉSIOLOGIE ET DES SCIENCES DE L'ACTIVITÉ PHYSIQUE, UNIVERSITÉ DE MONTRÉAL, MONTRÉAL,
CANADA

INTRODUCTION: The literature on the effect of fatigue on motor learning is limited and marked by inconsistent findings, likely due to significant variability in methodologies. This scoping review aimed to explore the available knowledge on the effects of fatigue induced by physical and mental exertion on motor learning. Specifically, this review sought to investigate: 1) how fatigue and motor learning were defined, 2) the methods used to induce and quantify fatigue, 3) the methods used to assess motor learning, and 4) the target populations that have been investigated.

METHODS: A pre-registered comprehensive search was conducted in 8 databases. The included studies had to apply a fatiguing protocol performed during the same session as the motor learning task and include at least one criterion to verify the successful fatigue induction. Studies were included if they involved practicing a motor learning task. All types of

fully published peer-reviewed articles and gray literature were eligible for inclusion. The language was restricted to English and French.

RESULTS: The initial database search returned 1887 references, of which 36 full texts met the inclusion criteria. An additional article was identified through forward citation searching. In total, 21 sources were included: 19 primary sources and 2 secondary sources (1 MSc thesis and 1 book chapter). Results from the 19 primary sources revealed that only 1 study included definitions for both fatigue and motor learning. Fatigue induced by physical exertion was the most frequently used method across studies, accounting for 84% of cases. Fatigue induced by mental exertion was employed in only 16% of the studies. No study employed a combined mental and physical exertion method to induce fatigue. Motor acuity was the most frequently used paradigm to infer motor learning, accounting for 53% of the studies. Adaptation and sequence learning paradigms accounted for 26% and 21% of the studies, respectively. No association paradigm was employed to infer motor learning. All participants were aged 19-31 years old. Of all the studies, 47% reported participants sex and 42% reported participants' gender. None of the studies included information about participants ethnicity.

CONCLUSION: This review underscores the critical need for clear, operational definitions of both fatigue and motor learning to enhance measurement consistency and reproducibility. Given the limited research on the effects of fatigue induced by mental and combined exertion, future studies should prioritize using these types of experimental manipulations to induce fatigue. Additionally, exploring adaptation, sequence learning, and association paradigms could provide deeper insights into how fatigue influences motor learning. Future studies should expand their participant pools to include middle-aged and older adults as well. Moreover, reporting key participant characteristics such as sex, gender, and ethnicity should be prioritized.

SIMULTANEOUS TRANSDERMAL APPLICATION OF CARBON DIOXIDE AND MENTHOL ACUTELY RESTORES LEG MUSCLE FUNCTION IMPAIRED BY PROLONGED STANDING

KIMURA, S., MITANI, R.2, TAKAO, Y.2, IWASAKI, A.2, TOYODA, Y.2, IKIGAKI, M.1, KITANO, J.1, SASAKI, K.2

1 KAO CORPORATION; 2 THE UNIVERSITY OF TOKYO

INTRODUCTION: Prolonged standing can cause neuromuscular fatigue, tissue swelling, and subjective fatigue in the legs (1). However, few studies have investigated recovery strategies for these symptoms. Carbon dioxide (2) and menthol (3) have been shown to improve peripheral circulation when applied transdermally and may serve as promising treatments for fatigue and swelling. We thus aimed to determine individual and combined effects of carbon dioxide and menthol on the recovery from prolonged standing.

METHODS: Thirteen healthy adults (7 men and 6 women) participated in this study. The participants first underwent 70 minutes of quiet standing and then rested in a seated position for 30 minutes with a gel sheet (12.5 x 8.5 cm) applied to the posterior aspect of both lower legs. Four types of gel sheets were tested in a randomized order on separate days: placebo (P), carbon dioxide (C), menthol (M), and a combination of carbon dioxide and menthol (CM). Ankle dynamometry combined with tibial nerve stimulation, surface electromyography, near-infrared spectroscopy, bioelectrical impedance analysis, and ultrasonography were used to comprehensively evaluate neuromuscular function and morphology in the lower leg before and after standing and after recovery. Subjective fatigue was assessed using a visual analog scale. One-way ANOVA was performed to test whether changes in each variable differed between conditions. A generalized linear mixed model was used to examine how the change in subjective fatigue was related to those in selected physiological variables.

RESULTS: No significant differences between gel sheets were observed for changes in heart rate, lower leg skin temperature, volume, extracellular water ratio, electromyographic activity of soleus (Sol) and medial gastrocnemius (MG) during maximum voluntary contraction, or subjective fatigue. CM more effectively reduced electromechanical delay, deoxygenated hemoglobin, circumference, and muscle hardness than did P, while increasing twitch force, maximum isometric torque production, voluntary activation, rate of torque development, and Sol and MG activity at 0-200 ms ($p < 0.05$, Tukey HSD test). C more effectively reduced muscle hardness and increased MG activity than P. M had no significant effect compared with P. The recovery of subjective fatigue was linked to the recovery of lower leg circumference, rate of torque development, and Sol activity.

CONCLUSION: Our results provide the first evidence that compared with the individual application, the simultaneous application of carbon dioxide and menthol markedly restores leg muscle function impaired by prolonged standing. The recovery of subjective fatigue was apparent even with the placebo application but may be partly attributed to improvements in peripheral circulation and neuromuscular function.

MECHANICAL PERFORMANCE IN LEG PRESS EXERCISE AND GLYCOLYTIC INVOLVEMENT DURING RESISTANCE TRAINING PROGRAMMES DIFFERING IN SET CONFIGURATION: INSIGHTS FROM THE CARE STUDY ON POSTMENOPAUSAL WOMEN

FARIÑAS, J., RIAL-VÁZQUEZ, J., NINE, I., RÚA-ALONSO, M., REVUELTA-LERA, B., GIRÁLDEZ-GARCÍA, M.A., RIVERA-MEJÍA, S.L., OVIES-GUTIÉRREZ, F., LENS-VALES, A., IGLESIAS-SOLER, E.

UNIVERSIDADE DA CORUÑA/ Q6550005J

INTRODUCTION: Resistance training is hardly recommended for postmenopausal women to counteract negative effects of hormonal changes (1). Furthermore, OMS guidelines include the recommendation of different levels of strength training depending on age. It has been demonstrated that set configuration can modulate velocity and power loss causing different levels of fatigue (2), but this topic has been mainly investigated in healthy and young people. The objective of this study was to compare the effects of set configuration on mechanical performance in leg press exercise of postmenopausal women.

METHODS: 50 physically active postmenopausal women participated in this study funded by the Spanish Ministry of Science, Innovation and University (PID2021-124277OB). After a medical exam and familiarization, women completed in a randomized order 3 experimental sessions differing in set configuration: 9 sets of 4 reps with 45s of inter-set rest; 6 sets of 6 reps with 72s of inter-set rest and 4 sets of 9 reps with 120s inter-set rest. They completed a total of 36 reps per exercise with 12RM load (i.e., leg press, bench press, prone leg curl and lat pull-down). Resting time between exercises was 4 min. Throughout leg press performance mechanical data (i.e. velocity and power loss) was collected. Blood lactate concentration samples (La) were obtained before and 1min after session. Explosive performance was also evaluated before and after each session by 2 reps at maximum intended velocity with 70% of 12RM in leg press exercise.

RESULTS: Regarding the percentage of velocity and power loss, a main effect of session ($p < 0.001$) was found with significant greater losses in 6S and 9S compared with 4S for both variables. La after session was significantly higher than before for all sessions, with greater values in 9S compared to 6S and 4S ($9S > 6S > 4S$) ($p > 0.001$). For neuromuscular test, main effect of session ($p = 0.035$) and time ($p < 0.001$) with no interaction ($p = 0.266$) was found, suggesting the same velocity reductions in the explosive test for all set configurations.

CONCLUSION: Set configuration modulated the mechanical performance of postmenopausal women in leg press exercise in terms of mechanical performance. Short configurations (i.e., 4S) allow to reduce the loss of velocity and power in leg press during training sessions with low lactate values, which helps preserve movement quality and may increase exercise adherence by reducing the effects of delayed onset muscle soreness.

INFLUENCE OF MUSCLE-SPECIFIC DIFFERENCES IN THE NEUROMUSCULAR FATIGUE DEVELOPMENT AND LOSS OF TORQUE COMPLEXITY INDUCED BY SEVERE-INTENSITY EXERCISE

CORREA JUNIOR, R., BARRETO, R.V., DENADAI, B.S., GRECO, C.C.

SAO PAULO STATE UNIVERSITY

INTRODUCTION: The use of hand (Handgrip, HG) and leg (Knee-extensors, KE) muscles for tasks such as holding or handling objects and walking or standing, respectively, needs distinct motor coordination tasks (1). These functional tasks performed by both muscles are linked to different morphological and physiological characteristics, including muscle size, fiber type proportions, recruitment strategies, and perfusion capacity, which can affect torque production, neuromuscular fatigue (NMF), and exercise tolerance (TLIM) [2-4]. This study investigated the effects of a high-intensity exercise until task failure on NMF and torque complexity in HG and KE muscles of untrained subjects.

METHODS: 11 Untrained males (23 ± 4 years, 76 ± 14 kg, 177 ± 6 cm) participated in this study. The following experimental procedures were carried out on different days: 1) Familiarization with HG and KE protocols; 2) 3-maximal voluntary contractions (MVC) to evaluate maximal torque production, and a 5-min all-out test (60 MVC of 3s/ 2s rest) to determine critical torque of HG and KE muscles; and 3) An intermittent constant-load test (3s effort/2s rest) at critical torque +15% until failure to assess NMF, torque complexity, and TLIM.

RESULTS: At baseline, KE muscles had greater MVC (KE 240 ± 58 N·m vs. HG 75 ± 17 N·m, $p < 0.001$), but lower voluntary activation (KE $81 \pm 13\%$ vs. HG $96 \pm 4\%$, $p < 0.001$) than HG muscles. Critical torque was not different between HG and KE muscles in relative terms (%MVC) ($p = 0.82$). Similarly, there were no differences in mean torque during constant load test, when normalized to MVC (KE $40 \pm 9\%$ vs. HG $40 \pm 6\%$, $p = 1.00$) and as percentage above critical torque (KE $15 \pm 3\%$ vs. HG $15 \pm 4\%$, $p = 0.85$). TLIM did not differ between KE and HG muscles (KE 413 ± 179 s vs. HG 319 ± 89 s, $p = 0.27$). KE muscles had a greater decrease on central (KE $-15 \pm 12\%$ vs. HG $8 \pm 5\%$, $p < 0.001$) and peripheral fatigue (KE $-64 \pm 21\%$ vs. HG $-29 \pm 14\%$, $p < 0.001$) than HG muscles, but there were no differences in MVC (KE $-40 \pm 14\%$ vs. HG $-47 \pm 10\%$, $p = 0.19$) loss. NMF reduced torque complexity in KE muscles (ApEn: 1.55 ± 0.09 to 1.25 ± 0.20 , $p < 0.001$; DFA- α : 1.40 ± 0.11 to 1.52 ± 0.06 , $p < 0.001$), while in HG, only DFA- α was affected (1.01 ± 0.16 to 1.24 ± 0.16 , $p < 0.001$).

CONCLUSION: When performing a similar task within the severe intensity domain, KE muscles experienced greater central and peripheral fatigue than HG muscles, despite their similar TLIM and MVC loss. Meanwhile, loss of torque complexity induced by NMF occurred in both muscles. These findings further highlight that factors such as muscle torque control may have contributed to the inability of the two muscles to sustain the task, thereby influencing their TLIM capacity.

THE EFFECTS OF THREE DAYS OF SLEEP RESTRICTION ON VIGILANCE, MANUAL DEXTERITY, AND HIGH-INTENSITY PHYSICAL PERFORMANCE IN RECREATIONAL ATHLETES

HOUGH, P., NORTH, J.S., PATTERSON, S.D., PEDLAR, C.R.
UNIVERSITY OF WESTMINSTER

INTRODUCTION: Athletes and military personnel commonly experience consecutive days of sleep restriction (SR) due to their demanding schedules. Consecutive nights of SR impair daytime alertness (1), mood, and motivation (2), which is thought to reduce physical performance (3). However, the effects of cumulative SR on vigilance and physical performance have rarely been explored concurrently. This study investigated the effects of three consecutive nights of SR on vigilance, manual dexterity, and high-intensity physical performance.

METHODS: Fifteen recreational athletes (12 males, age 37 ± 4.5 y; 3 females, age 39 ± 8.7 y) completed a familiarisation (FAM) trial involving subjective rating scales, the Psychomotor Vigilance Task (PVT), the Perdue Peg Board Test (PPT), a high-intensity intermittent cycling (HIIC) protocol (5 x 10s sprints) and an isometric mid-thigh pull (IMTP). Each participant wore a wrist-worn accelerometer and completed a daily sleep diary throughout the study. The laboratory tests (from FAM) were repeated after three nights of normal sleep (CON) and three nights of SR in a counterbalanced sequence. SR involved participants delaying bedtime by two hours and waking at their usual time for three consecutive nights. Differences between conditions were assessed using paired t-tests and Wilcoxon signed-rank tests.

RESULTS: Sleep duration was reduced from 7.5 ± 0.6 h (CON) to 5.4 ± 0.64 h (SR) per night, resulting in an average sleep deficit of 6.3 ± 1.5 h across three nights ($p < 0.001$). Subjective sleep quality decreased by 12% between CON (7.2 ± 1.1) and SR (6.4 ± 1.8 , $p = 0.04$). Sleep efficiency was unchanged between conditions. After SR, the rating of sleepiness ($p < 0.001$), fatigue ($p < 0.001$), and stress ($p = 0.02$) increased by 60%, 73% and 28%, respectively, and motivation to exercise decreased by 35% ($p < 0.001$). PVT median reaction time decreased by 3.6% ($p = 0.02$), and response speed increased by 2.6% ($p = 0.02$) compared to CON. No significant differences were observed for other PVT metrics between conditions. Performance in the manual dexterity tasks, IMTP peak force, and objective metrics measured during the HIIC remained unchanged between CON and SR. However, increased ratings of perceived exertion (2.1%, $p = 0.004$) and fatigue (10%, $p < 0.001$) were observed after SR.

CONCLUSION: Three consecutive nights of SR led to impaired reaction time, reduced motivation, and increased sleepiness, fatigue, and stress ratings. Although manual dexterity and indices of power and force during high-intensity physical tasks did not change after SR, subjective ratings of perceived exertion and fatigue increased. Individuals who regularly experience consecutive days of SR should seek evidence-based interventions, such as caffeine use and napping, to help mitigate the negative effects of SR on vigilance, motivation and perceived exertion.

FORCE DECLINE RATE IS SEX-DEPENDENT AFTER NORMALIZATION FOR CSA IN ECCENTRIC RESISTANCE EXERCISE TO EXHAUSTION

COSTAGLIOLA, C., ZAMBOLIN, F., GIURIATO, G., MCPHEE, J.S., KENNERLEY, A.J., VENTURELLI, M.
UNIVERSITY OF VERONA

INTRODUCTION: Eccentric exercise is known to induce a high incidence of neuromuscular fatigue during execution [1]. Recent studies suggest that knee extensor force generation is primarily dependent on muscle size rather than neural factors [2]. However, sex differences in response to eccentric resistance exercise remain unexplored. This study aims to investigate knee extensor force decline and rate of decline during an eccentric resistance exercise performed to volitional exhaustion and sex-related differences in fatigability.

METHODS: Nineteen physically active, healthy volunteers (9F/10M; age: 23.4 ± 4.0 years) performed repeated sets of 12 isotonic eccentric knee extensions at 100% of peak torque on the Kineo Multistation System (Globus Corp., Italy) until exhaustion. Quadriceps cross-sectional area (qCSA) was assessed via MRI scan at baseline; eccentric maximal voluntary contractions (eMVCs) and rate of perceived exertion (RPE) were recorded after each set.

RESULTS: Mean qCSA was significantly larger in males (90 ± 14 cm²) than in females (60 ± 9 cm²) ($p = 0.0002$). Similarly, baseline mean eMVC was higher in males (61 ± 17 kg) than in females (37 ± 6 kg) ($p = 0.002$). Males completed 93 ± 25 repetitions, while females completed 110 ± 24 ($p = 0.15$), with a mean %eMVC decline of $42 \pm 14\%$ in males and $41 \pm 9\%$ in females from start to end of the protocol ($p = 0.91$). The fatigability index, calculated as the change in eMVC from baseline to the end of exercise divided by repetitions, was 0.5 ± 0.6 in males and 0.2 ± 0.1 in females ($p = 0.11$). The force decline rate, assessed via one-phase decay analysis, was similar between sexes (τ : males 12 ± 7 , females 5 ± 4 ; $p = 0.06$). After normalizing for CSA, the fatigability index remained similar between sexes ($p = 0.30$), but the force decline rate differed significantly (τ : males 12 ± 7 , females 3 ± 2 ; $p = 0.018$).

CONCLUSION: Results suggest that while the percentage of force decline is not sex-dependent during eccentric resistance exercise to exhaustion, the rate of decline becomes sex-dependent after normalizing for muscle size (qCSA). Males expe-

rience a faster absolute force decline, likely due to their higher initial strength. However, after CSA normalization, their decline rate remains constant, indicating that fatigue resistance is influenced not only by muscle size but also by physiological and metabolic factors. In contrast, females exhibit a more rapid decline in force post-normalization.

Additionally, the fatigability index showed no significant sex differences in either absolute or normalized values. Further research is needed to explore the physiological mechanisms underlying sex-related differences in force decline rate during eccentric resistance exercise.

AGE-RELATED DIFFERENCES IN MAXIMAL STRENGTH AND MUSCLE FATIGUE: ASSOCIATION WITH MOTOR UNIT ACTIVATION PATTERN

FARAGHER, M., MCKIEL, A., JEVTIC, N., HOLMES, M., BEAUDETTE, S., FALK, B.
BROCK UNIVERSITY

INTRODUCTION: Differences in muscle strength and fatigue between children and adults are well documented, but the mechanisms explaining these differences are not understood. Beyond smaller muscles, differences in motor unit (MU) activation may also explain age-related differences in muscle performance. Studies of age-related differences in discrete MU activation are limited and inconsistent. Thus, the aim of this study was to investigate age-related differences in discrete MU recruitment patterns and firing rates (MUFRs) during maximal volitional isometric contractions (MVIC) of the knee extensors and during a fatiguing maximal contraction.

METHODS: Following a habituation session, MVIC was determined for 20 men (22 ± 3 yr) and 20 boys (10 ± 1 yr). Participants then completed a ramped MVIC at 33%/s, held for 20s. After a 30-min recovery, participants completed a 50s maximal contraction. sEMG from the vastus lateralis were recorded and decomposed into individual MU action potential trains (Trigno®, Galileo, Delsys Inc.). Recruitment thresholds (RT) and MUFRs were calculated for each MU. Boys-men differences in the MUFR-RT relationship during the ramped contraction were assessed using a linear mixed-effects model. A mixed-model ANOVA was used to assess group differences in MUFR during the fatiguing contraction.

RESULTS: MVIC relative to lean body mass was greater ($p < .001$) in men (4.3 ± 0.9 Nm/kg) than in boys (2.6 ± 0.7 Nm/kg). MUFR was lower in boys than in men in both the ramped MVIC and the fatiguing contraction (Age effects, $p < .01$). During the ramped MVIC the MUFR-RT slope was steeper in men than in boys (Age-RT interaction, $p = .005$). The initial RT at which MUs were identified were not different between groups ($p = 0.2$); however, the maximum detected RTs were greater in men compared with boys (71 ± 13 and 60 ± 17 %MVC, respectively, $p = .03$). During the 50s fatigue contraction, torque decreased more in men ($52 \pm 24\%$) than in boys ($40 \pm 22\%$) but differences were not statistically significant ($p = .13$). Both groups experienced a significant decline in MUFRs over the course of the contraction ($p < .001$). Furthermore, there was a significant age-time interaction ($p < .001$), wherein MUFRs decreased linearly in boys and remained initially stable with a steep decrease in the last 20s in men.

CONCLUSION: Our results demonstrate that boys display lower MUFRs compared with men during maximal and fatiguing isometric tasks. In maximal contractions, boys' RT range appears smaller. Additionally, the pattern of decrease in MUFR during fatigue differs between boys and men. It is suggested that children have different neuromotor strategies to complete maximal and fatiguing tasks compared with adults and support the notion that children may have a lesser ability to activate their higher-threshold MUs. The findings provide further insight into the mechanisms underlying age-related differences in muscle performance, and neuromuscular control.

UNDERSTANDING FATIGUE RESISTANCE: RELATIONS TO KEY PHYSIOLOGICAL LANDMARKS

TRISKA, C., PETRIDIS, S., TITZ, M., ERNST, J., SOUKUP, C., MATHY, A.
LEISTUNGSSPORT AUSTRIA

INTRODUCTION: Fatigue resistance is a key determinant of endurance performance and is often considered its fourth dimension. It influences the ability of an athlete to sustain high-intensity efforts over prolonged durations. Understanding the mechanisms underlying fatigue resistance is essential for optimizing training strategies and improving competitive performance in endurance sports. Despite extensive research on endurance performance, the specific determinants of fatigue resistance and their interrelationships remain an area of ongoing investigation. This study aims to assess fatigue resistance in well-trained cyclists by comparing fresh and fatigued time-trial (TT) performance following a race simulation. Furthermore, the study also aimed to examine the association between fatigue resistance and physiological parameters.

METHODS: Seven well-trained male cyclists (body mass: 68.8 ± 4.0 kg; stature: 1.79 ± 0.04 m; maximal oxygen uptake [$\text{VO}_{2\text{max}}$]: 69 ± 4 mL/min/kg; maximal minute power [MMP]: 6.05 ± 0.27 W/kg) completed a series of exercise tests. These included an initial graded exercise test to examine ventilatory threshold (VT) 1, VT2, MMP, $\text{VO}_{2\text{max}}$, and a 5-min TT familiarization, and a baseline testing session comprising steady-state testing at VT1 to assess gross efficiency (GE) and oxygen uptake kinetics (i.e., time constant τ), a 5-s all-out sprint test, and a 5-min TT. During the third visit, participants performed a 1-hour race simulation (ca. 15 kJ/kg) followed by a 5-min TT under fatigued conditions. The race simulation featured a fast start and multiple high-intensity efforts mimicking a cycling road race. Fatigue resistance was evaluated as

the relative change in power output (PO) between fresh and fatigued 5-min TTs. Pearson's correlation was used to analyse relationships between fatigue resistance and physiological parameters, while a paired samples t-test assessed differences in 5-min TT PO.

RESULTS: Mean 5-min TT PO was 5.77 ± 0.34 W/kg and 5.29 ± 0.31 W/kg for fresh and fatigued conditions, respectively ($P = 0.001$), corresponding to a $-8.3 \pm 3.7\%$ relative decline. This relative decline in 5-min TT PO was not significantly associated with relative PO associated with VT1 or VT2, relative MMP, relative VO₂max, GE, tau, or relative 5-min TT PO under fresh conditions ($0.088 < P < 0.995$).

CONCLUSION: These findings suggest that fatigue resistance is not related to traditional physiological markers typically assessed during laboratory testing. As recently proposed, fatigue resistance should be considered a distinct fourth dimension of endurance performance and be tested separately. The decline in 5-min TT PO following a 15 kJ/kg trial does not appear to be predicted by commonly used physiological variables.

ARTERIAL HYPERTENSION AND ITS DELETERIOUS EFFECTS ON CARDIOVASCULAR AUTONOMIC CONTROL BEFORE AND AFTER MENOPAUSE - THE ROLE OF AEROBIC PHYSICAL EXERCISE

SOUZA, H., PHILBOIS, S.V., FACIOLI, T.P., AGUILAR, B.A., BERNAL, J.V.M., DA VEIGA, A.C.

UNIVERSITY OF SAO PAULO

INTRODUCTION: Systemic arterial hypertension (SAH) affects pre-and postmenopausal women, and cardiovascular autonomic impairments are often observed. While pharmacological treatment can reduce blood pressure, it does not seem to restore cardiovascular autonomic control fully. In contrast, aerobic physical training may be decisive in this process, but little is known about its effects in these conditions. This study aimed to investigate the effects of aerobic physical training on baroreflex sensitivity (BRS), autonomic modulation of heart rate (HRV), and blood pressure variability (BPV) in hypertensive women, both pre-and post-menopause.

METHODS: A non-randomized clinical trial in which hypertensive women (35–65 years) treated with renin-angiotensin system inhibitors (RASi) were allocated to two groups: premenopausal (N=49) and postmenopausal (N=55). Hemodynamic, metabolic, cardiorespiratory, and cardiovascular autonomic modulation (spectral analysis) parameters were assessed before and after 16 weeks of aerobic physical training.

RESULTS: Before aerobic physical training, the premenopausal group exhibited a higher BRS gain (9.0 ± 4.8 vs. 5.6 ± 3.0 ms/mmHg) than the postmenopausal group. HRV spectral analysis revealed that the premenopausal group had higher values of low-frequency (LF, 396 ± 377 ms² vs. 173 ± 157 ms²) and high-frequency oscillations (HF, 593 ± 683 ms² vs. 142 ± 139 ms²), and a predominance of vagal autonomic modulation (LF/HF, 0.94 ± 0.64 vs. 1.42 ± 0.69). The differences in BRS gain, LF, and HF between the two groups persisted after aerobic physical training. However, significant increases in HRV parameters were observed, particularly in the postmenopausal group, which began to exhibit vagal dominance in cardiac autonomic modulation (LF/HF 0.97 ± 0.48). Additionally, a reduction in low-frequency BPV was observed in both groups.

CONCLUSION: SAH affects HRV, causing significant impairments in women, especially after menopause, even when the treatment with RASi is effective in reducing blood pressure values. Physical training is a fundamental therapeutic tool that counteracts cardiovascular autonomic impairments and increases cardiorespiratory fitness. However, its benefits in autonomic modulation of HRV and BRS were limited. The reason for this limitation is unknown and may involve adaptations induced by the genesis of hypertension in different autonomic regulation sites and adverse adaptations in the heart itself.

ANAEROBIC THRESHOLD AS A PREDICTOR OF SURGICAL COMPLICATIONS IN ROBOT-ASSISTED SURGERY: A PILOT STUDY

SALDANHA, J., JAMIESON, P., PRINTIE, S., SCULTHORPE, N., PICKARD, C., BURLEIGH, M.

NHS LANARKSHIRE

INTRODUCTION: Cardiopulmonary fitness testing (CPET) is recognised as a clinical risk stratification tool. This pilot study examined the relationship between CPET variables and postoperative complications in robot-assisted surgery (RAS).

METHODS: Retrospective analysis was conducted on RAS patients (n=80). Anaerobic threshold (AT) (mL/min/kg), Peak VO₂ (Peak) (mL/min/kg), BMI, age, sex, and Clavien-Dindo (CD) classification were analysed. Linear regression assessed relationships between AT, Peak and complications. Groups were compared with the Mann-Whitney U test.

RESULTS: The regression model explained 53.9% of the variance in AT ($R^2 = 0.539$, $p < 0.001$). Complications were associated with a lower AT ($\beta = -2.46$, 95% CI: -4.18 to -0.74 , $p = 0.006$, $d = 0.41$). CD classification was also significant ($p < 0.001$), with Class V patients recording lower AT (-11.49 mL/min/kg, 95% CI: -18.03 to -4.95 , $p < 0.001$, $d = 1.12$). Small effects were detected in the Mann-Whitney U tests, but these were not significant: Peak was lower in the complication group ($U = 634$, $p = 0.190$, $d = 0.20$, 95% CI: -0.60 to 2.20). AT was also lower in the complication group ($U = 623$, $p = 0.226$, $d = 0.33$, 95% CI: -0.40 to 1.90).

CONCLUSION: Although underpowered, this pilot suggests that lower AT is associated with the presence of complications following RAS and that patients with higher CD classifications were more likely to have a lower threshold. These findings support preoperative fitness assessment via CPET for risk stratification and care optimisation. Larger samples are required to confirm the findings.

EFFECTS OF ACUTE AND REPEATED EXPOSURE TO WHOLE-BODY CRYOSTIMULATION ON CARDIOVASCULAR RESPONSES IN HEALTHY YOUNG MEN

DOUZI, W., JDIDI, H., DE BISCCHOP, C., DUGUÉ, B.
UNIVERSITE DE POITIERS

INTRODUCTION: Whole-body cryostimulation (WBC), a non-pharmacological intervention, has been shown to improve cardiovascular and autonomic regulation. This study aimed to investigate the acute and repeated effects of WBC on baro-reflex sensitivity (BRS), heart rate variability (HRV), and blood pressure in physically active men.

METHODS: Fifty male participants (22 ± 4 years) were randomly assigned to an experimental group (N=25) and a control group (N=25). Within each group, participants were further classified according to BMI categories (normal weight and overweight). The experimental group underwent 10 WBC sessions over two weeks, while cardiovascular responses were assessed before and after the 1st and the 10th session of WBC. Heart rate (HR), BRS, HRV, and blood pressure (SAP, DAP, MAP) were measured.

RESULTS: A significant reduction in blood pressure was observed after repeated WBC exposures, with systolic arterial pressure (SAP) and mean arterial pressure (MAP) decreasing by 7% (-8.6 mmHg for SAP and -6.3 mmHg for MAP) ($p < 0.05$). In addition, acute WBC exposure significantly increased BRS by 42% after the 1st WBC exposure and 44% after the 10th ($p < 0.001$). Similarly, R-R intervals increased by 11% and 16%, while RMSSD rose by 19% and 34% after the 1st and 10th exposures, respectively ($p < 0.001$). However, no long-term adaptation was observed in HR, HRV, or BRS. No significant differences were found between normal-weight and overweight participants.

CONCLUSION: Our findings demonstrate that WBC induces acute improvements in autonomic regulation, as evidenced by increased BRS and HRV, while significantly lowering systolic and mean arterial pressures at rest. The observed reduction in SAP and MAP suggests beneficial vascular adaptations, potentially mediated by improved endothelial function and enhanced parasympathetic activity. These results align with previous studies highlighting the positive effects of WBC on cardiovascular regulation, supporting its role as a promising non-pharmacological intervention for blood pressure management.

The acute increase in BRS and HRV following WBC exposure indicates a transient enhancement in autonomic balance, which could be beneficial for individuals at risk of hypertension or cardiovascular dysregulation. Although WBC provides acute benefits, no long-term autonomic adaptations were observed, indicating that regular exposure may be needed to sustain its effects. The mechanisms behind blood pressure reduction, such as vascular compliance, nitric oxide availability, or sympathetic regulation, require further investigation.

WBC shows promise as a non-pharmacological strategy for blood pressure control, but further research is needed to evaluate its long-term effects, clinical applicability, and interactions with lifestyle factors. Future studies should also investigate individual variability based on age, metabolism, and cardiovascular conditions to optimize its therapeutic potential.

INTENSITY OF THE 6-MINUTE WALK TEST IN HEART FAILURE PATIENTS: INSIGHTS FROM CARDIOPULMONARY EXERCISE TESTING AND VENTILATORY THRESHOLDS

OPAZO, E., ANDRADE-MAYORGA, O., SOTO, F., LAVADO, A., CONTRERAS, F., LANG-TAPIA, M., ACEITUNO-PINTO, H., ROULIEZ, K., SERON, P.
UNIVERSIDAD DE CHILE

INTRODUCTION: The 6-minute walk test (6MWT) is widely used to assess functional capacity in individuals with heart failure (HF). However, its intensity compared to maximal cardiopulmonary exercise testing (CPET) remains controversial. The physiological threshold concept also requires the relative position intensity for proper exercise prescription. Identifying the intensity of the 6MWT in HF patients could enhance its utility for exercise prescription. This preliminary analysis explores the intensity of the 6MWT concerning physiological thresholds.

METHODS: A preliminary cohort from the CO-CREATION-HF study (33 individuals, 25M/8W, age 67.1 ± 11.8 , BMI 29.9 ± 4.9 , NYHA II-III) was assessed. The 6MWT recorded heart rate (HR), breathing rate (BR), and distance. The day after next, a 6-10W/min incremental ramp test (60 rpm, cycle ergometer) determined maximal HR, BR, and VO_2 . Shapiro-Wilk normality tests, Pearson correlation, and one-way ANOVA analyzed relationships and differences in 6MWT distance, HRmax, and BRmax (95% significance) with respect to physiological thresholds from CPET.

RESULTS: During the 6MWT, HRmax expressed as a percentage of threshold values was $109.1\% \pm 20.9$ (VT1), $94.1\% \pm 18.3$ (VT2), and $79.43\% \pm 13.0$ ($\text{VO}_{2\text{max}}$). During the 6MWT, BRmax was $106.3\% \pm 25.5$ (VT1), $89.4\% \pm 20.6$ (VT2), and $69.1\% \pm 18.4$ ($\text{VO}_{2\text{max}}$). A significant correlation was found between 6MWT distance and $\text{VO}_{2\text{max}}$ ($r=0.53$, $p=0.02$). Distance in the 6MWT correlated with %BRmax of 6MWT normalized to $\text{VO}_{2\text{max}}$ BR ($r=-0.33$, $p=0.34$) but not with VT1 or VT2 BR. HRmax in the 6MWT was not significantly different from HR at VT1 or VT2 but was significantly lower than $\text{VO}_{2\text{max}}$ HR. BR at VT2 and $\text{VO}_{2\text{max}}$ significantly differed from 6MWT BRmax, whereas VT1 BR showed no difference.

CONCLUSION: The 6MWT intensity, based on HR, falls between VT1 and VT2 but is significantly lower than VO₂max HR. Regarding BR, the 6MWT BRmax is only comparable to VT1 and significantly lower than BR at VT2 and VO₂max.

There were no differences in the distance achieved and the intensity relative to physiological thresholds in the 6MWT. These findings suggest that the 6MWT intensity aligns more closely with VT1 in individuals with NYHA II-III HF, supporting its use as a moderate-intensity exercise prescription tool.

IS PHYSICAL FITNESS LEVEL ASSOCIATED WITH HEART RATE RECOVERY IN THE GENERAL POPULATION?

BENITO PEINADO, P., BENÍTEZ-MUÑOZ, J.A., ARMERO-SOTILLO, A., RAMOS-CAMPO, D.J., MARTÍNEZ-GUARDADO, I., ROMERO-PARRA, N., NOBARI, H., ROJO-TIRADO, M.A., PEINADO, A.B.

UNIVERSIDAD POLITÉCNICA DE MADRID

INTRODUCTION: The relationship between heart rate recovery (HRR) and physical fitness has been previously studied in numerous studies [1-4]. However, a few studies have included a sufficiently large sample to determine whether a true association exists between these variables. Several studies have found a negative association between recovery time and physical fitness, examining different types of recovery [1]. Additionally, they suggested that measured HR recovery in beats per minute is not a reliable predictor of physical fitness [3, 4]. Therefore, our objective is to identify the variables most strongly associated with physical fitness within a heterogeneous sample.

METHODS: A total of 2815 participants (484 women and 2331 men; 36±10 yrs; 72.6±11 kg; 173.7±7.8 cm; maximum oxygen uptake (VO₂max): 53.8±10.6 ml/kg/min) underwent a ramp incremental exercise test. The cycle ergometer protocol involved a 2-10 min warm-up at 20-100 W followed by an incremental phase starting at 20-110 W, with power output increasing by 12-25 W/min. The treadmill protocol involved a 3-min warm-up at 4-6 km/h followed by an incremental phase starting at 4-8 km/h, with speed increasing by 1-1.5 km/h/min. Maximum HR (HRmax) and VO₂max were determined as the highest values averaged over 15 s intervals. Basal HR (HRrest) and HR at 2 min post-exhaustion (HR2min) were also recorded. The heart rate recovery index was calculated using Calderon's equation: $HRRI = (HR_{max} - HR_{2min}) / (HR_{max} - HR_{rest})$.

RESULTS: A weak but significant correlation was observed between HRRI and VO₂max, ($r=0.181$, $p<0.001$). In contrast, no association was observed between VO₂max and the absolute HR reduction at 2 minutes post-exhaustion ($HR_{2min} - HR_{max}$; $r=-0.005$, $p=0.778$). The obtained regression model indicates that percentage recovery by Calderon's equation is significantly associated with age (standardized $B=0.05$, $p=0.049$), VO₂max ($B=0.288$, $p<0.001$), sex ($B=-0.069$, $p=0.01$; 0 for female and 1 for male), and HRmax ($B=-0.147$, $p<0.001$). This model explains 6.0% of the variance ($R^2=0.060$) with a statistical error of mean (SEM= 9.7%).

CONCLUSION: HRR, when expressed as a cardiac reserve (HRRI), is significantly associated with physical fitness, while absolute HR reduction at 2 minutes post-exercise does not. Age and VO₂max are positively associated with HRRI, while sex and HRmax exhibit a negative correlation. However, the low explained variance indicates that additional factors likely influence HRR.

AFFERENT PATHWAY TO THE BRAIN IN SPASTIC STROKE FEMALES

LIMA, C.D., RUAS, C., CARLOS, B., VASQUEZ, P., SILVESTRE, J., BLAZEVICH, A., CASTELLANO, G.

UNIVERSITY OF CAMPINAS

INTRODUCTION: Stroke occurs when a blood clot causes thrombosis, often resulting in blockage of the arterial vessels; or when a weakened vessel ruptures. In both cases blood flow is prevented from reaching some brain region. This interruption can lead to various brain tissue lesions, particularly in sensory areas, and impairs effective communication along the afferent pathways to the brain. Inadequate afferent input may lead to spasticity, a condition characterized by persistent excitatory responses in the nervous system, causing muscle contractures, such as "frozen limb."

METHODS: Three female participants (age 60.3±6.4 years; height 161±3 cm; body mass 73±6 kg) were randomly recruited for this study. They had no history of epilepsy, no auditory or cardiac implants, and were free from musculoskeletal injuries. The participants completed a single session (acute) to assess the passive and active stiffness, maximum range of motion (ROM), reflex (Ia afferent) excitability (Hoffman reflex, H-reflex), and cerebral electrical activity (electroencephalography, EEG) of their affected side (left side of the body) before and after receiving cathodal transcranial direct current stimulation (c-tDCS) in combination with traditional rehabilitation.

RESULTS: Due to the small sample size, statistical analyses were not performed. However, mean values are presented to illustrate trends and offer insights for future studies using similar methods and populations. Maximum dorsiflexion ROM (ROMmax) (plantarflexor stretch) increased from pre- (+29.4±11.5 °) to post-c-tDCS (+31.8±4.1 °), and plantarflexion ROMmax increased from pre- (-26.6±17.1 °) to post-c-tDCS (-32.8±14.8 °). Maximal voluntary contraction (MVC) torque was lower for dorsiflexor (pre-c-tDCS: 2.1±1.9 kg; post-c-tDCS: 0.97±0.85 kg) and plantarflexor muscles (pre-c-tDCS: 5.2±2.2 kg;

post-c-tDCS: 4.4 ± 3.2 kg). Maximum passive force measured by handheld dynamometer during passive stretch with the help of a well-trained physiotherapist increased for both plantarflexor and dorsiflexor muscles from pre- (plantarflexor: 6.9 ± 5.3 kg; dorsiflexor: 1.4 ± 1.2 kg) to post-c-tDCS (plantarflexor: 31.9 ± 4.2 kg; dorsiflexor: 32.9 ± 14.9 kg). The soleus H:M ratio and H-reflex amplitude tended to increase in plantarflexion but decreased in dorsiflexion from pre- (plantarflexion: 0.6 ± 0.3 and 2.8 ± 1.8 mV; neutral: 0.5 ± 0.7 and 4.6 ± 3.0 mV; dorsiflexion: 2.5 ± 0.7 and 4.5 ± 1.3 mV) to post-c-tDCS (plantarflexion: 0.8 ± 0.3 and 5.5 ± 1.9 mV; neutral: 0.4 ± 0.4 and 3.5 ± 1.6 mV; dorsiflexion: 0.3 ± 0.2 and 2.4 ± 0.9 mV).

CONCLUSION: Maximum ankle ROM increased while resistance to stretch decreased following acute c-tDCS. Reflex (Ia) pathway excitability, measured by H-reflex, decreased with the ankle in dorsiflexion but not when in plantarflexion after c-tDCS, indicating potential improvements in spasticity symptoms. The H:M ratio changed minimally after c-tDCS, which may be attributed to the variability of muscle responses and because individuals with stroke often experience hemiparesis.

EFFECTIVENESS OF A 3-MONTH TELECOACHING TRAINING PROGRAM ON FUNCTIONAL MOBILITY AND QUALITY OF LIFE IN INDIVIDUALS WITH CHARCOT-MARIE-TOOTH DISEASE: PRELIMINARY RESULTS

LEALE, I., DI STEFANO, V., GIUSTINO, V., BRIGHINA, F., BATTAGLIA, G.

UNIVERSITY OF PALERMO: UNIVERSITA DEGLI STUDI DI PALERMO

INTRODUCTION: Charcot-Marie-Tooth disease (CMT) is the most common inherited neuromuscular disorder, with an estimated prevalence of 1 in 2,500 [1]. CMT is a hereditary peripheral neuropathy characterized by progressive muscle weakness, balance impairments, and reduced functional mobility [2]. Although exercise can help maintain strength, balance, and overall function, individuals with neuromuscular disorders typically exhibit low levels of physical activity [3]. Telecoaching (TC) is an innovative training approach that utilizes digital tools to remotely access and manage training services. This study aimed to evaluate the effects of a 3-month TC-based training program on physical performance and quality of life in individuals with CMT.

METHODS: A total of 15 participants (48.13 ± 12.15 years; 168 ± 0.09 cm; 73.04 ± 14.78 kg; 25.54 ± 4.00 kg/m²) were randomly assigned to either the experimental group (telecoaching-based training, $n = 8$) or the control group (usual care, $n = 7$). Primary outcomes included the Timed Up and Go (TUG) test, the Short Form Health Survey 36 (SF-36), handgrip test, and the Berg Balance Scale (BBS). Assessments were conducted at baseline and after 12 weeks. A mixed ANOVA was conducted for the analyses.

RESULTS: No statistically significant changes were observed between the groups. However, significant improvements over time were noted only in the experimental group for TUG ($p = 0.01$), SF-36 ($p = 0.03$), right handgrip ($p < 0.001$), and left handgrip ($p = 0.03$). No significant changes were found in the BBS scores ($p = 0.13$).

CONCLUSION: A 3-month TC-based training program effectively improved functional mobility, muscle strength, and quality of life in individuals with CMT. Despite no significant changes in balance, these findings suggest that TC can be a valuable approach to enhancing overall physical function in individuals with CMT. Further studies are needed to explore long-term benefits and optimize TC strategies.

PRELIMINARY EFFECTS OF A 12-WEEK FITNESS TRAINING WITH FRAME RUNNERS IN YOUNG ADULTS WITH MODERATE TO SEVERE SPASTIC CEREBRAL PALSY

KUNSTIC, A., MOSSER, N.1, BIRNBAUMER, P.1, SVEHLIK, M.2, TILP, M.1, VAN POPPEL, M.1, CORELL, L.3, VON WALDEN, F.3, KRUSE, A.1

1 UNIVERSITY OF GRAZ, 2 MEDICAL UNIVERSITY OF GRAZ, AUSTRIA, 3 KAROLINSKA INSTITUTET, STOCKHOLM, SWEDEN

INTRODUCTION: Spastic cerebral palsy (SCP) is the most common childhood-onset motor disorder, leading to reduced mobility, muscle weakness, and increased sedentary behavior [1]. Due to their high sedentary time, individuals with moderate to severe SCP (Gross Motor Function Classification System (GMFCS) III-IV) have the highest risk to develop non-communicable diseases compared to their mildly affected peers [2]. Frame Running, an adaptive athletic discipline, enables individuals with SCP to engage in sports and physical activity. Therefore, the use of frame runners may have the potential to induce important health effects to prevent the development of non-communicable diseases in this group. While benefits for mobility and well-being have already been recognized [3], the effects of training with frame runners on physical fitness remain unclear. This study evaluates the impact of a 12-week fitness training with frame runners on the cardiorespiratory fitness and lower limb muscle strength in young adults with moderate to severe SCP.

METHODS: Within our ongoing project (Grant-DOI 10.55776/V992, ClinicalTrials.gov ID NCT06330922), six young adults (3 males and 3 females) with moderate to severe SCP (GMFCS III-IV, age: 22 ± 3 years, height: 150 ± 9 cm) participated in a 12-week control period, followed by a 12-week training with frame runners consisting of two 60-minute sessions per week.

Assessments were performed at baseline (T0), after the control period/pre-training (T1), and after the training period (T2). Cardiorespiratory fitness was determined by use of the 6-Minute Frame Running Test (peak heart rate (HR_{peak}), distance) combined with gas exchange assessments (peak oxygen uptake (VO_{2peak})). Moreover, strength tests were performed to assess the isometric muscle strength of the knee extensors and knee flexors. Repeated Measures ANOVA was applied to assess differences over time.

RESULTS: Following the 12-week control period, no significant changes were observed in any measured parameter. However, after the 12-week training intervention with frame runners, a significant ($p=0.042$) increase in VO_{2peak} (+5.1 ml/kg/min) was observed. Moreover, the distance covered improved significantly (+138.3 m, $p=0.017$) from T1 to T2, with the greatest increase observed between T0 and T2 ($p=0.010$). No significant differences ($p>0.05$) were detected in any other parameter.

CONCLUSION: Our preliminary findings demonstrate that a 12-week fitness training with frame runners may significantly improve the cardiorespiratory fitness in young adults with moderate to severe SCP. While a larger sample size is needed to confirm the observation, the finding highlights the potential of training with frame runners to enhance aerobic capacity and mobility in individuals with SCP.

ASSESSMENT OF THE BALANCE AND STABILITY OF STUDENTS WITH VISUAL IMPAIRMENT: PRELIMINARY RESULT OF RCT IN A ROMANIAN SCHOOL

GUERRIERO, M., MOSCATELLI, F., MANCINI, N., RUBERTO, M., CAGGIANO, A., GROSU, E.F., MANIU, D.A., MANIU, E.A., FRATINI, T., ENACHE, A.V., COLECCHIA, F.P.

UNIVERSITY OF FOGGIA

INTRODUCTION: For visually impaired people, postural balance (PB) is a significant difficulty that affects their quality of life and motor development. Physical activity, particularly strength training, is advised by the WHO guidelines to improve function and well-being in children with disabilities [1]. Dynamic and static balance are worse in people with visual impairments [2], whereas athletes have better balance than sedentary people [2]. Plyometric and balance exercises in the school curriculum can enhance both dynamic and static balance in children whose balance is still developing [3], and postural control can also be improved [4].

The aim of this study is to assess and improve balance in students visually impaired engaged in 15-week plyometric training.

METHODS: A RCT is conducted from February 2025, with 36 students randomly split into an experimental group and a control group. For balance assessment, a balance board measurement was used with parameters such as center of pressure, weight distribution, plantar pressure, and Bruininks-Oseretsky Test of Motor Proficiency (BOT-2).

RESULTS: According to preliminary results, equilibrium is greatly impacted by changing the support surface or lowering the visual component. Students can maintain the position in bipodal support for over ten seconds (AVG 3, SD 0.90) with variation in monopodal. Students find it difficult to hold the stance for longer than 3 to 5 seconds with eyes closed, and the average drops to 2.9 (SD 0.79). With AVG ranging from 2.3 to 2.7, the difficulty rises when on a beam, indicating difficulties sustaining stability. These findings confirm stabilometric analyses that reveal oscillations due to increasing CoP distance and speed.

CONCLUSION: According to the results, students with visual impairments can greatly increase their stability and quality of life by participating in a school balance program.

CP-MH12 Cancer II

INDICATORS OF SARCOPENIA AND LUNG CANCER RISK AMONG NON-SMOKERS

CHIH JUN, L., CHIEN, K.L.

INSTITUTE OF EPIDEMIOLOGY AND PREVENTIVE MEDICINE

INTRODUCTION: Lung cancer is the second most commonly diagnosed cancer and the leading cause of cancer-related deaths, with about 10% of cases linked to non-tobacco-related factors. There is still a need to determine whether indicators of sarcopenia—such as grip strength, appendicular lean mass index, and walking speed—can act as early predictors of lung cancer in non-smokers.

METHODS: This study is a prospective cohort analysis utilizing data from the UK Biobank, focusing on participants aged 40 to 69 years. The primary outcome assessed was lung cancer in non-smokers. Indicators of sarcopenia evaluated included relative grip strength (RGS), appendicular lean mass (ALM) index, and walking speed. Grip strength was measured using a Jamar J00105 hydraulic hand dynamometer and normalized to body weight, resulting in the RGS. Appendicular lean mass was determined through bioelectrical impedance analysis and adjusted for height squared to calculate the ALM index. Walking speed was self-reported by the participants.

RESULTS: In this study, we evaluated 164,337 non-smokers without lung cancer and 586 non-smokers with lung cancer. Individuals with lung cancer demonstrated significantly lower grip strength (mean relative grip strength: lung cancer-free group 0.41 [SD 0.13] vs. lung cancer group 0.38 [SD 0.13], $P < 0.001$) and a reduced appendicular lean mass index (lung cancer-free group 8.14 [SD 1.34] vs. lung cancer group 8.00 [SD 1.23], $P = 0.009$). Additionally, the incidence of slow walking speed was higher in the lung cancer group at 11.1%, compared to 5.8% in the lung cancer-free group.

CONCLUSION: Non-smokers with lung cancer show significant impairments in muscular strength and physical performance compared to those without lung cancer. Specifically, they have lower grip strength and appendicular lean mass index, as well as a higher prevalence of slow walking speed. These findings suggest a potential association between sarcopenic indicators and lung cancer, underscoring the need for further research to explore the mechanisms involved and the implications for early detection and intervention strategies to enhance physical function and quality of life in this population.

ASSOCIATIONS BETWEEN PHYSICAL FITNESS, CANCER-RELATED FATIGUE, AND SLEEP QUALITY IN PATIENTS WITH CANCER: A CROSS-SECTIONAL STUDY

CIURNELLI, C., BORSATI, A., ADAMOLI, G., TONIOLO, L., BELLUOMINI, L., TRESTINI, I., TREGNAGO, D., INSOLDA, J., SCHENA, F., MILELLA, M., PILOTTO, S., AVANCINI, A.

UNIVERSITY OF VERONA

INTRODUCTION: Patients with cancer often experience fatigue and sleep disturbances due to the disease and treatment side effects. Physical exercise may help to alleviate this impairment, even if few data are available concerning the relationship with physical fitness components. This study examines the associations between fatigue, sleep quality, and physical performance in patients with cancer.

METHODS: The physical and patient-reported data, along with the clinical and demographic variables, were collected by a dedicated exercise professional. The parameters included in the analysis were: Body Mass Index (BMI), and the waist-to-hip (W/H) ratio; functional capacity, assessed using the Six-Minute Walk Test (6MWT); upper limb strength, with the handgrip strength test (HSGT); and flexibility of the upper and lower limbs, assessed with the back scratch (BST) and chair sit-and-reach tests (CSRT), respectively. Data on sleep quality and fatigue were also collected using the Pittsburgh Sleep Quality Index (PSQI) and the Brief Fatigue Inventory (BFI) questionnaires, respectively. Descriptive analysis, absolute frequencies, and Pearson's correlations were used for data analysis.

RESULTS: A total of 84 patients (mean age 59 years, 61% female) were included in the study. Regarding the disease type, 28% of patients had breast, 20% pancreatic, and 15% colorectal cancers. Overall, 40% presented an advanced stage of disease, 85% were receiving chemotherapy and 45% radiotherapy. Forty-five percent of patients reported poor sleep quality, while 9% experienced a clinically significant level of fatigue. Patients reached the following mean values in the physical fitness parameters: 523.8 m (± 91.4) for 6MWT, 60.8 kg (± 20.2) for HSGT (right plus left hand), -8.9 cm (± 23.8) for CRST and -12.2 cm (± 21.6) for BST. A moderate and significant correlation was found between fatigue levels and 6MWT ($r_s = -0.416$; $p < 0.001$), as well as a mild but significant correlation for upper limb strength and fatigue ($r_s = -0.247$; $p < 0.028$). Finally, high levels in upper limb strength were correlated with lower impairments in sleep quality ($r_s = -0.222$; $p = 0.048$).

CONCLUSION: Sleep quality and fatigue can significantly impair the quality of life in patients with cancer. Our study identified correlations between certain physical fitness parameters, lower fatigue levels, and improved sleep quality. Additional enrollments are currently underway to further clarify these associations.

CARDIORESPIRATORY ASSESSMENT IN CHILDHOOD CANCER SURVIVORS ONE YEAR POST TREATMENT

ZARDO, W., BUSIA, A., AIRAGHI, C., CHISARI, M., LANFRANCONI, F., MICHELON, E., CINISELLI, C., VERDERIO, P., MASSIMINO, M., ROVEDA, E., GOZZOLI, C., SPREAFICO, F.

PAEDIATRIC ONCOLOGY UNIT, FONDAZIONE IRCCS ISTITUTO NAZIONALE DEI TUMORI, MILAN, ITALY.

INTRODUCTION: Survival rates for children, adolescents, and young adults with cancer have increased over the years due to improved care and personalized treatment. Treatment may cause short- and long-term toxicity limiting their ability to participate in exercise programs and sports. Survivors engage in less physical activity, leading to reduced exercise tolerance. An important tool for assessing the reduced exercise tolerance is cardiopulmonary exercise test (CPET). The CPET provides key indicators such as VO_2 peak and cardiopulmonary efficiency that can be a predictive index of morbidity and mortality [1]. Despite the increased use of CPET in pediatric oncology units, what occurs during the first year of follow-up remains partially unknown. Our aim is to evaluate exercise tolerance in a cohort of survivors of solid pediatric cancers within one-year post-treatment and identify possible indicators of cardiopulmonary fitness shortly after ending cancer therapy.

METHODS: CPET was performed on a cycle ergometer at the pediatric oncology unit using an incremental workload protocol until exhaustion. At the beginning of the test, participants were asked whether they had participated in any exercise programs during their treatment. The predicted peak VO_2 was calculated using the gender-, age-, and weight-adjusted Hansen/Wasserman equations.

RESULTS: We tested 17 patients (7 females; median age 15.01 years; range 13-20 years) at median 8.90 months post-treatment. The averaged of VO_2 peak value was 30.63 ± 10.22 ml/min/kg (range: 14.10–52.20) for males and 28.28 ± 10.08 ml/min/kg (range: 19.20–46.30) for females. These values were reduced of 54% and 34%, respectively, comparing to the predicted values of healthy peers [2]. Analysis of cardiovascular efficiency, measured by slope of the relationship between heart rate (HR) and VO_2 , revealed significant differences depending on physical activity levels during treatment. Survivors who engaged in moderate-to-vigorous tailored exercise programs during treatment had statistically significant greater efficiency ($Y = 2.886 \cdot X + 67.68$) compared to those who did not train ($Y = 3.952 \cdot X + 66.03$) ($p = 0.009$).

CONCLUSION: These data highlight the importance of starting supervised precision-based exercise programs early in the disease trajectory. Additionally, we suggest that exercise should be continued soon after treatment to enhance recovery and improve long-term fitness outcomes. CPET has been shown to be an effective tool for assessing the fitness status of survivors, providing valuable insight into their exercise tolerance and guiding personalized training programs.

ASSESSING THE NEEDS AND POTENTIAL OF A MOTIVATIONAL APP TO SUPPORT CANCER SURVIVORS IN PHYSICAL ACTIVITY PARTICIPATION

FOSSTVEIT, S.H., VISTAD, I.2,3, LARSEN, T.B.4, LOHNE-SEILER, H.1, BERNTSEN, S.1

<1> UNIVERSITY OF AGDER, KRISTIANSAND <2> SORLANDET HOSPITAL, KRISTIANSAND <3> UNIVERSITY OF OSLO, OSLO <4> UNIVERSITY OF BERGEN, BERGEN

INTRODUCTION: Cancer survivors often experience treatment-related challenges such as pain, fatigue, and anxiety.1,2 Despite the well-documented benefits of physical activity in alleviating these symptoms and improving overall well-being3,4, only 18-47% meet recommended levels5,6. Integrating Internet and mobile technologies in healthcare shows promise in promoting physical activity among cancer survivors7, and leveraging municipal services could help make such solutions more accessible to a broader population. Therefore, before implementing new initiatives, this study explored the potential of a motivational app as a support tool, the availability of physical activity programs for cancer survivors, and municipal health workers needs regarding its integration and regular use in their work.

METHODS: A survey was distributed via SurveyXact to all 235 municipalities with healthy life centers in Norway, as listed by the Norwegian Directorate of Health.8 A total of 92 (39%) health professionals responded. We examined their perceived need for a motivational app, the existence of physical activity programs for cancer survivors, preferred app features, and the importance of combining digital and in-person support. Additionally, a stakeholder workshop was conducted with representatives from healthcare providers, patient organizations, municipal services, and user representatives to discuss app functionalities and implementation strategies.

RESULTS: Eighty percent of respondents reported not having specific physical activity programs for cancer survivors. Eighty-eight percent believed a motivational app could enhance their ability to support this population in being physically active. Key desired features included an intuitive interface (84%), access to up-to-date evidence on physical activity and cancer (83%), tailored exercise programs (71%), and goal-setting functionalities (60%). Ninety-nine percent favored combining app-based support with guidance from healthy life centers. The workshop confirmed these findings, suggesting social support features, self-assessment tools, improved tailoring for the needs of different cancer diagnoses, and a training course to improve app usability for both health professionals and cancer survivors.

CONCLUSION: This study highlights a significant gap in the availability of tailored physical activity programs for cancer survivors within Norwegian municipal health services. A motivational app with user-friendly, evidence-based functional-

ties and a tailored training course could address this gap. However, combining digital tools with in-person support remains crucial to optimizing outcomes.

ADDRESSING OPPORTUNITIES FOR INCLUSION IN LIFE AND SPORT FOR CHILDHOOD BLOOD CANCER SURVIVORS BEGINS AT THE TIME OF DIAGNOSIS

LANFRANCONI, F., VILLA, E., PELI, L., MORIGGI, T., CORTI, E., CORTI, M., RADAELLI, G., REDAELLI, R., GUARESCHI, S., NAVA, F., JANKOVIC, M., BALDUZZI, A.

FONDAZIONE MONZA E BRIANZA PER IL BAMBINO E LA SUA MAMMA

INTRODUCTION: Cancer is the leading cause of death from non-communicable diseases in children, adolescents and young adults (CAYA-c) in Europe. During blood cancer treatment, patients exercise tolerance and quality of life (QoL) are reduced due to side effects of therapies, physical inactivity/bed rest, and cancer-related fatigue. Personalized exercise training (PEX) in CAYA-c is a promising therapy to alleviate these problems if started soon after diagnosis. However, there is a lack of scientific evidence to support the use of PEX in pediatric oncology. To build on this rationale, it is compelling to recognize that the efficiency of the CAYA-C performance and QoL could still be reduced in the late phases of cancer treatment.

AIM Identify exercise tolerance and QoL outcomes in CAYA-c to address barriers to their inclusion in life and sports activities as early as possible.

METHODS: CAYA-c aged 9-21 years, both sexes, with a diagnosis of blood cancer, just after the intensive phases of cancer treatment, underwent a cardiopulmonary evaluation at exhaustion (CPET) and peak values were measured (oxygen uptake-VO₂, heart rate-HR, rating of perceived exertion-Borg RPE, skeletal muscle O₂ extraction by NIRS-HHb/isch). The following tests were used to determine strength and functional capacity: leg extension (LE), 6-minute walk test (6MWT), time up and down stairs (TUDS), sit to stand (StoS), quick motor function (QMFT). The PedsQL Generic Core Scales questionnaire was used (higher scores indicating better QoL).

RESULTS: Seventeen CAYA-c completed all evaluations (mean±SD: 14.7±3.3 yrs, 41.0% female). The diagnoses were acute lymphoblastic and myeloid leukemia (41% and 7%), lymphoma (52%), and 17% had undergone bone marrow transplantation, 64% were in the maintenance phase of cancer treatment and had already returned to activities outside the hospital, 46% had been off therapy for 14.4±0.2 months. No major clinically relevant events were observed during the evaluations. CPET peak values were impaired: VO₂ 28.0±4.9 ml/min/kg (68.2±1.3% of predicted values-range 42-89%); HR 167.5±17.2 bpm (84.5±1.0 of predicted values-range 72-105%); Borg RPM 15.9±2.8; HHb/isch 75.0±3.0% (range 26-102%). Strength and functional capacity were impaired: LE 5RM 51.8±25.0 kg; 6MWT distance 529.4±60.7 m; TUDS 5.6±0.7 sec; StoS 6.0±1.0 sec. QMFT scores were normal 63.0±2.0 on 64. PedsQL scores were 76.6±10.3 and 86.9±11.4 (range 67-91 and 71-100) for children and parents, respectively.

CONCLUSION: Performance assessments could be safely used even in complex clinical settings. Oxidative pathway, strength and functional capacity are still reduced in the final stages of cancer treatment as a result of the individual clinical history, with varying degrees of severity. QoL is affected. PEX introduced early from diagnosis can be an opportunity to address CAYA-c and their families willingness to participate in life and sports activities throughout their care and during long term follow up.

EXERCISE-INDUCED HYPOALGESIA IN CHILDHOOD CANCER PATIENTS: A PILOT STUDY

WYPYRSCZYK, L., DREISMICKENBECKER, E., KÜHN, M., NEU, M.A., DIEL, H., FABER, J.

UNIVERSITY MEDICAL CENTER OF THE JOHANNES GUTENBERG-UNIVERSITY MAINZ

INTRODUCTION: Pain is a common symptom in childhood cancer patients, which is a burden not only during cancer treatment but also beyond. Strategies to reduce pain perception are therefore of great importance for these patients. Recent studies in adults have demonstrated that acute exercise can lead to a temporary reduction in pain perception and an increase in pain thresholds, a phenomenon known as exercise-induced hypoalgesia (EIH). The aim of this pilot study was to determine whether acute endurance exercise on a cycle ergometer induces EIH in childhood cancer patients.

METHODS: A total of 13 childhood cancer patients aged 11.0 ± 4.9 years were examined following the completion of intensive cancer treatment. To measure the effects of potential EIH, pressure pain thresholds (PPT) were measured using a handheld pressure algometer (Citec Dynamometer CT3002; pain applicator). Immediately before and after an acute en-

duration exercise, punctual pressure was applied to the rectus femoris and deltoid muscle at a rate of 10 newtons per second. The endurance exercise consisted of a cycling protocol performed on an electronically braked cycle ergometer (Corival Pediatric or Corival CPET, Lode BV, Groningen, Netherlands) using a modified Godfrey protocol to voluntary exhaustion. A Wilcoxon signed-rank test was performed to analyze the differences in PPT before and after the endurance exercise. The significance level was set at $p < 0.05$, and effect sizes (r) were interpreted in accordance with Cohens guidelines ($r = 0.1 - 0.3$: small effect, $r = 0.3 - 0.5$: moderate effect, $r > 0.5$: strong effect).

RESULTS: The findings indicate a statistically significant increase in PPT following endurance exercise on the rectus femoris ($z = 2.04$, $p = .038$, $r = .57$) and on the deltoid muscle ($z = 2.17$, $p = .028$, $r = .60$). These effects can be considered strong.

CONCLUSION: This pilot study suggests that acute endurance exercise may induce EIH in children with cancer. These findings indicate that exercise therapy could be a non-pharmacological approach to reduce pain perception in this patient group. However, further studies with larger sample sizes are needed to confirm these preliminary results.

SKELETAL MUSCLE MASS AND STRENGTH AMONG OVERWEIGHT OR OBESE BREAST CANCER SURVIVORS: IMPLICATIONS OF BMI ON MUSCLE-RELATED OUTCOMES

FICARRA, S., PEREZ, M.L., WILSON, R.L., GONZALO-ENCABO, P., CHRISTOPHER, C.N., NORRIS, M.K., NGUYEN, D., LU, C., DIELI-CONWRIGHT, C.M.

DANA FARBER CANCER INSTITUTE

INTRODUCTION: Reductions in skeletal muscle mass and strength impairments, in combination with the presence of overweight or obesity, are associated with reduced survival and quality of life among breast cancer survivors. Among otherwise healthy individuals, higher body mass index (BMI) is associated with increased strength and muscle mass than those with lower BMI, suggesting that obese individuals are expected to be stronger than those who are overweight. However, this phenomenon has not been previously reported among breast cancer survivors. As a result, exercise specialists might underestimate levels of strength and prescribe resistance exercise at insufficient intensity. Therefore, the purpose of this cross-sectional analysis was to examine the differences in skeletal muscle mass and strength in overweight or obese breast cancer survivors.

METHODS: This analysis included sedentary breast cancer survivors with overweight or obesity ($BMI > 25 \text{ kg/m}^2$), enrolled in a randomized controlled exercise trial. At baseline, the following variables were assessed: muscle mass, measured by bioelectrical impedance analysis; strength measures with a handgrip strength test and 10 repetition maximum (RM) tests performed for leg press (LP), chest press (CP), leg curl (LC), seated row (SR), and leg extension (LE). The estimated 1-RM was calculated using the Bryzcki equation. Baseline participant characteristics were calculated as mean $\pm$ SD. Differences between overweight ($BMI 25\text{-}29.9 \text{ kg/m}^2$) and obese ($BMI > 30 \text{ kg/m}^2$) participants were explored using the two-sample t-test or the Mann-Whitney U test, according to normality assumption.

RESULTS: A total of 58 participants who completed baseline testing were included in this analysis. Of the included participants, 27 were obese ($34.2 \pm 3.1 \text{ kg/m}^2$) and 31 were overweight ($28.1 \pm 1.1 \text{ kg/m}^2$). Obese participants had significantly higher muscle mass compared to overweight participants (mean difference: obese vs overweight, 5.7 kg, 95% CI 3.1 to 8.4; $p < 0.001$). Higher levels of strength were observed among obese breast cancer survivors for handgrip (3.7 kg, 0.6 to 6.0; $p = 0.018$), LP (18.2 kg, -0.0 to 35.6; $p = 0.054$), and CP (6.4 kg, 2.1 to 11.0; $p = 0.009$). No significant group differences were observed for LC, SR, and LE, although obese participants showed higher strength performance in these exercises (mean differences, 6.1 kg, -0.9 to 13.0; 3.0 kg, -0.9 to 7.0; and 7.0 kg, -0.7 to 14.7; for LC, SR and LE, respectively).

CONCLUSION: Breast cancer survivors with obesity can present with higher muscle mass and strength compared to those who are overweight. This phenomenon highlights the need for personalized aerobic and resistance training interventions to enhance physical fitness. These data can help exercise specialists to accelerate exercise adaptations by leveraging baseline strength and muscle mass in untrained breast cancer survivors.

INFLUENCES OF DM AND HTA ON FUNCTIONAL TEST AND HEART RATE VARIABILITY IN INSTITUTIONALIZED ELDERLY WOMEN

QUINTEROS, F., CANO-CAPELLACCI, M.

UNIVERSIDAD DE CHILE

INTRODUCTION: The elderly population (EP) worldwide represents important challenges in public health policies. Chile is no exception with its exponential population growth. Chronic non-communicable diseases are the pandemic of the 21st century and strongly affect this population, losing years of healthy life. The EP in Chile has a 73.3% prevalence of suspected arterial hypertension (HTA), with only 60% aware of the condition and in treatment (DIPRECE, MINSAL). Regarding Diabetes Mellitus type 2 (DM2), 31% of EP have diabetes with low percentages of control of the pathology (SOCHED). For them, it is of great relevance to study these pathologies and how they may affect the performance of functional tests and heart rate variability (HRV) in institutionalized older women

METHODS: 91 older women who met the eligibility criteria participated on this study. Fall risk tests were measured (dynamometry, arm curl, single leg balance test, timed up and go -TUG-, quadrant test and sit to stand 30 seconds), as well as HRV at rest for 5 minutes. The sample was grouped into EP with DM2 and HTA, this was statistically analyzed with JAMOVI software and ANOVA of one-factor was used.

RESULTS: The tests that assess the risk of falls in institutionalized EP behave differently depending on the presence of DM2 or HTA, the median age of the observed population was 87 years (range 68-97). The prevalence of HTA 68% and DM2 was 20%. There was a lower performance in the different tests of risk of falls in people with DM2 in the hand dynamometry test ($p = 0.01$), as well as in the measurement of HRV, we observed lower values in pNN50 ($p = 0.043$) and pLF ($p = 0.044$). In EP with HTA we observed lower values in the different tests of risk of falls, dynamometry ($p = 0.002$), arm curl ($p = 0.017$), right and left one leg balance test ($p = 0.020$ and $p = 0.028$ respectively) and TUG ($p = 0.004$).

CONCLUSION: We can conclude that there are significant differences between the behavior of the tests of risk of falls in older adult women when they present HTA and DM2, we also observe that in HTA the indexes of the HVR are affected, while in EP with DM2 the tests of risk of falls are mainly affected, the common point is that in both pathologies the performance of the hand dynamometry is affected. It can be proposed the utility of a battery of test of application in institutionalized women to assess the follow-up of these health conditions.

THE EFFECT OF 2 VS 3 RESISTANCE TRAINING SESSIONS PER WEEK USING ELASTIC BANDS ON FUNCTIONAL FITNESS IN ELDERLY WOMAN

JEZDIMIROVIC STOJANOVIC, T., KARAC, A., NINKOV, A., MEDJEDOVIC, B., ANDRIC, N., PANTOVIC, R.
TRAINING EXPERTISE, NOVI SAD, SERBIA

INTRODUCTION: Elastic band strength training has been proved to enhance myriads of fitness attributes in elderly cohort [1]. However, effects of training frequency on fitness outcomes are less investigated, producing general recommendation that 2 to 3 resistance training per week provides the optimal stimulus for fitness improvements [2]. Therefore, we aimed to explore effects of 2 vs 3 elastic band training sessions per week on functional fitness in older woman.

METHODS: Eighty-two women were allocated randomly to an 2 sessions/week (2SW, $n = 41$, 75.7 ± 8.9 years, 70.8 ± 12.3 kg) or a 3 sessions/week group (3SW, $n = 41$, 74.5 ± 8.2 years, 72.3 ± 11.6 kg). Resistance training protocol consisted of equal volume, chair-based, low- load whole-body resistance exercises (2 sets, 12-15 repetitions, 40-60% of one repetition maximum-1RM) using an elastic band, for 12 weeks. Functional fitness (30-s Chair Stand, 30-s Arm Curl, 2-min Step Test, Chair Sit-and-Reach, Back Scratch, 8-Foot Up-and- Go, Handgrip Strength) were measured before and after the training period. A 2x2 repeated measures ANOVA was utilized to identify pre/post intervention changes and differences between groups.

RESULTS: At baseline, no statistically significant differences were found between 2SW and 3SW groups ($p > 0.05$). The participants adherence to training sessions of over 90% was reported. Both groups exhibited a statistically significant improvements over time for the following variables: 30-s Chair stand, Arm Curl, 2-min step test, Back Scratch, 8-Foot Up-and- Go and Handgrip Strength. Chair sit -and-reach improved in 2SW only. Furthermore, statistically significant interactions for time*group were found for the Handgrip strength (before = 39.6 ± 12.1 kg and after = 42.4 ± 12.5 kg compared to before = 28.2 ± 14.4 kg and after = 36.0 ± 15.6 kg for 2SW and 3SW, respectively, $p < 0.05$).

CONCLUSION: Implementing 2 or 3 elastic band training sessions per week over a duration of 12 weeks resulted in functional fitness benefits in elderly women that were comparable, in addition to improvements in handgrip strength. Therefore, both training approaches can be recommended for this particular population.

ASSOCIATION BETWEEN FEAR OF FALLING AND PREFRAILTY IN COMMUNITY-DWELLING OLDER ADULTS

LIU, Z., SAWADA, S., NAITO, H., MACHIDA, S.
JUNTENDO UNIVERSITY

INTRODUCTION: The fear of falling (FOF) is associated with frailty among older adults [1]. As the early stage of frailty, prefrailty is more reversible and regarded as a key focus in frailty prevention [2]. However, whether FOF is associated with prefrailty and whether this association differs by gender remain unclear. Therefore, this study aimed to examine the association between FOF and prefrailty among community-dwelling older adults by gender.

METHODS: This cross-sectional study included 489 community-dwelling older Japanese adults aged 65 years or older (132 men, mean age: 75.9 ± 5.3 years; 357 women, mean age: 73.9 ± 4.8 years). Assessments included anthropometric measurements (height, weight, BMI), physical function tests (grip strength and gait speed), and questionnaires. FOF was assessed using the Short Falls Efficacy Scale-International (Short FES-I), and prefrailty was assessed using the Japanese version of the Cardiovascular Health Study (J-CHS) criteria.

All statistical analyses were conducted separately for men and women. Comparisons were made between the prefrailty and robust groups, and binary logistic regression analyses were used to examine the associations between prefrailty status (dependent variable) and age, BMI, grip strength, gait speed, and Short FES-I (independent variables). Furthermore, for variables that showed significant associations, receiver operating characteristic (ROC) analyses were performed to assess their discriminatory ability in identifying prefrailty.

RESULTS: In men, Short FES-I scores did not significantly differ between the prefrailty and robust groups ($p = 0.273$), and binary logistic regression analysis showed no significant association between Short FES-I and prefrailty (OR: 1.04; 95% CI: 0.92–1.18; $p = 0.494$).

In contrast, women in the prefrailty group had significantly higher Short FES-I scores than those in the robust group ($p < 0.001$). Binary logistic regression analysis showed a significant association between Short FES-I and prefrailty (OR: 1.13; 95% CI: 1.05–1.22; $p < 0.001$). Furthermore, ROC analysis indicated that in women, the area under the curve (AUC) for the Short FES-I was 0.647 ($p < 0.001$), with an optimal cutoff value of 12 points for identifying prefrailty (sensitivity, 0.56; specificity, 0.69).

CONCLUSION: This study examined the association between FOF, assessed using the Short FES-I, and prefrailty in community-dwelling older adults. A significant association was observed only in older women, whereas no such association was found in men. This may be attributed to men having lower FOF levels than women, which could influence the association between FOF and prefrailty. These findings suggest that the association between FOF and prefrailty may differ by gender.

TIME-OF-DAY SPECIFIC RESISTANCE TRAINING IN ELDERLY WOMEN – EFFECT ON PERFORMANCE, BODY COMPOSITION AND BONE MINERAL DENSITY

SEDLIAK, M., STRELECKY, M., ORESKÁ, L., BUZGO, G., OLIVA, V., OKULIAROVÁ, M., ZEMAN, M.
COMENIUS UNIVERSITY IN BRATISLAVA

INTRODUCTION: Neuromuscular performance shows diurnal variation in a sinusoidal manner with a minimum in the morning and a peak in the early evening. However, only few studies have dealt with time-of-day specific adaptation to resistance training in regards with muscle strength and hypertrophy. The only study performed on elderly women found that time-of-day did not have a major effect on outcome variables, but some evidence suggests that training in the morning may be more beneficial for muscle hypertrophy the training. This study aimed to expand on studying time-of-day specific adaptation in elderly population not only on performance but also on bone health.

METHODS: We recruited 26 previously untrained women (age between 65 to 75 year) in total, who were divided into 3 groups - morning training group (MT, $n=10$), afternoon training group (AT, $n=10$) and control group (C – $n=6$). Both training groups underwent identical 12-week time-of-day specific resistance training. The only difference between the groups was the time of the training. MT and AT trained exclusively between 8:00 – 9:00 AM and 4:00 – 5:00 PM, respectively. Control group did not train but was tested for performance, body composition and bone mineral density measured by DXA before and after the 12-week period, similarly to both training groups.

RESULTS: In maximal gait speed, the significance was found only in the M group ($M: 5,11 \pm 0,09$ s vs $4,83 \pm 0,13$ s; $p \leq 0,05$), whereas no significance was found in afternoon group after 10 weeks of training ($A: 5,51 \pm 0,24$ s vs $4,27 \pm 0,15$ s). We modified a 6 min walk test into a 6 min Airbike tests where was confirmed also significance in both experiment groups ($M: 1730 \pm 33,47$ m vs $1866 \pm 28,94$ m; $p \leq 0,01$; $A: 1730 \pm 32,42$ m vs $1866 \pm 26,21$ m; $p \leq 0,01$). In lower body strength we found significant differences in legpress 6RM test ($M: 12,1 \pm 0,57$ kg vs $15,1 \pm 1,05$ kg; $p \leq 0,01$; $A: 11,9 \pm 0,46$ kg vs $15,3 \pm 0,90$ kg; $p \leq 0,01$), nonetheless in isometric regime we did not find a difference in between experiment groups and the C group

In bone mineral density, no difference was found neither in between the groups nor within the groups ($M: 27,26 \pm 0,79$ kg/m² vs $26,86 \pm 0,72$ kg/m²; $A: 26,77 \pm 0,88$ kg/m² vs $26,55 \pm 0,91$ Nm; $C: 27,55 \pm 1,63$ kg/m² vs $27,02 \pm 1,77$ kg/m²). Similarly, no difference was found in lean mass nor in total body bone mineral density.

CONCLUSION: This study founded that training in the morning and in the afternoon was similarly effective in improving performance parameters. The only parameter significantly improved in the morning was gait speed. Nor bone mineral density neither lean mass was significantly improved in the training groups. However, a positive trend in both parameters in both training groups and no sign of a change in the control group was seen.

"The study was partially supported by the Slovak Research and Development Agency (grant no. APVV-21-0164) and by grant VEGA nr. 1/0482/23."

EXERCISE INTERVENTION FAILED TO ATTENUATE COGNITIVE DYSFUNCTION IN AGED 3XTG-AD MOUSE MODEL OF ALZHEIMER'S DISEASE

RYU, B., TAN, Y., LEE, S., KIM, D., PARK, J., SO, B., JANG, J., PARK, J., KANG, C., LEE, H., HWANG, M., PARK, Y.
INCHEON NATIONAL UNIVERSITY

INTRODUCTION: Alzheimer's disease (AD) is a neurodegenerative disorder that causes cognitive impairments. Hippocampus plays a critical role in cognitive function including learning, short- and long-term memory, and spatial memory. Whereas exercise intervention has been shown to mitigate cognitive impairments in early-stage AD, it is unknown that this neuroprotective effect of exercise is still maintained in late-stage AD. The purpose of the study was to investigate whether exercise intervention mitigates cognitive dysfunction in super-aged triple-transgenic (3xTg)-AD mice; and whether mitochondrial function in hippocampus is associated with the changes in cognitive function.

METHODS: This study used 22-month old female 3xTg-AD (n=14) and age-matched wild-type C57BL/6J female mice (n=14). Mice were randomly assigned to sedentary or exercise group, generating 4 groups: Control (CONSED), Control with exercise (CONEX), Alzheimer's Disease (ADSED), and AD with exercise (ADEX). Exercise groups proceeded with a 16-week treadmill exercise training (30 mins, 5 days/week). Cognitive function was assessed using the novel object recognition (NOR) and novel arm Y-maze tests. Hippocampal mitochondrial function was measured using the Oroboros O2k instrument.

RESULTS: In NOR test, AD groups showed lower cognitive function compared to Control groups ($p < 0.01$). There was a trend that exercise increases cognitive function only in CON not in AD ($p = 0.06$ and $p = 0.4$, respectively). The Y-maze test demonstrated that AD groups showed lower cognitive function compared to Control groups. No exercise effect was found in both CON and AD. In hippocampal mitochondrial function, compared to sedentary, exercise groups tended to be greater in mitochondrial function during the ADP phase ($p = 0.09$).

CONCLUSION: While previous studies using the early-stage AD mouse model have shown the neuroprotective effect of exercise, our findings suggest that this exercise effect is disappeared in late-stage AD mouse model. Despite a trend of enhanced mitochondrial function in hippocampus following exercise intervention, both cognitive function tests demonstrated no exercise effect in late-stage AD mice. More studies are necessary to elucidate the underlying mechanisms linking hippocampal mitochondrial function and cognitive function.

INTRODUCTION: The aging of the population has increased the focus on early detection and treatment of age-related syndromes like frailty, characterized by a reduced physiological reserve and higher vulnerability to stressors. Frailty assessment comprises multiple components, one of which is handgrip strength (HG). Recently, lower-limb muscle power has emerged as a better predictor of aging, as it shows stronger associations with adverse events. This study aimed to include muscle power into frailty assessment using the Frailty Trait Scale short form (FTS5) and the Frailty Phenotype (FP) and to compare the effectiveness and predictive capacity of muscle power against HG strength.

METHODS: This prospective cohort study involved 1600 older adults (>65 years; 55% women). Frailty was evaluated using the FTS5, which assessed BMI, physical activity, balance, HG strength, and habitual gait speed (HGS). The FP assessed HG strength, HGS, low physical activity, tiredness, and involuntary weight loss. Lower-limb muscle power was assessed using the 5-repetition sit-to-stand (STS) test and the Alcazar's equation [1] with cut-off points for relative power set at 0.36 W·kg⁻¹ (men) and 0.32 W·kg⁻¹ (women) based on the worst BMI. Also, the incidence of disability in basic activities of daily living (BADL; Katz index) was assessed after 5 years, and hospitalization and all-cause mortality were recorded after 3 and 5 years of follow-up, respectively. Binary logistic regression and ROC curves adjusted by covariates were done.

RESULTS: Frailty assessed with the FP including relative STS power showed significant associations with all-cause mortality (OR [95% CI] = 2.45 [1.50, 4.01]) but not with hospitalization ($p = 0.99$) or incidence of BADL disability ($p = 0.11$). When evaluated using HG strength, frailty showed associations with mortality (OR [95% CI] = 2.11 [1.30, 3.42]) and incidence of BADL disability (OR [95% CI] = 3.19 [1.47, 6.91]) but not with hospitalization ($p = 0.88$). Frailty assessed with the FTS5 including relative STS power showed significant associations with all-cause mortality (OR [95% CI] = 3.43 [2.29, 5.13]), hospitalization (OR [95% CI] = 1.45 [1.06, 1.98]), and incidence of BADL disability (OR [95% CI] = 1.74 [1.24, 2.45]); while the FTS5 including HG strength showed associations with all-cause mortality (OR [95% CI] = 2.84 [1.89, 4.26]) and incidence of BADL disability (OR [95% CI] = 1.78 [1.24, 2.57]), but not with hospitalization ($p = 0.20$).

CONCLUSION: Relative STS muscle power test is a feasible and relevant tool for assessing frailty, similar to HG strength. Frailty definitions that included relative STS power showed significant associations with mortality (both FP and FTS5), hospitalization and BADL disability (FTS5), enabling low relative STS power as a criteria of frailty associated with future adverse outcomes.

CORRELATION BETWEEN ULTRASOUND-DERIVED ECHO INTENSITY BANDS AND PQCT-DERIVED MUSCLE FAT

PINTO, M., PINTO, R.S., MARKARIAN, A.M., TAAFFE, D.R., NEWTON, R.U., GALVÃO, D.A.

EDITH COWAN UNIVERSITY

INTRODUCTION: Fat tissue infiltration in muscle tissue increases with aging, disuse, and pathologies, and is associated with reduced muscle quality and function (1). Peripheral quantitative computed tomography (pQCT) is commonly used to estimate muscle fat content based on density (2). However, pQCT involves radiation exposure and lacks portability. In contrast, ultrasonography (US) is a low-cost, non-invasive, and portable alternative that estimates fat content through the echo signal intensity (echo intensity; EI) reflected by soft tissue structures. Traditionally, the mean pixel intensity in grayscale has been used as a proxy for intramuscular fat; however, it provides limited information. Recently, we introduced histogram-based EI bands to refine this estimate by quantifying pixel intensity across grayscale intervals (1). Early bands are thought to reflect contractile proteins, while bands >51 are believed to reflect intramuscular fat. Preliminary evidence suggests that EI bands are more sensitive to age- and disuse-related changes (1,3). However, further exploration is needed to understand the relationship between EI bands and pQCT-derived fat estimates.

METHODS: Twelve participants (n=8 healthy; n=4 with spinal cord injury; sex: male/female; age range: 27–61 years) were assessed for elbow flexors and quadriceps muscles using extended field-of-view (EFOV) US and pQCT on the same day. Mean EI and EI bands (0-50, 51-100, 101-150, 151-200, 201-255) were determined from US images, while muscle density was estimated using pQCT. Linear regression analyses were performed to examine the relationships between EI and pQCT-derived muscle density.

RESULTS: Analyses revealed significant correlations between EI mean, EI bands, and density for the quadriceps ($P < 0.001$), but not for the elbow flexor muscles ($P > 0.05$). EI mean was strongly and negatively correlated with muscle density ($R^2 = 0.83$). The EI 0-50 band was strongly positively correlated with density ($R^2 = 0.79$), while the EI 201-255 was moderately negatively correlated ($R^2 = 0.55$). No correlations were observed for EI bands 51 to 150 and density ($P > 0.05$).

CONCLUSION: The findings support that the EI 0-50 band is associated with higher contractile tissue density, while the EI 201-255 band correlates with fat tissue and lower density. Additionally, EI bands appear to be more accurate than mean EI in differentiating muscle tissue composition. However, these relationships were muscle-specific or influenced by factors such as pennation angle, as no correlation was found in the biceps, consistent with previous findings (4). Future studies should consider other factors that may affect EI.

SUSTAINING EXERCISE TO ENHANCE COGNITIVE HEALTH IN OLDER ADULTS WITH SUBJECTIVE COGNITIVE IMPAIRMENT

BROWN, B., MARSTON, K., SEWELL, K., SOHRABI, H., PEIFFER, J.

MURDOCH UNIVERSITY

INTRODUCTION: Epidemiological studies indicate higher habitual physical activity levels are associated with enhanced cognitive function. However, meta-analyses of randomised controlled trials (RCTs) have not consistently demonstrated exercise interventions improve cognitive function in older adults, likely due to various methodological factors including exercise intensity. Additionally, long-term follow-ups indicate exercise is often not sustained after intervention cessation. This pilot RCT aims to examine the effect of exercise intensity parameters on cognition, while evaluating the efficacy of behavioural change strategies to prolong exercise adherence.

METHODS: Forty-six older adults (aged 65+) with subjective cognitive impairment were randomised into one of three groups: high-intensity exercise, moderate-intensity exercise, or a control group. The exercise groups participated in supervised aerobic exercise and progressive resistance training three times per week for 12 weeks, followed by a nine-month maintenance period (involving supervised booster sessions, and regular follow-up phone calls). Exercise group participants also attended weekly cognitive behavioural therapy group sessions during the 12 week supervised period. The control group engaged in thrice-weekly balance and stretching sessions for 12 weeks, followed by a non-contact maintenance period. Physical fitness and cognitive assessments were conducted at baseline (pre-intervention), 12 weeks (post-supervised intervention), and 12 months (post-maintenance period). Group differences across time points were evaluated for all outcome measures. Additionally, based on prior literature, associations between changes in fitness and cognition were examined.

RESULTS: The cohort had a mean age of 71.9 (4.5) years and was 67% female. The most notable fitness changes occurred from baseline to 12 week follow-up, including in 1RM row ($\beta = -2.52$, $p < 0.01$), 1RM leg curl ($\beta = -3.75$, $p < 0.001$), 1RM bench press ($\beta = -2.60$, $p < 0.01$), and 1RM leg press ($\beta = -7.50$, $p < 0.01$), with a stepwise improvement observed across groups (high-intensity < moderate-intensity < control). No significant differences in cognitive outcomes were observed across groups. Following combination of both intervention groups, changes in the one-card learning task from baseline to 12 weeks were associated with changes in 1RM row ($\beta = 0.66$, $p < 0.01$), and 1RM leg curl ($\beta = 0.56$, $p < 0.05$), over the same time. These findings were not observed following the maintenance period.

CONCLUSION: We did not observe any group effects of exercise, nor exercise intensity, on cognitive outcomes. As expected, the three-month supervised intervention induced physical fitness changes, and some of these changes were associated with some cognitive improvements. However, the observed effects were not sustained beyond the supervised exercise intervention. Future research should explore behavioural intervention strategies to enhance long-term adherence to exercise programs in older adults.

VALIDATION OF THE ITALIAN TRANSLATION AND CULTURAL ADAPTATION OF THE CANADIAN ASSESSMENT OF PHYSICAL LITERACY-2 (CAPL-2) QUESTIONNAIRES FOR CHILDREN

IANNACONE, A., AGOSTI, V.2, CUDICIO, A.3, FAELLA, P.1, CROTTI, M.3, FEDERICO, B.1, FALESE, L.1, DIGENNARO, S.1

1> UNIVERSITY OF CASSINO AND SOUTHERN LAZIO; 2> UNIVERSITY OF SALERNO; 3> UNIVERSITY OF BERGAMO

INTRODUCTION:Physical literacy (PL) is an inclusive and holistic concept, conceived from its inception to promote lifelong health and well-being by centering on the person-in-the-world and their lived experience within their cultural context (1). Consequently, different cultures, governance structures, geographical locations, and physical environments may necessitate distinct conceptualizations and pedagogies to effectively foster physical literacy (2). Thus, it is crucial to provide physical and sport educators with validated assessment tools to ensure accurate evaluation within different contexts. One of the best-known and validated assessments of PL is the Canadian Assessment of PL (CAPL-2) (3). This study aimed to validate the Italian translation and cultural adaptation of the CAPL-2 questionnaire.

METHODS: We recruited 111 children (57 females, 8-12 year old, BMI = 17.9 kg/m²) who completed the Italian version of CAPL-2 questionnaire twice over a 10-day interval under trained supervision. Internal consistency was evaluated with Cronbach's alpha ($\alpha = 0.60$). The study was Approved by the IRB of University of Cassino. We used ROC curve analysis and AUC to evaluate the capacity of CAPL-2 score to predict adherence to WHO physical activity guidelines measured using CAPL-2 items about self-reported physical activity. Before data collection, the CAPL-2 questionnaire was translated via a forward-backward procedure by bilingual experts. A pilot test with 10 children identified and resolved comprehension and cultural issues.

RESULTS: Results showed high internal consistency for the motivation and confidence domain (Cronbach's α : 0.88–0.97; mean: 5.3 ± 1.4) and lower internal consistency for the knowledge and understanding domain (Cronbach's α : 0.20–0.34; mean: 9.3 ± 0.98).

Furthermore, the results revealed that the CAPL-2 questionnaire exhibited highly predictive performance in identifying children active for at least 5 days (AUC: 0.95) compared to those active for at least 6 days (AUC: 0.89).

CONCLUSION:Although the knowledge and understanding domain exhibited low internal consistency—likely due to limited variability—our findings suggest that the CAPL-2 questionnaire, translated and culturally adapted for the Italian context, is a reliable measurement tool, thereby supporting the full adaptation of the CAPL-2 test battery for Italian children aged 8 to 12 years.

A WIN-WIN: TEACHING PRE-SERVICE TEACHERS HOW TO NURTURE EXECUTIVE FUNCTION DEVELOPMENT THROUGH PHYSICAL ACTIVITY

SELLES, D., SCHAERZ, S., DUFFY, T., TRINH, F.

UNIVERSITY OF LETHBRIDGE

Background: Executive functions (EF) play a crucial role in academic performance, influencing students' ability to plan, regulate behavior, and adapt to complex tasks [1]. Given the well-established cognitive benefits of physical activity [2], physical education (PE) serves as an important vehicle for fostering EF development in children and youth. The aim of this literature review was to create a framework for teaching pre-service teachers (PST) about the relationship between physical activity and EF, with a focus on how to integrate these insights into their PE practices.

Method: A literature search using PubMed and SportDiscus identified key articles on the benefits of physical activity for EF development in children and youth (search terms: physical activity OR exercise OR sport AND executive function OR inhibitory control OR working memory OR cognitive flexibility AND child OR youth OR adolescent). The Pedagogical Content

Knowledge model [3] provided the theoretical framework for analysis, guiding the organization of findings into three domains: content knowledge, pedagogical knowledge, and curricular knowledge.

Results: PST should be able to define EF as comprising inhibitory control, working memory, and cognitive flexibility and recognize its role in academic success [1]. They should be able to explain basic neurobiological mechanisms linking physical activity to EF [2] and identify optimal physical activity parameters—complex movements in unpredictable environments [4] at moderate-to-high intensity [5] for at least 30 minutes [6]. Developing pedagogical knowledge requires translating content into effective teaching. PST should be familiar with how Modeled Learning can be leveraged to teach students about perceived intensity, and how Cooperative Learning can maximize activity time while scaffolding both fundamental and functional movement skills in cognitively engaging ways [7]. PST should also be able to recall and explain regional educational standards and demonstrate how exercise-cognition science aligns with them. Assessments such as case-based problem-solving, time-on-task analyses, and interdisciplinary lesson plans help evaluate PST skills and competencies across these domains.

Conclusion: This literature review highlights the importance of educating PST on how PE can be leveraged to nurture EF development. By developing content, pedagogical, and curricular knowledge, PST can effectively integrate exercise-cognition science into their teaching, ensuring PE supports EF development and, by extension, success in the classroom.

COMPARISON OF PHYSICAL FITNESS BETWEEN IRANIAN AND HUNGARIAN FEMALE STUDENTS

GHAAZVINI, N., HAMAR, P., OZSVÁTH, K., SOÓS, I.
HUNGARIAN UNIVERSITY OF SPORTS SCIENCES

INTRODUCTION: Health status has always been a vital concern for all governments, and practical assessment of it is challenging and costly (Lovecchio et al., 2019). Physical fitness is a significant measure of health, and Eurofit tests are one of the standard and widespread methods for measuring physical fitness (Mijanovic, 2022). This study aimed to examine and compare physical fitness between Iranian and Hungarian female students using standardized Eurofit tests.

Methods

Physical fitness tests were assessed on 539 students aged 13-15 years (Mean age = 13.93; SD = 0.82) from Iran and Hungary. Participants were selected from five Iranian schools and nine Hungarian schools. The investigation utilized a cross-sectional design. Data was collected during the academic year 2022-2023. The Research Ethics Committee of the Hungarian University of Sports Science approved this study with the reference number TE-KEB/27/2022.

RESULTS: The results of the MANOVA test indicated a significant difference in physical fitness levels between countries, age groups, and countries*age groups. The Hungarian female students performed better in all tests, with the exception of the Plate Tapping test, compared to the Iranian female students. The findings of the Univariate test of variance (ANOVA) indicated that the countries effect on all variables, with the exception of the Sit and Reach test, is significant. The interaction of Age groups and Countries*Age groups affected fewer variables with smaller effect sizes.

Discussion and conclusions

The reasons for these results are primarily to be found in the differences in the public education systems of the two countries. An important factor is the number of lessons in PE, which in Hungary is five hours per week, while in Iran it is two hours per week. Among the reasons could be the differences in the cultural habits and lifestyles of female adolescents, as well as the different infrastructural conditions. The data can serve as a standard norm for easily assessing the physical fitness and health status of 13-15-year-old female students in Iran and Hungary.

THE EFFECT OF THE SPORT EDUCATION MODEL ON PHYSICAL LITERACY ATTRIBUTES: A SYSTEMATIC REVIEW AND META-ANALYSIS

MAI, B., CHOI, S., DONG, H., LEI, S.
UNIVERSITY OF MACAU

INTRODUCTION: School physical education plays a critical role in nurturing physical literacy (McLennan & Thompson, 2015). One effective curriculum and instructional model that supports this development is the sport education model (Hastie & Wallhead, 2015), which is designed to provide students with authentic and educationally rich sport experiences (Siedentop et al. 2019). Previous reviews on the sport education model have primarily focused on students' learning outcomes, and psychological and prosocial attributes. This study aims to examine how this model holistically influences physical literacy attributes.

METHODS: Utilising the PRISMA Guidelines, a comprehensive search was conducted across databases to identify relevant sport education model interventions. A meta-analysis of articles meeting the inclusion criteria was performed to examine the effects of these interventions on five physical literacy attributes including affective, physical competence, behaviour, cognitive, and social. Standardised mean differences with 95% confidence intervals were calculated to assess the effects across the different categories.

RESULTS: A total of 2,359 potentially relevant studies were initially identified across the databases, with 42 eligible studies included in the final analysis. Despite notable heterogeneity across subgroups, the sport education model demonstrated the most significant effect on behaviour (SMD = 0.72; 95% CI = 0.36–1.08), followed by affective (SMD = 0.61; 95% CI = 0.39–0.83), social (SMD = 0.24; 95% CI = 0.07–0.40), cognitive (SMD = 0.13; 95% CI = -0.23–0.49), and physical competence (SMD = 0.10; 95% CI = -0.11–0.32).

Discussion: The sport education model significantly enhances the affective, behavioural, and social domains of physical literacy. However, its impact on students' physical abilities and cognitive development does not significantly differ from traditional teaching, possibly due to the latter's emphasis on intensive skills training while often neglecting affective and behavioural domains. The lack of cognitive differences may stem from research bias, including insufficient professional development that affects the curriculum delivery. Overall, the meta-analysis confirms the effectiveness of sport education model and suggest its integration to cultivate holistic and lifelong participation in physical activity.

A FRAMEWORK ANALYSIS OF EXPERIENCES OF UNDERGRADUATE UNIVERSITY STUDENTS WHO COMPLETED MANDATORY PHYSICAL EDUCATION COURSES: A QUALITATIVE STUDY

HO, R., SZE, C.Y., LEUNG, E.F.

THE CHINESE UNIVERSITY OF HONG KONG

INTRODUCTION: Physical activity (PA) among university students is essential for enhancing overall well-being as it promotes both physical and mental health as shown by existing synthesized evidence. However, not all university provides mandatory physical education (PE) on guiding professional sport knowledge, instructions and practice to undergraduate students. Whether a mandatory PE courses in the undergraduate studies curriculum would benefit physical and mental health, as well as motivating students to self-practice certain sport that learned from mandatory PE courses remained unclear. The objective of this qualitative study is to identify the feedback provided by undergraduate students who completed mandatory PE courses during their first two semesters at university.

METHODS: To obtain feedback from university students who enrolled for the required and elective PE courses, a qualitative study was conducted among students upon completion of one of their selected PE courses including physical conditioning, track and field, swimming, basketball, volleyball, softball, handball, soccer, tennis, squash, badminton, table tennis, wood ball, yoga, tai chi, taekwondo, modern dance, cycling, hip-hop dance, golf and martial arts. Students were invited to participate in a focus group interview. During the focus group interviews, the participants discussed about their experience and comments for PE courses based on a set of pre-designed semi-open questions. Purposive sampling was used to capture experience of students who had positive feedback (n=15) and students who had negative feedback (n=15) to the required and elective PE courses via focus group interviews. Design and analysis followed a framework analysis approach, with reference to an existing systematic review (SR) on PA and physical fitness among university students. Themes emerging outside of this SR were purposefully explored.

RESULTS: Students with positive feedbacks of the PE courses expressed that the professional qualifications, extensive experience and high enthusiasm among the PE lecturers strongly motivated them to choose, engage and participate in the activities and content of the course. In turn they were more actively involved, learned and played the sport themselves in their spare time. Students with negative feedbacks of the PE courses mentioned the required and elective PE courses were too exam-orientated. Students claimed that the grouping in PE classes was problematic, as putting students of different skill levels in the same class was not ideal.

CONCLUSION: Findings of the qualitative study indicated that students could positively initiate their self-interest in engaging sports that taught by the PE lecturers. Grouping of students based on their prior experience and abilities of the sport before classes commence might be suggested to be a better approach in designing and structuring required and elective PE classes among university students.

MOVEMENT PATTERNS AND COGNITIVE-ADAPTIVE FUNCTIONS. AN EXPLORATORY EVALUATION IN THE EARLY YEARS OF PRIMARY SCHOOL

PERRONE, R., ABATE, M., MARCHESANO, M.V., MINGHELLI, V., PALLONETTO, L., PALUMBO, C.

UNIVERSITY OF SALERNO; *UNIVERSITY OF SALERNO/VERONA

INTRODUCTION: Motor-sport activities are widely recognized by scientific literature and national and international regulations as fundamental tools for integral personality development, in terms of acquiring personal, cognitive and interpersonal skills (1). However, the rapid technological changes of recent decades are leading to a significant increase in sedentary lifestyles, with consequent appreciable repercussions already in childhood, both on motor and cognitive development. Reduced physical activity in children affects not only the quantity and quality of motor experience, but also the nervous systems ability to integrate and coordinate the sensory and motor information necessary for the acquisition of functional movement patterns. In the light of the most recent neuroscientific contributions, the consolidation of motor praxis and the development of coordination represent complex embodied cognitive processes that depend on the simultaneous interaction between perception, motor control and adaptation to environmental stimuli. The present exploratory study aims to observe the state of acquisition of "movement patterns" and "cognitive-adaptive functions", to investigate the quality of movement experiences in physical education in primary school.

METHODS: The study involved a convenience sample of 263 children (M=124; F=139) attending the first and second year of primary school, who were administered the APCM-2 (2) test for the assessment of praxic skills and motor coordination.

RESULTS: From the point of view of "cognitive-adaptive functions", the results show slight difficulties in the processes of motor planning and sequencing, essential aspects for the development of efficient action schemes for the regulation of movement in response to environmental stimuli. In terms of "movement patterns", there is partial acquisition of basic motor patterns, with greater difficulty in activities requiring integration between balance and dynamic coordination. The data suggest the possibility of implementing educational interventions within Physical Education activities aimed at improving the development of these areas, even in the early years of primary school, in order to positively influence the later development of more complex movement patterns.

CONCLUSIONS:

This preliminary exploratory study, which examines a specific age target for which the presence of the specialised teacher is not yet foreseen in the national educational context, seems to emphasise the need for an intervention aimed at the early and systematic introduction of structured motor activities in the school context, in order to foster the harmonious development of motor and cognitive skills from the earliest stages of learning.

QUALITY OF LIFE AND ITS ASSOCIATION WITH PHYSICAL ACTIVITY, PHYSICAL FITNESS, AND ENJOYMENT OF PHYSICAL EDUCATION IN YOUTH: A STUDY ON GENDER DIFFERENCES

PRÜNSTER, V., NIEDERMEIER, M., GREIER, K., COCCA, A., RUEDL, G.

UNIVERSITY OF INNSBRUCK

INTRODUCTION: The COVID-19 pandemic significantly reduced quality of life among children and adolescents, exacerbating psychosomatic complaints, mental health disorders, and social isolation. Physical fitness (PF) also declined, highlighting the importance of physical education (PE) for promoting activity levels and well-being. Research shows gender differences in responses to PE, with boys benefiting more from competitive aspects while girls favour cooperative approaches. Enjoyment of PE, influenced by autonomy and instructional quality, is a key factor for engagement and long-term activity. Despite extensive studies, gaps remain in understanding gender-specific impacts of PE and enjoyment on quality of life, necessitating targeted research and interventions.

METHODS: A cross-sectional study was applied with schoolchildren from fifth grade of 5 public schools in the west of Austria (a total of 176 adolescents, of whom 48.29 % were girls and the mean age was 15.60 ± 0.63). Physical activity (PA), health-related quality of life (HRQoL), and enjoyment in PE were self-reported using previously validated questionnaires (KIDSCREEN-10, FEFS-J: pleasure, flow experience, recovery). PF was assessed using the German motor performance test 6-18. Multiple linear regression was carried out to analyse the regression between HRQoL and PA, PF, and dimensions of enjoyment in PE for girls and boys.

RESULTS: The mean T-score for HRQoL in the entire cohort was 52.11 ± 10.92 . Spearman's correlation coefficients demonstrated significant moderate to strong positive correlations between HRQoL and the three dimensions of enjoyment in PE for girls. In contrast, among boys, only the "pleasure" dimension of enjoyment in PE exhibited a significant positive relationship with HRQoL, showing a moderate effect size. Multiple regression analyses showed that pleasure in PE was positively associated with HRQoL for both girls ($\beta=0.49$; $R^2=0.30$) and boys ($\beta=0.52$; $R^2=0.09$).

Discussion: The findings emphasize the importance of enjoyment in physical education and gender-specific differences in the impact of physical activity on quality of life. Tailored approaches addressing the distinct needs of boys and girls are crucial to enhance motivation and support long-term physical and mental well-being.

CP-MH15 Paralympic Athletes

REQUESTS FOR MEDICAL INTERVENTION DURING THE FIRST TRANSPLANT FOOTBALL WORLD CUP

TOTTI, V., FERRARI, F., PALTRINIERI, S., CARACENI, P., ROI, G.S.

IRCCS AZIENDA OSPEDALIERO-UNIVERSITARIA DI BOLOGNA

INTRODUCTION: Football (soccer) is one of the most popular sports, practiced by millions of people all around the world. Regular recreational football is considered one of the best long-term guarantees of good health [1], having important potential as health-promoting activity also for solid organ transplant recipients [2]. Thus, the World Transplant Games Federation is working to improve the lives of transplant patients by encouraging participation in Olympic-type events, promoting the 1st Transplant Football World Cup which took place on September 2024 in Cervia (Italy). The aim of this study is to investigate the epidemiology of this type of new competition.

METHODS: Matches were played according to FIFA rules for 7-man teams, with some modifications to safeguard the athletes' transplanted organs. Teams consisted of a maximum of 16 female and male players of all ages. Matches lasted 20 minutes with unlimited substitutions. Two regular FIFA pitches of 60 x 40 m, with a 3 m goal were utilized at the same time. Two sports physicians were always present, providing medical assistance along with an ambulance to deal with any emergencies. They filled out a form specifically designed to collect information about any request for medical intervention (RfMI).

RESULTS: Eleven teams participated involving 172 transplanted players of kidney (N=103; 60%), liver (N=25; 15%), bone marrow (N=18; 10%), heart (14; 8%), kidney-pancreas (N=7; 4%), lung (N=5; 3%). They played 35 matches corresponding to 326 hh 40 min exposition. RfMI were 28 (16% of the participants), involving 13 (52%) liver, 9 (9%) kidney, 3 (21%) heart, 2 (11%) bone marrow and 1 (14%) kidney-pancreas recipients. They were 26 males, and 2 females, aged 36.0 ± 11.1 years, playing as defenders (10), strikers (8), midfielders (6) and goalies (4).

Mechanisms of injury were by noncontact (n=12; 43%), indirect contact (n=9; 32%), direct contact (n=7; 25%). Injuries were classified as: acute (n=23; 82%), acute on chronic (n=4; 12%) and chronic (1; 4%), and as: contusions (n=9; 32%), sprains (n=6, 21%), muscle strain (n=5; 18%), abrasions (n=4; 14%), foot tendinopathy, wound from shoe studs, minor concussion and big toe infection (n=1; 4%, each one). RfMI incidence was 85.7/1000 h (117.4-54.0; $\pm 95\%$ CI); time loss injuries (TLI) were 17, with incidence of 52.0/1000 h (76.8-27.3). All injuries were treated on site, except the wound sent to hospital.

CONCLUSION: Despite the high incidence of TLI, only four injuries were of moderate severity (8-28 days) and no injuries to the transplanted organs were reported. The risks for a recreational footballer represent far less of a danger than the much greater threat posed by a lack of exercise.

EFFECTS OF BLOOD FLOW RESISTANCE TRAINING ON MUSCLE SIZE, STRENGTH AND SWIMMING PERFORMANCE IN AN ELITE PARA SWIMMER: A CASE STUDY

TANG, J., LUM, D., XU, C.Z., YAN, Y.Y.

SINGAPORE SPORT INSTITUTE

INTRODUCTION: Charcot-Marie-Tooth disease (CMT) is a group of neuromuscular disorder that typically affects the distal motor and sensory nerves, resulting in muscle atrophy and weakness [1]. The challenge for coaches lies in increasing muscle size and strength due to the inability to increase workloads. The aim of this study is to investigate the effects of a 4-week moderate load resistance training combined with blood flow restriction (ML-BFR) on upper body muscle size and strength, and swimming performance in a world-class paralympic swimmer with CMT.

METHODS: A multi-paralympic gold medallist female para swimmer (32y, 49.94kg) with CMT completed 8 sessions of ML-BFR training across 4 weeks. For each session, the participant performed 4 exercises (60% 1RM, 3-4 sets, 5-6 repetitions, 90s passive rest between sets) with a pneumatic cuff placed around the most proximal portion of the arm, and pressure set at 50-60% of arterial occlusion pressure (AOP). Pressure was only fully released upon completion of the final set of each exercise. Pre- and post-measurements included: 1) magnetic resonance imaging (MRI) to determine muscle cross-sectional area (CSA), 2) one-repetition maximum (1RM) testing, 3) mean concentric velocity (MVC) outputs at submaximal loads and 4) 100m swim time trial.

RESULTS: Muscle CSA of both bicep brachii (0.7%) and pectoralis major (13.0%) increased whereas triceps brachii (-6.0%) latissimus dorsi (-0.8%) CSA decreased. 1RM for all exercises increased: 2.6% lat pulldown, 5.26% bench pull, 3.03% bench press and 6.25% shoulder press. MVC in both lat pulldown and bench press also improved 5.05% and 6.35% respectively. Swim performance time lowered by 11.5%.

CONCLUSION: Results of the present study indicated that ML-BFR leads to strength increases but did not allow for a definitive conclusion of the hypertrophic response of ML-BFR training. Due to the single pre-post design of this study, it was unknown whether the changes in swimming performance were a result of BFR or specific sport training effect. Future research with a single case experimental design over multiple training blocks is warranted to fully understand the effects of BFR on muscle hypertrophy and strength.

BALANCE PARAMETERS AMONG CLASSES OF TOP-LEVEL PARA-KARATE ATHLETES

HADŽA, R., AUGUSTOVICOVÁ, D., HORNIKOVA, H., HRUBY, M.

COMENIUS UNIVERSITY, FACULTY OF PHYSICAL EDUCATION AND SPORT

INTRODUCTION: Para-karate is modality of karate focused on developing discipline of "kata" for wheelchair athletes, visually impaired (VI) athletes and athletes with intellectual impairments (II) and is a fully integrated part of operations of World Karate Federation (WKF) [1]. There are three categories for individual kata: visually impaired (VI: K10), intellectually impaired (II) – IQ less than 75 (II: K21) and Down Syndrome (DS: K22). These categories are divided into sport classes. A compensation points are given according to degree of impairment assessed by expert WKF classifiers during classification session. The system aims to determine who is eligible to compete at Paralympic Games, while ensuring that it is not degree of impairment but sporting excellence that ultimately determines which athlete or team is victorious [2]. A closer view into performance during a balance test offers practitioners better understanding of the differences among classes of para-karate athletes. This information can be a valuable clue to the detailed performance deficiencies. Intentional addressing in the training process can lead to an increase in sports performance [3].

METHODS: Fifty-eight top-level para-karate athletes participated in the study (VI: $n=23$, aged 30.0 ± 8.7 ; II: $n=16$, aged 26.5 ± 5.2 , DS: $n=17$, aged 27.5 ± 6.4). We aimed at differences among classes in parameters of 30 second balance test: parallel stance, opened eyes, hands on hips and no manipulation. Athletes were instructed to step on plates, standing still for 30 seconds, maintaining eye contact with the picture on the wall in front of them during test. All completed 2 attempts with resting interval of 60 seconds. We took best attempt for statistical analysis. We used device Kistler Force plates. Parameters obtained were total path [mm] and velocity [mm.s⁻¹] of centre of pressure (COP). Athletes performed test as a classification session of World Para-karate championship 2023. For statistical analysis we used Kruskal-Wallis H and Mann-Whitney U test.

RESULTS: We found significant differences among classes for total path $H(2) = 13.21$, $P < .001$, and revealed significant differences between VI and II ($U = 70.5$, $p < .001$) and II and DS ($U = 217$, $p = .035$) and no differences between VI and DS ($p = .112$), as well for total area $H(2) = 12.93$, $P < .002$, we revealed significant differences between VI and II ($U = 129$, $p = .047$) and VI and DS ($U = 76.0$, $p < .001$) and no differences between VI and II ($p = .184$).

CONCLUSION: VI athletes showed a significantly higher rate of COP movement during the test compared to mentally disabled karatekas of both groups showing need for working on the stability in strength and conditioning preparation. Among mentally disabled athletes, II athletes showed more pronounced fluctuations of COP in multiple directions (medio-lateral and antero-posterior) but at a lower velocity compared to DS group, suggesting better control of the COP movement for II athletes.

CHARACTERISTICS OF PARA ALPINE SKIING FALLS DURING THE BEIJING 2022 WINTER PARALYMPIC GAMES

YUKI, T., KAZUKI, K., TSUBASA, T., SATOSHI, A., TAKUMI, N., RURINA, Y., JUNPEI, S., NORIAKI, M.

HIROSHIMA UNIVERSITY

INTRODUCTION: Para alpine skiing has a high injury incidence of 19.9 per 1,000 athlete days [1], with falls as a key contributing factor. Para alpine skiing consists of five events: Downhill, Slalom, Giant Slalom, Super G, and Super Combined Slalom, each differing in course length and flag gates. Athletes compete in the standing and the sitting categories, with the standing category further subdivided into visual, upper limb, lower limb, and combined upper and lower limb impairments. Fall incidence likely varies by the event, category, and environmental factors such as temperature and snow quality, yet their relationship remains unclear. This study aimed to clarify the characteristics of falls in para alpine skiing using video analysis.

METHODS: We analyzed official competition footage of para alpine skiing during the Beijing 2022 Winter Paralympics, obtained from the official website of the International Paralympic Committee. A total of 898 races across all five events in both mens and womens categories were examined, excluding "Did Not Start" entries. Falls were identified by three physiotherapists, requiring at least two judges to confirm an incident [2]. A fall was defined as any body parts making contact with the snow surface. Basic information on the athletes and environmental conditions during the competition was recorded from the official result book. Statistical analysis included Pearson χ^2 test or Fisher exact test for categorical comparisons based on the occurrence of falls, with adjusted residuals for post hoc tests. The significance level was set at $p < 0.05$.

RESULTS: A total of 146 falls occurred in 898 races (0.16 falls per race). A significant difference in fall incidence was found only among categories ($p < 0.01$). Residual analysis revealed that falls were significantly lower in the combined upper and lower limb impairment category (9 falls in 109 races, 0.08 falls per race) and higher in the sitting category (79 falls in 307 races, 0.26 falls per race). Among the 146 falls that occurred, 115 falls (78.8%) resulted in Did Not Finish (DNF) or Disqualified (DSQ).

CONCLUSION: Our findings suggest that fall incidence in para alpine skiing is primarily influenced by the categories. Since the PyeongChang 2018 Winter Paralympics, environmental measures during races have been implemented as fall pre-

vention [3], leading to the assumption that environmental factors did not affect fall incidence. Notably, the sitting category showed the highest fall incidence. It may have been influenced by the characteristics of sit-ski, where balance must be maintained using the upper body. Given the about 80% of the fallen athletes were DNF or DSQ, they may have sustained injuries preventing them from continuing the race. Fall prevention measures tailored to each category are crucial for both injury prevention and competition.

UPPER LIMB STRENGTH EVALUATION OF PARALYMPIC SUMMER SPORTS SITTING ATHLETES

PUGLIESE, G., CICCARELLI, A., SQUEO, M.R., GUERRA, E., PELUSO, I., BERNARDI, M.

UNIVERSITY OF ROME

INTRODUCTION: Strength (St) is a fundamental health related component of physical fitness (I), linked to quality of life in wheelchair bound individuals and to performance in different winter sports practiced by paralympic athletes (PA) with a locomotor impairment (LI) (2). The present retrospective chart review is aimed at describing the maximal strength of upper body muscles of PA with a LI (PA-LI) consequent to spinal cord injury (SCI), lower limb amputation (LLA) and other health conditions (OHC) determining a LI and competing in different Paralympic summer sports.

METHODS: Seventy-two male PA-LI, 48 with SCI (all with paraplegia), 24 NON-SCI (13 LLA and 11 with OHC) were included in the study and divided into 3 groups (G) of sport type: G1, skill sports(SS) (25 PA), G2, aerobic and anaerobic mixed metabolism sports (MS) (30 PA) and power sports (PS) (6 PA) and G3, endurance sports (ES) (11 PA). Maximum isometric strength of both finger flexors (handgrip, HG) and shoulder lowering muscles (SLM) was measured using a laboratory made dynamometer (MK7, Dal Monte, Italy). For both tests maximal voluntary contraction (MVC) was assessed in right and left muscles and the best value of 3 MVCs of the 2 sides were summed for the strength evaluation. Absolute and normalized (per kg of body mass) data were considered for statistics. Data were analyzed using a 1-way analysis of variance (ANOVA) design in which sport type was considered as categorical independent variable (factor) and strength as dependent variable. Through a Tukey honestly significant difference test, the probability for post hoc test was calculated.

RESULTS: Strength of PA competing in ES (1334.6 ± 352.72 N - 19.4 ± 3.85 N/kg) was significantly higher than in PA competing in SS (1166.5 ± 228.83 N - 15.7 ± 4.03 N/kg) ($p=0.018$). No significant differences between SS- MS and PS (1218.1 ± 252.82 N - 16.7 ± 3.36 N/kg), and ES- MS and PS were found. No significant difference in means among the groups was found in the analysis of SLM: SS (967.0 ± 141.29 N - 12.9 ± 2.54 N/kg), MS and PS (1014.0 ± 193.21 N - 13.8 ± 2.96 N/kg), and ES (991.0 ± 181.20 N - 14.6 ± 2.95 N/kg). Between SCI and NON-SCI there weren't significative differences in both HG and SLM: SCI (1228.6 ± 249.01 N - 17.1 ± 3.89 N/kg) NON-SCI (1195.4 ± 313.46 N - 15.9 ± 3.64 N/kg) and SCI (964.6 ± 168.50 N - 13.4 ± 2.14 N/kg) NON-SCI (1053.2 ± 191.89 N - 14.0 ± 2.14 N/kg).

CONCLUSION: Strength, which should be the main physical features components of power sports, has been found very high in Paralympic athletes with locomotive impairments competing in endurance sports, such as bike seating, north skiing and long distance wheelchair racing.

INFLAMMATORY RISK AND CARDIORESPIRATORY FITNESS IN PARALYMPIC ATHLETES WITH A LOCOMOTOR IMPAIRMENT

CICCARELLI, A., PELUSO, I., PUGLIESE, G., AIELLO, P., VALENTINI, F., SQUEO, M.R., DI GIOIA, G., POGGIOGALLE, E., BERNARDI, M.

UNIVERSITY OF SAPIENZA

INTRODUCTION: Individuals with spinal cord injury (SCI) have higher levels of chronic low-grade systemic inflammation (LGSII), health condition (HC) strictly related to non-communicable chronic diseases and in particular to atherosclerotic cardiovascular disease (ACVD), than their able-bodied counterparts (I), and this HC is highly represented in athletes with a locomotor impairment (LI) (2). Previously, we showed an association between ACVD risk factors (RF) and cardiorespiratory fitness (CRF), meaning that a low CRF is associated with a high number of ACVDRF and vice versa (3). The present study aimed at evaluating both the inflammatory status (4), assessed through the ratio between neutrophil and lymphocyte counts (neutrophil-lymphocyte ratio-NLR) in PA with different HC and competing in different sports and the relationship between CRF and NLR.

METHODS: Data from 153 male PA (82 PA with SCI and 71 with other HC PA-OHC) recruited from the pre-participation screenings preceding Paralympic Games from Sydney 2000 and Sochi 2014 (2) were retrospectively evaluated. PA had competed in skilled sport-SS (24.8%), power sports-PS (18.3% of PA), aerobic and anaerobic mixed metabolism sports-MS (39.9%) and endurance sports-ES (17.0%). They were screened through anthropometric measurements, to assess body mass and height, blood samples, to assess neutrophil and lymphocyte counts, and an incremental cardiopulmonary maximal exercise test to assess peak of oxygen uptake (VO_{2peak}) expressed in $ml \cdot kg^{-1} \cdot min^{-1}$. After having checked the absence of normal distribution of the variables, Mann-Whitney test and Kruskal-Wallis test were used to compare the two groups of HC and the 4 groups of sports, respectively. Spearman correlation was performed to evaluate the relationship between VO_{2peak} and NLR.

RESULTS: NLR did not show differences when comparing both PA-SCI (1.68; 0.9-4.1) and PA-OHC (1.56; 0.7-3.8) and sport type: 1.71 (0.7-3.8) in SS, 1.61 (0.9-3.2) in PS, 1.61 (0.9-4.1) in MS and 1.41 (0.9-2.7) in ES. The prevalence of PA with high inflammatory status (cut-off NLR>3) was in accordance with health condition 6.09% in PA-SCI and 4.22% in PA-OHC and in accordance with sport type was 5.2% in SS, 3.5% in PS, 8.2% in MS and 0% in ES. VO₂peak, lower in PA-SCI (28.6; 15.2-54.5) than in PA-OHC (35.1; 19.4-58.2), significantly differed in the 4 types of sports (23.88; 15.2-39.7 in SS; 32.38; 17.1-50.8 in PS; 33.26; 16.4-44.7 in MS and 43.12; 27.5-58.1) and correlated negatively with NLR.

CONCLUSION: NLR, which resulted globally high in PA-LI, showed an inverse relationship with aerobic fitness. PA-LI competing in SS which displays low VO₂peak values should train also in ES to counteract LGS.

SELF-MEDICATION AND PARASPORT: A STUDY ON ADULT AMATEUR ATHLETES WITH MOTOR DISABILITIES

KAUX, J., BEAUDART, C., PRAILLET, P., LE VAN, P., MICHEL, J., XHROUET, S., JARDON, C.

UNIVERSITY OF LIÈGE

INTRODUCTION: Limited research has been conducted on self-medication (SM) practices in sports, particularly among amateur athletes with motor disabilities. While SM is prevalent among able-bodied athletes, there is a lack of data on its use among amateur disabled athletes.

This study aimed to determine the prevalence of self-medication among amateur sportsmen and women with physical disabilities, identify factors influencing self-medication behaviors, and address misconceptions associated with these practices.

METHODS: Quantitative cross-sectional study conducted using an anonymous online self-administered questionnaire. The study included amateur disabled sportsmen and women from Belgium and France. Self-medication behaviors were assessed for dietary supplements (DS), over-the-counter drugs (OTC), and formerly prescribed drugs (FPD) through self-reported procedures. Data on participant characteristics, sports practice, consumed products, and knowledge were collected. Descriptive statistical analyses, group comparisons, and logistic regressions were performed to assess factors influencing self-medication.

RESULTS: 164 disabled sportsmen and women recruited 38.7% of self-medication practices in the context of sports reported (23.2% used DS, and 25.6% used MEDS (OTC and FPD combined)). Self-medication with DS: positively associated with age, consumption of caffeinated and energy drinks, and self-medication with MEDS. Self-medication with MEDS: positively associated with the number of hours of sports practice, consumption of caffeinated drinks, and self-medication with DS. Paracetamol was the most commonly consumed pharmaceutical molecule, while proteins were the most commonly used DS. 36.4% of participants using MEDS and 42.1% using DS believed that self-medication posed no health risks.

CONCLUSION: High prevalence of self-medication among amateur sportsmen and women with physical disabilities. Fortunately, paracetamol, which is one of the most commonly used medications, is generally associated with a low risk of side effects. However, even with this seemingly innocuous medication, recent research has raised concerns about potential safety issues, emphasizing the need for a more cautious approach to usage of any medications. The associated risks, reliance on unreliable sources of advice and information (e.g., the internet), and lack of awareness regarding the dangers of self-medication highlight the need for educational strategies targeting amateur disabled athletes. Further research is required to gain a deeper understanding of self-medication behavior in this population.

MAPPING THE SCIENTIFIC LITERATURE ON THE PARALYMPIC GAMES AND PARALYMPIC SPORT

CAVEDON, V., DE DONATO, R., LORENZET, N., MILANESE, C.

UNIVERSITY OF VERONA

INTRODUCTION: In recent decades, research on Paralympic sport has expanded; however, the extent of its interdisciplinarity remains uncertain. The field is predominantly shaped by biomedical and rehabilitation studies, while disciplines such as social sciences, psychology, and sports economics remain underrepresented [1], limiting comprehensive analysis of key aspects such as classification, accessibility, and inclusion.

Given this context, the present study aimed to: (1) map the scientific literature on Paralympic sport by identifying trends and thematic areas through a bibliometric analysis; (2) assess interdisciplinarity by examining co-citation networks, connections between journals and institutions, and keyword clustering; and (3) identify gaps and disciplinary imbalances by analyzing thematic concentration and proposing strategies for greater integration.

METHODS: This study employed a bibliometric approach, analyzing articles published in the Web of Science, Scopus, PubMed, and JSTOR databases. The analysis included bibliometric indicators such as co-citation networks, keyword analysis, and collaboration networks between journals and institutions [2]. Data were processed using the Bibliometrix package in R [3].

RESULTS: A total of 718 articles were included in the study. The analysis revealed a significant increase in scientific production since 2016, with a peak in 2020. However, the results showed that interdisciplinarity remains limited: 35% of studies fall within sports sciences, followed by rehabilitation (21%) and physiology (4%), while disciplines such as sociology and applied psychology account for less than 2%. Co-citation networks indicated distinct disciplinary clusters with minimal connections between biomedical and social sciences. Keyword clustering further highlighted the dominance of terms related to performance and functional classification, whereas concepts such as inclusion and accessibility appeared marginal.

CONCLUSION: The findings confirmed the growth of research on Paralympic sport but highlighted persistent challenges in achieving interdisciplinary integration. The dominance of biomedical studies limits attention to inclusion, accessibility, and sports policies. Furthermore, the concentration of publications in a limited number of high-impact journals may reduce methodological diversity. To address these challenges, greater collaboration between biomedical, sports, and social sciences is needed to foster a more integrated approach to key issues in the field.

CP-MH16 Ageing III - Covid-19

COLLISIONS AND CONTAGIONS: EXPLORING THE OVERLAP OF CONCUSSION AND COVID-19 ON SENSORIMOTOR AND AUTONOMIC FUNCTION IN COMMUNITY DWELLING AUSTRALIAN FOOTBALL LEAGUE ATHLETES

MCGRATH, M., WADDINGTON, G., BISSETT, B., FEARON, A., WITCHALLS, J.

UNIVERSITY OF CANBERRA

INTRODUCTION: Concussion is a concern in contact sports, as it may disrupt the sensorimotor pathways essential for movement control – visual, vestibular, and somatosensory (VVS) systems – and potentially affects autonomic nervous system (ANS) function (1,2). Emerging evidence suggests that COVID-19 may similarly impact VVS and ANS function (3). This study investigated the relationship between self-reported history of COVID-19 and/or self-reported sport related concussion (SSRC) on VVS and ANS function in athletes.

METHODS: 120 community level Australian Football League athletes (51 females, aged 16–37 years) participated in this study as part of pre-season baseline testing. Participants completed a self-report questionnaire, enabling categorisation into four groups: no history of COVID-19 or SSRC within the past 12 months (n=82), SSRC within the past 12 months (n=11), COVID-19 infection within the past 12 months (n=22), and both COVID-19 and SSRC within the past 12 months (n=5). Assessments were then conducted to evaluate visual-vestibular function (smooth pursuit and voluntary saccades), somatosensation (Active Movement Extent Discrimination Assessment, AMEDA), and autonomic function (pupillary light reflex). Independent samples t-test was performed in RStudio to detect differences between groups: no-history – COVID, no-history – SSRC, no-history – both. Significance set at $p < 0.05$.

RESULTS: Athletes with self-reported history of COVID-19 infection in past 12 months demonstrated significant reductions in sympathetic ($p=0.016$) and parasympathetic ($p=0.049$) function, when compared to the no-history group. Those with combined histories of COVID-19 and SSRC exhibited significant declines in sympathetic function ($p=0.042$), when compared to the no-history group. No significant differences in VVS function were observed across groups, and the SSRC-only group showed no significant ANS or VVS reductions.

CONCLUSION: This is the first study to examine the combined impact of self-reported history of COVID-19 and SSRC on VVS and ANS function. History of COVID-19 infection significantly impaired ANS function in this population. Insufficient power limited between-group comparisons, with post-hoc analysis indicating 30 athletes required per group. While SSRC alone did not significantly affect VVS or ANS function, the combined impact of both COVID and SSRC history resulted in detectable deficits even in a small sample. Reliance on self-reported data may have introduced bias. These findings underscore the lingering effects of COVID-19 and the potential compounding effects of SSRC and COVID-19 on ANS function in athletes.

PROTECTIVE EFFECT OF PHYSICAL ACTIVITY AGAINST COVID-19 IN THE OLDER PEOPLE: THE PROOF COHORT

CAZENEUVE, C., CHOUCHOU, F., CELLE, S., ROCHE, F., HUPIN, D.

UNIVERSITY OF LA REUNION

INTRODUCTION: Epidemiological studies showed that age was a risk factor for the coronavirus disease 2019 (COVID-19) infection, severity, hospitalization and mortality [1,2]. In the same time, epidemiological studies showed a reduced risk of COVID-19 severity with the practice of regular physical activity (PA) in clinical populations [1,2] but it is unknown if is the same in elderly population. Here, we investigate the effect of PA against COVID-19 infection in elderly population.

METHODS: The PROOF cohort study (2001-) was used to prospectively allow assessment of the predictive value of PA among a healthy retired French population, with regard to COVID-19 infection (2020-2021). Moderate-to-vigorous physical activity (MVPA) and sedentary behaviour were assessed by a validated self-administered questionnaire (POPAQ) investigating 5 different types of PA during the 7 previous days. PA was measured in metabolic equivalent of task (MET)-h, which refers to the amount of energy (calories) expended per hour of PA. SB was measured in hour/day. Medical histories were

taken during each clinical visit. The relationships between MVPA and COVID-19 infection were analyzed by univariate and multivariate logistic analysis, adjusted for several covariates.

RESULTS: Among 372 subjects (214 women, mean age: 74.79 ± 0.96 years), 14 (3,76%) reported COVID-19 infection. Univariate logistic analysis revealed no association between COVID-19 infection and sitting time in hours per day (odds ratio (OR) 0.95; 95% confidence interval (CI) 0.66 to 1.36; $p=0.773$) or the number of hours per day of PA greater than or equal to 3 Metabolic Equivalent of Task (METs) (OR 0.65; 95% CI 0.38 to 1.09; $p=0.099$). Finally, multivariate logistic analysis controlled for the covariates age, body mass index, alcohol consumption, high blood pressure, cholesterol, cancer and non-insulin-dependent diabetes showed that the number of hours per day of PA greater than or equal to 3 METs per day was independently associated to low risk of COVID-19 infection (OR 0.53; 95% CI 0.30 to 0.96; $p=0.037$), but not sitting time in hours per day (OR 0.94; 95% CI 0.65 to 1.35; $p=0.726$).

CONCLUSION: The results showed that, for older people, the number of hours spent sitting per day does not seem to have an impact on the risk of COVID-19 infection. However, regular physical activity of moderate to vigorous intensity could offer protection against COVID-19 infection independently of known confounding factors. In a context of global warming with future emerging viral diseases, further researches are needed to understand the association of PA and various viral infections (such as dengue or chikungunya).

THE RELATIONSHIP BETWEEN SUBJECTIVE AND OBJECTIVE ASSESSMENT OF THE LEVEL OF PHYSICAL ACTIVITY IN OLDER WOMEN

LI, M., YU, H., QIAN, G., OSSOWSKI, Z.

GDANSK UNIVERSITY OF PHYSICAL EDUCATION AND SPORT

INTRODUCTION: Physical activity is a key determinant of health in elderly women. While self-reported questionnaires provide subjective assessments, wearable devices offer objective measures [1]. Understanding the correlation between these two methods is essential for improving health monitoring strategies. This study aims to examine the correlation between subjective PA assessments obtained through International Physical Activity Questionnaire (IPAQ) and objective PA measurements from wearable sensors.

METHODS: This study analyzed PA data from 71 older women (aged 60 years and above), all of whom were of Caucasoid ethnicity. Subjective PA assessment was conducted using IPAQ, while objective PA tracking was performed using a Polar V-800 heart rate monitor (Polar Electro Oy, Finland). Additional variables included self-reported health status, pain experience, and PA levels, which were compared against device-measured standing, walking, and running times. Differences between subjective and objective PA assessments were analyzed using ANOVA, and Pearson correlation coefficients were calculated to assess associations between self-reported and device-measured PA levels.

RESULTS: Preliminary analysis identified a statistically significant discrepancy between self-reported and device-measured PA levels (mean $\pm$ standard deviation: 3098 ± 2540 MET-min/week vs. 1647 ± 324 MET-min/week, $p < 0.05$). Further correlation analysis revealed no significant association between self-reported health status, pain experience, and objectively measured PA levels ($p > 0.05$). However, education level exhibited a significant negative correlation with self-reported PA levels ($r = -0.28$, $p < 0.05$), whereas chronic pain status demonstrated a significant positive correlation with self-reported PA levels ($r = 0.29$, $p < 0.05$).

CONCLUSION: These results indicate that self-reported PA assessments may be influenced by individual characteristics, emphasizing the need for integrating objective measurement tools to enhance accuracy in PA monitoring. Future research should explore additional factors influencing self-reported PA accuracy and develop refined assessment models tailored to diverse populations.

MASTER ATHLETES AND CANCER RISK: EXPLORING THE PROTECTIVE BENEFITS OF LIFELONG EXERCISE

SOARES, C., PEDROSA, A., MOURA, J., RAMA, L., SARMENTO, H., URBANO, A., TEIXEIRA, A.

CIPER, UNIVERSITY OF COIMBRA, PORTUGAL; MOLECULAR PHYSICAL CHEMISTRY R&D UNIT, UNIVERSITY OF COIMBRA, PORTUGAL; DEPARTMENT OF LIFE SCIENCES, UNIVERSITY OF COIMBRA, COIMBRA, PORTUGAL.

INTRODUCTION: Physical activity and exercise are associated with a decreased cancer risk and lower mortality rates[1]. This association is also observed among elite athletes, who tend to have longer lifespans[2]. Over the past two decades, various research groups have hypothesised that some of these protective benefits may stem from reducing cancer risk factors, such as obesity, and directly affecting cancer cell viability[3]. However, the cellular and molecular mechanisms involved are not yet fully understood, and studies on the effects of lifelong exercise remain limited and inconsistent. Master athletes who engage in lifelong exercise could be a model of healthy ageing, providing insights into the cellular and molecular mechanisms underlying the protective benefits of lifelong exercise against cancer. Our work aimed to reinforce and expand knowledge in the emerging field of exercise oncology. We analysed the effect of lifelong exercise on cancer

risk factors and serum profiles. Furthermore, we explored the effects mediated by serum profiles conditioned by lifelong exercise and high-intensity exercise on markers of the degree of transformation of cancer cells.

METHODS: Using a non-randomized control trial study design, we assessed the body composition, cardiorespiratory fitness (VO₂ max) and serological profile (lipoproteins, cytokines and growth factors) of master athletes—as a model of lifelong exercise—and healthy age-matched non-exercisers, before and after a progressive maximal aerobic test. Through in vitro assays, we assessed the effect of serum at rest and post-exercise from master athletes and healthy non-exercisers on markers of the degree of transformation of human lung carcinoma cells (A549) such as adhesion and/or resumption of proliferation, proliferation rate, clonogenic potential, the capacity of migration and bioenergetic phenotype.

RESULTS: Master athletes had an increased relative VO₂ max of 7.86 ± 2.09 mL kg⁻¹ min⁻¹ ($p \leq 0.05$), an increase of $3.41 \pm 1.46\%$ in muscle mass, and a reduced fat mass of -5.44 ± 2.29 kg ($p \leq 0.05$) when compared to the non-exercisers. The growth factors and cytokine arrays (99 proteins) approach showed a cohort-dependent serum profile with master athletes' serum at rest with lower factors linked to the senescence-associated secretory phenotype. Master athletes' acute exercise-conditioned serum significantly increased cell adhesion and/or resumption of proliferation, reduced cell proliferation rate, reduced colony size (2.12 ± 0.3 to 1.25 ± 0.2 μm²), and reduced L-lactate production (0.058 ± 0.01 to 0.025 ± 0.03 μmol) compared to the at-rest serum.

CONCLUSION: Our results suggest that lifelong exercise modulates cancer risk factors and serum profiles in ageing, influencing cancer prevention with each exercise session creating a chronic effect. Furthermore, the beneficial effects of exercise directly on cancer cells might depend on its characteristics, such as intensity and duration.

ASSESSMENT OF PHYSICAL FITNESS IN CHILEAN INSTITUTIONALIZED ELDERLY WOMEN

CANO-CAPELLACCI, M., QUINTEROS, F.

UNIVERSIDAD DE CHILE

INTRODUCTION: Assessing functional mobility and strength in institutionalized elderly women is essential for the planning of tailored interventions (1). This study evaluates the relationships between handgrip dynamometry, risk of falling test, and functional performance, utilizing the Barthel Index and various physical tests.

Reference:

1. Courel-Ibáñez, J., Buendía-Romero, Á., Pallarés, J. G., García-Conesa, S., Martínez-Cava, A., & Izquierdo, M. (2022). Impact of tailored multicomponent exercise for preventing weakness and falls on nursing home residents' functional capacity. *Journal of the American Medical Directors Association*, 23(1), 98-104.

METHODS: A cohort of institutionalized elderly women ($n=91$, 85 ± 7 years old, 25.5 ± 5.2 kg/m²) underwent a series of assessments including handgrip dynamometry, Barthel Index, arm curl, one-leg stance (left and right), Timed Up and Go (TUG), and the 30-second sit to stand test (30s STS). Statistical analyses, including correlation and regression, were performed to explore the relationships between the Barthel Index scores and the physical performance metrics. This study was approved by the institutional ethic committee. The statistical analysis was conducted with Jamovi software.

RESULTS: Significant correlations were found between the Barthel Index and handgrip strength ($r=0.40$, $p<0.001$), arm curl performance ($r=0.21$, $p<0.04$), and 30s STS ($r=0.40$, $p<0.001$). The one-leg stance test revealed weaker but statistically significant associations with Barthel Index (left leg: $r=0.27$, $p<0.009$; right leg: $r=0.28$, $p<0.007$). TUG times were significantly inverse correlated with Barthel scores ($r=-0.46$, $p<0.001$); as functional ability improved, mobility times decreased. The regression model accounted for 55% of the variance in Barthel scores based on performance in these tests ($F(5,94) = 12.3$, $p<0.001$).

CONCLUSION: The findings indicate that higher functional independence, as assessed by the Barthel Index, is positively associated with handgrip strength, arm curl, and sit-to-stand test performance while inversely related to TUG times. These results underline the importance of incorporating strength and mobility serial assessments to enhance care strategies for institutionalized elderly women, aiming to reduce risks of falling and promote functional independence. Future studies should explore intervention strategies focused on improving these physical capabilities to enhance overall quality of life in this vulnerable population.

CARDIOVASCULAR ADAPTATION AND RECOVERY DYNAMICS IN ADULTS: INSIGHTS FROM PULSE WAVE ANALYSIS AND POST-EXERCISE HEMODYNAMIC RESPONSES

MENG, Y., SU, H.

BEIJING SPORT UNIVERSITY

INTRODUCTION: Cardiovascular adaptability and post-exercise recovery are critical indicators of metabolic and vascular health, yet their interplay with age, gender, and body composition remains underexplored. This study investigates hemodynamic and vascular stiffness parameters in adults to evaluate how exercise impacts cardiovascular resilience and recovery, with implications for personalized health interventions.

METHODS: A cross-sectional analysis was conducted on 350 participants (aged 33–87 years, 62% female). Key metrics included resting heart rate (HR), systolic/diastolic blood pressure (SBP/DBP), pulse wave velocity (PWV), ankle-brachial

index (ABI), and BMI. Post-exercise recovery HR, vascular stiffness (classified as normal, moderately stiff, or stiff), and 3-minute HR recovery were measured. Data were analyzed using descriptive statistics and ANOVA for age/gender stratification.

RESULTS: 1.Vascular Stiffness: 42% of participants exhibited elevated vascular stiffness (PWV >1400 cm/s), with higher prevalence in males (55%) and those aged >60 (68%).

2.Recovery Dynamics: Post-exercise HR recovery lagged in older adults (Δ HR: -28 bpm vs. -42 bpm in <50-year-olds, $p < 0.01$).

3.Body Composition: Higher BMI (>28) correlated with increased vascular stiffness (OR=2.1, $p=0.003$) and delayed DBP normalization.

4.Gender Differences: Females showed lower resting HR (72 ± 11 vs. 78 ± 14 bpm, $p=0.02$) but comparable PWV values to males.

CONCLUSION: Age and body composition significantly influence vascular stiffness and post-exercise recovery, highlighting the need for age-tailored exercise regimens. Elevated PWV in older adults underscores the role of vascular health in exercise tolerance. Gender-specific differences in HR dynamics suggest divergent cardiovascular adaptation mechanisms. These findings advocate for integrating vascular stiffness metrics into routine fitness assessments to optimize exercise prescriptions and mitigate cardiovascular risks. Limitations include potential confounding factors (e.g., undiagnosed vascular calcification) and incomplete recovery data in select cases.

CP-MH17 Physical Activity / Inactivity and Mental Disabilities

HIGH ADHERENCE TO 24-HOUR MOVEMENT GUIDELINES ASSOCIATED WITH BETTER DIET QUALITY IN MULTI-DISCIPLINARY FOOTBALL STAFF

COOPE, O., SPURR, T., JORDÁN-FISAS, E., LEVINGTON, A., LLOYD, B., ROMAN-VIÑAS, B.

UNIVERSITY RAMON LLULL

INTRODUCTION: Support staff in elite sports face similar stressors as athletes, yet their health behaviours remain under-researched. Studies suggest their well-being impacts team success (1). Understanding whether they meet the health recommendations they advocate for players is crucial. This study examines the association between adherence to 24-hour movement (24HM) guidelines and diet quality (DQ) among football sports staff, a group affected by irregular schedules and high-pressure environments.

METHODS: 120 male ($n = 73$) and female ($n = 47$) members of staff in England ($n = 65$) and Spain ($n = 55$) in competitive-elite football enrolled by invitation (age: 33.1 ± 9.3 years, height: 174.2 ± 9.1 cm, mass: 75.1 ± 14.9 kg). 24HM adherence is established by the Canadian 24-hour Movement Guidelines (2). Partial adherence is set at >150min of moderate-to-vigorous physical activity (MVPA) per week, >3h of light physical activity (LPA), <8h of sedentary behaviour (SB) per day and >7h of sleep per night. Total adherence includes the above criteria plus 2 sessions of resistance training per week (RT), movement if sedentary for >1h (SM), consistent bed and wake-up time (BWT) and <3h of screen time (ST) per day. The validated Mini-EAT dietary screener was used to evaluate DQ (3) and calculates a summary score. Bootstrap resampling with logistic regression was used to estimate confidence intervals for the odds ratio of the effect of DQ on 24HM adherence, with Spearman correlation to assess the relationship between 24HM adherence and DQ. ANOVA and Tukey's HSD were used to examine the influence of descriptive factors on 24HM adherence. The trial is open between January 15th to March 15th and a minimum of 229 participants will be enrolled upon closing.

RESULTS: Preliminary results show 37.5% of participants meet partial adherence to 24HM, with 10% of participants achieving total adherence. Improved DQ is positively associated with a 10.3% increase in the odds of meeting total 24HM adherence criteria (OR = 1.103, 95% CI: 1.003–1.264) and a 4.1% increase in partial adherence of 24HM, but with non-significant 95% CI (0.986–1.094). Higher DQ is significantly associated with adherence to guidelines for MVPA (OR = 1.1 [1.043, 1.162], $p = 0.0002$), RT (OR = 1.15 [1.083–1.231], $p = 0.0001$) and SM (OR 1.065 [1.008–1.137], $p = 0.03$). Job type was significantly associated with total adherence to 24HM ($p = 0.005$), with notable differences between Performance Nutritionists and both Head Coaches ($p = 0.03$) and Goalkeeping Coaches ($p = 0.02$).

CONCLUSION: Total adherence to 24-hour movement guidelines is associated with better diet quality in multi-disciplinary football staff, notably when staff follow the guidelines for MVPA, RT and SM.

SOCIOECONOMIC FACTORS, PHYSICAL ACTIVITY, AND SEDENTARY BEHAVIOUR AMONG AUTISTIC ADULTS AGED 40–70 YEARS: EVIDENCE FROM THE UK BIOBANK

FENG, Y., HOU, X., CAO, M.

GUANGZHOU SPORT UNIVERSITY

INTRODUCTION: Autism is a neurodevelopmental condition marked by social impairments and repetitive behaviour. Research shows autistic individuals tend to have lower physical activity (PA) and higher sedentary behaviour (ST), increasing the risk of chronic diseases. Understanding the sociodemographic factors affecting PA and ST is crucial for developing targeted health promotion strategies to enhance the health and well-being of autistic adults.

METHODS: Using the UK Biobank database, this study included 408 autistic individuals diagnosed by professional institutions. Baseline data were analysed, focusing on sociodemographic factors such as sex, ethnicity, education, family income, housing ownership, residential population, and employment status. Sedentary behaviour was measured by screen time (TV and computer use) and total sedentary time (including screen time and driving). PA was assessed through frequency and volume, with total PA level as an outcome. Logistic regression models were used to examine the associations between sociodemographic factors and PA and ST outcomes.

RESULTS: Male participants were more likely than females to have longer screen time per day (≥ 4 hours: OR 1.08, 95% CI: 1.08–3.29, compared with ≤ 2 hours) and more total ST time per day (≥ 5 hours: OR 2.14, 95% CI: 1.26–3.61, 3–5 hours: OR 2.07, 95% CI: 1.23–3.50, compared with < 3 hours). Males were also less likely to meet the recommended PA levels (≥ 150 minutes of moderate PA or 75 minutes of vigorous PA per week: OR 2.36, 95% CI: 1.25–4.46), but had lower walking frequency (> 3 days/week: OR 0.52, 95% CI: 0.28–0.96). Compared with individuals with a bachelors degree, those with lower education levels had more total ST time per day (≥ 5 hours: OR 1.82, 95% CI: 1.07–3.09) and were more likely to meet the ≥ 3 days of moderate PA per week (OR 1.78, 95% CI: 1.14–2.78). Individuals with family incomes below £31,000 per year had increased screen time per day (≥ 4 hours: OR 4.35, 95% CI: 1.08–17.56, compared with < 2 hours) relative to those with incomes above £100,000. Employment or self-employment was associated with lower screen time (≥ 4 hours/day: OR 0.36, 95% CI: 0.19–0.70) and a higher likelihood of engaging in moderate PA (OR 2.94, 95% CI: 1.59–5.42) compared with unemployed or retired individuals.

CONCLUSION: Gender, education level, family income, and employment status are linked to sedentary time (ST) and physical activity (PA) in autistic adults. Males, those with lower income or education, and the unemployed or retired tend to have higher ST and lower PA. These findings underline the importance of targeted health interventions for autistic individuals, particularly those from disadvantaged backgrounds. Public health initiatives should focus on promoting PA and reducing sedentary behaviour, especially in autistic males and those with lower socioeconomic status.

CARDIORESPIRATORY FITNESS AND CAROTID INTIMA-MEDIA THICKNESS IN ADULTS WITH AND WITHOUT DOWN SYNDROME

OVIEDO, G., CARBÓ-CARRETÉ, M., JAVIERRE, C.

MISSISSIPPI STATE UNIVERSITY; UNIVERSITAT DE BARCELONA

INTRODUCTION: Adults with Down syndrome (DS) present different clinical characteristics that may influence their cardiorespiratory fitness and cardiovascular health. Carotid intima-media thickness (cIMT) is an established cardiovascular risk marker that has not been sufficiently studied in this population. Therefore, we aimed to describe and compare the cIMT values in adults with and without DS (Non-DS). We also examined the relationship between cardiorespiratory fitness and cIMT.

METHODS: Sixteen adult males with DS (29 ± 6 yrs) and 16 Non-DS males (28 ± 5 yrs) participated in this study. An informed consent and a health screening questionnaire were completed by each participant and/or legal guardian. We assess height, weight, maximum oxygen consumption (VO_2 peak) during a metabolic treadmill test; systolic blood pressure (SBP), and diastolic blood pressure (DBP). The right common carotid artery was imaged longitudinally 1 to 2 cm upstream of the bifurcation using a 6.0 to 13.0 MHz linear array transducer (GE L6-12-RS, GE Medical Systems, Horton, Norway). After familiarization, participants rested lying for 5–10 minutes before the measurements were taken. The cIMT was obtained using specific software (Cardiovascular Suite, Quipu, Pisa, Italy) and ultrasound (LogiqV2, GE Medical Systems, Horton, Norway) measurements.

Descriptive data were obtained for all variables. After checking the normality of the data (Shapiro-Wilk test), we used independent t-tests to check the differences between groups. Person's correlation was used to evaluate associations between VO_2 and cIMT. Statistical significance was defined as a two-sided p-value $< .05$.

RESULTS: Non-DS participants were taller (1.75 ± 0.77 vs. 1.58 ± 0.70 m) and heavier (73.92 ± 10.21 vs. 67.98 ± 9.16 kg) than the DS group (all $p < .05$). Not statistical differences between groups were observed for BMI; SBP and DBP.

Relative and absolute VO_2 peaks were significantly higher in the Non-DS group (46.10 ± 6.95 vs. 29.43 ± 7.62 ml/kg/min; 3.34 ± 0.54 vs. 2.02 ± 0.49 L/min; all $p < .01$).

The cIMT in the DS group was significantly higher than the Non-DS group (0.59 ± 0.12 vs. 0.46 ± 0.07 mm; $p < .01$). A negative correlation between absolute VO_2 peak and cIMT was found in the DS group ($r = -0.54$; $p = .03$).

CONCLUSION: Adults with DS exhibited significantly higher cIMT compared to their Non-DS counterparts, suggesting an increased cardiovascular risk in this population. Despite similar BMI values between groups, individuals with DS demonstrated markedly lower cardiorespiratory fitness. Additionally, a significant negative correlation between absolute VO_2

peak and cIMT in the DS group suggests that higher cardiorespiratory fitness may be associated with better vascular health. These findings emphasize the importance of promoting physical fitness interventions to increase cardiorespiratory fitness among adults with DS and potentially mitigate cardiovascular risks.

TOTAL BRAIN AND HIPPOCAMPAL VOLUME ARE ASSOCIATED WITH METABOLIC ADAPTATION TO AEROBIC EXERCISE

OHAYON, R., KNAAN, T., ZIV-AV, E., DUBNOV-RAZ, G., MELANSON, E., GEPNER, Y.

TEL AVIV UNIVERSITY, UNIVERSITY OF COLORADO, UNIVERSITY OF COLORADO ANSCHUTZ MEDICAL CAMPUS

INTRODUCTION: Exercise training intervention studies have shown that total daily energy expenditure (TDEE) increases are less than expected, and consequently, less weight loss than predicted occurs [1,2]. However, the physiological mechanisms for exercise-induced metabolic adaptation (MA) remain unclear. This sub-study investigated changes in total brain volume (TBV) and hippocampal volume (HV) and their relationship to MA following aerobic exercise.

METHODS: Sixteen participants with overweight (BMI 25–30 kg/m²), aged 21–45 years (8 men, 8 women), completed a 12-week supervised aerobic exercise intervention of moderate-intensity walking (65–75% of maximal heart rate) of 20 kcal/kg/week. Participants exercised 3 to 5 times per week, with the total energy expenditure tailored to individual needs. Resting metabolic rate (RMR) changes were measured using whole-room indirect calorimetry, and TDEE and body composition were assessed using doubly labelled water. TBV and HV were evaluated using 3-Tesla magnetic resonance imaging. MA was determined by comparing observed and predicted post-intervention TDEE and RMR. Pearson correlations were used to examine relationships between brain volume changes and MA and t-tests were used to determine changes over time.

RESULTS: Following 12 weeks of aerobic exercise with a 95.4% ± 8.2% adherence rate, no significant changes were found at the group level in body weight (-0.2 ± 1.9 kg) or in TDEE per fat-free mass (-2.9 ± 4.8). However, a significant MA in RMR (-87 ± 118 kcal, $p = 0.019$) was observed. TBV (0.0003 ± 0.008) and HV (0.007 ± 0.04) did not change significantly. Yet, at baseline, a strong positive correlation found at baseline between TDEE and TBV ($r = 0.78$, $p < 0.000$) and RMR and TBV ($r = 0.71$, $p = 0.003$) persisted post-intervention ($r = 0.59$, $p = 0.026$ for TDEE; $r = 0.62$, $p = 0.025$ for RMR). Additionally, changes in TBV were positively correlated with MA in TDEE ($r = 0.605$, $P = 0.022$), and changes in right HV correlated positively with MA in RMR ($r = 0.660$, $p = 0.019$).

CONCLUSION: This study suggests that brain volume, particularly TBV and HV, is associated with MA in response to moderate-intensity aerobic exercise training. Individual differences in brain structure may influence energy expenditure responses, warranting further research on neurobiological mechanisms.

PHYSICAL FITNESS AND ACADEMIC PATHWAYS: IS THERE A RELATIONSHIP? OBSERVATIONAL EXPLORATORY STUDY.

MARIN, L., VANDONI, M., PIRAZZI, A., RE, F., CORTESE, L., VIGO, A., CAVALLO, C., PATANÈ, P.

UNIVERSITY OF PAVIA

INTRODUCTION: Despite the widely recognized benefits of physical activity on health and well-being, studies highlight a significant decline in exercise participation and an increase in sedentary behaviors during university years. However, differences in physical fitness among students from different academic programs remain largely unexplored.

METHODS: Forty-five university students (age, 22.62 ± 2.82; 26 Female) were enrolled and divided into three groups of 15, based on their degree program: Motor Science (MS), which includes courses based on the practice of physical activity, Psychiatric Rehabilitation Therapy (TERP) and Physiotherapy (PT), which do not have any. Assessments were done in May 2024 at the University of Pavia with two standardized test batteries: the Alpha-Fit Test Battery and the Health Assessment Battery. These tools enabled the evaluation of the follow functional capacities: aerobic fitness, 6-Minute Walking Test (6MWT), 2 km Walking Test (2KMWT); muscular strength, 30-Second Push-Up Test, Modified Push-Up Test, 30-Second Sit-Up Test, Dynamic Sit-Up Test; muscular power, standing Broad Jump (SBJ), Jump and Reach; flexibility, Sit and Reach Test, Shoulder-Neck Flexibility Test; balance, One-Leg Stand Test. Statistical analysis was performed using SPSS software. One-way ANOVA or the Kruskal-Wallis test were applied, depending on data distribution. A statistical significance threshold of $p < 0.05$ was set. Post hoc comparisons were conducted to identify significant differences between groups.

RESULTS: Compared to PT and TERP, MS showed superior performance in aerobic fitness (2KMWT, $p = 0.011$), muscular strength (30-second sit-up, $p < 0.001$; 30-second push-up, $p = 0.012$; modified push-up, $p < 0.001$; dynamic sit-up, $p = 0.043$) and power (SBJ, $p = 0.002$; jump and reach, $p < 0.001$). Balance was significantly better in MS compared to PT ($p = 0.004$); whereas no significant differences emerged between MS and TERP. Flexibility results showed no significant differences among groups. The comparison between TERP and PT showed no significant differences in any of the outcomes.

CONCLUSION: This study underscores the impact of academic pathway on physical fitness of the university students. Despite the small sample, the observed differences suggest that curricular physical activity levels may play a crucial role in shaping physical fitness.

Future research should explore the long-term implications of these findings and investigate targeted interventions to improve the physical fitness of university students regardless of their academic background.

DISTINCT EFFECTS OF LONG-TERM RESISTANCE EXERCISE ON ALZHEIMERS DISEASE-RELATED COGNITIVE DEFICITS, NEUROTROPHINS, AND AMYLOID PATHOLOGY IN APP/PS1 MICE

LONGO, B., AZEVEDO, C., CAMPOS, H., FIGUEIREDO, E., OTAVIANO, S., PEREIRA, A., ALVES, L., BRAGA, M., GIMENES, C., BOLDARINE, V., OYAMA, L., PENITENTE, A., FERREIRA, S., ARIDA, R.

FEDERAL UNIVERSITY OF SAO PAULO - UNIFESP

INTRODUCTION: Alzheimers disease (AD), the leading cause of dementia in the elderly, is marked by cognitive deficits, memory loss, and vascular dysfunction, with amyloid-beta (A β) accumulation and metabolic changes contributing to neuronal impairment. Women face a higher risk of AD due to hormonal, metabolic, and immune differences. Sarcopenia, characterized by muscle loss and cognitive decline, exacerbates aging and dementia. Physical exercise offers preventive and therapeutic benefits, improving cognition, metabolism, and reducing A β accumulation, as shown in humans and animal models. Resistance exercise (RE), recognized for its role in combating sarcopenia and enhancing muscle, strength, and bone health, also supports neuroplasticity and cognitive function. However, the long-term effects of RE on AD and sex-specific responses remain underexplored.

METHODS: Our study aimed to evaluate how long-term 4-month RE influences behavior, neurotrophic factor levels and amyloid pathology in males and females, exploring distinct sex differences in response to RE. We utilized 6-month-old double-transgenic APP/PS1 and wild-type control mice of both sexes, divided into sedentary and RE groups. The RE protocol involved climbing a 110 cm ladder with progressive loads 3x week. Behavioral assessments included the Open Field (locomotor activity), Object Recognition (short-term memory), and T-Maze (spatial long-term memory) tests. Brain VEGF, IGF-1, BDNF and A β levels were measured via ELISA, while A β plaques were quantified in hippocampal sections. Data were analyzed using appropriate statistical tests to evaluate the effects of RE on cognitive performance, neurotrophic factors, and amyloid pathology.

RESULTS: The results showed positive effects of long-term RE in modulating cognitive deficits, locomotor activity, trophic factor levels, and amyloid pathology in APP/PS1 mice, with distinct improvements observed in males and females. In APP/PS1 females, RE reduced hyperlocomotion, rescued short-term memory, increased VEGF levels, and reduced brain A β levels and amyloid plaque density, showing a robust neuroprotective effect. In APP/PS1 males, RE also showed beneficial effects by reducing hyperlocomotion, recovering long-term memory, and increasing IGF-1 and BDNF levels, suggesting a positive impact of RE on cognitive performance and neurotrophic levels associated with brain plasticity.

CONCLUSION: Our findings indicate that males and females have distinct behavioral and biological responses to RE and suggest that, despite identical initial age, sedentary female APP/PS1 mice exhibit a more advanced progression of the disease compared to males. These findings contribute to a deeper understanding of the behavioral and molecular impacts of RE as an alternative exercise strategy for delaying AD progression, emphasizing the importance of sex differences. These results provide insights into the potential of RE as a tool to investigate differences between sexes in response to interventions for AD conditions.

THE EFFECTS OF PHYSICAL EXERCISE ON COGNITIVE AND LANGUAGE FUNCTIONS IN ADULTS WITH DOWN SYNDROME

FISCHER, M., HERMSDÖRFER, J., LEVIN, J.

LMU KLINIKUM MUNICH

INTRODUCTION: Individuals with Down Syndrome (DS) demonstrate significantly lower levels of physical exercise (PE) compared to the general population 1, which contributes to an increased risk of associated lifestyle-related diseases 2. Moreover, individuals with DS exhibit cognitive decline as early as their 50s and are at an elevated risk for developing Alzheimers disease (AD) 3. Research suggests that endurance and coordination training can positively influence cognitive functions across the lifespan and may also contribute to lifestyle-based prevention measures for AD 4,5. Despite these risks, structured PE programs tailored to DS individuals remain largely absent.

The "DS in Motion" project is an innovative approach to addressing this gap by investigating the effects of a structured PE program on language, cognitive, and motor functions in adults with DS. Additionally, it aims to foster an active lifestyle, ultimately supporting quality of life and independence.

METHODS: This randomized controlled trial utilizes a six-week structured exercise intervention based on four pillars: (1) a sport program focusing on endurance, strength, and coordination; (2) educational awareness to enhance intrinsic motivation; (3) empowerment strategies to encourage long-term PE; and (4) a "train-the-trainer" module for caregivers and trainers, aimed at creating external framework conditions to ensure the long-term implementation of an active lifestyle. Adult participants with DS are recruited and undergo pre-, post-, and follow-up assessments. Language, cognitive, and motor functions, body composition, and movement behavior are assessed.

RESULTS: The project is ongoing, with preliminary data analysis in progress. Initial subjective feedback from participants suggests increased self-perceived attentiveness in daily life, fewer complaints about back pain, and an overall improvement in fitness levels.

CONCLUSION: The objective of this project is to contribute to lifestyle-based prevention measures for AD while also promoting well-being and independence throughout life. The "DS in Motion" project represents a novel approach to address-

ing the cognitive and physical health challenges in adults with DS. The project aims to enhance PE engagement to support cognitive, motor, and language functions, as well as overall well-being. To this end, it implements a structured PE program within care facilities and community groups.

PERCEPTION AND AWARENESS OF MUSCLE POWER DEVELOPMENT IN GENERAL POPULATION

DI LASCIO, G., ALIBERTI, S., RAIOLA, G.

UNIVERSITY OF VERONA

INTRODUCTION: Muscular Power, defined as the product of force and velocity, is a key element in mental and physical well-being, as it is closely related to the efficiency of the human body. With advancing age, power output tends to decline, necessitating the use of exercise programs. However, few studies exist in the literature on power development in the non-athlete population. There is a lack of research examining the influence of opinion and perception, as well as knowledge, on the effectiveness of physical exercise protocols for power development for health and well-being. In addition, there are no apparent studies that relate power development to perception, opinion, and awareness of the benefits obtained.

the objective of the study is to evaluate the effectiveness of the physical exercise protocol for power development for general population in relation to participants perceptions and opinions. In addition, it aims to identify the connection between power development with the usefulness of such an physical exercise protocol to provide awareness about the benefits of power development.

METHODS: Fourteen participants (12 males, 2 females, ages 16-45 years) with no experience in power training were involved. The protocol included specific exercises three times a week for 12 weeks. The Counter Movement Jump test (CMJ) and a fatigue perception and awareness questionnaire were administered at the beginning, after 6 weeks, and at the end of the course. Statistical analysis was conducted by ANOVA for repeated measures and Friedmans test.

RESULTS: ANOVA showed significant differences between Pre, In-litinerary and Post measurements for both CMJ height and power output. ANOVA for repeated measures found significant change in CMJ jump height ($p=0.013$) and power output ($p=0.034$), suggesting progressive improvement over time. Direct comparison between Pre and Post by t-test for dependent samples confirmed a significant increase in both variables. CMJ height increased significantly ($p<0.0001$), as did power output ($p<0.0001$). In addition, Friedmans test showed significant changes in perceived physical ability ($p<0.0001$), reduction in perceived fatigue ($p<0.0001$), and awareness of the benefits of power ($p<0.0001$).

CONCLUSION: The exercise protocol proved effective not only in increasing muscle power, but also in improving subjective perception of ones abilities and awareness of the benefits of developing muscle power. These results highlight the value of power training as a tool for improving mental and physical well-being in the general population.

INTERNATIONAL CONSENSUS ON THE DEFINITION OF FUNCTIONAL TRAINING: MODIFIED E-DELPHI METHOD

PEREIRA, H., TEIXEIRA, D.S., FISHER, J., FLECK, S.J., HELMS, E., IDE, B.N., IZQUIERDO, M., NEDERGAARD, A., PHILIPS, S., PINTO, R.S., PLOTKIN, D.L., TURNER, A.N., SCHOENFELD, B.J.

FACULDADE DE EDUCAÇÃO FÍSICA E DESPORTO - UNIVERSIDADE LUSOFONA

INTRODUCTION: The inconsistency and disparities in existing functional training definitions have led to confusion when explaining the concept and its potential. The wide range of interpretations suggests that any training approach could be deemed functional, thereby diminishing the significance of the term and significantly limiting its understanding and application. Thus, this paper aimed to develop the first consensual definition of functional training using an international e-Delphi method.

METHODS: From a panel of 31 experts initially selected, 13 participated in the consensus.

RESULTS: The panel presented the following definition: "Functional training is a physical interventional approach that contributes to the enhancement of human performance, according to individual goals, in sports, daily life, rehabilitation, or fitness, and takes into consideration the specificity of the task and the unique responsiveness of each individual."

CONCLUSION: However, redundancy of the functional training definition emerged as a relevant consideration for this conceptual and methodological advancement, and a proposal to avoid the distinction between functional training and the general concept of training was presented (i.e., no real use of functional training as a concept). It was proposed that a training program or regimen could be analyzed based on a continuum of functionality, which could support further developments in this topic.

RELATIONSHIPS BETWEEN NEURO-MUSCULAR AND PHYSICAL FITNESS PARAMETERS IN BASKETBALL PLAYERS WITH INTELLECTUAL DISABILITIES

DE DONATO, S., CAVAGGIONI, L., FORMENTI, D., MANENTE, A., CANTON, S., CASALINI, L., GRANITO, F., MAGRO, C., LOVECCHIO, N., CASTIGLIONI, P., MERATI, G.

UNIVERSITY OF INSUBRIA

INTRODUCTION: Individuals with intellectual disabilities (ID) often exhibit lower physical fitness levels compared to their neurotypical peers, leading to negative health outcomes and a reduced quality of life (1). Limited motor control, higher obesity rates, and restricted access to sports activities further exacerbate this disparity (2). This study aims to analyse the relationship between neuro-muscular and physical fitness parameters in basketball players with ID, to provide valuable data for designing targeted intervention strategies.

METHODS: A total of 26 basketball players with ID (age 28.7 ± 9.6 yrs; body mass 77.8 ± 2.4 kg; height 1.72 ± 0.10 m, $m \pm SD$) were assessed during a tournament organized by the Italian Federation of Paralympic Sports for Intellectual and Relational Disabilities (FISDIR). Anthropometric data (e.g., weight, height, circumferences, and skinfold thickness), strength tests (handgrip), static balance, lower-limb explosiveness (countermovement jump, CMJ), and clinical reaction time (CRT) were collected. Statistical analyses were performed using linear regression models (with Pearson's correlation coefficients calculation). The significance level was set at $p < 0.05$.

RESULTS: Higher body fat percentage was associated with lower jump height ($r = -0.40$, $p = 0.04$) and slower reaction times ($r = -0.48$, $p = 0.01$), consistent with previous research on neuromuscular efficiency in individuals with ID (3). Greater handgrip strength correlated with faster reaction times ($r = -0.41$, $p = 0.04$), underscoring the role of strength training in cognitive-motor integration (4). Additionally, BMI negatively impacted on postural balance, increasing centre-of-pressure oscillations, which aligns with findings on vestibular deficits in individuals with ID (5).

CONCLUSION: These results highlight the importance of structured training programs to reduce body fat and improve strength and coordination in individuals with ID. Considering the early onset of cardio-metabolic risks within this population, tailored interventions should be prioritized. However, future studies should aim to explore the causal relationships between training and motor skill improvements in this particular population.

VARIATIONS IN CHILDRENS SOCIAL AND EMOTIONAL SKILLS SCORES BY PHYSICAL ACTIVITY LEVEL: A PROPOSAL FOR A SHORT OECD SOCIAL AND EMOTIONAL SKILLS SCALE

NAKANO, T., SAKAI, T., MURAYAMA, T., OYAMA, Y., SAKAGUCHI, Y., KAMEOKA, M.

CHUKYO UNIVERSITY

INTRODUCTION: Childrens physical activity has various educational effects and improves physical fitness and health. However, children have lost interest in physical activity, and video games are the most popular form of play. Regarding educational effects, non-cognitive and cognitive skills have been emphasized recently. This also applies to physical activity. Non-cognitive skills are called social and emotional skills (SES) by the Organization for Economic Co-operation and Development (OECD), and the research results of an international comparison have recently been published. However, Japan has not participated in this survey. Therefore, there is a lack of understanding of the current situation in Japanese childrens SES, including the importance of SES as an educational effect. Thus, this study aimed to construct and validate the OECD SES scale short version and to examine the relationship between SES scores and elementary school childrens physical activity habits.

METHODS: A questionnaire comprising four items related to physical activity habits (physical activity preference, physical activity time [weekdays or weekends], number of friends to play with) and a 45-item SES scale—short version—was administered to 2223 elementary school children in Grades 4–6. The OECD SES Scale comprises 120 items, and 15 sub-factors have been identified by factor analysis (OECD, 2021). Considering the survey burden on children, we created a short version with 45 items by selecting the top three items representing each factor from the published factor analysis results. We then applied factor analysis to the collected data and confirmed that the SES scale short version retains the same simple structure with 15 factors as the OECDs original dataset. A one-way ANOVA was conducted to examine the differences in each factor score and the composite score of the 45 items (SES total) based on childrens physical activity habits.

RESULTS: Factor analysis was applied to the SES Short version data, and a simple structure of 15 factors was confirmed. The total variance explained was 63.0%, and high-reliability coefficients were confirmed for all aspects. Significant differences in SES Total scores were confirmed for all items about physical activity habits. Children with better physical activity scored significantly higher for all factors except creativity and responsibility.

CONCLUSION: The short version of the SES scale was proposed to assess SES adequately. The SES total score was higher for children with better physical activity habits, and many subfactor scores were also significantly higher. This suggests that children's physical activity is effective in increasing their SES. Conversely, because no significant differences were found in the creativity and responsibility factors, the effect of physical activity on these factors appears to be minimal.

THE IMPACT OF SPORT-ORIENTED SCHOOL CURRICULUM ON COGNITIVE AND MOTOR PERFORMANCE IN HIGH SCHOOL STUDENTS: A PILOT STUDY

ROMANAZZI, M., CAZZOLI, S., LATINO, M., LUCHESE, G., AGOSTINO, S., ABATE DAGA, F., BALLABIO, K.

UNIVERSITY OF TURIN

INTRODUCTION: Scientific literature agrees that regular participation in structured sports activities during school benefits academic performance (1). However, Italian students remain reluctant to engage in regular physical activity. According to ISTAT, in 2021, continuous sports participation among 3-17-year-olds dropped from 51.3% to 36.2%, while sedentary behavior increased from 22.3% to 27.2% (2). Despite this decline, studies emphasize the positive impact of sports on academic success, particularly team sports, which foster discipline, time management, and dedication—skills that enhance both school performance and daily life (3). However, uncertainties remain regarding the specific effects of school curriculum and sport participation. For this reason, the present study aims to analyse high school students' profiles, comparing sport-oriented high school curriculum versus traditional curriculum ones on motor and cognitive attributes.

METHODS: 50 high school students attending 11th grade of the Italian school system (60% boys and 40% girls,) were recruited for this study. Each participant was assigned to Sport-Oriented (SOG) or Traditional (TRG) group according to the personal school curriculum. All participants must declare to practice at least a sport discipline to be involved in the study. All parents approved their attendance at this study by signing informed consent. Physical fitness was assessed with the Leger Multistage Fitness Test (aerobic fitness), 10m and 30m sprints (speed), CMJ (lower-body strength) and Reactive Agility Test (RAT) for reaction and agility. At the same time, cognitive performance was evaluated with computerized and validated battery of specific cognitive tests (3).

RESULTS: No significant differences were detected in motor profile evaluation ($p > 0.05$) except for RAT ($p < 0.05$) in favour of SOG. In addition, a trend to significance ($p = 0.061$) was detected in aerobic fitness in favour of SOG. Cognitive profile analysis underlines a significant correlation in favour of SOG for "search and selection" ($p < 0.05$), working memory ($p < 0.01$), attention distribution ($p < 0.01$) and attention shifting ($p < 0.01$).

CONCLUSION: Sport-oriented high school students showed better cognitive performance in working memory, attention distribution, and cognitive flexibility. Motor differences were minimal, except for superior reactive agility and a trend towards better aerobic fitness. These findings suggest that a sport-focused curriculum may contribute to enhanced cognitive abilities, likely due to the combination of structured physical activity and the skills promoted through sports participation. Further research is needed to explore the long-term effects of such curricula on both academic and personal development.

A COMPARATIVE STUDY OF EXERCISE HABITS AND PHYSICAL FITNESS AMONG PRESCHOOL CHILDREN IN JAPAN AND KOREA

MIJIN, K.

SAITAMA JUNSHIN COLLEGE

INTRODUCTION: In Japan and Korea, concerns have been raised about both declining physical fitness among children and the polarization of exercise habits. The gap between children who regularly engage in physical activities and those who rarely do so is widening, a trend that becomes apparent from early childhood. While exercise habits of preschool children in both countries likely differ due to variations in childcare systems and lifestyle patterns, few studies have compared the relationship between exercise habit polarization and physical fitness. Examining this relationship across both countries could provide important insights for establishing effective exercise support measures. This study aimed to investigate the actual conditions of exercise habit polarization among preschool children in both countries and clarify its relationship with physical fitness.

METHODS: The subjects were 232 Japanese children (118 boys, 114 girls, mean age 4.12 ± 0.8 years) and 245 Korean children (120 boys, 125 girls, mean age 3.93 ± 0.8 years) aged 3-5 years. Parents completed questionnaires about their children's regular exercise activities and types of exercise. Physical fitness was assessed using the MKS Preschool Physical

Fitness Test, which included six items: 25m sprint, standing long jump, tennis ball throw, continuous jumping, body support duration, and ball catching. Based on the MKS test evaluation criteria, average scores were calculated and classified into three groups (high, average, low) for analysis with exercise habits.

RESULTS: Results showed that in Japan, 54.2% of 3-year-olds, 59.0% of 4-year-olds, and 78.6% of 5-year-olds regularly exercised ($p < 0.01$). In Korea, 6.9% of 3-year-olds, 24.1% of 4-year-olds, and 37.5% of 5-year-olds regularly exercised ($p < 0.001$). The most common activities in Japan were swimming, gymnastics, and sports club activities, while in Korea, they were Taekwondo and swimming. Regarding the relationship between exercise habits and physical fitness items, Japanese children showed significant correlations in five test items: 25m sprint ($p < 0.01$), tennis ball throw ($p < 0.001$), continuous jumping ($p < 0.05$), body support duration ($p < 0.01$), and standing long jump ($p < 0.01$). Children who exercised regularly demonstrated higher fitness scores in all categories except ball catching. In Korea, only the standing long jump showed a significant correlation with exercise habits ($p < 0.01$).

CONCLUSION: While the proportion of Japanese children with exercise habits increased markedly with age, Korean children showed a lower overall rate of regular exercise, with less than 40% participating even at age 5. The significantly higher physical fitness scores among children with regular exercise habits suggest that regular physical activity has broad effects on the development of basic motor skills during early childhood. Further longitudinal studies considering qualitative differences in exercise habits and cultural-social backgrounds are needed to verify these effects.

COMPARING PHYSICAL ACTIVITY, PHYSICAL FITNESS AND MOTOR SKILLS ACROSS DIFFERENT ORGANISED AND NON-ORGANISED PROFILES IN CHILDREN AGED 3–13

LUUKKAINEN, N., SÄÄKSLAHTI, A., CÔTÉ, J., TOLVANEN, A., NIEMISTÖ, D., SARKKINEN, E., LAUKKANEN, A.
UNIVERSITY OF JYVÄSKYLÄ

INTRODUCTION: Children's levels and types of physical activity vary individually and across different ages. This study aims to examine the profiles of organised sports participation and non-organised outdoor time among children aged 3–13 years. Additionally, the study explores how these profiles are associated with differences in physical activity, physical fitness, and motor skills.

METHODS: The study involved 1,115 Finnish children (50.0% girls), aged 3 to 13 years. They were assessed three times—T1 (3–7 years), T2 (6–11 years), and T3 (9–13 years)—between 2015 and 2023. The goal was to connect their participation in physical activities with their fitness and motor skills outcomes. The participation rate in sports and outdoor time on weekdays and weekends was queried via a parental questionnaire at all time points. We created profiles based on the patterns of organised sports participation and outdoor time using the latent class analysis (LCA) conducted with Mplus statistical software. LCA was conducted to identify distinct profiles, which were subsequently compared in terms of physical activity (T2, T3), physical fitness (T3), and motor skills (T1, T2). Physical activity was measured with accelerometers, and a 20-meter shuttle run test assessed physical fitness and push-ups in 60s. Motor skills were evaluated using a shortened version of the Test of Gross Motor Development – 3rd edition (TGMD-3), including locomotor skills (hopping, skipping), and object control skills (one-hand stationary dribbling, overhand throwing). Missing data was assumed to be missing at random.

RESULTS: LCA identified four distinct participation patterns: (1) multisport with high outdoor time ($n=234$), (2) multisport with moderate outdoor time ($n=310$), (3) one-sport participation with low outdoor time ($n=275$), and (4) non-organised sport with high outdoor time ($n=296$). Comparisons across these classes revealed significant differences in physical activity, physical fitness, and motor skills ($p < 0.05$).

The multisport with high outdoor time group exhibited significantly higher levels of physical activity, physical fitness and motor skills than the other classes. However, the multisport group with moderate outdoor activity also exhibited better outcomes than groups 3 and 4, though the motor skills at T2 did not show significant differences. The one-sport participation with low outdoor time group showed the lowest values of physical activity, and the non-organised sport with high outdoor time group exhibited lower levels of physical fitness and motor skills compared to the other groups.

CONCLUSION: These findings suggest that encouraging children to engage in multisport activities combined with substantial outdoor time may enhance their physical activity, fitness and motor skills. Coaches, educators, and parents should consider promoting a balanced approach to physical activity that includes both organised sports and unstructured outdoor activities to foster comprehensive motor development and overall fitness in youth.

CHILDHOOD AEROBIC FITNESS AND NEUROELECTRIC INDICES OF INHIBITION

JASON, K., RAINE, L.B., WATROUS, J.N.H., HILLMAN, C.H.
NORTHEASTERN UNIVERSITY

INTRODUCTION: Greater childhood aerobic fitness has been associated with cognitive and brain outcomes including greater allocation of attention and working memory resources during stimulus processing (Hillman et al., 2005). Positive associations between aerobic fitness and executive function, including inhibitory control, have also been well documented (Donnelly et al., 2016). This study investigated the relationship between aerobic fitness, attention and inhibitory control during a Go/NoGo task, which modulated stimulus processing and inhibition control demands.

METHODS: Event related potentials (ERP) and task performance were concurrently measured. Fifty-two (mean age=9.99 years $\pm$ 0.69) preadolescent children were included based on aerobic fitness and bifurcated into higher-fit (HF; $n=26$, 13

females) or lower-fit (LF; $n=26$, 13 females) groups based on whether their VO_{2max} fell above the 75th percentile or below the 25th percentile according to normative data (Shvartz and Reibold, 1990). Response accuracy was analyzed using independent t-tests separately for each task. P3 amplitude and latency were analyzed using a 2 (Group: HF, LF) $\times$ 7 (Site: Fz, FCz, Cz, CPz, Pz, POz, Oz) repeated measures MANOVA separately for each task.

RESULTS: For both tasks, target accuracy was lower for LF (Go: 94.76% $\pm$ 7.59%; NoGo: 70.62% $\pm$ 12.66%) relative to HF (Go: 98.23% $\pm$ 2.61%; NoGo: 77.69% $\pm$ 8.74%), $t(50) > 2.199$, $p < .033$, respectively. The omnibus analysis for the P3-ERP during the Go task indicated an effect for fitness $F(1,50)=4.354$, $p=0.042$. For the NoGo task, a Fitness $\times$ Site interaction was uncovered, $F(1, 50)=3.191$, $p<0.031$, which was decomposed using simple effects and paired t-tests to examine group differences. Findings revealed a site effect in the HF group, with fronto-central scalp distribution, indicating the expected scalp topography for the NoGo task. No such effect was observed in the LF group.

CONCLUSION: The results indicate higher fitness was related to greater allocation of attentional and inhibitory control resources, exhibiting the expected adult-like pattern of neuroelectric activation. Findings suggest higher fitness benefits to cognitive and brain health, as indicated by enhanced prefrontal inhibitory control in preadolescent children.

SCHROTH EXERCISE ON THREE-DIMENSIONAL PARAMETERS OF THE SPINE AND PARAVERTEBRAL MUSCLES FOR ADOLESCENT IDIOPATHIC SCOLIOSIS

ZHANG, X., LIN, Y., LIAO, B.

GUANGZHOU SPORT UNIVERSITY

INTRODUCTION: Asynchronous growth of muscle and skeleton is a well-recognized risk factor for curve progression in adolescent idiopathic scoliosis (AIS), often resulting in a vicious cycle. Studies indicate that a reduction in the paraspinal muscle mass is the primary contributor for the disparity in growth rates between muscle and skeleton. Therefore, improving the muscle mass under spinal–pelvic alignment becomes the key for treatment. Although studies have shown that the Schroth Method could control the severity of the curves, the lack of quantification of skeletal and muscle changes during exercise limits its reproducibility, as the specificity of the deformity frequently relies on the subjective experience of the therapist. We aimed to quantify the changes in the skeletal and paravertebral muscles of patients with AIS during Schroth exercise using three-dimensional ultrasound reconstruction.

METHODS: Patients with a single type of Cobb angle in the thoracic curvature of 20°–45° were included in this cross-sectional study. We used muscle cylinder, door handle exercise, self-corrective standing, and self-corrective sitting postures to compare habitual standing with habitual sitting postures and observe changes in spinal alignment and muscle volume parameters. Metrics including paravertebral muscle volume (cm³) of the upper end vertebrae (UEV), apex vertebrae (AV), and lower end vertebrae (LEV) were captured, with simultaneous recordings of the ultrasound curve angle (UCA), ultrasound spinous process angle (SPA), and axial vertebral rotation (AVR).

RESULTS: Overall, 15 participants were included. The results showed that all four corrective postures decreased the UCA ($p < 0.05$). Self-corrective standing ($p = 0.01$) and muscle cylinder ($p = 0.01$) decreased the TSPA in patients with Rigo A. Self-corrective sitting ($p < 0.001$), door handle exercise ($p = 0.03$), and muscle cylinder ($p = 0.01$) increased the LSPA. Door handle exercise improved the AVR ($p = 0.03$). Self-corrective standing increased the muscle volume on the concave ($p = 0.03$) and the convex ($p = 0.02$) of the AV, and increased the muscle volume on the concave ($p = 0.02$) and the convex ($p = 0.04$) of the UEV. Muscle cylinder increased the muscle volume on the concave ($p = 0.02$) and the convex ($p = 0.01$) of UEV. Self-corrective sitting increased the muscle volume on the convex ($p = 0.03$) of the LEV and the convex ($p = 0.02$) of the UEV. Door handle exercise increased the muscle volume on the convex ($p = 0.03$) of AV and the convex ($p = 0.01$) of UEV.

CONCLUSION: Self-corrective standing, Muscle cylinder, Self-corrective sitting, and Door handle exercise all decreased the coronal plane angle, sagittal plane parameters, and paravertebral muscle symmetry, whereas they partially improved the horizontal plane parameters. Therefore, these postures may intensify sagittal plane and paravertebral muscle imbalances in AIS patients with Rigo A who should be cautiously treated in clinical applications.

CORRELATES OF MODERATE-TO-VIGOROUS PHYSICAL ACTIVITY AMONG PORTUGUESE CHILDREN IN THE REACT PROJECT: A QUANTILE REGRESSION APPROACH.

MAIA, J., HEDEKER, D.2, CHAPUT, J.P.2, TANI, G.4, GARBELOTO, F.4, GARGANTA, R.1, FARIAS, C.1, BARREIRA, T.5, KATZMARZYK, P.6, PEREIRA, S.1

1UNIVERSITY OF PORTO; 2UNIVERSITY OF CHICAGO; 3UNIVERSITY OF OTTAWA; 4UNIVERSITY OF S. PAULO; 5UNIVERSITY OF SYRACUSE; 6PENNINGTON BIOMEDICAL RESEARCH CENTER.

INTRODUCTION: There is evidence that moderate-to-vigorous physical activity (MVPA) positively affects childrens well-being and health [1,2]. Furthermore, during childhood, MVPA is associated with a diverse range of covariates [3,4]. Although children vary in their levels of MVPA, this observation is often based on group averages [5,6]. Instead of using MVPA averages, we relied on its distribution and used different percentiles (P25th, P50th, P75th) for this analysis. Therefore, we analyzed MVPA differences between boys and girls and examined whether body mass index, fundamental movement skills (FMS), physical fitness, and sleep were associated with MVPA across different percentiles.

METHODS: Children of both genders (boys: $n=483$; girls: $n=533$), aged 6-10 years, were randomly sampled from northern Portugal. Physical activity was objectively assessed (Actigraph wGT3X-BT) for seven consecutive days. The average daily duration of MVPA and sleep (min/day) was estimated over seven days. Body mass index was calculated from height and weight and expressed in z-scores (BMIz). The overall score for FMS (five object control skills) was estimated using factor

analysis, and an overall z-score for physical fitness (five tests assessing motor, musculoskeletal, and aerobic components) was calculated. Quantile regression was conducted using STATA 18 software.

RESULTS: Overall, boys were more active than girls, and MVPA declined with age. This trend was maintained even when adjusting for covariates (BMI, sleep, FMS, and physical fitness). Quantile regression revealed different effect sizes for covariates. For example, boys had more MVPA than girls (P25th, $b=8.6$, $p<0.05$; P50th, $b=13.9$; P75th, $b=18.1$), yet a similar effect size was observed for age (P25th, $b=-6.4$, $p<0.05$; P50th, $b=-6.2$, $p<0.05$; P75th, $b=-6.6$, $p<0.05$). BMIz, FMS, and physical fitness z-score also had a differential relationship with MVPA across P25th, P50th, and P75th. Sleep was not significantly associated with MVPA at any percentile analyzed.

CONCLUSION: There was a consistent decline in childrens MVPA levels across all percentiles, with the decline being more pronounced in girls. This decrease was similar across age groups and percentiles. Notably, BMI z-scores had a stronger negative association with MVPA at the upper end of the distribution, while FMS and physical fitness showed stronger positive associations. Therefore, we recommend tailoring interventions to address the decline in MVPA by adopting strategies specific to boys and girls of different ages, particularly targeting children with higher BMI, lower physical fitness, and less proficiency in FMS.

ASSOCIATION BETWEEN COMPLIANCE WITH 24-HOUR MOVEMENT GUIDELINES AND TEMPERAMENT TRAITS IN PRE-SCHOOL CHILDREN

HSUEH, M., CHU, Y.H.

UNIVERSITY OF TAIPEI

INTRODUCTION: Temperament factors in preschoolers (surgency/extraversion, negative affectivity, and effortful control) are critical for socio-emotional behavior development. The 24-hour movement guidelines (24-HMG) for preschoolers—comprising physical activity, screen time, and sleep duration—have been shown to influence their physical and mental health development. However, the relationship between adherence to the 24-HMG and temperament factors remains underexplored. This study aimed to investigate the relationship between meeting the 24-HMG and temperament factors among preschool children.

METHODS: A convenience sampling method was used to recruit 127 preschool children (mean age = 5.54 ± 0.97 years) from public kindergartens in northern Taiwan. Parents were invited to have their children wear an ActiGraph wGT3X-BT accelerometer continuously for 24 hours over seven consecutive days to measure activity levels. Temperament factors were assessed using the Chinese version of the Children's Behavior Questionnaire–Very Short Form. Descriptive statistics and multiple linear regression analyses were performed.

RESULTS: Preschoolers who met the "Physical Activity Guidelines" were significant predictors of "surgency/extraversion" ($\beta = 0.194$, $p = 0.048$). Preschoolers who adhered to the "Screen Time Guidelines" ($\beta = -0.346$, $p < 0.0001$) and simultaneously met the "Screen Time/Sleep Guidelines" ($\beta = -0.319$, $p = 0.001$) significantly predicted lower levels of "negative affectivity".

CONCLUSION: Meeting the recommended 180 minutes of daily physical activity, including at least 60 minutes of moderate-to-vigorous physical activity, contributes to the development of socio-emotional behaviors such as extraversion. Additionally, preschoolers who simultaneously achieve ≤ 1 hour of daily screen time and ≥ 10 hours of sleep duration may demonstrate more positive emotional behaviors.

MORE DAYS, GREATER HEALTH: ASSOCIATIONS BETWEEN DAILY MVPA AND CARDIOMETABOLIC RISK IN YOUTH

HAN, J.1, LEE, H.2, VITIELLO, D.1

1. INSTITUT DES SCIENCES DU SPORT SANTÉ DE PARIS, URP 3625, PARIS, FRANCE 2. SANGMYUNG UNIVERSITY, SEOUL, KOREA

INTRODUCTION: The 2020 World Health Organization (WHO) guidelines recommend that children and adolescents achieve an average of 60 minutes per day of moderate- to vigorous-intensity physical activity (MVPA) across the week. This shift from requiring 60 minutes daily to allowing day-to-day variability reflects recent evidence. However, it remains unclear whether the number of days achieving 60 minutes of MVPA provides additional health benefits independent of the total weekly MVPA. This study investigated associations between the number of active days and cardiometabolic health risks in children and adolescents.

METHODS: Data were drawn from the International Childrens Accelerometry Database (ICAD), a pooled dataset of 21 studies involving children aged from 3 to 18 years old. Among these studies, 2 were selected, where participants wore an Actigraph device for 7 consecutive days. Individuals were categorized into 5 groups: category 0 = <420 minutes of MVPA per week (did not meet WHO guidelines), and categories 3 to 6 = met the guideline, with 1–3 days (category 3), 4 days (category 4), 5 days (category 5), and 6–7 days (category 6) of at least 60 minutes of MVPA. A clustered cardiometabolic risk score (CCMR) was computed using waist circumference, blood pressure, lipids, and glucose metabolism. For fasting participants ($n = 1,308$), CCMR included triglycerides, glucose, and insulin; for non-fasting participants ($n = 1,998$), these were excluded.

RESULTS: MVPA-adjusted models for the fasting group showed that CCMR was significantly lower in categories 3 ($B = -0.989$, 95% CI = -1.945 to -0.034), 4 ($B = -1.852$, 95% CI = -2.753 to -0.952), 5 ($B = -1.856$, 95% CI = -2.800 to -0.911), and 6 ($B = -2.531$, 95% CI = -3.728 to -1.335) compared to category 0. Post-hoc tests showed that category 6 had significantly lower CCMR than category 3 ($t = 2.41$, $p < .05$). For the non-fasting group, CCMR was significantly lower in categories 4 ($B = -0.454$, 95% CI = -0.838 to -0.069), 5 ($B = -0.845$, 95% CI = -1.238 to -0.453), and 6 ($B = -0.676$, 95% CI = -1.183 to -0.170) compared to category 0, but not in category 3. Wald tests showed significantly lower CCMR in categories 5 ($t = 3.61$, $p < .001$) and 6 ($t = 2.59$, $p < .05$) compared to category 3.

CONCLUSION: These findings suggest that achieving at least 60 minutes of MVPA on more days throughout the week is associated with greater reductions in cardiometabolic risk, independent of total weekly MVPA. Engaging in MVPA consistently, rather than accumulating it over fewer days, appears more beneficial for reducing health risks in youth.

IS A WEEKEND WARRIOR PHYSICAL ACTIVITY PHENOTYPE SUFFICIENT FOR FUNDAMENTAL MOVEMENT SKILLS, PHYSICAL FITNESS, AND BODY MASS INDEX IN CHILDREN?

PEREIRA, S.1,2, KATZMARZYK, P.T.3, GARBELOTO, F.4, GARGANTA, R.1, FARIAS, C.1, BARREIRA, T.5, CHAPUT, J.P.6, TANI, G.4, HEDEKER, D.7, MAIA, J.1

1 UNIVERSITY OF PORTO; 2 LUSÓFONA UNIVERSITY; 3 PENNINGTON BIOMEDICAL RESEARCH CENTER; 4 UNIVERSITY OF SÃO PAULO; 5 SYRACUSE UNIVERSITY; 6 UNIVERSITY OF OTTAWA; 7 UNIVERSITY OF CHICAGO

INTRODUCTION: The "weekend warrior" concept refers to engaging in concentrated exercise or sports on one or two days, typically the weekend, rather than spreading physical activity across the week as regularly active individuals do [1]. While this pattern has been positively linked to adult health outcomes [2], its impact on children's fitness and motor development is seldom explored. This study examined whether children who engage in 60 minutes of moderate-to-vigorous physical activity (MVPA) over one or two days (the "weekend warrior" group) differ in fundamental motor skills (FMS), physical fitness (PF), and body mass index (BMI) compared to three other groups: "inactive" (0 days of MVPA), "moderately active" (3–5 days of MVPA), and "active" (6–7 days of MVPA).

METHODS: This cross-sectional sample comprised 995 Portuguese children aged 6–10 years from the REACT project [3]. Physical activity was objectively measured (Actigraph wGT3X-BT) over 7 consecutive days, and MVPA was obtained. BMI was calculated from height and weight and expressed as z-scores (BMIz). Physical fitness was assessed (standing long jump, handgrip strength, shuttle-run, 50-yard dash, and pacer), and FMS (object control tasks including stationary dribble, kick, catch, overhand throw, and underhand roll) were evaluated with the Meu Educativo ® platform [4]. All test results were converted into z-scores, with their sums representing overall PF (PFz), and FMS (FMSz). A multivariable regression model was used, with sex and age as covariates.

RESULTS: The "inactive" group had lower FMSz ($b = -0.32$, $p = 0.011$) and higher BMIz ($b = 0.67$, $p = 0.037$) compared to the "weekend warrior" group, with no differences in PFz ($p > 0.05$). Also, no statistically significant differences ($p > 0.05$) emerged between the "moderately active" group for FMSz, PFz, and BMIz and the "weekend warrior" group. However, the "active" group had higher FMSz values ($b = 0.37$, $p < 0.001$) and PFz levels ($b = 1.68$, $p < 0.001$) than the "weekend warrior" group but did not differ in BMIz ($p > 0.05$).

CONCLUSION: This study suggests that children who are active for just one or two days per week ("weekend warrior" group) experience significant benefits compared to the "inactive" group (except for PF), and their outcomes are similar to those who engage in activity across three to five days ("moderately active" group) in terms of FMS, PF, and BMI. However, children who are active six or seven days ("active" group) were found to be more fit and skillful than the "weekend warrior" group. These findings highlight that while the "weekend warrior" approach offers benefits, being consistently active throughout the week is more effective, particularly for developing FMS and PF.

WORKLOAD ASSESSMENT IN TWO TYPES OF MOTOR-COGNITIVE TRAINING: A COMPARISON OF DUAL-TASK AND SYNERGISTIC TRAINING.

CHARTIER, C., GODARD, J., ALLAIN, P., BESNARD, J.

UNIVERSITÉ DANGERS

INTRODUCTION: Herold et al. (2018) [1] distinguished between two types of simultaneous motor-cognitive training: additional (dual-task (DT)) and incorporated (synergistic (SYN)). In DT, cognitive and physical task objectives differ, whereas in SYN, they align, potentially reducing workload required. As outlined in cognitive load theory, when information is complementary, attention division is unnecessary, leading to lower perceived workload (principle of contiguity). Consequently, in SYN condition, unlike in the DT condition, task execution may be facilitated and the subjective workload perceived as

lower. Nevertheless, both training appear to be equivalent in terms of brain plasticity. This study compared the perceived and objective cognitive workload in SYN and DT cognitive-motor training in healthy adults.

Method: A total of 19 participants ($M=26.89$) completed six exercises: 3 DT exercises and 3 SYN exercises. Each targeted a specific executive function (EF). The 6 items of the NASA-Task Load Index [2] (NASA-TLX) were completed at the end of the 6 exercises. The objective performance data collected included the number of items processed, the percentage of correct responses, and the number of errors. Cognitive load and participant performance in each exercise were compared using a one-way analysis of variance (ANOVA). The "training" factor included both DT and SYN training, while the "EF" factor covered working memory (WM), flexibility, and inhibition.

RESULTS: Preliminary results do not indicate the influence of the training modality on objective performance measures or subjective workload assessments. However, the trained cognitive function appears to be a key determinant of the perceived workload during cognitive-motor training.

Discussion: Despite the absence of statistically significant differences between the two cognitive-motor training modalities, a trend can still be observed. The mean scores on the NASA-TLX suggest a slight advantage of SYN training for the "mental demand" and "performance" items. With respect to physical demand, the added value of synergy appears to be counterbalanced by task automation in the DT condition. Concerning EF, WM exercises were perceived as more cognitively demanding, likely due to time constraints and their crucial role in workload management. Inhibition exercises were perceived as less demanding, irrespective of the training modality. It is also possible that these exercises were easier than WM exercises.

THE DEVELOPMENT OF YOUNG ATHLETES SELF-COMPETENCES DURING THE TRANSITION FROM PRIMARY SCHOOL TO ELITE SPORTS SCHOOL

SCHRÖDER, S.

OTTO VON GUERICKE UNIVERSITY MAGDEBURG

Objectives

The objective of the study is to examine the progression of self-control abilities in young athletes who were identified as talents in primary schools and subsequently enrolled in 7th grade at an elite sports school. The study's findings will inform the implementation of measures to enhance support for these students, with the objective of mitigating the risk of motivation loss and subsequent dropout (Granz et al., 2019; Schröder & Knisel, 2024). The study will also draw comparisons between the performance of these young athletes and that of athletes already enrolled in upper secondary school.

METHODS: Fifty students aged between 10 and 18 years old (mean age: 15.33, $SD= 3.39$) took part in the study, which was based on the SSI-K3 (Kuhl & Fuhrmann, 2004). Participants were recruited from an elite sports school in Berlin and divided into two groups. Thirty-five students had been enrolled in the sports school for several years and were in their final year (mean age: 17.74, $SD= 0.85$). The second group ($N= 15$, mean age: 10.67, $SD= 0.72$) consists of pupils who were still attending primary school at time t1 and are in 7th grade at the elite sports school at time t2. A longitudinal study of self-control skills will therefore also be carried out for the second group, whereby the results will also be compared with the results of the older pupils as part of a cross-sectional study in order to be able to draw conclusions here too.

RESULTS: The SSI-K3 demonstrates good validity ($\alpha= .78$), thus confirming the results previously reported by Kuhl & Fuhrmann (2004, $\alpha= .73-.90$). The findings of the present study indicate that there are some differences in the self-competences. Specifically, there were notable differences in the area of self-access, which decreased significantly in the younger athletes (mean t1=1.94, mean t2=1.63, $p=.039$, $d= 0.53$). A cross-sectional comparison showed significant differences in the area of self-regulation ($p= .008$, $d= .79$) between the groups of older students (mean= 1.54, $SD= .58$) and the results of the younger athletes (mean= 1.96, $SD= .38$).

CONCLUSION: The findings indicate that close supervision is necessary to ensure optimal long-term support for athletes. The observed decline in self-access skills from t1 to t2 is attributed to the new and varied demands of an elite sports school, which reduce opportunities for in-depth self-awareness. The significant differences in self-regulation skills suggest that the resources available for recovery in competitive sports training are not yet fully understood. A high level of self-regulation skills has been shown to be indicative of increased performance in competitive sports (Wilson et al., 2021; Young et al., 2023). One proposed solution is to develop a concept that enables athletes to optimally reconcile the stresses of school with those of sport.

THE IMPACT OF SUSTAINED COGNITIVE EFFORT ON BEHAVIORAL PERFORMANCE AND NEURAL RESPONSES: INSIGHTS FROM A DUAL 2-BACK TASK

BENRAISS, A., LORCERY, A., GIRAULT, A., ANDRÉ, N., BERNARD, O., AUDIFFREN, M.

CENTRES DE RECHERCHES SUR LA COGNITION ET L'APPRENTISSAGE

INTRODUCTION: Cognitive effort refers to mental resources allocated to tasks requiring sustained attention, concentration, and active information processing. It is essential for complex functions such as problem-solving, decision-making, memory updating, and attentional control. Engaging in cognitively demanding tasks for extended periods can be mentally exhausting, as it places significant demands on executive functions and may lead to mental fatigue. The more complex, unpredictable, or unfamiliar a task is, the greater the cognitive effort needed to maintain performance. In mental fatigue research, cognitive effort plays a central role, as prolonged engagement in demanding tasks is linked to declining performance and impaired cognitive control. However, the underlying neural mechanisms remain poorly understood. This study examines how sustained cognitive effort affects behavioral and neurophysiological responses, focusing on event-related potentials (ERPs) and subjective perceptions of motivation, fatigue, boredom, and drowsiness.

METHODS: Seventy participants completed a 30-minute Dual 2-back (D2B) task consisting of 1,100 trials, requiring visual and visuospatial working memory updating. In each trial, a geometric figure appeared at the center, with a dot randomly positioned around it (8 possible positions). Either the figure or the dot was randomly colored red. If the dot was red, participants indicated whether its position matched that of trial $n-2$; if the figure was red, they determined whether it was the same as in trial $n-2$. Responses (Yes/No) were made using two buttons. EEG activity was recorded from 64 channels to analyze event-related potentials (ERPs) and examine mental fatigue in relation to behavioral data and self-reported cognitive states.

RESULTS: The behavioral and EEG data recorded over 30 minutes were segmented into four periods of 7.5 minutes each. Analysis of reaction times (RT) for correct responses revealed a significant decrease for "No" responses, while remaining stable for "Yes" responses throughout the task. Additionally, the error rate remained stable for "No" responses but significantly increased for "Yes" responses. Furthermore, d' -prime, an index of discrimination between trials n and $n-2$, decreased over the course of the task. Finally, analysis of event-related potentials (ERPs) showed a significant decrease in the amplitude of the P300 component. This decrease was not correlated with any behavioral or subjective data.

Discussion: This study highlights the impact of prolonged cognitive effort on performance and neural activity. A decrease in d' -prime and an increase in errors for "Yes" responses suggest a decline in stimulus discrimination. The reduction in P300 amplitude reflects diminished attentional and working memory resources. However, this decrease was not correlated with behavioral or subjective measures. This result tends to put into perspective the role of motivation in explaining the decline in performance.

BEYOND FITT: A SCOPING REVIEW ON THE APPLICATION OF PROGRESSIVE OVERLOAD IN LONG-TERM EXERCISE INTERVENTIONS TARGETING IMPROVEMENTS IN EXECUTIVE FUNCTIONS

FOX, X., SCHAERZ, S., DUFFY, T., BROWN, D.

UNIVERSITY OF LETHBRIDGE

Background: Executive functions (EF) are cognitive processes essential for goal-directed behavior, comprising inhibitory control, working memory, and cognitive flexibility [1]. Physical exercise has been shown to enhance EF across the lifespan, with the effects influenced by frequency, intensity, time, and type (FITT) of exercise [2]. However, while much is known about how FITT parameters moderate the impact of exercise on EF, less attention has been given to the dynamic adjustments of these parameters over time and their influence on long-term EF improvements. Accordingly, the purpose of this scoping review was to examine recent long-term exercise intervention studies and map how the principle of progressive overload has been applied to optimize EF.

Methods: This review followed the PRISMA extension for scoping reviews [3]. A comprehensive literature search was conducted in PubMed, SPORTDiscus, and Web of Science for peer-reviewed studies published between 2014 and 2024. Eligible studies included human participants, assessed at least one core EF domain, and incorporated long-term exercise interventions. Studies were excluded if they were cross-sectional, focused on acute exercise, or lacked intervention details. Study design, intervention parameters (FITT), progressive overload parameters, EF domains, and findings were extracted from the articles.

Results: A total of 1,335 articles were identified from PubMed ($n=472$), SPORTDiscus ($n=177$), and Web of Science ($n=686$). After removing 842 studies (duplicates, non-English, pre-2014, and grey literature), 493 were screened. Screening, based on title relevancy, eliminated another 333 studies, leaving 160 for full-text review. Of these, 116 were excluded (abstract-only, duplicates, animal studies, and not reporting progressive overload), resulting in 44 studies included in the scoping review. The subsequent analysis revealed intensity ($n=24$) and type/complexity ($n=16$) as the most commonly overloaded parameters. Studies reporting moderate to large effect sizes most often overloaded type/complexity ($n=13$), followed by intensity ($n=8$). Only 28% of the studies retrieved for full-text review reported on progressive overload, and of those, just 34% provided a detailed account of its application, specifying the FITT parameter that was overloaded, the frequency of overload, and its magnitude. No study directly examined the effect of progressive overload on EF.

Conclusion: There is a need for research that empirically investigates how the progressive overload in exercise type/complexity and intensity impacts EF. Additionally, more comprehensive reporting on the application of progressive

overload in long-term intervention studies is essential for advancing the understanding of exercise-induced cognitive adaptations.

GAME-READY MINDS: A PILOT STUDY ON ACUTE EXERCISE, EXECUTIVE FUNCTION, AND ESPORTS PERFORMANCE

SCHAERZ, S., JOHNSON, N., DUFFY, T., FISHER, A., QUESADA, R.

LETHBRIDGE POLYTECHNIC AND UNIVERSITY OF LETHBRIDGE

Background: Esports, especially competitive games like League of Legends (LoL), rely on core executive functions— inhibitory control (IC), working memory (WM), and cognitive flexibility (CF)—for strategic decision-making during gameplay [1,2]. Emerging evidence suggests that acute exercise enhances executive functions, potentially benefiting Esports performance [3,4]. However, the impact of different exercise modalities on LoL performance remains underexplored. This pilot study aimed to evaluate the feasibility of a protocol comprised of different exercise modalities, gather preliminary findings, and provide recommendations for future large-scale investigations.

Methods: Nine male participants (age: 27 ± 7.28 years, BMI: 23.14 ± 2.58 , weekly moderate-to-vigorous physical activity: 153.33 ± 96.40 min), experienced in LoL (3.50 ± 2.78 years), completed a randomized, repeated-measures crossover protocol. Three conditions were tested: moderate-intensity cycling (EC), moderate-intensity cycling with cognitive challenges (CEC), and a sedentary control (CC). After each condition, IC, WM, and CF were tested using the Stroop Colour-Word Test, Corsi Block-Tapping Task, and Trail Making Test (Part B), respectively. LoL-specific performance, including single-attempt kills (SAK) and Jungler callouts (JC), was assessed during simulated gameplay immediately after the executive function tests. Heart rate (HR) and rating of perceived exertion (RPE) were recorded during each condition.

Results: Preliminary results indicated that IC reaction times were faster in the CEC (810.90 ± 165.68 ms, $ES = -0.54$ [CI: -1.38, 0.29]) relative to the CC (875.64 ± 102.22 ms). Similarly, WM scores were higher in the CEC (13.11 ± 1.90 blocks, $ES = 0.55$ [CI: -0.28, 1.38]) compared to the CC (12.22 ± 1.72 blocks). JC scores were also higher in the CEC ($80.20 \pm 18.50\%$, $ES = 0.54$ [CI: -0.29, 1.37]) relative to the CC ($72.12 \pm 19.08\%$). HR data confirmed that participants reached moderate intensity during both the EC ($69.95 \pm 3.39\%$ HRmax) and CEC ($74.54 \pm 4.77\%$ HRmax). RPE scores in the CEC (11.87 ± 1.61) and EC (11.52 ± 1.23) were similar (RPE for CC: 6.00 ± 0.00). From the first to the third lab visit, improvements were observed in IC, WM, and CF.

Conclusion: Faster IC reaction times and higher WM and JC scores in the CEC warrant a larger sample investigation to assess significance and generalizability. The CEC and EC elicited moderate intensity—an intensity consistently identified in the literature as effective for enhancing cognitive outcomes [5]. Both the EC and CEC were well tolerated, with RPE scores indicating light to somewhat hard exertion. IC, WM, and CF improvements across visits suggest a learning effect, which could be better controlled by measuring pre- and post-condition differences in future investigations.

EXAMINING THE CONTRIBUTION OF AFFECTIVE EXERCISE EXPERIENCES IN PREDICTING PHYSICAL ACTIVITY

JONES, L., ESCHLE, T.

UNIVERSITY OF STRATHCLYDE

Physical inactivity remains a pertinent health issue in western nations. Approaches to understanding and promoting physical activity behaviour have traditionally been viewed from a cognitively driven perspective (e.g., the rational-education model) but new approaches are being proposed that include greater acknowledgement of affect [1]. How people feel about exercise, their prior experiences of exercise, and their feelings during exercise are proposed as important factors in future exercise behaviour. The present study sought to examine the contributions of cognitive and affective variables in accounting for physical activity behaviour measured using smartphone data. It was hypothesised that affective experiences associated with exercise would significantly contribute to the variance accounted for in weekly step count, and positive affective exercise experiences would predict a larger number of steps. To measure cognitively driven predictors of exercise, behavioural intentions and perceived behaviour control items from the Theory of Planned Behaviour [2] were recorded; to measure affective experiences of exercise, the AFFEX questionnaire [3] was administered; measurement of physical activity was self-reported from participants who reported their daily step counts from the previous seven days as recorded by their smartphone. Data was collected online using Qualtrics. Preliminary data from 28 participants (female = 16, male = 12, mean age [SD] = 19.96 [0.79] years) indicated that cognitive and affective variables did not significantly predict weekly step counts ($p = .41$). Hierarchical multiple regression showed that a total of 15.4% of variance for weekly step count could be accounted for by the cognitive (12.1%) and affective (15.4%, cumulative) predictors. Behavioural intention

and affective antecedent appraisal appear the most positive predictors of physical activity. These data extend our understanding of a new instrument to account for affective exercise experiences (AFFEXX), and the use of device-based physical activity measurement in this context represents a novel contribution.

CP-PN04 Exercise Biomarkers

PRELIMINARY FINDINGS ON SALIVARY AND PLASMA IRISIN CONCENTRATIONS FOLLOWING HIGH-VOLUME RESISTANCE EXERCISE

MARANO, L., MISSAGLIA, S., MARTEGANI, E., BONANOMI, A., TREMOLADA, C., MORDENTE, A., TAVIAN, D., MARCHETTI, A., DI DIO, C., CATELLANI, P., VEZZOLI, M., CEREDA, F.

CATHOLIC UNIVERSITY OF SACRED HEART

INTRODUCTION: Irisin is a myokine mainly released in response to exercise, playing a role in energy expenditure, white adipose tissue browning, and metabolic regulation (1). While it is widely recognized that aerobic exercise consistently increases plasma irisin levels (2), the response to resistance exercise remains inconclusive. Some studies report increased irisin levels following resistance exercise, while others show no change or a decrease (3, 4). Additionally, irisin analysis is usually assessed in blood samples, which are invasive and may not always be practiced in some settings. Saliva sampling offers a non-invasive alternative, but limited research has evaluated its reliability for irisin detection to date (5). This study aimed to investigate acute irisin responses in both plasma and saliva following a high-volume resistance training session.

METHODS: Seven healthy, resistance-trained men (23.5 ± 2.5 years; training experience: 5 ± 3 years) were enrolled. The study involved three preliminary test sessions (10RM, TUT, 1RM) and one experimental training session (TS). The TS consisted of 30 sets performed to failure, with a time under tension (TUT) of 5-1-2-1, emphasizing eccentric movements. Blood and saliva samples were collected at baseline (T0), 15 minutes (T1), 24 hours (T2), and 48 hours post-exercise (T3). Plasma and salivary irisin levels were measured by ELISA, while plasma creatine kinase (CK) and visual analogue scale (VAS) levels were analyzed as indirect markers of muscle damage. Nonparametric statistical tests (Friedman and Pearson correlation) were applied, with significance set at $p < 0.05$.

RESULTS: Plasma irisin levels significantly increased between T0 and T1 (10.44 ± 0.9 to 11.38 ± 1.4 ng/mL, $p < 0.05$). Similarly, salivary irisin levels rose significantly from 0.051 ± 0.006 to 0.053 ± 0.008 ng/mL ($p < 0.05$). CK values peaked at T2, confirming markedly exercise-induced muscle damage ($p < 0.001$). Also, VAS values peaked at T2 to then decrease at T3, suggesting that muscle soreness was higher 24 h after exercise. A significant correlation was observed between percentage changes in plasma and salivary irisin ($r = 0.86$, $p < 0.05$), suggesting a potential link between the two biological fluids in irisin release kinetics.

CONCLUSION: This pilot study is the first to suggest a concurrent increase of plasma and salivary irisin following high-volume resistance exercise in trained men. The correlation between plasma and salivary irisin suggests that saliva sampling may serve as a viable and non-invasive method for assessing irisin responses to resistance exercise. Future research should investigate the increase of salivary irisin concentration in larger cohorts and different training modalities.

OPTICAL PARAMETERS AND MUSCLE OXYGENATION LEVELS AT DIFFERENT INTENSITIES OF MUSCLE CONTRACTION ASSESSED BY TIME-DOMAIN NEAR-INFRARED SPECTROSCOPY IN RELATION TO SKINFOLD THICKNESS.

MONOT, T., LACERENZA, M., COLOSIO, A.

UNIVERSITÉ JEAN MONNET

INTRODUCTION: Near-Infrared Spectroscopy (NIRS) allows non-invasive assessment of tissue oxygenation and provide insights into skeletal muscle metabolism and fatigue in sports and health context. For these reasons, NIRS devices have

recently gained attention and popularity. Most NIRS devices (i.e. based on continuous wave technique) assume constant optical parameters of the tissue investigated (i.e., differential path length factor (DPF)) which influence hemodynamic measurements' accuracy. However, the DPF differs between individuals, measurement sites, adipose tissue under the probe and potentially exercise intensity. More advanced time-domain (TD) NIRS enable real-time DPF retrieval and could therefore improve measure accuracy with significant impact on NIRS applications. This study investigated the evolution of DPF and tissue oximetry values at different intensities of muscle contractions and examined their relationship with skinfold thickness (ST).

METHODS: Ten healthy subjects (6F, 4M, BMI: 18.2-28.8) performed a knee extensor isometric contraction protocol. A 2-min baseline was followed by a warm-up and an initial maximum voluntary contraction (MVC). Subjects were then asked to perform 10s contractions at 25, 50, 75 and 100% of their MVC. Muscle oxygenation (MO) variables at the vastus lateralis were continuously monitored using the NIRSBOX tissue oximeter (PIONIRS, Italy). DPF and the evolution of MO variables (e.g. muscle oxygen saturation (StO₂)) were determined as the peak responses (min/max) reached during a 20s window from the onset of contraction. DPF across intensities were compared using repeated measures ANOVA and the relationships between ST and both DPF and MO parameters were investigated by Pearson correlations.

RESULTS: The group mean ST was 14.3mm (range: 7.3-21.9mm). DPF at baseline was correlated with ST ($R^2=0.66$, $p<0.01$). The minimum measured DPF decreased with exercise intensity ($p<0.05$) and stabilised at 75% of MVC. Individual slopes of the decrease in DPF were not correlated to ST ($p<0.05$). Additionally, there was no significant correlation between ST and StO₂ at baseline ($p>0.05$) and the overall change of minimum StO₂ from baseline across all intensities ($p>0.05$). All other NIRS parameters showed the same behaviour relative to ST.

CONCLUSION: DPF is a key factor in tissue oximetry measurement, varying dynamically during exercise, particularly with contraction intensity. ST appears to strongly influence DPF which could lead to measurement errors if not considered. In our study using TD-NIRS oximetry, ST did not hinder the tracking of MO variables. Our findings, which need to be validated across a broader range of ST levels, are likely due to TD-NIRSs ability to directly measure DPF, which helps to account for the optical effects of local ST.

SEASONAL VARIATIONS IN BONE MINERAL CONTENT, BONE MINERAL DENSITY AND BLOOD MARKERS IN MALE AND FEMALE ELITE-SUBELITE FOOTBALL PLAYERS

ERMIDIS, G., LARSEN, M.N., RUPPERT, C.R., RØMER, T., HANSEN, M.T., SAHL, R.E., POGGI, A.I., RANDERS, M.B., POVOAS, S., ERMIDIS, G., JØRGENSEN, N.R., HELGE, J.W., KRUSTRUP, P.

UNIVERSITY OF SOUTHERN DENMARK

INTRODUCTION: Bone mineral content (BMC) and bone mineral density (BMD) are crucial factors related to the risk of bone fractures, a severe injury, leading to long recovery periods. Blood markers like osteocalcin, PINP, and β -CTX-I reflecting bone metabolism, balancing between bone formation and bone resorption. It was hypothesized that BMD, BMC, and bone markers would fluctuate between preseason and competitive periods, with elite players demonstrating more stable values due to long-term skeletal adaptations, whereas sub-elite players, especially females, would show greater variability due to differences in training load and competition exposure.

METHODS: This study examined BMD, BMC, osteocalcin, PINP, and β -CTX-I changes from early preseason to competitive seasons in elite and sub-elite male football players and sub-elite female players. Players from one professional male football team (Danish 1st tier), two sub-elite female teams (Danish 2nd tier), and three sub-elite male teams (Danish 3rd tier) participated in the study. Laboratory testing occurred in January (winter preseason), in March (competitive season for elite male players but the final part of preseason for sub-elite players) and summer (August/September for the elite male team and in June for the female teams). Testing involved whole-body dual-energy x-ray absorptiometry (DXA) scans to determine total and regional BMD and BMC (323 observations), and venous blood samples taken immediately before the scan for osteocalcin, PINP, and β -CTX-I (273 observations) that were analyzed using mixed models and independent t-tests for comparisons between different periods, gender and competitive levels.

RESULTS: BMD fluctuated in elite male players, decreasing in summer (1.41 ± 0.09 g/cm²) compared to January (1.50 ± 0.10 g/cm², $p=0.008$) and March (1.50 ± 0.10 g/cm², $p=0.006$), primarily in the upper body. Additionally, elite male players had higher BMD (1.50 ± 0.10 g/cm²) than sub-elite male players (1.39 ± 0.08 g/cm², $p=0.001$). However, sub-elite male players had higher BMD (1.39 ± 0.08 g/cm²) and BMC (3607 ± 361 g) than sub-elite female players (1.31 ± 0.09 g/cm², 2786 ± 317 g, $p=0.001$). Blood markers did not significantly vary across periods, but gender differences were found in sub-elite players: males had higher β -CTX-I (1049 ± 527 ng/L) than females (500 ± 260 ng/L, $p=0.001$). Sub-elite males had higher osteocalcin (32 ± 15 μ g/L) and β -CTX-I (1049 ± 527 ng/L) than elite males (osteocalcin: 25 ± 11 μ g/L, $p=0.009$; β -CTX-I: 659 ± 434 ng/L, $p=0.001$).

CONCLUSION: Elite male players have denser bones and require less remodeling, likely due to years of high-intensity training and structured recovery. In contrast, sub-elite players may experience greater fluctuations and higher turnover markers due to a more varied and less structured training load. This highlights the importance of load management and tailored training to support bone health throughout an athletes career.

ADIPOCYTOKINES' RESPONSES TO ACUTE EXERCISE IN ELITE ATHLETES: RELATIONSHIP WITH BODY FAT PERCENTAGE

DJELIC, M., VUJOVIC, A., NESIC, D., MAZIC, S.

MEDICAL FACULTY, UNIVERSITY OF BELGRADE

INTRODUCTION: Adipocytokines, also known as adipokines, are signaling molecules secreted by adipose tissue that play a role first in regulation energy metabolism, but also, reproductive, bone, muscle, immune function and inflammation. In elite athletes, the response of adipocytokines to acute exercise can provide insight into their metabolic health, exercise adaptations, and recovery mechanisms. Because exercise training improves the hormonal status, there is interest in the effects of exercise on adipocytokines' responses to acute exercise in elite athletes and whether these peptides may provide better understanding of how exercise improves health. The purpose of this study was to investigate adipocytokines' responses to high-intensity acute exercise in athletes with different body fat amount and sedentary controls.

METHODS: Sixteen athletes with body fat percentage (BF%) <12%, fifteen athletes with BF% ≥12% and sixteen sedentary young normal weight subjects participated in this study. After anthropometric measurements, all subjects were exposed to the high-intensity exercise test on the treadmill to examine the acute adipocytokine's response. Blood samples were taken before (basal levels), immediately after the exercise test, as well as in the 30 minutes of recovery. Separated serum and/or plasma were used for the hormone (insulin, leptin, adiponectin and visfatin) ELISA analysis.

RESULTS: In athletes with BF% <12%, basal leptin concentration was significantly lower compared to sedentary controls and athletes with BF% ≥12% ($p < 0.05$). No significant changes were found in the basal level of adiponectin and visfatin between groups. In all three groups, insulin concentration increased significantly after exercise and stayed higher throughout the recovery period ($p < 0.05$). There were no significant postexercise and recovery changes in adiponectin concentration ($p > 0.05$). In sedentary controls, leptin concentration was significantly reduced after exercise and decreased more in recovery period ($p < 0.05$). No differences in leptin concentration over time were observed in athletes' groups ($p > 0.05$). In athletes with BF% ≥12%, visfatin concentration increased significantly after exercise, but reduced in recovery period ($p < 0.05$). In controls, visfatin concentration was significantly reduced and stayed lower throughout the recovery period ($p < 0.05$). No differences in visfatin concentration over time were observed in athletes with BF% <12% ($p > 0.05$).

CONCLUSION: Our findings show leptin and visfatin, but not adiponectin responses to acute exercise. High-intensity acute exercise elicited an inverse visfatin response in athletes BF% ≥12% and sedentary controls. Also, these results suggest that leptin is altered after acute exercise only in sedentary controls. It seems that athletes' body fat is more resistant to high-intensity exercise-induced energy deficit.

SALIVARY PH AS A NON-INVASIVE MARKER FOR PHYSICAL ACTIVITY AND PHYSICAL FITNESS LEVELS IN SCHOOLCHILDREN.

PRATS-PUIG, A., ÁLVAREZ-HERMS, J., JÒDAR-PORTAS, A., VASILEVA, F., FERRUSOLA-PASTRANA, A., HOMES-ÀVILA, J.

EUSES

INTRODUCTION: Salivary pH has been related to athletic performance as a proxy of body's metabolic responses during physical exertion. However, studies in children analysing the association between salivary pH with physical activity and physical fitness are scarce. The purpose of this study was to investigate the relationship between physical activity, fitness, and salivary pH in schoolchildren.

METHODS: Eighty-seven primary schoolchildren were included in the study. Salivary pH was obtained using a universal indicator pH paper test (One+Step). Minutes per day spent in moderate-to-vigorous physical activity (MVPA) were measured with a triaxial accelerometer (Actigraph) and used to create and compare tertiles. Physical fitness was assessed by the handgrip strength (handgrip dynamometer) and agility (10 × 5 m shuttle run test). The collected data was analysed by SPSS version 29.

RESULTS: We found a significant inverse correlation between time spent in MVPA and salivary pH ($r = -0.398$, $p < 0.001$). Children with lower MVPA levels (36.37 ± 0.86 minutes/day) had salivary pH levels 15% higher than more active children (86.39 ± 15.29 minutes/day), with mean pH values of 7.11 ± 0.86 and 6.17 ± 0.70 , respectively. Interestingly, salivary pH also correlated with physical fitness measures, exhibiting a negative association with handgrip strength ($r = -0.348$, $p < 0.001$) and a positive association with time to complete the 10 × 5 m shuttle run test ($r = 0.267$, $p = 0.038$). Linear regression analysis, using physical activity and fitness measures as independent variables, revealed that only MVPA showed a significant negative association with salivary pH ($\beta = -0.345$, $p = 0.005$). The adjusted R-squared for the model was 17.9%.

CONCLUSION: Taken together, our results show that a more alkaline salivary pH was related to lower physical activity levels. Moreover, children with lower MVPA levels had salivary pH levels 15% higher than more active children. These findings may help the monitoring of practicing more physical activity to optimize health. Finally, salivary pH may be a non-invasive and useful health indicator, which is especially important for the paediatric population.

RELATIONSHIP BETWEEN EXHALED AND SKIN GAS ACETONE CONCENTRATION DURING MAXIMAL EXERCISE

KATO, R., YAMADA, K., MATSUDAIRA, H., IDE, D., OCHIAI, A., OGURI, H., YAMAMOTO, K., MIURA, Y., YOSHIGA, M., CHOI, Y., SHIMIZU, K., FUNAHASHI, N., TOMITA, A., SAITOU, K., MIYAZAKI, M., TSUDA, T., ITOH, H.

GRADUATE SCHOOL OF ENGINEERING, NAGOYA INSTITUTE OF TECHNOLOGY

INTRODUCTION: Ketone bodies are composed of acetoacetic acid (AcAc), β -hydroxybutyric acid (β HB), and acetone, which are produced in the mitochondria of the liver. AcAc and β HB are consumed as energy sources, but acetone is not used by the body as an end product of metabolism and is eliminated through expiration and skin [1]. Previous study has reported

that exercise increases acetone concentrations in exhaled breath and skin gas. This is attributed to enhanced fatty acid oxidation in the mitochondria of the liver during exercise due to increased oxygen uptake [2]. However, little is known about the relationship between acetone concentrations in exhaled breath and skin gas before and during exercise. Therefore, this study aimed to investigate the relationship between acetone concentrations, excretion of acetone in exhaled breath and skin gas acetone concentrations during the maximal exercise.

METHODS: Eight healthy male students (23.9 ± 1.7 years; mean $\pm$ SD) consumed incremental maximal cycling exercise that reached 100% HR(HRmax) within 30 minutes after starting. The skin-gas samples were obtained from the dominant hand by covering with a polyethylene bag in which pure nitrogen gas (200mL) was introduced for 60 sec and collected in a sampling bag at rest, 5, 10, 15, 20, 25, minutes during exercise, and immediately after exercise. Exhaled breath samples were also collected at the same time, furthermore ventilation volume, oxygen uptake was simultaneously measured using a gas analyzer (Cardio Coach PRO MC-2200). Acetone concentration was analyzed by gas chromatography.

RESULTS: The incremental maximal exercise significantly increased the concentration (ppm) and excretion (mol/min) of acetone in exhaled breath with increasing exercise intensity. The acetone concentration in skin gas (ppm) also increased similarly. Thus, significant positive correlations were observed between acetone concentration in exhaled breath and skin gas ($r=0.6312$, $p<0.0001$, $n=64$), as well as between acetone excretion in exhaled breath and acetone concentration in skin gas ($r=0.8973$, $p<0.0001$, $n=64$) following the maximal exercise.

CONCLUSION: This study confirmed a significant positive relationship between exhaled acetone excretion and skin gas acetone concentration during the maximal exercise. These results of this study indicated that changes in skin gas acetone concentrations before and during exercise could potentially serve as indicators of ketone body production in the liver and markers of whole-body acetone excretion.

RELATIONSHIP BETWEEN EXHALED ACETONE EXCRETION AND OXYGEN CONSUMPTION DURING SUBMAXIMAL EXERCISE

TOMITA, A., SAITOU, K., YAMADA, K., IDE, D., MATSUDAIRA, H., OGURI, H., KATO, R., OCHIAI, A., YAMAMOTO, K., MIURA, Y., YOSHIGA, M., CHOI, Y., SHIMIZU, K.2, FUNAHASHI, N.3, TSUDA, T.2, ITOH, H.2

NAGOYA GAKUIN UNIVERSITY

INTRODUCTION: Ketones (β -hydroxybutyrate, acetoacetate and acetone) are generated in mitochondria of the liver, mainly from the oxidation of fatty acids, and are exported to peripheral tissues, such as the brain, heart, kidney, and skeletal muscle for use as energy fuels (Laffel 1990). Previous study has reported that exercise increases acetone concentrations in exhaled breath and skin gas (Yamai et al. 2009). This is attributed to enhanced fatty acid oxidation in the mitochondria of the liver during exercise due to increased oxygen uptake. However, no one has confirmed the relationship between acetone concentration in exhaled breath and oxygen consumption during exercise. Therefore, this study aimed to investigate the relationship between acetone concentration, excretion of acetone in exhaled breath and oxygen consumption during submaximal exercise.

METHODS: Eight healthy male students (23.9 ± 1.7 years; mean $\pm$ SD) performed 30 minutes of incremental cycling exercise that reached 50% HRmax approximately 25 minutes after starting. Exhaled gas samples were continuously collected at rest, 5, 10, 15, 20, 25, 30 minutes during exercise, and 5 minutes after exercise. The concentration of acetone in the exhaled breath was measured by gas chromatography, and oxygen consumption and energy expenditure (kcal/min) were calculated using a gas analyzer (Cardio Coach PRO MC-2200).

RESULTS: The incremental exercise at 50% HRmax significantly increased the concentration (ppm) and excretion (mol/min) of acetone in exhaled breath with increasing exercise intensity. There was a significant relationship between excretion of acetone in exhaled breath and oxygen consumption before and during exercise ($r = 0.9205$, $p<0.001$, $n=64$). Moreover, a significant correlation ($r=0.9163$, $p < 0.001$) was also observed between the acetone excretion in exhaled breath and energy expenditure before and after exercise.

CONCLUSION: This study confirmed that changes in exhaled breath acetone excretion related oxygen consumption and energy expenditure during submaximal exercise. These results suggest that the excretion of acetone in exhaled breath was revealed to be not only an indicator of fatty acid oxidation in the mitochondria of the liver but also a potential marker of oxygen consumption and energy expenditure during submaximal exercise.

CHANGES IN EXHALED ACETONE AND SKIN GAS NITRIC OXIDE CONCENTRATION DURING MAXIMAL EXERCISE

OGURI, H., MATSUDAIRA, H., YAMADA, K., IDE, D., OCHIAI, A., KATO, R., YAMAMOTO, K., MIURA, Y., YOSHIGA, M., CHOI, Y., SHIMIZU, K., FUNAHASHI, N., TOMITA, A., SAITOU, K., MIYAZAKI, M., TSUDA, T., ITOH, H.

GRADUATE SCHOOL OF ENGINEERING, NAGOYA INSTITUTE OF TECHNOLOGY

INTRODUCTION: Nitric oxide (NO) [1] is known as an endothelium-derived vasorelaxant factor and is catalyzed by NO synthase (NOS), which is produced by three known enzymes: endothelial-type NOS (eNOS), neural-type NOS (nNOS) and induced-type NOS (iNOS). During exercise, increasing NO production facilitate blood flow in muscle tissues, muscle energy metabolism, and mitochondrial respiration. Chirpaz-Oddou et al. [2] reported that although the concentration of NO in exhaled breath decreases during maximal exercise with incremental loading, NO output in exhaled breath reflects aro-

bic metabolism. However, no one has confirmed the relationship between NO concentration in exhaled breath and skin gas NO concentration during exercise. Therefore, this study aimed to investigate the relationship between NO concentration, excretion of NO in exhaled breath and skin gas NO concentration during maximal exercise.

METHODS: Subjects were 10 healthy male students (23.3 ± 0.98 : Mean $\pm$ SD) who rested in the supine position for 30 min and then underwent incremental pedaling exercise. The exercise started at 60w load and 60 rpm, and the load and rpm were increased every 2 minutes, with each subjects protocol set to reach HRmax within 30 minutes. The skin-gas samples were obtained from the dominant hand by covering with a polyethylene bag in which pure nitrogen gas (200mL) was introduced for 60 sec and collected in a sampling bag at rest, and during exercise. Exhaled breath samples were also collected at the same time, and furthermore, ventilation volume and oxygen uptake were simultaneously measured using a gas analyzer (Cardio Coach PRO MC-2200). NO concentration was measured by a chemiluminescence analyzer (Pico-Device Co., Ltd., Japan).

RESULTS: The incremental maximal exercise significantly decreased the concentration of NO in exhaled breath ($\mu\text{mol/l}$) compared to the resting values, however, excretion of NO in exhaled breath ($\mu\text{mol/min}$) significantly increased with increasing ventilation volume compared to the resting values during the exercise. Furthermore, the maximal exercise significantly increased skin gas NO concentration ($\mu\text{mol/l}$) compared to the resting values with increasing exercise intensity. A significant relationship was found between excretion of NO in exhaled breath and skin gas NO concentration before and during exercise ($r = 0.858$, $p < 0.001$, $n = 60$).

CONCLUSION: This study confirmed that NO concentration in skin gas related to exhaled breath NO excretion during maximal exercise. These results indicated that skin gas NO concentration could be an indicator of total NO production in the body via eNOS, iNOS, and nNOS, as well as a marker of whole-body NO excretion during exercise.

EXPLORING THE CHANGES IN CONCENTRATIONS OF BLOOD BIOMARKERS THROUGHOUT A SEASON OF RUGBY UNION IN UNIVERSITY-LEVEL FEMALE PLAYERS

IANSON, H., PROSSER, S.P., STROM, A., CASHMORE, I., WALTON, D., COE, J., WHITE, C., OHALLORAN, P., STEVENS, A., BELLI, A., ALDRED, S., ELSWORTHY, R.J., LUCAS, S.J.E.

UNIVERSITY OF BIRMINGHAM

INTRODUCTION: Rugby union is a high-contact sport, leading to the risk of head injury. Previous research focusses on concussion, including the diagnosis and recovery. However, there is little research that investigates the effects of sub-concussive head impacts or cumulative head impacts. A sub-concussive head impact involves insufficient impact to cause clinical symptoms to be present (1), however, repeated sub-concussive head impacts can lead to long-term health concerns (2). How the accumulation of such impacts affects the levels of blood-based biomarkers proposed to support the diagnosis of concussion is unknown. This study examined the changes in concentrations of blood-based biomarkers associated with concussion in a group of rugby union players during a playing season.

METHODS: Ten female university-level rugby union players were recruited (age 20.0 ± 1.8 years) via the University of Birmingham Concussion Clinic. Participants completed pre-season baseline tests using the Sport Concussion Assessment tool 6th Edition (SCAT6) and provided a blood sample, which was repeated following 8 weeks of training and games. Blood samples were then batch analysed using Single Molecular Array to quantify glial fibrillary acidic protein (GFAP), neurofilament light chain (NfL), total Tau and ubiquitin C-terminal hydrolase (UCH-L1) concentrations. Paired t-tests were used to assess changes across this 8-week period.

RESULTS: Overall, there were no group-level changes in concentrations of any blood biomarker (all $p > 0.23$). Interestingly, the one participant in this cohort that had a concussion during this 8-week period (at week 4, then followed the return to play protocol, returned to play at week 7) had elevated levels of NfL (up 141% vs 6% for remaining participants ($n = 9$)) and UCH-L1 (up 58% vs a group decrease of 15%) after 8 weeks. Total number of SCAT6 symptoms were similar between time points ($p = 0.30$), including the participant with higher NfL and UCH-L1 data (5 vs. 0 total symptoms, for initial vs 8 weeks respectively).

CONCLUSION: Findings demonstrate that across a short rugby union season there were no significant changes in blood-based biomarkers linked with concussion. Nevertheless, elevated levels were observed in the context of a recent concussion, albeit in only one case, which highlights the potential for longer-term effects persisting beyond the resolution of symptoms. Future research should implement the use of impact monitoring tools alongside biomarker measures to better track sub-concussive head impacts and their potential impact on brain health outcomes.

EFFECT OF ASHWAGANDHA (WITHANIA SOMNIFERA) SUPPLEMENTATION ON BLOOD LEVELS OF BIOCHEMICAL MARKERS OF POST-EXERCISE RECOVERY IN YOUNG, HEALTHY MEN

JÓWKO, E., DŁUGOLECKA, B., KLUSIEWICZ, A., CHARMAS, M., PRZYBYLSKA, I.

FACULTY OF PHYSICAL EDUCATION AND HEALTH

INTRODUCTION: Ashwagandha is an herbal plant with potential health properties. Due to its wide range of phytochemicals, ashwagandha root extract is thought to be useful in treating a variety of conditions, including neurodegenerative diseases and cognitive/memory impairment. However, little is known about its potential to regulate anti-inflammatory and antioxidant pathways under high intensity exercise. The purpose of this study was to evaluate the effects of 8-week ashwagandha supplementation (600 mg/day) on blood markers of oxidative stress and inflammation in healthy male non-athletes undergoing an high-intensity interval training (HIIT).

METHODS: The study was performed in randomized, double-blind, placebo-controlled manner (placebo group, P, n=20; ashwagandha group, A, n=18). HIIT was performed on a rowing ergometer (3 sessions/week, 5-7 sets of 1.5 minutes in each session, at a load of 85-95% of maximum aerobic power, with rest intervals between sets of 1.5 minutes). Before (term 1) and after (term 2) the 8-week intervention, participants completed maximal graded exercise test (GXT) on rowing ergometer. Blood samples from the ulnar vein were obtained prior to (pre) and 5 min after (post) GXT, as well as after 24-hour recovery period (24h). Serum levels of total antioxidant capacity (TAC), total oxidant status (TOS), interleukin 6 (IL-6), tumor necrosis factor α (TNF α), interleukin 10 (IL-10), as well as heat shock proteins (HSP70, HSP27) and creatine kinase (CK) were determined. Moreover, the activity of antioxidant enzymes: superoxide dismutase (SOD) and glutathione peroxidase (GPx) were measured in erythrocytes.

RESULTS: In both terms of the study, similar GXT-induced changes in pro- and anti-inflammatory markers were observed in both groups, i.e. an increase in IL-6, IL-10 and HSP70 post, followed by a decrease in IL-6 and HSP70 at 24h ($p < 0.0001$). No significant changes were observed in TNF α and CK levels ($p > 0.05$). As a result of 8-week HIIT, a decrease in HSP27 pre, while an increase in SOD pre and TAC at 24h were found (changes in term 2 vs term 1, in both groups, $p < 0.05$). This indicates the need to mobilize antioxidant defence due to increased free radical production. Indeed, oxidative stress (an increase in TOS post) was particularly pronounced in term 2, with a significant change in P group alone ($p < 0.05$). Meanwhile, ashwagandha supplementation reduced oxidative stress, as in term 2, group A showed lower levels of TOS post, SOD at 24h and GPx at 24h compared to P group ($p < 0.05$). In addition, in term 2, there was a reduction in anti-inflammatory IL-10 at 24h in P ($p < 0.05$) but not in A group ($p > 0.05$).

CONCLUSION: Ashwagandha supplementation can modulate the antioxidant and anti-inflammatory response to an intense exercise/training program in young men. This indicates the potential of ashwagandha to accelerate post-exercise recovery in physically active individuals. However, these results need to be confirmed by further studies in a group of competitive athletes.

CP-PN05 Energy Restriction

CONTINUOUS GLUCOSE MONITORING – A NOVEL TOOL FOR BEHAVIOUR CHANGE IN RELATIVE ENERGY DEFICIENCY IN SPORT (REDS)?

MATKIN-HUSSEY, P.1, BAKER, D.1,2, STYLES, S.1, COX, G.3, BOWLER, A.L.4, COFFEY, V.3, OGILVIE, M.5, BEABLE, S.2, BLACK, K.1

1 UNIVERSITY OF OTAGO, NEW ZEALAND 2 AXIS SPORTS MEDICINE, NEW ZEALAND 3 BOND UNIVERSITY, AUSTRALIA 4 UNIVERSITY OF THE SUNSHINE COAST, AUSTRALIA 5 ERH ASSOCIATES, NEW ZEALAND

INTRODUCTION: Relative Energy Deficiency in Sport (REDS) is a multi-factorial clinical condition associated with profound adverse long-term health and performance consequences. The predominate treatment for REDS is to increase energy availability (EA) via increasing energy intake (EI), with the athlete understanding their own EA equation playing a key role in their recovery. However, knowledge alone may not be enough to create the required behaviour modifications around increasing EI and/or improving EA across the day. Yet, there is a dearth of evidence regarding behaviour change to increase EA in those with, or at risk of REDS. This descriptive qualitative study investigated the acceptability of continuous glucose monitoring (CGM) in athletes clinically diagnosed with REDS, and how biofeedback from CGM may play a role in creating the required behaviour change for the recovery of REDS.

METHODS: Females (n=8, 26.8 ± 6.4 years) with a diagnosis of REDS by an experienced medical specialist, participated in a seven-day trial whereby they wore an unblinded CGM sensor and were instructed to scan the sensor at least every eight hours. Participants were provided with only minimal information on what to expect in their glucose readings; no specific education was given as to how their glucose readings might reflect nutritional timing or choices. Participants also recorded their exercise data each day and their dietary intake for four days of the trial. A semi-structured interview guide was used to collect qualitative data to gain an understanding of the participants' experience of wearing a CGM. Data were analysed using thematic analysis inductively for key themes.

RESULTS: Two main themes emerged from the data. The first theme, "Acceptable but aware", captured the participants' experience of wearing the CGM during their recovery of REDs. Participants found it easy to use, predominately unobtrusive, and showed low to no anxiety with regards to the continuous access to their interstitial glucose levels. The second theme, "Engagement with the data", portrayed the spectrum to which participants connected with the CGM data and identified the potential of CGM to impact nutrition behaviour in the recovery of REDs, particularly in response to exercise.

CONCLUSION: The CGM appeared to provide an 'objective permission' to some participants to change their nutritional intake behaviours. This was predominately regarding fuelling before training, having linked their subjective feelings to the objective metrics on the CGM. However, there is a clear need to ensure individuals understand the CGM data, particularly around exercise, to be able to make meaningful change. CGMs do not appear to create anxiety in those diagnosed with REDs. With an accompanying education, CGM may have a potential role in creating behaviour change with regards to nutrition around exercise.

THE EFFECT OF EXERCISE TRAINING AND BARIATRIC SURGERY-INDUCED WEIGHT LOSS ON RESTING METABOLIC RATE AND ITS ASSOCIATION WITH HIGHLY METABOLIC ORGANS; SIX-MONTH RANDOMIZED CLINICAL TRIAL

FRIEDMAN, L., GOLDENSHLUGER, A., TURJEMAN, T., KAIS, H., GOITEIN, D., KEIDAR, A., DUVNOV-RAZ, G., MHALER, I., SAKRAN, N., DICKER, D., GEPNER, Y.

TEL AVIV UNIVERSITY

INTRODUCTION: Bariatric surgery (BS) is highly effective for weight loss, but up to 50% of individuals regain weight within five years, largely due to reduced resting metabolic rate (RMR) linked to fat-free mass (FFM) loss. Changes in liver and kidney volume, highly metabolic organs, may explain RMR changes after BS. This study examined the effect of BS-induced weight loss on RMR and its association with highly metabolic organs.

METHODS: Fifty-eight candidates (39.2 ± 10.7 y, 114.3 ± 17.5 kg, 41.7 ± 4.4 kg/m²) for BS were enrolled in a six-month open-label randomized controlled trial. Participants were randomly assigned to standard care (control, n=16), aerobic (n=15), strength (n=13), or combined exercise training (n=14) for 26 weeks of intervention. Training sessions were supervised online, and gradually increased to 60 minutes per session, three times a week. From week 5 each group participated in a specific progressive training regimen. Pre- and post-intervention RMR was measured by indirect calorimetry, body composition (FFM and fat mass) by dual-energy X-ray, and highly metabolic organs volume using 3-tesla magnetic resonance imaging (MRI).

RESULTS: Forty-seven participants completed the 6-month intervention (81%). Participants in the exercise training groups (n=39) significantly increased their physical activity (PA) level by $79.8 \pm 90.8\%$. Significant ($p < 0.01$) reductions were observed in body weight (-31.1 ± 8.7 kg), FFM (-6.61 ± 2.6 kg), fat mass (-24.4 ± 7.4 kg), kidney volumes (-35.1 ± 25.2 cm³), liver volume (-384 ± 250 cm³) and absolute-RMR (-397 ± 264 kcal/day), all similar between the study groups. However, a significant metabolic adaptation of 368 ± 234 kcal/day was observed following BS-induced weight loss regardless of the type and load of PA. The metabolic adaptation was significantly correlated with liver volume changes ($B = 0.379$, $p = 0.005$) contributing 36% to the observed metabolic adaptation.

CONCLUSION: Our study provides the first evidence that metabolic adaptation in bariatric patients is significantly mediated by changes in liver volume, highlighting its critical role in influencing RMR. Further research is needed to validate these findings and determine their relevance for personalized weight management strategies post-bariatric surgery.

OVERNIGHT FAST ALTER MOTOR UNIT ACTIVATION PROPERTIES IN HUMAN: DOUBLE-BLIND RANDOMIZED CONTROLLED TRIAL

IGAWA, K., TAKEDA, R., NISHIKAWA, T., UEDA, S., MITA, Y., WATANABE, K.

CHUKYO UNIVERSITY

INTRODUCTION: Energy utilization in skeletal muscle during contraction depends on muscle fiber type. Slow twitch fibers have higher fat oxidation capacity, while fast-twitch fibers are greater glycolytic metabolism. Previous studies have shown fat oxidation during low-intensity exercise increases after overnight fast, a phenomenon linked to changes in central nervous system (CNS) that enhance hormone secretion promoting lipid breakdown. Since muscle fibers are innervated by motor neurons, fast-induced changes in CNS also alter motor unit activation properties. We hypothesized that during low-intensity exercise after an overnight fast, the activity of motor units (MUs) with lower recruitment thresholds, which have muscle fibers with higher fat oxidation capacity, is enhanced. The present study aimed to investigate the effects of overnight fast on motor unit activation properties and its recruitment threshold dependency.

METHODS: Eighteen adults participated in this study. After an overnight fast, participants performed measurements in the morning under two conditions in a double-blind, randomized controlled design. In non-intake condition (NIN), participants had a jelly containing 0 kcal and intake condition (IN), they had a jelly containing about 450 kcal. Two conditions were provided on separated days for each participant. On each day, respiratory exchange ratio (RER) during knee extension-flexion exercise at about 20% of $\dot{V}O_{2peak}$, maximal voluntary contraction (MVC) strength of knee extension, high-density surface electromyography (HDsEMG) from the vastus lateralis at 30% of MVC, and evoked twitch torque of knee extensors were measured. HDsEMG signals were decomposed into individual motor unit action potentials, and motor unit firing rate (MUFR) and recruitment thresholds (MURT) were calculated. Only MUs tracked between two days/conditions were analyzed. Shapiro-Wilk tests were performed to check the normality of all variables, followed by paired t-test or Wilcoxon

signed-rank test. To investigate threshold-dependent changes in MU between conditions, Spearman's rank correlation analysis was performed on the changes in MUFR and MURT (NIN-IN) and MURT.

RESULTS: RER was significantly lower in NIN than that in IN ($p < 0.01$). There were no significant differences in MVC strength and evoked twitch torque between two conditions. A total of 116 MUs were tracked and analyzed. MUFR and MURT were significantly lower in NI than that in IN ($p = 0.03$, $p = 0.02$). The change in MUFR from NIN to IN and MURT was not significantly correlated ($p > 0.05$), but the change in MURT from NIN to IN and MURT were significantly correlated ($p = 0.28$, $p < 0.01$).

CONCLUSION: The present study showed overnight fast with no energy intake enhanced fat oxidation during low-intensity exercise in the morning and enhancement of MUs recruitment with relatively lower recruitment threshold. Our results suggest alterations in energy metabolism induced by overnight fast is accompanied with changes in motor unit activation properties.

BODY COMPOSITION ADAPTATION DURING HIGH ALTITUDE TREK

MARZOLA, M., LUCERO, A., SANTANGELO, C., BONDI, D., VERRATTI, V.
UNIVERSITY

INTRODUCTION: High-altitude trekking is characterized by changes in body composition. However, how body composition (BC) varied is still debated [1]. This study aimed to evaluate the short-term BC changes through two different field methods according to the somatotype of participants.

METHODS: A group of 12 healthy young adults (6m and 6f, with mean age of 26.4 y BMI of 22.9 kg/m²) participated in a scientific expedition (20 days) up to the Pyramid Lab in the Himalayas (5050m). BC was evaluated through bioimpedance analysis (BIA), skinfold equations, sum of skinfold, and corrected girth at three times: before, at peak altitude, and four days after the trek. Somatotype was calculated for each participant. Energy and protein daily intake were evaluated through three food diaries, recorded on the same day as BC. All anthropometric measurements were performed according to the International Society of the Advancement of Kinanthropometry (ISAK) protocol [2].

RESULTS: Body weight dropped during the hypoxic trek from 69.1 kg at baseline (T0) to 67.4 kg at peak altitude (T1) to 68.2 kg once back in Kathmandu (T2). A reduction of fat mass percentage (FM%) estimated was observed mainly from Durnin and Womersley equation (21.1 to 19 to 19.5%, $p < 0.001$) than from BIA (18.5 to 17.1 to 17.8 %, $p = 0.425$). FM% estimates comparison from BIA and Durnin and Womersley equation resulted in a mean bias of 2.7 (95%CI 1.3- 6.7), at T0, 1.83 (95%CI 0.9- 4.6) at T1 and 2 (95%CI Lower -1.9, Upper 6.1) at T2. Therefore, we considered the sum of skinfolds as a key variable to monitor fat mass changes during HA expedition; that variable changes from 80.1 mm to 71.7 to 71.6, thus evidencing a reduction ($p < 0.001$) of subcutaneous body fat as a result of the hypoxic trek. Free fat mass estimated from BIA remained more stable during expedition ($p = 0.177$), similarly to the corrected girth (0.092), utilized as indicators of skeletal muscle mass. The somatotype representative of trekkers changed from Endomorphic-mesomorph (3.1-3.4-2.5) to balanced mesomorph (2.9-3.5-2.4). At T0 the somatotype mean for male and female trekkers was balanced mesomorph (2.7-4.3-2.2) and balanced endomorph (3.7-2.8-2.4); differences in the reduction of FM% estimated from Durnin and Womersley equation and the sum of skinfold was found between male and female ($p = 0.005$). The mean energy intake was 2423 and 1926 kcal/day for men and women, and the protein intake was 99 and 75 g/day, respectively.

CONCLUSION: The relatively low energy and protein intake and the reduction in body weight and FM% obtained during the hypoxic trek were in line with the BC adaptation in the literature [1]; instead, skeletal muscle mass was preserved. The different somatotype at baseline between the two sexes can explain the greater reduction in FM% and the sum of skinfolds in females over males.

THE EFFECT OF WITHIN-DAY ENERGY DISTRIBUTION ON LEAN BODY MASS AND BODY FAT IN ATHLETES

KNEFFEL, Z., CANTRELL, G.2, MURLASITS, ZS.3

1. HUNGARIAN UNIVERSITY OF SPORTS SCIENCE, 2. ARKANSAS STATE UNIVERSITY, 3. UNIVERSITY OF PECS FACULTY OF SCIENCES

INTRODUCTION: Nutritional habits have a considerable effect on exercise performance as they determine both acute energy availability for sport activities, and long-term changes in body composition (BC) (muscle mass (MM) and fat mass (FM)). The aim of the study was to summarize the available evidence on the effects of within-day energy balance on FM and MM in athletes.

METHODS: The systematic search strategy executed via the databases of Embase, PubMed, Scopus, SportDiscus and Web of Science using the combination of the following terms: meal frequency, eating frequency, feeding frequency, meal pattern, eating pattern, feeding pattern, meal distribution, eating distribution, feeding distribution, within-day energy balance, within-day energy deficit, body composition, lean mass, muscle mass, and athletes. Inclusion criterion were: athletes, over 14yrs, report data on the BC and energy balance within a day, full text, peer-reviewed papers and published in English language.

RESULTS: The search identified 3831 unique papers; 20 were suitable for full text assessment and 7 papers were included in the systematic review. From the seven papers two used meal frequency as an indication of energy distribution, while

five calculated hourly energy surplus and deficit to determine within-day energy balance. The average score on the PEDro scale checklist was 4 and none of the included studies was of poor (score less than 4) quality. Findings revealed that within-day energy balance is a significant factor in the regulation of body composition in athletes, and that negative within-day energy balance may impair muscle protein synthesis and promote fat accumulation. During food restriction (weight cutting), a more frequent meal schedule may help preserve LM and reduce FM by maintaining a higher metabolic rate and stimulating protein synthesis. During weight gain, a large 24-hour energy surplus ensures continuous positive energy balance, and the timing and the frequency of meals are not as important.

CONCLUSION: Assessment of hourly, rather than daily energy balance would assist with the development of tailored approaches to target energy balance to enhance performance and BC of athletes. Consuming high glycemic index carbohydrate and protein rich snack within ~30 minutes after exercise seems beneficial to replenish glycogen stores and promote muscle remodeling. Large 24-hour energy surpluses may be sufficient for athletes aiming for lean mass gain, as meal timing and frequency become less critical in such scenarios.

RESISTANCE TRAINING AS A KEY STRATEGY FOR HIGH-QUALITY WEIGHT LOSS IN MEN AND WOMEN

LAHAV, Y., GEPNER, Y.

TEL AVIV UNIVERSITY SACKLER FACULTY OF MEDICINE

INTRODUCTION: Background. Preserving fat-free mass (FFM) during weight loss is critical to prevent sarcopenia and maintain metabolic health. This study aimed to investigate the role of resistance training (RT), aerobic exercise (AR), and no exercise (NO) on body composition during a calorie-restricted diet.

METHODS: This retrospective cohort study included 304 participants (183 men, 121 women) aged 20–74 years with a body mass index (BMI) of 18.5–45 kg/m². Participants followed a hypocaloric diet with a 500–700 kcal/day energy deficit and self-selected of RT, AR, or NO. Body composition was assessed using dual-energy X-ray absorptiometry (DXA), and abdominal circumference (ABC) was measured to evaluate central obesity.

RESULTS: Over an average follow-up of 4.9±0.4 months, all groups achieved similar weight loss (RT: -8.0±4.3 kg, AR: -8.2±3.9 kg, NO: -8.3±3.5 kg). However, significant differences in body composition changes were observed depending on exercise modality. FFM decreased in NO (-2.2±1.5 kg) and AR (-0.7±1.7 kg), while RT gained FFM (+1.1±1.7 kg, *p*<0.05 vs. AR, NO). Fat loss was greatest in RT (-8.1±4.2 kg) compared to AR (-6.9±3.3 kg) and NO (-4.6±5.9 kg). The FM-to-weight loss ratio was lowest in NO (0.7±0.2) and highest in RT (1.1±0.7, *P*<0.0001 vs. NO, *P*<0.005 vs. AR).

CONCLUSION: These findings suggest that RT supports high-quality weight loss, characterized by reduced FM and preserved FFM. Incorporating RT into weight management programs may improve health outcomes, mitigate sarcopenia, and promote metabolic health.

DESIRE TO LOSE WEIGHT AND EATING HABITS AMONG FEMALE PHYSICAL EDUCATION STUDENTS IN JAPAN

SHIRAISHI, M., KAYO, K.

JAPAN WOMEN'S COLLEGE OF PHYSICAL EDUCATION GRADUATE SCHOOL

INTRODUCTION: national health campaign, "Health Japan 21" was established by the Ministry of Health, Labour and Welfare in Japan to outline nutrition and dietary objectives, including reducing underweight prevalence among young women, increasing vegetable intake, and improving fruit intake. Over 20% of women in Japan have a BMI below 18.5 and are underweight; many women consider their ideal body type as skinny. For women in their 20s, being underweight (BMI<18.5 kg/m²) may lead to reduced bone mass, sarcopenic obesity, and decreased ADLs in later life. Preference for thinness, inadequate energy intake due to weight loss efforts, and insufficient vegetable and fruit consumption pose serious challenges for female athletes. However, the relationship between desire to lose weight and eating habits among female athletes has not yet been elucidated. This study aimed to clarify the relationship between desire to lose weight and eating habits among female college students in physical education.

METHODS: Using Google Forms, a survey was conducted in January 2025 with 1,421 students from Japan's Women's College of Physical Education; 588 valid responses (41.4%) were received. The questionnaire included items on height, current/ideal weight, exercise habits, desire to lose weight, and eating habits. Items on eating habits included skipped meals, cereal intake frequency, and Dietary Variety Score (DVS; 0–10 points). To examine the relationship between desire to lose weight and other factors, the participants were divided into two groups based on an ideal BMI of 18.5. The desire to lose weight was set at less than the ideal BMI 18.5 kg/m². Those with ideal BMI <18.5 kg/m² were categorized as the desire to lose weight (DLW) group (*n*=178), while those with ideal BMI ≥18.5 kg/m² were in the non-desire to lose weight (NDLW) group (*n*=410). Height, current/ideal weight, current BMI, and DVS were analyzed using a *t*-test, while other items were analyzed using a chi-square test. The significance level was set at 5%.

RESULTS: The average BMI was 20.9, with 8.5% (*n*=50) having a BMI below 18.5. Exercise frequency did not differ significantly between the DLW and NDLW groups; 39.3% and 22.9% of the DLW and NDLW groups specialized in cheerleading/dancing, respectively (*p*<0.001). Conversely, 12.4% and 37.8% of the DLW and NDLW groups specialized in ball games, respectively (*p*<0.001). Both groups had low DVS scores, averaging 2 points (*p*=0.089), with no significant differences in individual food group intake. However, grain intake frequency differed significantly, with 64.1% of the DLW group and 52.2% of the NDLW group reporting "eating every meal" (*p*=0.013).

CONCLUSION: In this study, 30.3% of participants expressed a desire to lose weight. This desire was linked to sports category and grain intake frequency. In aesthetic sports such as cheerleading and dancing, nutritional education that involves eating staple foods (bread, rice, or noodle) at every meal is necessary.

DIETARY INADEQUACIES AMONG BRAZILIAN AMATEUR AND ELITE ATHLETES: A NARRATIVE REVIEW

GABIATTI, M., NAKAMOTO, F.P., QUARESMA, M.V.L.S., HANSEN, F.

FEDERAL UNIVERSITY OF SANTA CATARINA

INTRODUCTION: Despite dietary guidelines emphasizing the importance of adequate nutrition, carbohydrate restriction and insufficient energy intake (IE) are commonly observed among athletes. This review aims to evaluate dietary adequacy among Brazilian amateur and elite athletes (Tiers 2–5) aged over 18 years, comparing energy and macronutrient intake adequacy across sex, sports, and Tier.

METHODS: A search was conducted in PubMed, Web of Science, LILACS, SciELO, and Scopus databases using specific MeSH terms to identify studies assessing mean energy and macronutrient intake inadequacy. Studies without Tier classification were excluded.

RESULTS: A total of 877 studies were identified and 22 studies met the eligibility criteria. They included 328 males and 143 females aged 18–55 years. Among 471 adults, 68.36% were classified as Tier 2, 15.07% as Tier 3, 15.28% as Tier 4, and 1.27% as Tier 5. Dietary intake over multiple days was assessed in 12 studies. Only two studies observed adequate dietary intake. In the other 20 studies, nutritional inadequacies were observed at different levels across sexes, Tiers, and sports. Adequate energy and macronutrient intake were observed in female team sports Tier 5 (1 study). Among Tier 4 athletes, insufficient carbohydrate intake was observed in all 4 studies, except for females in endurance sports ($n = 6$) and combat sports ($n = 4$). Intake above the recommended levels was observed for energy in females ($n = 6$) and protein and fat in males ($n = 28$) and females ($n = 6$) in endurance sports. Insufficient EI was observed only in male ($n = 12$) and female ($n = 12$) weightlifters. In Tier 3, all three studies observed adequate EI. However, carbohydrate intake was insufficient in males (Crossfit®, $n = 6$ of 13, endurance sports, $n = 6$ of 37) and females (Crossfit®, $n = 6$ of 12, endurance sports, $n = 9$ of 9). In endurance sports, mean protein and fat intake above the recommended level was observed for both sexes. For less trained individuals (Tier 2, 14 studies), only one study observed adequate mean energy and carbohydrate intake in both male ($n = 6$) and female ($n = 3$) endurance athletes. One study showed adequate carbohydrate intake in both male ($n = 2$) and female ($n = 2$) Crossfit® athletes.

CONCLUSION: Brazilian athletes present a high prevalence of energy and carbohydrate inadequacy. Even with adequate energy intake, the risk of carbohydrate deficiency remains in Tiers 3 and males Tier 4, mainly due to higher protein and/or fat consumption. Despite the increase in energy and carbohydrate intake recommendations with training level, less-trained athletes (Tier 2) show the highest carbohydrate and EI inadequacy, possibly due to lower awareness of their nutritional needs or limited access to tailored support, mentioned in only one study with Tier 2 individuals. These findings highlight the need for a comprehensive nutritional approach considering energy and macronutrient balance while addressing sex, sports, and Tier.

INTERMITTENT FASTING ENHANCES PHASE ANGLE AND VO_2 MAX IN ATHLETES: A PRELIMINARY STUDY

CANO, R., FLORES, J., SÁNCHEZ-BERNAL, G., CASAÑAS, J.J., JIMÉNEZ, E.

CENTRO UNIVERSITARIO SAN ISIDORO

INTRODUCTION: Intermittent fasting (IF) has been proposed as a strategy to optimize metabolic flexibility, enhance fat oxidation, and improve aerobic performance. However, its effects on cellular integrity (assessed via phase angle, PhA) and maximal oxygen consumption (VO_2 max) remain underexplored in trained individuals. Given the metabolic adaptations induced by fasting, we hypothesize that IF can positively influence these parameters, leading to improved athletic performance.

METHODS: Previously twenty-eight volunteers underwent bioelectrical impedance analysis (Tanita MC-780MA) and incremental treadmill tests (Cosmed) to assess their body composition and aerobic capacity. Next, participants were divided into two groups: an IF group (16 hours fasting, 8 hours feeding during 8 weeks) and a control group (regular diet during 8 weeks). PhA and VO_2 max are assessed before and after 8 weeks in the control and IF group. These data analyses are currently in progress.

RESULTS: Our data show a positive correlation between PhA and VO_2 max, with athletes participants displaying higher PhA values and higher VO_2 max levels ($PhA = 7.35 \pm 0.19$, $VO_2 = 55.62 \pm 1.62$ ml/min/kg, $N=15$) while less physical active participants showed lower values ($PhA = 6.67 \pm 0.31$, $VO_2 = 41.39 \pm 1.53$ ml/min/kg, $N=13$). Additionally, we observed that individuals with higher PhA values also presented increased intracellular water levels, suggesting a relationship between cellular hydration, membrane integrity, and aerobic performance. These findings indicate that PhA could serve as a biomarker for endurance capacity and metabolic efficiency in athletes. This ongoing study investigates the effects of a 16:8 intermittent fasting protocol on PhA and VO_2 max in physically active individuals. Participants are divided into two groups: an IF group (16 hours fasting, 8 hours feeding) and a control group (regular diet).

CONCLUSION: Our initial data support the hypothesis that IF could enhance PhA, ICW, and VO_2 max, likely due to improved mitochondrial function, cellular hydration, and metabolic substrate utilization. Further analysis will determine whether

these adaptations are significantly influenced by intermittent fasting, potentially providing a novel nutritional strategy for optimizing sports performance.

THE EFFECTS OF ACETIC ACID SUPPLEMENT AND VOLUNTARY WHEEL RUNNING ON GUT-MICROBIOME IN OVARIECTOMIZED MICE

TAN, Y., PARK, K.W., RYU, B.J., LEE, S.M., KIM, D.Y., PARK, J.W., SO, B.H., JANG, J.H., PARK, J.H., KANG, C.H., LEE, H., HWANG, M.H., PARK, Y.M.

INCHEON NATIONAL UNIVERSITY

INTRODUCTION: There exists a correlation between a healthy physiological state and the diversity of gut microbiome. Menopause-induced deteriorations in whole body metabolism, including insulin resistance and obesity, negatively contribute to microbial diversity. Firmicutes including UCG009 is associated with enhanced energy storage leading to metabolic dysfunction and obesity. Acetic acid supplement or exercise intervention has been somewhat documented for its beneficial effects on gut microbial composition. However, the combined influence of acetic acid supplement and exercise intervention on gut microbiome remains unknown. The purpose of the study was to investigate 1) whether menopause negatively influences gut microbial diversity including firmicutes abundance; and 2) whether the combined treatment of acetic acid and exercise rescues this microbial dysbiosis, and which specific bacteria is related to this rescuing effect.

METHODS: This 15-week study used female C57BL/6J wild type mice (n=40, 8 weeks old), which were randomly assigned to Sham (SHM), ovariectomy (OVX), ovariectomy with exercise (OVXE), ovariectomy with acetic acid (OVXA), and ovariectomy with exercise and acetic acid (OVXAE) groups. Gut microbial diversity including abundance profiling in phylum level was accessed using Next Generation Sequencing (NGS). Beta diversity using Bray-Curtis Index and Unweighted UniFrac Index measured diversity differences between groups. Phylogenetic cladogram was used to analyze the group difference in specific bacteria.

RESULTS: In the abundance of firmicutes, OVX exhibited a tendency for an increase compared to SHM. However, OVXA showed no difference compared to SHM (SHM: 50.6%; OVX: 57.2%; OVXE: 52.0%; OVXA: 50.6%; OVXAE: 56.5). In microbial diversity, while there was no difference between SHM and OVX, acetic acid supplement groups (OVXA and OVXAE) showed greater diversity compared to SHM and OVX ($p < 0.05$). In phylogenetic cladogram analysis, compared to OVX, OVXA and OVXAE had lower level of UCG009 and Akkermansia ($p < 0.05$).

CONCLUSION: Ovariectomy, a model of menopause, tended to increase the relative proportion of Firmicutes. Acetic acid supplement partially maintained the Firmicutes proportion in ovariectomized mice. The noteworthy finding of the study is that, independent of exercise intervention, acetic acid supplement showed a significant, beneficial effect on microbial diversity in ovariectomized mice. Future research should explore the potential role of UCG009 in protecting against the menopause-related metabolic dysfunction.

THE EFFECT OF ORAL CONTRACEPTIVES ON EARLY ADAPTATION IN SKELETAL MUSCLE TO A RESISTANCE TRAINING PROGRAM

LADOUCEUR, R., WAGEH, M., LIM, C., MCKENDRY, J., PARISE, G.

MCMASTER UNIVERSITY

INTRODUCTION: Estrogen, a primary female sex hormone, plays a key role in the adaptation of muscle after exercise (1,2). Possible mechanisms for the estrogen-muscle interaction include regulating satellite cells, which are important in repair and remodelling of muscle, and inhibiting muscular inflammation after exercise (1,3). Estrogen exerts its effects through acting on estrogen receptors located on skeletal muscle (4). How synthetic female sex hormones, such as the ones found in oral contraceptive pills (OCPs), impact skeletal muscle after exercise, including fibre size, lean body mass, and the satellite cell response remains unknown. The purpose of this study was to determine the effect that OCP use has on the response to the early phases of a resistance training program.

METHODS: Twenty-eight healthy, young females (21.2 ± 1.1 years, 64.5 ± 4.0 kg) were recruited and categorized as either OCP users (n=14) or naturally cycling (n=14). Each participant underwent a four-week resistance training protocol. Muscle characteristics (fiber cross sectional area, fiber type), strength, lean body mass via DEXA scanning, as well as satellite cell content were evaluated using immunofluorescent staining.

RESULTS: There were no significant differences between OCP users and naturally cycling individuals with respect to fiber cross sectional area, fiber type, strength gains, and satellite cell content after 4 weeks of resistance training ($p > 0.05$). OCP users gained significantly more lean body mass as measured by DEXA compared to naturally cycling individuals ($p < 0.05$), but both groups improved lean leg mass, equally, with training ($p = 0.01$).

CONCLUSION: OCP use does not differentially impact fiber cross sectional area, fiber type, strength, and satellite cell content compared to naturally cycling individuals after 4 weeks of resistance training. The results obtained from this study further simplify inclusion criteria for future muscle physiology studies aiming to recruit female participants.

ARGININE-CITRULLINE SUPPLEMENT INCREASE QUADRICEPS MUSCLE BLOOD FLOW ACCOMPANYING WITH INCREASING SKIN GAS NITRIC OXIDE CONCENTRATIONS FOLLOWING MAXIMAL RUNNING EXERCISE

OCHIAI, A., MATSUDAIRA, H., YAMADA, K., TAKEHARA, K., IWATA, Y., ITO, R., SATO, T., HAGINO, Y., MIYAZAKI, M., TSUDA, T., ITOH, H.

NAGOYA INSTITUTE OF TECHNOLOGY

INTRODUCTION: The combination of oral L-arginine and L-citrulline immediately and synergistically increases plasma arginine and nitrite/nitrate (NOx) concentrations more than either citrulline or arginine alone (1,2). Nitric oxide (NO) is the most important endothelium-derived relaxing factor, which plays a pivotal role in modulating smooth muscle tone (3). During exercise, increasing NO production facilitate blood flow in muscle tissues, muscle energy metabolism, and mitochondrial respiration, therefore previous human study has reported that oral arginine-citrulline supplement improved exercise performance due to increase NO bioavailability (1). However, there is little data concerning the effect of arginine-citrulline supplement on skin-gas NO concentration during exercise. The present study examined to confirm the effect of arginine-citrulline supplement on blood flow of active muscles and skin-gas NO concentrations following maximal running exercise.

METHODS: A double-blind randomized placebo-controlled 2-way crossover study was employed. Ten healthy male students (23.0 ± 0.5 years; mean $\pm$ SD) consumed arginine-citrulline supplement (VELOX Charge: Kyowa Kirin Co., Ltd., Japan) or placebo orally 1 h before incremental maximal running exercise exhausting within 30 min. The skin-gas samples were obtained from the dominant hand by covering with a polyethylene bag in which pure nitrogen gas (250mL) was introduced for 100 sec and collected in a sampling bag at rest and 0, 5, 10, 15, 30 min recovery of the exercise. The skin-gas NO concentration was measured by a chemiluminescence analyzer (Pico-Device Co., Ltd., Japan). Blood flow measured using a laser tissue blood flow meter from non-dominant hand skin surface (Omegaflo, Omega Wave, Japan).

RESULTS: The arginine-citrulline supplement significantly ($p < 0.05$) increased running time and distance compared to the placebo. Maximal exercise in this study significantly increased skin-gas NO concentration ($p < 0.05$) and blood flow ($p < 0.001$) after the exercise compared to the resting values. Significant higher levels were observed in skin-gas NO concentration ($p < 0.001$) and blood flow ($p < 0.001$) in the supplemental condition compared to the placebo. Moreover, there were significant relationships between skin-gas NO concentration and blood flow both in supplemental ($r = 0.5676$, $p < 0.001$) and placebo ($r = 0.6050$, $p < 0.001$) conditions.

CONCLUSION: Significantly higher levels of skin-gas NO concentration has indicated that the arginine-citrulline supplement increased NO production and NO bioavailability in the whole body during the maximal exercise. As a result, blood flow, energy metabolism, and mitochondrial respiration in active quadriceps muscle during the maximal running exercise facilitated by the arginine-citrulline supplement, consequently improved exercise performance (1).

WOMEN'S HOSPITAL HEALTH CENTRE, H214 4500 OAK STREET, BOX 42B, VANCOUVER, BRITISH COLUMBIA, CANADA

INTRODUCTION: Menopause-associated changes in skeletal muscle composition, including increased intramuscular fat can impair muscle contractility and performance. While ovariectomized models have shown an increase in intramuscular triglyceride content in skeletal muscles, this model does not mimic the natural transition to menopause that occurs in humans. Therefore, in the present study, we investigated the gradual menopausal transition using a VCD-induced ovarian failure mouse model, which better represents human menopausal hormonal profiles and physiological responses.

Specifically, we determined the effects of VCD-induced ovarian failure on intramuscular fat accumulation in slow-type (soleus) and fast-type (extensor digitorum longus; EDL) muscles, as well as the ability of estrogen replacement following the development of menopause to attenuate intramuscular fat accumulation.

METHODS: Female CD1 mice (n=19; 78-105 days old) were assigned to one of 3 groups: age-matched controls, VCD, or VCD + estrogen replacement (VCD+E2). VCD treatment (160 mg/kg) was administered for 15 days. Estrogen replacement (0.16 ug/day of 17-beta-estradiol, administered via subcutaneous pellet) began after confirmation of ovarian failure and continued for 8 weeks. Soleus and EDL muscles were harvested, flash-frozen, cryosectioned (10µm), and stained with Oil Red O. Sections were imaged at 20x magnification and intramuscular lipid content was quantified using colour thresholding analysis in ImageJ.

RESULTS: There was an interaction of group × muscle for intramuscular fat ($p < 0.05$). For the soleus muscle, there was no significant difference between groups. However, in the EDL muscle, intramuscular fat content was ~190% and ~90% greater in the VCD group compared with Control and VCD+E2 groups, respectively ($p < 0.05$), with no difference between Control and VCD+E2 groups ($p > 0.05$).

CONCLUSION: We observed a muscle-dependent effect of decreased estradiol levels following ovarian failure on intramuscular fat accumulation with the fast-type EDL showing marked increases in fat content which was reversed following estrogen supplementation. While the soleus appeared to be protected from ovarian failure-induced intramuscular fat accumulation. These fiber-type specific differences highlight the complexity of effects of estrogen deficient states on skeletal muscle.

PHARMACOKINETICS OF KEY MICRONUTRIENTS IN THE FOUNDATIONAL NUTRITION SUPPLEMENT AG1

TOWNSEND, J., LA MONICA, M., KIRBY, T., SAPP, P., EDWARDS, C., SANDROCK, J., ZIEGENFUSS, T., VERGNE, M., AKERS, W., NYMAN, L., ESPOSITO, R.

AG1

INTRODUCTION: The interaction of nutrients in multi-ingredient supplements can be complex and may alter the absorption and bioavailability of nutrients following consumption. Pharmacokinetic data regarding micronutrient absorption when consumed in combination with other ingredients is scarce. The purpose of this randomized clinical trial was to define the absorption parameters of key micronutrients in AG1, a foundational nutrition supplement containing vitamins, minerals, probiotics, and phytonutrients, following acute consumption.

METHODS: A randomized, double-blind placebo-controlled crossover trial was conducted in 16 healthy males (n = 8; 27.4 ± 8.9 yrs; 81.5 ± 11.8 kg) and females (n = 8; 33.1 ± 9.7 yrs; 68.9 ± 6.0 kg) to measure the plasma appearance of key nutrients over 8 hours after acute AG1 consumption. Following a screening visit, participants reported to the laboratory after a 10-hour overnight fast and consumed 1 serving (13 g) of AG1 or placebo (maltodextrin matched for taste and appearance) mixed in 10 oz of water in a randomized, counterbalanced, crossover fashion separated by a one week washout period. Serial resting blood samples were subsequently taken over an 8-hour period (before and 30-, 60-, 90-, 120-, 180-, 240-, 360-, and 480 min post ingestion) and key circulating nutrient levels were assessed (folate, calcium, zinc, vitamin C, biotin, nicotinamide, pyridoxine, riboflavin, thiamin). Area under the curve (AUC) over the 8-hour period was calculated to assess the extent to which these nutrients were absorbed into the bloodstream and became available for use in the body. Repeated measures ANOVAs and paired t-tests were used to analyze the time course of nutrient availability between conditions. Additionally, product tolerability and adverse events were monitored following ICH-GCP guidelines.

RESULTS: Compared to the placebo, AG1 consumption resulted in a significantly higher AUC ($p < 0.05$) for folate, calcium, zinc, vitamin C, biotin, nicotinamide, riboflavin, and thiamin over the course of 8 hours. A trend ($p = 0.075$) for higher pyridoxine AUC was found in the AG1 treatment compared to placebo and pyridoxine concentrations were significantly elevated ($p < 0.05$) within 30 minutes following AG1 vs. placebo. There were no adverse events reported in either condition and both products were well tolerated.

CONCLUSION: These data demonstrate that all vitamins and minerals that were measured in AG1 were absorbed and entered circulation following consumption. Collectively, the results of this study validate the ability of AG1 to effectively increase circulating nutrient levels, indicating good bioavailability, and the potential to provide a meaningful physiological benefit to human health.

CARNITINE SUPPLEMENTATION: SAFETY CONSIDERATIONS

MANNUCCI, C., FERIOLO, D., TRIMARCHI, F., DI MAURO, D.

1) DEPARTMENT OF BIOMEDICAL SCIENCES, DENTAL SCIENCES, AND MORPHO-FUNCTIONAL IMAGING, UNIVERSITY OF MESSINA, MESSINA, ITALY.

INTRODUCTION: L-carnitine is a naturally occurring compound synthesized from lysine and methionine, playing a crucial role in energy metabolism by facilitating the transport of long-chain fatty acids into the mitochondria for β -oxidation. While endogenous production and dietary intake from animal-based sources are typically sufficient for maintaining physiological levels, supplementation has gained popularity, particularly among athletes seeking to optimize performance and recovery.

In sports, L-carnitine supplementation is primarily associated with enhanced endurance, improved fat metabolism, reduced muscle damage, and accelerated post-exercise recovery. Studies suggest that L-carnitine may contribute to glycogen sparing by increasing fatty acid utilization, thus prolonging time to exhaustion and delaying fatigue. Additionally, its

role in reducing oxidative stress and inflammation has been linked to improved muscle recovery following intense physical activity. The safety of L-carnitine supplementation has been a subject of debate. At recommended doses (500–2000 mg/day), L-carnitine is generally well tolerated, with mild gastrointestinal discomfort being the most common side effect. Despite the widespread use of carnitine in sport, data on its safety comes mainly from clinical reports.

METHODS: The data obtained were extrapolated from the EudraVigilance database. EudraVigilance, managed by the European Medicines Agency (EMA), is a system for monitoring the safety of medicines within the European Economic Area (EEA). It collects and analyzes reports of suspected adverse reactions to authorized medicines.

RESULTS: The results show that there are approximately 238 adverse reactions, reported mainly in Italy ($n = 168$). 107 concern those aged between 18 and 64, 58 for those over 65. 145 concerned women and 88 concerned men. Among the adverse reactions reported, 67 concerned skin reactions, 55 gastrointestinal reactions, 56 general disorders and administration type; 51 the nervous system and 31 psychiatric pathologies.

CONCLUSION: Carnitine remains a popular supplement among endurance athletes, while side effects are generally mild, population should consider dosage, individual tolerance, and dietary habits before supplementation, further research is needed to clarify its long-term effects.

ACUTE KETONE MONOESTER SUPPLEMENTATION INCREASES THE OXYGEN COST OF SUBMAXIMAL EXERCISE: A SYSTEMATIC REVIEW AND INDEPENDENT PARTICIPANT DATA META-ANALYSIS

MCCARTHY, D.G.1,3, HOBSON, S.J.2, BONE, J.3, BRADY, A.J.4,5, ROBBERECHTS, R.6, POFFÉ, C.6, HESPEL, P.7, DEARLOVE, D.J.8, BERKE, O.2, EGAN, B.4, GIBALA, M.J.3

1 DEPARTMENT OF HUMAN HEALTH AND NUTRITIONAL SCIENCES, UNIVERSITY OF GUELPH, GUELPH, CANADA; 2 POPULATION MEDICINE, UNIVERSITY OF GUELPH, GUELPH, CANADA; 3 DEPARTMENT OF KINESIOLOGY, MCMASTER UNIVERSITY, HAMILTON, CANADA; 4 SCHOOL OF HEALTH & HUMAN PERFORMANCE, DUBLIN CITY UNIVERSITY, DUBLIN, IRELAND; 5 DEPARTMENT OF MOLECULAR MEDICINE AND SURGERY, KAROLINSKA INSTITUTET, SWEDEN; 6 REHABILITATION RESEARCH CENTER, HASSELT UNIVERSITY, DIEPENBEEK, BELGIUM; 7 DEPARTMENT OF BIOMEDICAL KINESIOLOGY, KU LEUVEN, LEUVEN, BELGIUM; 8 UNIVERSITY OF OXFORD, OXFORD, ENGLAND, UNITED KINGDOM

INTRODUCTION: Ketone monoester supplement (KES) ingestion rapidly induces nutritional ketosis and has been reported to increase, decrease, or have no effect on oxygen uptake (VO_2) during matched-work exercise. This could depend on many factors including: KES dose and the resulting change in blood ketone body concentration (i.e., ΔKB), exercise intensity, duration and type; participant training status; substrate oxidation rate and respiratory exchange ratio (RER); nutritional state (e.g. fasted vs. fed, co-ingestion of other nutrients); and biological sex. The equivocal existing data regarding the effect of KES ingestion on exercise VO_2 may be due to between-study differences in the factors listed above, the magnitude of the effect, and statistical power to detect potentially small changes.

METHODS: The present systematic review and independent participant data meta-analysis (IPD-MA) asked the review question(s): (1) Does acute ingestion of a KES affect exercise efficiency/economy? (2) Can the variance in question 1 be explained by participants cardiorespiratory fitness, supplement dose, timing and the corresponding blood ketone concentration, co-ingestion of a KES with carbohydrate, exercise intensity, exercise duration, exercise modality, biological sex, and/or nutritional state? (PROSPERO ID: CRD42024573290). A systematic search using PubMed revealed 140 studies, 12 of which were randomized, crossover studies that involved the acute ingestion of a KES or a ketone-free control before work-matched exercise in endurance-trained adults. Individual participant data ($n=134$) were made available for inclusion from 11 of these studies from four independent laboratories. Outlier data were removed, per model assumptions, including if exercise VO_2 was not measured at steady state, exercise duration was >60 min, RER was >1.00 , or the absolute change in exercise VO_2 in KES vs. control (ΔVO_2) was >400 mL/min. A "one-step" IPD-MA was performed with a linear-mixed effects regression model using forward-selection. The outcome was ΔVO_2 and random effect was participants nested within studies nested within labs. Exercise duration, KES dose, and absolute workload were not included in the model due to significant correlations with other purported modifying factors breaking model assumptions.

RESULTS: ΔVO_2 was not different than zero when not considering modifying factors (mean[95% confidence intervals], $+9[-46$ to $+66]$ mL/min, $p=0.76$). ΔVO_2 was related to ΔKB ($+15[2$ to $29]$ mL/min/mM, $p=0.042$) and an interaction between ΔRER and relative exercise intensity ($+29[7$ to $50]$, $p=0.009$). There were no significant associations between ΔVO_2 and carbohydrate co-ingestion ($p=0.55$), fasting status ($p=0.64$), sex ($p=0.66$), exercise type ($p=0.33$), or maximal VO_2 ($p=0.63$).

CONCLUSION: In conclusion, KES ingestion increased VO_2 during submaximal constant-load exercise, more so when blood ketone bodies were higher and at higher relative exercise intensities.

MORINGA OLEIFERA LEAF EXTRACT MITIGATES DEXAMETHASONE-INDUCED MUSCLE ATROPHY IN C2C12 MYOTUBES

DURANTI, G., MALDINI, M., LA ROSA, P., SIRENO, L., OLSON, M.E., DIMAURO, I., CECI, R.

UNIVERSITY OF ROME FORO ITALICO

INTRODUCTION: Muscle atrophy occurs in various physio-pathological conditions, including severe muscle injury, disuse, hormone imbalances, cancer, sepsis, and aging. A common feature of these conditions is the presence of cellular oxidative damage and pro-inflammatory processes. Dexamethasone (DEXA) is a synthetic glucocorticoid that is widely used as an anti-inflammatory agent. However, chronic DEXA treatment can lead to side effects such as diabetes mellitus, obesity and, ultimately, muscle atrophy.

There is ongoing research aimed at identifying tools to counteract muscle atrophy and improve the quality of life for affected individuals. Among the promising approaches, the use of plant-based extracts has garnered significant attention. In particular, *Moringa oleifera* leaf extracts (MOLE) has been shown to support muscle cells metabolism ¹ and mitigate the negative effects of oxidative stress ².

METHODS: In this study, we investigated the effects of MOLE on DEXA-induced muscle atrophy and the underlying mechanisms in C2C12 myotubes.

RESULTS: Exposure to 100 micromolar DEXA for 24 hours induced muscle atrophy, as evidenced by increased levels of the specific markers as MuRF-1 and Atrogin-1, and reduced levels of myosin heavy chain (MHC).

MOLE (0.15 mg/mg dried powder) was administered either concomitantly, or 24 hours before or after DEXA exposure.

MOLE treatment was effective in reducing atrophy markers and improving the status of C2C12 myotubes, as reflected by increased MHC levels and fiber size in all experimental conditions involving DEXA.

Interestingly, the most pronounced effects were obtained when MOLE was administered to cells that had already undergone DEXA treatment.

CONCLUSION: In conclusion, these findings suggest that MOLE can alleviate DEXA-induced muscle atrophy in C2C12 myotubes by reducing atrophic markers and restoring the proper myotubes phenotype.

IRISIN AMELIORATES PALMITIC ACID-INDUCED HEPATIC LIPID ACCUMULATION BY SUPPRESSING ENDOPLASMIC RETICULUM STRESS ACTIVATION

CHEN, C., CHAN, Y.C., LO, C.W., CHEN, H.W., TSAI, S.C.

CHINA MEDICAL UNIVERSITY

INTRODUCTION: Palmitic acid is considered to play a dominant role in the development of non-alcoholic fatty liver disease (NAFLD), including the progression of endoplasmic reticulum (ER) stress and NLRP3 inflammasome activation, ultimately leading to hepatic lipid accumulation. Combined resistance and aerobic exercise training is considered the most optimal approach for treating NAFLD, and its reversal effect may be linked to myokine production, particularly irisin. However, the effects of different exercise intensities on irisin production and its role in PA-induced NAFLD remain unclear. Therefore, we aim to investigate whether irisin can reverse PA-induced hepatic lipid accumulation by suppressing ER stress and NLRP3 inflammasome activation.

METHODS: Hepatocytes were treated with palmitic acid alone or co-cultured with varying concentrations of irisin. Protein expression levels were analyzed by Western blot, and lipid accumulation in hepatocytes was assessed using Oil Red O staining. Cell viability was determined using the MTT assay. Data are presented as mean $\pm$ SD. One-way ANOVA was used to compare differences between groups, with a p-value < 0.05 considered statistically significant.

RESULTS: Results showed that palmitic acid significantly increased the protein expression of p-PERK and p-IRE1 α (ER stress biomarkers), which in turn activated TXNIP and NLRP3, leading to accelerated hepatic lipid accumulation via the ACC-FAS signaling pathway. Moreover, palmitic acid induced cell death. To investigate the potential protective effects of irisin, we co-treated cells with low, medium, and high doses of irisin to mimic the exercise-induced irisin production from skeletal muscle. We found that co-treatment with a low dose of irisin did not ameliorate palmitic acid-induced hepatic lipid accumulation. However, medium and high doses of irisin effectively reduced the ER stress response and NLRP3 activation while preventing lipid accumulation by suppressing the ACC-FAS pathway in hepatocytes, particularly at the high dose of irisin. Nevertheless, none of the irisin doses prevented palmitic acid-induced cell death.

CONCLUSION: We summarized that a high concentration of irisin can reduce palmitic acid-induced ER stress and NLRP3 activation, thereby diminishing lipid storage in hepatocytes through the downregulation of the ACC-FAS signaling pathway.

CP-PN07 Respiration and Gas Exchange

BREATH RETRAINING IN RUNNERS USING LOCOMOTOR-RESPIRATORY COUPLING: A PILOT STUDY

HARBOUR, E.

UNIVERSITY OF SALZBURG

INTRODUCTION: Breathing strategies such as Locomotor-Respiratory Coupling (LRC) have the potential to improve ventilatory efficiency and running performance (Harbour et. al, 2022) but have scarcely been reported in field or intervention

experiments. It is unknown if digital technologies can guide runners to learn LRC during exercise, and what physiological consequences result.

METHODS: Ten female runners completed an outdoor 5k time trial and indoor treadmill test to exhaustion. Runners were familiarized to LRC via a smartphone application (Harbour et. al, 2024) and completed 10 runs independently with the application over four to six weeks. The 5k and treadmill test were repeated after the intervention without LRC specific instruction.

Hexoskin smart shirts (Carre Technologies, CAN) were used to detect breathing pattern and LRC. A Suunto smartwatch was used to measure running pace outdoors, while spiroergometry (Cosmed, L.L.C., Rome, Italy) was used indoors. Questionnaires were asked regarding rating of fatigue, breathlessness, and flow. Pre and post-intervention data was compared using paired signed rank tests and Cohen's d effect sizes.

RESULTS: Participants expressed greater degrees of LRC in the post-tests, utilizing mostly 4:1 steps per breath in the outdoor run. Outdoors, runners decreased breathing rate while increasing diaphragmatic contribution ($p=0.02$, $d=1.2$) and pulse-respiration quotient ($p=0.03$, $d=0.68$) despite no change in running pace ($p=0.58$). During the indoor run, participants expressed higher tidal volume ($p=0.03$, $d=1.3$) especially at VO_{2max} where breathing rate was lower ($p=0.04$, $d=-0.30$). No meaningful changes were observed in VO_{2max} , ventilatory efficiency, or questionnaire responses.

CONCLUSION: This study demonstrates that LRC can be habituated over a 4-6 intervention period, resulting in changes to breathing pattern in field and indoor maximal conditions. Further investigations are needed using control comparisons and incorporating data from the intervention period.

CIGARETTE SMOKING SLOWS DOWN THE CARDIORESPIRATORY AND METABOLIC KINETICS DURING MODERATE EXERCISE IN YOUNG PHYSICALLY ACTIVE MALES

BORRELLI, M., MOTALLI, A., DORIA, C., TONINELLI, N., LIMONTA, E., GALASSO, L., LONGO, S., CORATELLA, G., CÈ, E., RAM-PICHINI, S., ESPOSITO, F.

UNIVERSITÀ DEGLI STUDI DI MILANO

INTRODUCTION: Cigarette smoking (CS) is the leading preventable cause of death, causing systemic changes that harmfully impact cardiovascular and pulmonary function at rest and during exercise. Indeed, nicotine overstimulates the sympathetic nervous system, tar alters O_2 diffusion, and carbon monoxide reduces O_2 transport and extraction (1). Although these effects are well-established in sedentary, middle-aged smokers (SM) with pulmonary disease, limited and controversial studies have focused on young SM without comorbidities (2). Hence, the aim of this study was to evaluate the cardiorespiratory and metabolic kinetics during moderate exercise in young, physically active SM without known lung or cardiovascular disease. It was hypothesized that, despite their brief smoking history and good fitness level, which could mitigate the negative CS effects, SM would exhibit slower kinetics, due to early alterations in oxidative stress, autonomic response and O_2 delivery.

METHODS: The study enrolled 10 physically active SM (age: 21 ± 2 yr., body mass: 78 ± 6 kg; stature: 1.79 ± 0.07 m; 12 ± 5 cigarette/day for 6 ± 2 yr.; mean $\pm$ SD) and 12 non-smokers (CTRL; age: 24 ± 3 yr., body mass: 78 ± 9 kg; stature: 1.80 ± 0.08 m) matched for age and exercise habits. Participants completed an incremental test ($25W/2$ min) on a cycle ergometer to determine the maximum pulmonary oxygen uptake ($\dot{V}O_{2max}$). After pulmonary evaluation, participants performed four 6-min square wave tests at 90% first ventilatory threshold VT_1 (3). The time constant (t) for expiratory ventilation ($\dot{V}E$), $\dot{V}O_2$, heart rate (f_H) and cardiac output (Q') during the increasing (on-phase) and decreasing (off-phase) transients was assessed using a mono-exponential model.

RESULTS: Static lung volumes were similar between SM and CTRL; however, SM had lower peak expiratory flow (-21% ; $P=0.004$) and maximal voluntary ventilation (-12% ; $P=0.004$). Additionally, SM had lower $\dot{V}O_{2max}$ (3657 ± 325 vs 3397 ± 316 ml·min $^{-1}$ for CTRL and SM, respectively; $P=0.037$) and mechanical power at VT_1 (201 ± 26 vs 185 ± 16 W for CTRL and SM respectively; $P=0.045$). During the on-phase, t in SM was longer for f_H ($+24\%$; $P=0.006$), $\dot{V}O_2$ ($+40\%$; $P=0.009$), $\dot{V}E$ ($+49\%$; $P=0.018$) and Q' ($+22\%$; $P=0.024$). Similarly, during the off-phase SM showed longer t for f_H ($+37\%$; $P=0.014$), $\dot{V}O_2$ ($+20\%$; $P=0.004$), $\dot{V}E$ ($+35\%$; $P=0.045$) and Q' ($+51\%$; $P=0.020$).

CONCLUSION: These results demonstrate that CS negatively impacts cardiorespiratory and metabolic kinetics at moderate exercise, thereby elevating cardiovascular risk in SM, despite their young age, relative short smoking history and physical fitness level.

CARDIORESPIRATORY AND OXYGEN UPTAKE KINETICS DURING A SQUARE-WAVE TRANSITION: THE IMPACT OF CIGARETTE SMOKING IN YOUNG, PHYSICALLY ACTIVE MALE ADULTS

MOTALLI, A., BORRELLI, M., DORIA, C., TONINELLI, N., LONGO, S., LIMONTA, E., CÈ, E., RAMPICHINI, S., ESPOSITO, F.
UNIVERSITÀ DEGLI STUDI DI MILANO

INTRODUCTION: Cigarette smoking (CS) has a detrimental impact on cardiorespiratory and metabolic response to exercise. Indeed, CS alters the sympathetic drive of the autonomic nervous system, increases airway resistance and oxidative stress, and impairs oxygen delivery (1). It is well-reported a diminished cardiorespiratory fitness in sedentary, middle-aged smokers (SM) with pulmonary disease, index of higher cardiovascular risk. By contrast, limited and controversial studies exist on CS effects in young, physically active SM with a short history of CS (2). Thus, the study aims to investigate the impact of CS on cardiorespiratory and metabolic kinetics during the onset of a square-wave moderate exercise in this population.

METHODS: Ten SM (age: 22 ± 2 yrs, body mass: 78 ± 6 kg, stature: 1.79 ± 0.07 m, 11 ± 5 cigarette/day for 6 ± 2 yrs; mean $\pm$ SD) and 11 non-smokers (CTRL; age: 23 ± 1 yrs, body mass: 78 ± 8 kg, stature: 1.80 ± 0.09 m) completed a pulmonary function evaluation. Then, they performed an incremental step test to assess cardiorespiratory and metabolic variables at peak exercise and the two ventilatory thresholds. Lastly, participants performed four 6-minute square-wave exercise (90% of the first ventilatory threshold) to assess the kinetics of expiratory ventilation (VE), oxygen uptake (VO₂) and heart rate (fH) responses. Breath-by-breath values of all these variables were averaged and then fitted by a bi-exponential function to determine the amplitude (AMP) and the time constant (τ) of the cardiorespiratory and metabolic kinetics.

RESULTS: Static lung volumes were similar between groups. However, SM showed a reduced peak expiratory flow (8.4 ± 1.8 vs 10.5 ± 1.8 l·s⁻¹, respectively; $P=0.01$) and lower maximum voluntary ventilation (168 ± 14 vs 191 ± 23 l·min⁻¹; respectively, $P=0.01$) compared to CTRL. At peak exercise, despite similar VO₂ (3384 ± 318 vs 3623 ± 333 ml·min⁻¹; for SM and CTRL, respectively), SM exhibited lower mechanical power output (253 ± 21 vs 278 ± 27 W, respectively; $P=0.01$) and VE (125 ± 11 vs 139 ± 11 l·min⁻¹, respectively, $P=0.02$). In addition, SM reached ventilatory threshold earlier than CTRL. During constant moderate exercise, SM displayed prolonged VO₂ phase I (τ : 17 ± 9 vs 12 ± 4 s for SM and CTRL, respectively; $P=0.03$) and reduced phase II amplitude (886 ± 301 vs 1111 ± 295 ml·min⁻¹, for SM and CTRL, respectively; $P=0.05$). Moreover, SM exhibited a slower fH response during phase II (61 ± 18 vs 48 ± 13 s, respectively; $P=0.03$).

CONCLUSION: The longer cardiorespiratory kinetics demonstrate that CS alters the cardiorespiratory and metabolic responses to exercise even in young, asymptomatic SM with a relatively short smoking history.

DIFFERENCES IN BASAL VENTILATORY FUNCTION BASED ON TRAINING STATUS AND SEX

ARMERO-SOTILLO, A., BENÍTEZ-MUÑOZ, J.A., BENITO, P.J., CUPEIRO, R., ALCOZER-AYUGA, M., ROJO-TIRADO, M.A., RAMOS-CAMPO, D.J., MARTÍNEZ-GUARDADO, I., PEINADO, A.B.
UNIVERSIDAD POLITÉCNICA DE MADRID

INTRODUCTION: The respiratory system does not adapt in response to repetitive physical training as well as other systems such as the cardiovascular or musculoskeletal (1,2). This could lead to the respiratory system limiting performance in highly trained individuals (2). However, there are studies in the literature showing that athletes have better ventilatory function [forced vital capacity (FVC) and forced expiratory volume in 1 second (FEV₁)] than sedentary individuals (3,4). To date, the relationship between training status and ventilatory function showed an association between VO₂max and both FEV₁ and FVC (5). Unfortunately, the participant's VO₂max was rather low, which prevented a clear understanding of what happens to ventilatory function in individuals with a higher VO₂max, i.e., those with a higher likelihood of experiencing ventilatory limitation when exercising at high intensities. Hence, the aim of determining whether ventilatory function differs between individuals presenting a wide range of training status.

METHODS: We examined 198 males (M: 41 ± 10 yrs, 74.0 ± 8.1 kg, 175.2 ± 6.5 cm, $18.5 \pm 6.8\%$ fat) and 60 females (F: 37 ± 14 yrs, 59.1 ± 8.4 kg, 164.7 ± 6.1 cm, $25.7 \pm 8.6\%$ fat) who performed different spirometry tests to assess ventilatory function (FVC and FEV₁). The spirometry tests were thoroughly explained and demonstrated by the technician, following the ATS/ERS Task Force Recommendations (6). The training status of the participants was determined based on VO₂max (5), dividing them into low, medium or high training levels according to VO₂max tertiles.

RESULTS: A main effect of training status was found on FVC ($p < 0.001$; $\eta^2 p = 0.063$) and FEV₁ ($p = 0.003$; $\eta^2 p = 0.045$). Pairwise comparisons showed a lower FVC in low training status (M: 4.8 ± 0.7 L; F: 3.37 ± 0.67 L) than in the medium (M: 5.14 ± 0.69 L; F: 3.87 ± 0.49 L; $p = 0.026$; $d = 0.527$) or high (M: 5.53 ± 0.68 L; F: 3.98 ± 0.53 L; $p < 0.001$; $d = 0.88$). Whereas FEV₁ showed a lower FEV₁ in the low training status (M: 3.91 ± 0.61 L; F: 2.78 ± 0.57 L) than in the high (M: 4.58 ± 0.59 L; F: 3.39 ± 0.53 L; $p = 0.002$; $d = 0.737$). Both FVC ($p < 0.001$; $\eta^2 p = 0.211$; $d = 1.64$) and FEV₁ ($p < 0.001$; $\eta^2 p = 0.197$; $d = 1.57$) were found to be lower in females than in males.

CONCLUSION: Baseline ventilatory function was higher in individuals with greater training status, with differences in FVC observed between low and medium training levels, but not in FEV₁. These findings emphasize the importance of considering training status when assessing respiratory function. Additionally, females exhibited lower ventilatory function than males across all relative training status levels, indicating a sex-related difference independent of training status.

COMPETITION-PHASE BREATHING STRATEGIES IN SPORTS: A SCOPING REVIEW

MIGLIACCIO, G., RUSSO, L., AKBULUT, T., PADULO, J.

SAN RAFFAELE OPEN UNIVERSITY

INTRODUCTION: Breathing strategies in sports involve both slow-paced (4-10 breaths/min) and fast-paced (>20 breaths/min) breathing, showing distinct physiological and psychological effects on performance. While these techniques are widely used across different competition phases, their integrated impact remains poorly understood, particularly regarding phase-specific adaptations and sport-specific requirements. **PURPOSE:** To systematically map the evidence regarding slow- and fast-paced breathing strategies across competition phases, analyzing both physiological and psychological outcomes in competitive sports

METHODS: PubMed, Web of Science, and Scopus were searched from inception to September 2024. Studies examining voluntary breathing strategies in competitive sports were included. Two independent reviewers screened articles following JBI methodology. Data were categorized by breathing type (slow/fast), competition phase, physiological outcomes (HRV, blood pressure, oxygen delivery), and psychological outcomes (anxiety, focus, arousal).

RESULTS: Of 612 identified articles, 45 met inclusion criteria. Pre-competition studies (n=21) showed slow breathing enhanced parasympathetic activity and reduced anxiety, while fast breathing improved activation states. During-competition research (n=15) revealed sport-specific breathing patterns adaptations, with endurance athletes utilizing both techniques based on competition demands. Post-competition studies (n=9) demonstrated recovery optimization through slow breathing protocols. Only 12% of studies examined integrated breathing approaches across all phases.

CONCLUSION: This review unveils a promising frontier in sports performance enhancement through phase-specific breathing strategies. The evidence suggests that tailored combinations of slow and fast breathing techniques could revolutionize how athletes prepare, perform, and recover. Future research integrating these approaches could transform current training paradigms, particularly in developing sport-specific protocols that optimize both physiological and psychological outcomes.

CREWS STUDY: GAS EXCHANGE IS MILDLY IMPAIRED ACROSS A SINGLE WILDFIRE SUPPRESSION SHIFT

BREWSTER, M., LICHTY, D., WOEHRLE, N., FROESE, K., BROZNITSKY, N., AINSIE, P.

UNIVERSITY OF BRITISH COLUMBIA OKANAGAN

INTRODUCTION: An increase in the severity of global wildfires necessitates examination of the associated health risks, particularly in wildfire personnel. Exposure to particulate matter from smoke and ash (respirable PM, less than 4 microns in aerodynamic diameter) as well as soil (respirable crystalline silica as alpha quartz, RCS) have previously been linked to acute respiratory dysfunction and are common exposures in the wildfire suppression milieu. Despite evidence of chronic reductions in diffusion capacity of the lungs in firefighters who responded to a multi-day fire event, which was correlated with estimated particulate matter exposure, gas exchange across a single shift of wildfire suppression has not been previously examined. Therefore, we tested the hypotheses that 1) gas exchange would be impaired across a single shift of wildfire suppression and 2) this impairment would be associated with increased personal exposure to smoke-derived PM and RCS exposure.

METHODS: To do this, we conducted personal air sampling for respirable PM and RCS in 32 wildland firefighters (31M/1F; Age: 30.8+/-8.5; BMI: 25.5+/-3.0) from the British Columbia Wildfire Service across 10 days of wildfire suppression with concurrent pre- and post-shift measurements of gas exchange. Smoke-derived PM was calculated by subtracting RCS from respirable PM. Alveolar-arterial oxygen difference was estimated using a validated noninvasive pulmonary gas exchange monitor (MediPines Gas Exchange Monitor; MediPines Corp., Yorba Linda, CA).

RESULTS: We found that the estimated alveolar-arterial oxygen difference (oxygen deficit) was increased from pre- to post- (3.4+/-4.9 vs 6.2+/-6.6 mmHg, p=0.01) wildfire suppression shift (average shift length: 8.9+/-2.4 hours). This was supported by a reduction in oxygen saturation (pre vs. post: 97.6+/-0.8% vs 96.3+/-1.3%, p<0.0001), suggesting a mild impairment in gas exchange associated with acute wildfire suppression. The time weighted averages for smoke-derived PM (0.65+/-0.5 mg/mg³) and RCS (17.9+/-15.8 ug/m³) were near - but did not exceed - occupational exposure limits (respirable PM: 0.7 mg/m³; RCS: 25 ug/m³). Neither smoke-derived PM (p=0.18) nor RCS (p=0.97) were not correlated with the impairment in gas exchange.

CONCLUSION: However, this lack of correlation may be due to disparities in environmental exposure versus biological dose and does not account for changes in ventilation or potential lag time between exposure and physiological response.

Future research is needed to determine the mechanism(s) and implications of the cross-shift impairments in gas exchange observed in wildland firefighters.

ASSESSMENT OF OXYGEN UPTAKE KINETICS MEASURED USING THE MIXING CHAMBER METHOD DURING INCREMENTAL EXERCISE

HATANO, K., GOTO, H., KOIZUMI, J., MATSUBAYASHI, T.

JAPAN INSTITUTE OF SPORT SCIENCES

INTRODUCTION: The mean response time (MRT), which reflects the speed of the oxygen uptake (VO₂) kinetics at the transition from rest to exercise, is one of the indicators of aerobic exercise capacity [1]. Although the breath-by-breath method is known to be most suitable for the assessment of VO₂ kinetics, the mixing chamber method may also be applicable when high-frequency sampling is performed (e.g., at 5-s intervals). This study aimed to assess VO₂ kinetics measured using the mixing chamber method during incremental exercise and to examine its relationship with the maximal oxygen uptake (VO_{2max}) and the lactate thresholds (LT1 and LT2).

METHODS: Fifty-seven Japanese middle- or long-distance runners (44 males, 13 females) performed a multi-stage incremental treadmill running test at a slope of 1%. Each stage consisted of 3 minutes of running followed by 1 minute of rest, with running speed increasing by 20 m/min per stage until the blood lactate concentration (BLa) exceeded 4 mmol/L. The initial running speed was set between 210–250 m/min based on sex and specialty. After the BLa exceeded 4 mmol/L, subjects rested for 3 minutes before performing an additional incremental exercise test to assess VO_{2max}, where running speed increased by 10 m/min every minute to exhaustion. Throughout the test, VO₂ was continuously measured using the mixing chamber method with a sampling frequency of 5 s (AE-310S, Minato, Japan). MRT was calculated by fitting a mono-exponential function to the VO₂ data of each stage. LT1 and LT2 were determined respectively at the fixed BLa of 2 and 4 mmol/L.

RESULTS: MRT was 36.1 ± 5.5 s at the first stage and increased significantly at the stages where the BLa exceeded LT1 (42.0 ± 6.8 s, $p < 0.05$) and LT2 (41.9 ± 7.9 s, $p < 0.05$). The mean VO_{2max} was 72.9 ± 5.9 ml/kg/min. There was no significant correlation between MRT of each stage and VO_{2max}. A negative correlation was observed between the first-stage MRT and the relative exercise intensity at LT1 ($81.0 \pm 4.8\%$ VO_{2max}, $r = -0.41$, $p < 0.05$) and LT2 ($90.8 \pm 3.6\%$ VO_{2max}, $r = -0.29$, $p < 0.05$), but no correlation was found with the MRT of other stages.

CONCLUSION: The increase in MRT with higher exercise intensity is consistent with previous studies [1, 2], indicating that the MRT observed in this study is similar to that obtained by using the breath-by-breath method in relation to exercise intensity. There was no correlation between MRT and VO_{2max}, and this study did not demonstrate a relationship between VO₂ kinetics and maximal aerobic capacity. However, the negative correlation between first-stage MRT and relative LT1 and LT2 intensity indicates that individuals with higher relative LT intensity tend to have a shorter MRT during low-to-moderate intensity exercise. Therefore, these results suggest that assessment of VO₂ kinetics with the mixing chamber method may provide insight into aerobic exercise capacity.

BIOENERGETICS OF THE VO₂ SLOW COMPONENT BETWEEN EXERCISE INTENSITIES AND DOMAINS

MASSIMO, T., FELLES, C., BOONE, J., COLOSIO, A., POGGIAGHI, S.

HAMAD BIN KHALIFA UNIVERSITY

INTRODUCTION: VO₂ slow component (VO_{2sc}) is a slowly developing increase in VO₂ above predicted values during heavy and severe exercise domains. In the heavy, the VO_{2sc} has been attributed to a prolonged shift from anaerobic to aerobic energy sources rather than to an augmented cost of locomotion. Whether a delayed metabolic shift and/or a loss of efficiency of locomotion explains the VO_{2sc} in the severe domain is under debate. Purpose: by determining the total cost of exercise, accounting for the anaerobic and aerobic energy sources, we hypothesized that i) a loss of efficiency is present in severe intensities only while a delayed metabolic shift will explain the VO_{2sc} in heavy, ii) the size of the VO_{2sc} will be larger with larger early anaerobic contribution and the resulting bigger decrement in its contribution over time.

METHODS: 25 young adults (10 females) performed 9-min constant exercises at the lower and upper range of moderate, heavy, and severe. For each intensity, we calculate: i) VO_{2sc} as the excess VO₂ beyond the 3rd min, ii) aerobic (VO₂ – restVO₂ – VO₂ of ventilation) and anaerobic contribution (O₂ equivalent of lactate accumulation) determining the cost of exercise (AdjO₂Eq) for the 0-3, 3-6, and 6-9 time segment (mL·3min⁻¹), and iii) the decrement slope in the anaerobic contribution beyond the 3rd min. The energetic contributors and AdjO₂Eq were compared across intensities and time segments by a two-way RM-ANOVA. Correlation analyses were performed between VO_{2sc} and 0-3min anaerobic contribution and its decrement slope.

RESULTS: VO_{2sc} increases with intensity ($p < 0.001$), however, the cost of exercise remains stable in moderate and heavy (6-9 = 3-6min, mean differences: -6 ± 123 mL·3min⁻¹ AdjO₂Eq; $p > 0.10$ for all intensities) as a result of a decreasing anaerobic mirrored by increasing aerobic contribution over time (respectively, 6-9 vs 3-6min mean differences: -47 ± 107 mL·3min⁻¹ and $+42 \pm 130$ mL·3min⁻¹ O₂Eq; $p < 0.05$ for all comparisons). Conversely, in severe, the increasing aerobic was larger than the decreasing anaerobic contribution (respectively, 6-9 vs 3-6min mean differences: $+525 \pm 297$ mL·3min⁻¹ and -94 ± 344 mL·3min⁻¹ O₂Eq; $p < 0.001$ for all comparisons) resulting in an increased cost of exercise (6-9 > 3-6min, mean differences:

+431 $\pm$ 365 mL $\cdot$ 3min $^{-1}$ AdjO₂Eq; $p < 0.001$ for both intensities). Lastly, the VO_{2sc} was strongly correlated with the 0-3min anaerobic contribution ($r^2 = 0.80$, $p < 0.001$) and its decrement slope ($r^2 = 0.67$, $p < 0.001$).

CONCLUSION: In the heavy, VO_{2sc} can be explained by a delayed metabolic shift between energy sources, while in the severe, an increased cost of exercise suggests the emergence of a true loss of efficiency. Moreover, the size of the VO_{2sc} can be partially related to the size of the early anaerobic contribution and the resulting decrease during phase III of the oxygen uptake kinetics (i.e., beyond the 3rd min), suggesting being affected by the metabolic shift.

DIFFERENCES IN VO₂MAX-MEASUREMENTS BETWEEN BREATH-BY-BREATH AND ADAPTIVE MIXING CHAMBER MODE IN THE COSMED QUARK CPET

WINKERT, K., DE LA CRUZ LASTRE, L.D., ALIMORADINASRABADI, B., STEINACKER, J.M., KIRSTEN, J.
UNIVERSITY OF ULM

INTRODUCTION: Maximal oxygen consumption (VO₂max), accepted as a descriptive measure of aerobic capacity, is widely used to monitor training-induced adaptation, predict sports performance, or classify athletic populations. Automated metabolic analyzers are commonly used to determine VO₂max, with results that might be influenced by the analyzer's technological approach. Therefore, we aimed to determine differences in VO₂max measures between the breath-by-breath (BxB) and the recently introduced adaptive mixing chamber approach (AMC) of the COSMED Quark CPET (Rome, Italy).

METHODS: Eighteen trained to highly trained participants ($n = 8$ female, age 30 ± 7 years, peak power 417 ± 88 W, VO₂max 59.3 ± 4.9 mL/kg/min) performed a maximal ramp test on a bike ergometer (Lode Excalibur, Groningen, Netherlands). The ramp protocol started at 40 W and increased by 20-40 W per minute, depending on the participants self-reported fitness. To minimize intra-individual biological variability and inter-device measurement differences, all tests were performed using two identical Quark CPET metabolic analyzer units customized for simultaneous measurement. One unit was equipped with the AMIS 24 (COSMED, Rome, Italy) for AMC mode, and the other operated in BxB mode, with mode distribution counterbalanced between units. VO₂max was calculated as the highest 30-second rolling average for both modes, with BxB data corrected for additional dead space of the customized setup beforehand. Mode differences reported as means with 95% confidence intervals (95% CI) were analyzed using paired Student's test and effect sizes were calculated using Cohen's d .

RESULTS: VO₂max (-2.15% 95% CI $[-3.60; -0.67]$), carbon dioxide output (VCO₂)@VO₂max (-4.10% 95% CI $[-5.80; -2.37]$), and minute ventilation (VE)@VO₂max (-11.54% 95% CI $[-14.12; -7.85]$) were significantly lower in BxB vs. AMC mode, with effect sizes ranging from moderate to large (Cohen's d -0.613 - 1.402).

CONCLUSION: During simultaneous measurements of two COSMED Quark CPET units in a bike ergometer ramp test, we obtained significantly lower VO₂max values in BxB vs. AMC mode. The VO₂max difference may be caused by time delay issues reported for BxB systems, occurring especially at high ventilation rates. In contrast, AMC mode addresses this by adjusting the mixing chamber size based on the ventilation per breath, potentially reducing time delays and enhancing measurement validity, especially at high ventilation rates as seen in a population of elite athletes. In the absence of the Douglas bag method as a reference, we emphasize that the observed inter-mode differences in VO₂max for the COSMED Quark CPET do not directly indicate higher validity of the AMC vs. BxB mode, and results should not be generalized to other devices. However, our results highlight the importance of reporting the device and technological approach used for VO₂max measurements, as these factors should be considered when comparing results across studies and laboratories.

LISTENING TO MUSIC WHILE RUNNING ALTERS VENTILATORY EQUIVALENTS FOR OXYGEN (VE/VO₂) AND CARBON DIOXIDE (VE/VCO₂): A PILOT STUDY

VENTURA, L., MORRONE, M., NATALE, D., BOI, A., MARTINEZ, G., BANDIERA, P., CUGUSI, L., DERIU, F., MANCA, A.
AZIENDA OSPEDALIERO UNIVERSITARIA DI SASSARI, SASSARI, ITALY; DEPARTMENT OF BIOMEDICAL SCIENCES, UNIVERSITY OF SASSARI, ITALY

INTRODUCTION: Music listening while exercising has been associated with several positive effects including higher compliance with exercise programs, increased endurance, reduced rate of perceived exertion (RPE), and other psychological benefits. To date, it is still unclear whether listening to music while running alters the ventilatory responses to exercise and the energy expenditure.

METHODS: This pilot study with randomly ordered, repeated exposures to no music and up-tempo music (120 beats per minute; song track "Moves like Jagger" by Maroon 5) at moderate-high volume (85 decibels) while running on a treadmill for 15-minute stints at 8 km/h was carried out enrolling young (18-30 years old) casual runners. Outcome measures included ventilation, VO₂ consumption, VCO₂ production as well as ventilatory equivalents for oxygen (VE/VO₂) and carbon dioxide (VE/VCO₂), all assessed by open circuit ergospirometry. Blood lactate was also measured at the start and at the end of each running stint and five minutes into the recovery phase. RPE was measured using a Borg 6-20 scale every 5 minutes during the test. Running biomechanics was assessed by a photocell, optoelectrical system to determine space-time parameters of the running cycles.

Main effects of Condition (music/no music), Gender (male/female) and Condition*Gender interaction were tested by repeated measures ANOVA (RM ANOVA).

RESULTS: Complete data were obtained from 13 physically active volunteers (7M, 6F). None of the participants reported adverse events or injuries associated with the study procedures. RM ANOVA with Bonferroni adjusted pairwise comparisons revealed significant increases in ventilatory and gas exchanges measurements when running with music compared to running in physiological conditions. More specifically, ventilation increased by 5.2% (from 71.8 to 75.5 L/min; $p=0.04$), VE/VO_2 by 6.5% (from 24.7 to 26.3; $p=0.04$), and VE/VCO_2 by 3.1% (from 29.3 to 30.2; $p=0.03$). Blood lactate measured five minutes after the end of the running stints showed higher concentrations following the music condition (2.7 mmol/L) compared to running without music (2.3 mmol/L), whereas RPE was 3.3% lower at the end of the test with the music stimulation, although neither reached statistical significance ($p=0.067$; $p=0.091$, respectively).

Space-time descriptors of running biomechanics were also found to change during music compared to no-music condition. Largest changes involved step length, which decreased by a significant 4.6% (from 91 to 87 cm; $p=0.002$) and correlated significantly with ventilatory changes (all r coefficients ≥ 0.5 , $p<0.01$). The observed changes were comparable between male and female participants.

CONCLUSION: Music stimulation led to ventilatory and blood changes compatible with higher rate of effort. The association of these alterations and the observed biomechanics changes suggests that music listening may reduce the efficiency of running, despite not increasing the rate of perceived exertion.

THE RELATIONSHIP BETWEEN BODY TEMPERATURE AND SLEEP PARAMETERS IN FEMALE LONG-DISTANCE RUNNERS

OKAMOTO, S., LIN, C., HIROMATSU, C., GOTO, K.

RITSUMEIKAN UNIVERSITY

INTRODUCTION: For athletes, daily condition assessment is important for maintaining exercise performance. Although several markers for the assessment (e.g., exercise performance, scores of subjective feelings, hormones, resting heart rate) are proposed, a factor that affects recovery process is sleep related variables. While body temperature fluctuations may affect diurnal fluctuations in sleep-related hormones such as cortisol and melatonin (Kräuchi, et al., 2006; Hickie et al., 2013), changes in nocturnal body temperature and sleep quality following daily training have not been elucidated sufficiently in endurance athletes. Therefore, the aim of the present study was to investigate the relationship between skin temperature rhythm at the night and sleep parameters in female long-distance runners. We hypothesized that the day with strenuous training would alter nocturnal skin temperature and sleep quality compared to the day without training.

METHODS: Eleven female long-distance runners were evaluated skin temperature (proximal site) and sleep parameters for 7 consecutive days. Skin temperature was measured continuously every 5 min by attaching the button-type thermometer on the area of the groin using a seal. Sleep parameters were measured using an actigraphy, including sleep efficiency, total sleep time, sleep latency, and wake time after sleep onset (WASO). During the measurement period, the data were compared between two conditions: a day when strenuous training was conducted (TR) and a day when training was not conducted (REST).

RESULTS: The total sleep time in TR was significantly longer than in REST (447.6 ± 60.5 min vs. 360.2 ± 45.3 min; $P<0.05$). Skin temperature was significantly higher on TR compared with REST at 10 min and 20 min after bedtime ($P < 0.05$). At 60 min, skin temperature was significantly lower on TR compared with REST ($P < 0.05$). From 90-130 min, skin temperature was significantly elevated compared with the value of bedtime ($P < 0.05$).

CONCLUSION: The strenuous training affected the body temperature rhythm during night and total sleep time in female long-distance runners.

CAFFEINE SUPPLEMENTATION DID NOT OPTIMIZE MUSCLE STRENGTH AND MUSCULAR ENDURANCE IN HEALTHY, PHYSICALLY ACTIVE MEN AND WOMEN: A DOUBLE-BLIND, RANDOMIZED, CROSSOVER, PLACEBO-CONTROLLED CLINICAL TRIAL.

QUARESMA, M., BRITO, C., LEAL, T., SILVA, M., NOAL, B., FERREIRA, J., MALECHESK, G., RODRIGUES, A., ALVARES, L., FERREIRA, R., NAKAMOTO, F.

CENTRO UNIVERSITÁRIO SÃO CAMILO

INTRODUCTION: Caffeine (CAF) reduces perceived fatigue and effort by antagonizing adenosine receptors and is widely recognized as an ergogenic aid. In women, hormonal fluctuations due to the menstrual cycle or oral contraceptive use may influence CAF metabolism, potentially modifying its ergogenic effects. However, few studies have directly compared the effects of CAF on men and women. This study aimed to investigate the ergogenic effects of CAF on recreationally active women and men.

METHODS: This was a crossover, double-blind, randomized, placebo-controlled clinical trial. Participants were selected based on eligibility criteria and randomly allocated in a crossover design to receive either CAF or a placebo (PLA). Thirty minutes after meal ingestion, participants consumed CAF (6 mg.kg⁻¹) or PLA. Muscle strength (MS) was assessed for handgrip (HGS), quadriceps femoris (QF), gluteus medius (GMe), gluteus maximus (GMa), biceps brachii (BB), triceps bra-

chii (TB), deltoid (D), latissimus dorsi (LD), and pectoralis major muscle (PMM). Muscle endurance was evaluated using the push-up test (PUT) and the static squat test (SST).

RESULTS: A total of 50 individuals were contacted, but only 14 (seven men, seven women) participated. The mean age was 24.0 ± 6.3 and 25.7 ± 3.20 years for women and men, respectively; mean BMI was 24.2 ± 2.83 kg/m² and 25.0 ± 2.92 kg/m², respectively. Body fat percentage was $25.9 \pm 3.30\%$ for women and $17.3 \pm 4.16\%$ for men. No increase was observed in right-hand HGS ($p=0.400$; $n_2p=0.065$), with a mean difference (MD) of -1.95 kg for women ($p=0.736$) and -0.48 kg for men ($p=0.995$). Similarly, left-hand HGS remained unchanged ($p=0.994$; $n_2p=0.000$), with MDs of -0.129 kg for women ($p=1.000$) and -0.112 kg for men ($p=1.000$). QF MS was not affected ($p=0.455$; $n_2p=0.047$), with MDs of -4.42 kg for women ($p=0.576$) and -0.72 kg for men ($p=0.996$). Similarly, no increase was found in GMa MS ($p=0.213$; $n_2p=0.126$), with MDs of -2.8 kg for women ($p=0.603$) and -1.33 kg for men ($p=0.930$). CAF did not improve GMe MS ($p=0.702$; $n_2p=0.013$), with MDs of 0.924 kg for women ($p=0.847$) and -0.294 kg for men ($p=0.994$). BB MS remained unchanged ($p=0.670$; $n_2p=0.016$), with MDs of 0.548 kg for women ($p=0.923$) and -0.005 kg for men ($p=1.000$). No increase was found in PMM MS ($p=0.622$; $n_2p=0.021$), with MDs of 1.01 kg for women ($p=0.579$) and -1.57 kg for men ($p=0.235$). D MS was also unaffected ($p=0.424$; $n_2p=0.054$), with MDs of 0.301 kg for women ($p=0.990$) and -1.48 kg for men ($p=0.485$). CAF supplementation did not improve SST performance ($p=0.522$; $n_2p=0.035$), with MDs of -5.80 s for women ($p=0.259$) and 3.03 s for men ($p=0.742$). Similarly, PUT performance remained unchanged ($p=0.714$; $n_2p=0.012$), with MDs of -0.477 s for women ($p=0.984$) and 1.18 s for men ($p=0.812$).

CONCLUSION: CAF supplementation did not enhance MS or muscular endurance in healthy adult women and men. Possible reasons for not observing an effect of CAF include sample size, the type of test applied, and the CYP1A2 CC genotype.

EVALUATING THE EFFECT OF NEW ZEALAND BLACKCURRANT POWDER AND CAFFEINE INTAKE ON HIGH-INTENSITY INTERMITTENT EXERCISE PERFORMANCE

ALI, A., NANAVATI, K., HURST, R., VITZEL, K., RUTHERFORD-MARKWICK, K.
MASSEY UNIVERSITY

INTRODUCTION: Intake of New Zealand blackcurrant (NZBC) powder and extract has shown to increase fat oxidation during exercise and improve running and cycling performance in recreationally active individuals. Acute consumption of caffeine has shown to sustain higher speeds during a high-intensity intermittent running protocol. Thus, combining NZBC with caffeine may provide an additive or a synergistic effect to improve exercise performance.

METHODS: Fourteen recreationally active males (29.5 ± 9.3 yrs, VO_{2max} 48.8 ± 4 ml·kg⁻¹·min⁻¹) participated in a double blind, randomised controlled crossover trial with each participant taking part in four main trials (>7-day washout between trials): placebo (PLA), placebo + caffeine (CAFF), NZBC drink, and NZBC + caffeine drink (NZBC-CAFF). Each main trial was divided into two visits across two consecutive days. On the afternoon of Day 1, participants consumed either PLA or NZBC and completed a ~90-min cycling protocol at ~60% maximal power output. Substrate oxidation was assessed using breath by breath indirect calorimetry. On Day 2 of the trial, participants consumed one of the four experimental beverages and took part in the ~90 min modified Loughborough Intermittent Shuttle Test (m-LIST), and changes in sprint speed and distance covered were evaluated. During both trials, blood samples were taken before, during and immediately after the exercise to measure plasma free fatty acids (FFA) concentration.

RESULTS: Consumption of the NZBC drink had no effect on substrate oxidation during the cycling protocol. However, there was a trend for energy expenditure to be lower in the NZBC compared to PLA group ($p=0.076$, $\eta^2=0.111$). Plasma FFA concentration increased with time during cycling ($p<0.001$) and was higher with NZBC intake compared to PLA ($p=0.035$). For the m-LIST trial, there was a trend for the NZBC-CAFF and CAFF groups to sustain higher sprint speed from blocks 1 to 6 compared to NZBC and PLA groups ($p=0.099$, $\eta^2=0.259$). Plasma FFA concentrations increased with time during the m-LIST ($p<0.001$) and there was a trend for plasma FFA concentrations to be higher in CAFF and NZBC-CAFF ($p=0.066$, $\eta^2=0.755$) compared to the other groups.

CONCLUSION: While the intake of caffeine showed a trend for faster sprint times when consumed acutely, consumption of the NZBC drink alone did not offer similar benefits. This was the first study to observe a trend and a significant increase in plasma FFA levels during high-intensity intermittent running and cycling in recreationally active males with acute intake of NZBC with and without caffeine. The increase in plasma FFA concentrations during cycling with no changes in substrate oxidation following acute consumption of the NZBC drink, further highlights the need for investigating different intervention strategies (dose and duration) for insights on fat metabolism during exercise.

EFFECT OF TOTAL LOAD OF STEPS DURING A MARATHON ON MARATHON-INDUCED MUSCLE DAMAGE AND INFLAMMATION

ISHIKURA, K., TOKINOYA, K., TAKEKOSHI, K., NABEKURA, Y.
JOSAI UNIVERSITY

INTRODUCTION: We have previously shown that a reduced pace during the end of a marathon is related to blood muscle damage and inflammation markers, which in turn are associated with the total number of steps taken during the race. We hypothesized that the total load of steps during the marathon might influence these damage and inflammation mark-

ers. The aim of this study was to estimate the total load of steps during a marathon and clarify its effect on muscle damage and inflammation.

METHODS: Twenty-two healthy non-professional runners (15 men, 7 women, average age 23.2 ± 1.7 years old) who participated in the 43rd Tsukuba Full-Marathon race (Tsukuba-city Japan) were recruited as volunteers. They ran with a GPS watch which has a built-in accelerometer. Stride rate and stride length were obtained from the watch. Serum muscle damage markers (serum creatine kinase activity, etc.), inflammation markers (serum CRP, etc.) as well as muscle soreness were measured before, immediately after, and the one day after the marathon. The distance covered during a 12-minute run was measured beforehand. Additionally, on non-race days, a walking load system was used to measure the load on the soles of the feet at the marathon running speed. The total load was estimated by multiplying the load per step by the total number of steps during the marathon.

RESULTS: The ratio of change in pace from the second segment of the marathon (5–10 km) to the final segment (35–40 km) showed a negative correlation with serum creatine kinase (CK) activity. The total load during the marathon showed a positive correlation with finish time of the marathon, body weight, body mass index (BMI), and total number of steps during of the marathon, and a negative correlation with stride length during the marathon and the distance covered during a 12-minute run. In men, the total load during the marathon showed a positive correlation with serum CRP levels one day after the marathon.

CONCLUSION: The total load during the marathon is related to body weight and total number of steps during the marathon, and runners with longer stride lengths had lower total loads during the marathon. Runners with high level of total load during a marathon may influence marathon-induced skeletal muscle inflammation. It is suggested that men, who weigh more than women, have a larger total load during the marathon, which may increase skeletal muscle inflammation. Since we measured the load in a fresh state other than race days, it is possible that the load would be higher under the fatigued conditions typical during the marathon itself. This remains a subject for future research.

RACE WALKING METABOLIC COST INCREASES LINEARLY WITH SPEED

PAVEI, G.1,2, BOCCIA, G.2,3, BRIGATI, N.4, DI CASTRO, A.4, PARCESEPE, P.2,5, SERRANÒ, S.2, TENGATTINI, M.2, LA TORRE, A.1,2, RIGHETTI, S.2,6

1 UNIVERSITY OF MILAN; 2 ITALIAN ATHLETICS FEDERATION; 3 UNIVERSITY OF TURIN; 4 ITALIAN NATIONAL OLYMPIC COMMITTEE; 5 CHINESE ATHLETICS FEDERATION; 6 IRCCS SAN GERARDO DEI TINTORI, MONZA

INTRODUCTION: The metabolic cost (C , J/(kg m)), the energy needed to move one kilogram of body mass along one meter, is an important physiological factor also for performance prediction and monitor. Indeed, according to di Prampero's model (1) performance velocity is given by the ratio of the oxygen consumption fraction and C . In running, C is speed independent (at least up to 5 m/s), in walking C shows a U-shape profile and it becomes higher than running at about the walk-run transition speed (1). Race walking is an Olympic discipline of the athletics since the early '900. It is supposed to be a walk, by the rule, although performed at speeds typical of running (3.5–4.5 m/s) (2). The aim of this study was to compute race walking C as a function of speed.

METHODS: Eight international-level race walkers (5 men: $1h20'48'' \pm 2'51''$ 20 km PB, with the Olympic champion; 3 women: $1h33'15'' \pm 2'50''$ 20 km PB) were asked to race walk at increasing speed steps (3.2–4.4 m/s) for 4 minutes, while gas exchanges were collected by a metabolic cart. C was calculated as the net oxygen consumption multiplied by energy equivalent of oxygen and divided by race walking speed. Linear hierarchical regression analyses were performed adopting the speed as independent variables and C as dependent variable.

RESULTS: C increased as a function of speed in all athletes, although with different slopes and intercepts. The linear mixed-effect model with random intercepts for speed nested within subjects showed a significant main effect of speed ($\beta=0.732$; $SE=0.084$; $F=75.3$; $P<3.0 \times 10^{-10}$) explaining 93.7% of the variance (conditional $R^2=0.937$). The C vs. speed relationship can thus be described by this linear equation: $C = 0.73 \times v + 2.15$ (with v in m/s).

CONCLUSION: Race walking Cost is higher than running at each speed, and the difference increases as a function of speed. It is also higher than walking, but the slope is lower than the extrapolated walking parabolic profile. Albeit the adherence to the rule, C can be a determinant for the maximal race walking speed that can be sustained during an official (aerobic) competition: with 65 ml/(kg min) of oxygen consumption, a top speed of about 4.3 m/s can be reached by race walking, whereas it would be almost 5.8 m/s by running.

DOES CAFFEINE AFFECT WOMENS ENERGY THROUGH GENES? THE IMPACT OF CYP1A2 GENOTYPE ON ACUTE CAFFEINE EFFECTS ON MAXIMAL STRENGTH, MUSCLE POWER, AND STRENGTH ENDURANCE IN ADORA2A C ALLELE CARRIERS.

GREN, A., SZUMOWSKA, E.2, CACAK, J.2, BONARSKA, K.2, LIGEZA, T.2, WIECEK, M.3, KUSMIERCZYK, J.3, FILIP-STACHNIK, A.1,3

ACADEMY OF PHYSICAL EDUCATION IN KATOWICE, JAGIELLONIAN UNIVERSITY, UNIVERSITY OF PHYSICAL CULTURE IN CRAWOW

INTRODUCTION: Although the effects of caffeine may be influenced by both ADORA2A and CYP1A2 polymorphisms, previous studies on women have analyzed these genetic variants separately. Consequently, it remains unclear how their combined influence modulates the acute effects of caffeine on physical performance. This study aimed to investigate the impact of the CYP1A2 genotype on the acute effects of a 3 mg/kg dose of caffeine on maximal strength, muscle power, and strength endurance in ADORA2A C allele carriers.

METHODS: Fourteen resistance-trained women (AA homozygotes: $n = 8$; C-allele carriers: $n = 6$) of the CYP1A2 gene participated in a randomized, double-blind, placebo-controlled, counterbalanced, crossover trial. Each participant completed three experimental sessions under the following conditions: (a) no supplementation (control, CON); (b) ingestion of a placebo (PLAC), and (c) ingestion of 3 mg/kg of caffeine (CAF). During each session, participants performed the following tests: (a) a one-repetition maximum (1RM) test in the bench press exercise; (b) three sets of three repetitions of an explosive bench press exercise at 50% 1RM; (c) a countermovement jump (CMJ), and (d) a strength endurance test in the bench press exercise at 50% 1RM. Saliva samples were analyzed to determine each participant's genotype for the -163C > A polymorphism in the CYP1A2 gene (rs762551) and the 1976T > C polymorphism in the ADORA2A gene (rs5751876). Differences in 1RM, strength endurance, and CMJ were analyzed using a two-way ANOVA with repeated measures (3 conditions $\times$ 2 genotypes). Differences in mean and peak velocity were analyzed using a three-way ANOVA (3 conditions $\times$ 3 sets $\times$ 2 genotypes).

RESULTS: The two-way repeated-measures ANOVA indicated no significant main effect of condition, condition $\times$ genotype, and condition $\times$ set interaction for 1RM, strength endurance and CMJ ($p > 0.05$ for all). The three-way repeated-measures ANOVA revealed a significant main effect of condition for peak bar velocity ($p = 0.036$), but no significant main effect of condition for mean bar velocity, nor condition $\times$ genotype or condition $\times$ set interactions for both variables ($p > 0.05$ for all). Post hoc indicated significant increases in peak velocity between PLAC and CAF condition ($p = 0.025$; 1.26 ± 0.17 m/s vs 1.34 ± 0.23 m/s; Effect Size = 0.37, Delta = - 6.35%).

CONCLUSION: Caffeine supplementation at an absolute dose of 3 mg/kg did not significantly enhance maximal strength, strength endurance, or jump performance in resistance-trained women who are ADORA2A C allele carriers. However, a significant acute improvement in muscle power during the bench press exercise was observed following caffeine ingestion. Notably, the ergogenic response to acute caffeine intake was not influenced by CYP1A2 polymorphism. Thus, women who are ADORA2A C allele carriers may still experience some performance benefits from caffeine supplementation, regardless of their CYP1A2 genotype.

AEROBIC EXERCISE INDUCES A REDUCTION IN MUSCLE METABOLIC EFFICIENCY DURING ROUTINE LOW-INTENSITY PHYSICAL ACTIVITY AS A METABOLIC ADAPTATION

KNAAN, T., ZIV-AV, E., DUBNOV-RAZ, G., MELANSON, E., GEPNER, Y.

TEL AVIV UNIVERSITY

INTRODUCTION: Exercise training intervention studies have shown that total daily energy expenditure (TDEE) increases less than expected, and consequently, less weight-loss than predicted. However, the physiological mechanisms for exercise-induced metabolic adaptation (MA) remain unclear. This study aimed to identify changes in the muscle metabolic efficiency that occur as a physiological adaptation to exercise training.

METHODS: A clinical trial protocol was used, enrolling 16 overweight (body mass index: 28.1 ± 2.1 kg/m²) men ($n = 8$) and women ($n = 8$) aged 38.9 ± 3.7 years. Participants underwent a 3-month supervised exercise intervention at moderate intensity (65%-75% HR_{max}) equating to 20 kcal/kg/week. Doubly labeled water (DLW) was used to assess changes in TDEE and body composition. MA was evaluated by calculating the discrepancy between the observed post-intervention TDEE and the predicted energy expenditure. Muscle metabolic efficiency was assessed using a cycling ergometer, incorporating a range of workloads (10w, 25w, and 50w) and a real-life scenario involving low-intensity physical activities (stationary sitting, computer typing, washing dishes, and walking slowly). Daily physical activity (PA) was evaluated by a tri-axial accelerometer pre- and post-intervention.

RESULTS: Mean adherence to exercise training was 95%. While body weight did not change (0.0 ± 2.8 kg), fat-free mass (FFM, 1.0 ± 1.0 kg, $p = 0.003$), and fat mass (FM, -1.2 ± 2.1 kg, $p = 0.002$) significantly improved. TDEE increase significantly by 194 ± 304 kcal/day ($p = 0.03$) but, TDEE relative to FFM did not change, indicating MA. In addition, participants exhibited a MA of 97 ± 235 kcal/day or $39 \pm 116\%$ relative to exercise-induced energy expenditure (222 ± 40 kcal/day). Following the PA intervention, a decrease in EE was observed during washing dishes and walking slowly but not during lower activities (sitting or typing). Additionally, no significant changes in EE were observed at varying intensities during cycling. There was an overall increase of 15 ± 23 minutes daily in moderate and vigorous PA, but this increment fell short of the expected 28 ± 5 minutes daily increase in structured exercise.

CONCLUSION: Compensatory mechanisms induced by chronic exercise at moderate intensity may be mediated, at least partly, by behavioral compensation manifested as a lower-than-expected elevation in moderate-intensity physical activity.

This is coupled with a physiological compensatory mechanism, indicated by increased skeletal muscle efficiency during routine low activities. This trial was registered at clinicaltrials.gov as NCT04460040.

HIGH VS. LOW TORQUE IN ALL-OUT SHORT SPRINTS: A PHYSIOLOGICAL COMPARISON

RIESCO, J., ESCRIBANO-PASCUAL, A., GONZÁLEZ, A., PROTZEN, G., GIL-CALVO, M., BOULLOSA, D.
UNIVERSITY OF LEON

INTRODUCTION: Short sprint interval training (sSIT) can enhance both aerobic and anaerobic fitness through various protocols, with sprinting bouts lasting ≤ 10 s (Boullosa et al. 2022). However, the limited available evidence does not allow a comprehensive understanding of the acute psycho-physiological effects of applying different torques during cycling sSIT protocols with very short "all out" sprints (Samozino et al., 2007). This study aims to evaluate the impact of high (HT) versus low (LT) torques on neuromuscular performance, cardiometabolic, and perceptual responses during a sSIT session of 5-s sprints.

METHODS: Fifteen physically active individuals (22 ± 2 years; 23.5 ± 1.8 IMC kg/m²). After familiarization and determination of HT and LT with a graded sprinting test, 15 physically active individuals completed, in random order, 2 sSIT sessions (12, 5-s sprints on a cycle ergometer) with HT and LT. Physiological (i.e. surface electromyography [sEMG], oxygen consumption [VO₂], HR, blood pressure, and muscle oxygenation [SmO₂]), and perceptual parameters (i.e. affective valence [FS]) were assessed during sessions and acute recovery.

RESULTS: The mean RMS amplitude was higher in LT ($p=0.004$). However, FS was higher in the HT condition ($p = 0.01$). Mean RMS, Mean VO₂, HR, RPP, and FS increased across sets in both groups ($p < 0.001$). However, mean RMS, mean and peak VO₂, and HR showed no significant main effect or interaction. No differences were found in deoxygenation and reoxygenation rates or peak Bl_a concentrations between conditions.

CONCLUSION: Torque variations influence neuromuscular engagement and perceived effort but do not significantly alter acute metabolic and cardiovascular responses during sSIT. This suggests that torque adjustments can be used to modulate neuromuscular and perceptual demands without affecting overall cardiometabolic load, providing a strategy to tailor sSIT protocols for more specific training goals.

INFLUENCE OF TIME OF THE DAY OF EXERCISE ON CARDIORESPIRATORY FITNESS IN ADULTS – A RANDOMIZED CONTROLLED TRIAL

KNAIER, R., BRUGGISSER, F., INFANGER, D., RITTER, E., HANSSEN, H.
UNIVERSITY OF BASEL

INTRODUCTION: Current guidelines for exercise include recommendations about Frequency, Intensity, Time (duration), and Type of exercise (FITT), but not for time of the day. This is surprising considering the well-known impact of the circadian timing system on human health [1] and the well-documented diurnal variations in peak oxygen uptake (VO₂peak) [2] as well as many other physiological outcomes. A recent meta-analysis [3] showed that to this date no study has investigated the effect of exercising around noon or the late evening on VO₂peak. While some studies have investigated the effect of exercising in the morning or afternoon, they show several methodological limitations. The aim of this study was to investigate the effect of exercising at different times of the day on VO₂peak.

METHODS: Participants completed cardiopulmonary exercise tests using a ramp protocol on a cycle ergometer to determine VO₂peak before being randomly allocated to an exercise time at which they exercised three times a week for 12 weeks. Exercise times were 8:00, 12:00, 16:00 or 20:00. Nutrition, sleep and physical activity were closely monitored during the intervention period to control for confounding factors. The same exercise test was done after the intervention to compare post-intervention VO₂peak values between the four groups adjusted for baseline values using analysis of covariance. VO₂peak was confirmed using pre-specified verified criteria for RERmax in those participants that did not show a VO₂-plateau.

RESULTS: Participants' ($n=59$, 42% female) mean (standard deviation – SD) age was 68.3 (4.9) years and body mass index was 24.2 (2.9) kg/m². Baseline VO₂peak (mL/kg/min) values of the groups were 29.4 (6.9) for 8:00, 32.3 (5.2) for 12:00, 29.2 (5.6) for 16:00, and 32.5 (5.8) for 20:00, respectively. The observed mean differences (mL/kg/min) (95% confidence interval [95%CI]) for exercising at 8:00 compared to 12:00, 16:00, and 20:00, were -1.1 (-4.7; 2.5), -0.2 (-4.4; 4.0), and 0.3 (-3.3; 3.9), respectively. For the comparison of 12:00 compared to 16:00 and 20:00 it was 0.9 (-3.3; 5.2) and 1.4 (-2.0; 4.9), and for 16:00 compared to 20:00 it was 0.5 (-3.7; 4.7).

CONCLUSION: In contrast to our hypothesis, we found no evidence that the timing of exercise impacted the changes in VO₂peak during the exercise intervention period. The well-known diurnal variation in physical performance, thus might not affect long-term adaptations to physical exercise.

CARDIORESPIRATORY FITNESS OF CONCORDIA CREW MEMBERS LIVING IN EXTREME ENVIRONMENT FOR ELEVEN MONTHS

NERI, M., MENDT, S., MARCIANO, A., MAGGIONI, M., PORCELLI, S.
UNIVERSITY OF PAVIA

INTRODUCTION: Long-duration space missions are characterized by prolonged isolation and confinement in extreme environments. In these living conditions, astronauts face desynchronisation of the circadian rhythms with relevant consequences of physical and mental health [1]. In Antarctica, crew members of Concordia station are exposed to environmental conditions (hypobaric hypoxia, absence of sunlight) and lifestyle changes (isolation, confinement, modification of daily physical activity) similar to astronauts, resulting in an ideal experimental setting to test human physiological adaptations and circadian rhythms alteration [2,3]. As physical activity levels and changes in cardiorespiratory fitness seem to play a pivotal role on circadian rhythms [4], we aimed to evaluate how prolonged exposure to Antarctic extreme environment affects cardiorespiratory fitness of crew members living at Concordia station for eleven months.

METHODS: Twenty-four male subjects (age: 39 ± 11 ys, height: 177 ± 8 cm, weight: 79 ± 10 kg) were recruited. Before flying to Concordia (BDC), participants performed i) a ramp incremental cardiopulmonary test (CPET) up to exhaustion on a cycloergometer and ii) two constant work rate (CWR) exercise at 40% (MOD) and 70% (HVY) of peak work rate (W_{peak}). At Concordia station, participants performed MOD and HVY tests on monthly base. Pulmonary ventilation ($\dot{V}_E$), oxygen consumption ($\dot{V}O_2$) and carbon dioxide production ($\dot{V}CO_2$) were monitored. Heart rate (HR) was recorded. Rate of perceived exertion (RPE) using 6-20 Borg Scale and blood lactate were collected before and at the end of exercise. Two-way ANOVA for repeated measures was used to evaluate changes in cardiorespiratory fitness, using time and intensity (MOD vs HVY).

RESULTS: At BDC, W_{peak} and $\dot{V}O_{2peak}$ were 244 ± 38 W and 35.8 ± 5.4 ml*min⁻¹*kg⁻¹, respectively. Peak values of HR (174 ± 14 bpm), RER (1.40 ± 0.11), RPE (16 ± 2) and lactate (10.6 ± 1.7 mM) confirmed exhaustion. MOD was performed at 101 ± 16 W. HR was 123 ± 11 bpm and RPE was 10 ± 2 . HVY was performed at 173 ± 25 W. HR was 155 ± 38 bpm and RPE was 14 ± 2 . At Concordia, MOD and HVY work rate were reduced of about 25% due to hypoxic environment. HR and RPE were higher in HVY vs MOD at all time points ($p < 0.05$). No time effect or time x intensity interaction were observed ($p > 0.05$) for both HR and RPE. In MOD, HR (109 ± 14 bpm) and RPE (9 ± 2) were not affected between visits. Also for HVY, HR (131 ± 15 bpm) and RPE (13 ± 2) were not affected among visits.

CONCLUSION: Cardiovascular and perceptual responses to MOD and HVY exercises were not affected by eleven months at Concordia station. Thus, cardiorespiratory functions seems unaltered during prolonged confinement and hypoxia suggesting that other environmental stressors may alter circadian rhythms.

EFFECT OF REDUCED-EXERTION HIGH-INTENSITY INTERVAL TRAINING ON CARDIORESPIRATORY FITNESS: A META-ANALYSIS

PARK, J., KIM, D., LEE, E., HWANG, J., KANG, N., HWANG, M.
INCHEON NATIONAL UNIVERSITY

INTRODUCTION: Regular aerobic exercise plays a pivotal role in improving cardiorespiratory fitness (CRF) and preventing cardiovascular morbidity and mortality. Despite the clear health benefit of regular aerobic exercise of 150 minutes or more per week, many adults do not perform recommended amount of aerobic exercise due to time constraints. Recently, reduced-exertion high-intensity interval training (ReHIT) has been proposed as a time-efficient alternative. The effects of ReHIT on CRF remain inconclusive due to the limited number of studies with small sample sizes conducted to date. Without comprehensive analyses, it is difficult to determine the effects of ReHIT on CRF and cardiovascular disease (CVD) risk factors, and the minimum required amount of exercise. Therefore, the aim of this meta-analysis was to evaluate the effects of ReHIT on changes in CRF, a CVD risk factor, in sedentary adults.

METHODS: The literature search was performed using two electronic databases including the PubMed and Web of Science from Oct 10 2024 to Dec 5 2024. We included the studies that focus on:

- (a) sedentary adults, (b) ReHIT, (c) comparison with control (CONT) group or moderate-intensity continuous training (MICT) group, (d) CRF, and (e) randomized controlled trials (RCT).

The criteria for ReHIT were as follows:

(a) total duration of session: ≤ 10 minutes, (b) mode of exercise: Cycling, (c) minimum period ≥ 4 weeks.

RESULTS: Total eight studies were included in this meta-analysis. The random effects meta-analysis revealed that ReHIT group demonstrated significantly higher VO_{2peak}, a marker of cardiorespiratory fitness, than untrained CONT group (effects size = 0.972; 95% CI = 0.185-1.759, $p = 0.015$; I² = 74%). However, there was no significant difference in VO_{2peak} in comparison with MICT group (effect size = 0.110; 95% CI = -0.518 to 0.737, $p = 0.731$; I² = 61%). Additionally, there were no significant effects on body weight reduction in either CONT (effects size = -0.525; 95% CI = -1.387-0.337, $p = 0.337$; I² = 79%) or MICT group (effects size = -0.237; 95% CI = -0.915-0.441, $p = 0.493$; I² = 65%).

CONCLUSION: The findings of this meta-analysis indicates that ReHIT can be an effective alternative for the typical moderate-intensity aerobic exercise with 150 minutes or more per week for improving CRF and reducing CVD risk in habitually sedentary adults. However, it seems difficult to expect additional health benefits through weight loss since the absolute amount of exercise in ReHIT is relatively low.

A NIGHT WITH 6 HOURS OF SLEEP RESTRICTION WORSENS PERFORMANCE IN RODENTS UNDERGOING PERIODIZED RESISTANCE TRAINING.

DAUBIAN-NOSÉ, P., OYAMA, L.M., AQUINO, V., MINARI, A.L.A., DOS SANTOS, R.V.T.

UNIVERSIDADE FEDERAL DE SÃO PAULO

INTRODUCTION: Physical exercise is a powerful physiological and biomolecular stimulator capable of promoting various physiological responses. The physiological responses arising from physical exercise depend on the training load imposed between each session. Studies carried out in humans and animal models prove that sleep restriction has significant consequences on physical performance.

METHODS: Thirty 60-day-old male Wistar rats were used, divided into four groups (Sedentary Control (SC; N = 5), Sedentary Sleep Restriction (SRS; N = 5), Trained Control (TC; N = 10), and Trained Sleep Restriction (SRT; N = 10)). The animals were subjected to an initial maximal strength test, followed by a periodized strength training protocol lasting six weeks. Subsequently, the animals were subjected to a period of six hours of sleep restriction, with reassessment of the maximum strength test.

RESULTS: The present research found an increase in the total body mass of all animals at the end of the six weeks of study. Six hours of sleep restriction was able to reduce the strength capacity of the TRS group by 18.4% compared to the TC group. There were no significant differences in glycogen values between the experimental groups for either the plantaris muscle or the soleus muscle. There was no significant difference in CLOCK protein concentrations in the plantaris and soleus muscles. The work also demonstrated a significant difference in 15 metabolites from the anaerobic glycolysis pathway through metabolomic analysis.

CONCLUSION: We conclude that sleep restriction attenuates the performance of maximal strength capacity in trained animals, also demonstrating that the training process reduces the impact of sleep restriction on performance, altering several metabolites of the anaerobic glucose pathway.

ACUTE FATIGUE, CELLULAR STRESS, AND SIGNALING RESPONSES TO POWER-ORIENTED VS. STRENGTH-ORIENTED RESISTANCE EXERCISE

VÅRVIK, F., BJØRNSSEN, T.2, TORSTVEIT, M.K.1, RAASTAD, T.3

1 UNIVERSITY OF AGDER, 2 UNIVERSITY OF STAVANGER, 3 NORWEGIAN SCHOOL OF SPORT SCIENCES

INTRODUCTION: Maximal strength training and power training can result in partly similar but also distinct adaptations (1), mediated by the acute responses to exercise (2). Understanding these acute responses is important for optimizing training strategies and adaptation. Previous work has observed greater acute neuromuscular fatigue and slower recovery after strength- compared to power training (3). Nonetheless, comparisons of cellular stress and signaling following such training protocols remain largely unexplored. This study compared acute neuromuscular fatigue, cellular stress, and signaling responses following strength versus power training sessions.

METHODS: Twenty-six resistance-trained sub-elite female handball players were randomized into strength-oriented (SO: n = 13, 20 ± 3 yrs, 171 ± 6 cm, 69 ± 8 kg) or power-oriented (PO: n = 13, 21 ± 3 yrs, 171 ± 6 cm, 65 ± 7 kg) training groups. After completing a 12-week training period, we measured acute changes in neuromuscular fatigue, heat shock proteins, and intramuscular signaling responses, immediately before and 1-1.5 hours after time-matched training sessions. SO performed heavy squat and split squat (3 x 5 repetitions, 85% 1RM, 1 rep in reserve), whereas PO performed squat jump (4 x 5, 50% 1RM), body weight split squat (3 x 5), drop jumps (3 x 10), and box jumps (3 x 5). Neuromuscular assessments included quadriceps maximal isometric force and rate of force development (RFD: 20 ms peak and six-time intervals; 0-30 up to -250 ms), and countermovement jump height (CMJ). Muscle biopsies were taken from vastus lateralis. Results are reported as mean changes with standard deviations and were analyzed using independent t-tests and Pearson correlation.

RESULTS: Acutely after the training sessions, no group differences were observed in quadriceps force loss ($p = 0.16$), RFD ($p = 0.16-0.98$), or jump height ($p = 0.11$). Both groups reduced quadriceps force (SO: $-10 \pm 5\%$; PO: $-6 \pm 6\%$) and jump height ($-12 \pm 6\%$; PO: $-8 \pm 6\%$), all $p < 0.01$. Changes in force and CMJ correlated ($r = 0.37$, $r^2 = 0.14$, $p = 0.04$). No changes were observed in RFD peak (SO: $-13 \pm 24\%$, $p = 0.09$; PO: $-4 \pm 21\%$, $p = 0.50$) or across all RFD intervals (SO: -6 to $-11\% \pm 16-38\%$,

$p = 0.10-0.71$; PO: 0 to $-8\% \pm 12-37\%$, $p = 0.14-0.79$). Muscle biopsies are still being analyzed, and the results will be presented at the conference.

CONCLUSION: Strength-oriented and power-oriented training resulted in acute neuromuscular fatigue, indicating that both groups experienced training stress, with no between-group differences. Despite a moderate correlation, the low r -squared value suggests MVC and CMJ should not be used interchangeably to assess neuromuscular fatigue. The RFD results did not reveal fatigue, possibly due to higher test variability. Muscle biopsy analyses will reveal possible difference in stress between type I and II fibers and signaling responses.

OPTIMIZING SLEEP IN OFFSHORE SAILING TEAMS: IMPACT OF SHIFT MANAGEMENT AND HOURS OF SLEEP ON PERFORMANCE AND FATIGUE

CECCANTI, S., CARFAGNA, T., FRUMENTO, P., FARAGUNA, U.

UNIVERSITY OF PISA

INTRODUCTION: Sleep is crucial for sports performance, especially in endurance sports like offshore sailing regattas. Unpredictable environmental conditions and the need for prolonged alertness over days or weeks make sleep management challenging. This is even more complicated in crew racing, where individual sleep must align with team dynamics and race demands. Despite growing interest in optimizing sleep, research on sleep strategies in offshore sailing is limited. This study aims to (a) explore the influence of sleep on team performance and perceived effort, (b) assess the impact of shift management based on chronotypes and evaluate sleep patterns post-competition

METHODS: The study was conducted on 65 participants (47 ± 14.6 yrs) during the 151 Miglia-Trofeo Cetilar 2024. Crews were divided in 2 groups based on boat characteristics. Before regatta, participants completed a pre-race questionnaire and the Psychomotor Vigilance Task (PVT). After the regatta, participants repeated the PVT, filled out a post-race questionnaire and wore actigraphs to monitor sleep in the following week. Descriptive statistics, chi-square tests, ANOVA, Pearson's correlation, paired t-tests for comparisons, and multivariate regression models were used for analysis

RESULTS: The sample included 13 E-Type, 34 N-Type, and 18 M-Type chronotypes. After the regatta, participants reported an average sleep duration of 5.84 hours (± 3.53), perceived sleep quality of 4.90 (± 2.82), physical and mental fatigue of 4.95 (± 1.97) and 6.05 (± 2.04) out of 10, respectively. Higher-ranked teams had larger ($p = 0.001$) and younger crews ($p = 0.03$), but older participants had greater experience ($p = 0.001$) and lower perceived mental effort ($p = 0.005$). Higher rankings were also associated with less sleep ($r = 0.473$, $p = 0.006$), increased perceived physical effort ($p = 0.04$), and greater mental effort. Post-regatta sleepiness (ESS) was lower in M-type ($p = 0.02$). PVT declined with better rankings ($p = 0.008$), fewer navigation hours ($p = 0.006$), and higher physical exertion ($p = 0.003$). Longer reaction times (RT) were associated with fewer sleep hours ($p = 0.04$), more errors ($p = 0.01$), and greater physical exertion ($p = 0.02$). Pre- and post-race comparisons showed no significant differences in PVT ($t = 1.94$, $p = 0.06$), but ESS significantly increased post regatta ($t = -3.34$, $p = 0.001$). Chronotype had no significant effect on sleep timing preferences in the regatta ($p = 0.93$), nor on post-race mid-sleep point (MSP) ($p = 0.94$), though higher physical exertion was associated with a delayed MSP ($r = 0.40$, $p = 0.03$). Comparison between similar boats showed that higher-ranked teams slept less (4.27h vs. 7.7h, $p = 0.003$) and favored self-managed sleep shifts ($p = 0.006$)

CONCLUSION: Teams with self-regulated sleep shifts performed better, suggesting rigid schedules are less effective. Optimal sleep management over duration is probably key in endurance sports. Future research should explore how personalized sleep strategies can enhance both individual and team performance.

RUNNING AGAINST THE CLOCK: THE ROLE OF VOLUNTARY EXERCISE IN CIRCADIAN RE-ENTRAINMENT AFTER LIGHT-DARK CYCLE INVERSION

CIORCIARI, A., IRIZARRY, E., GALASSO, L., CASTELLI, L., ROVEDA, E., CARRARO, A., MONTARULI, A., LAMIA, K.

UNIVERSITY OF MILAN

INTRODUCTION: Core body temperature (CBT) is a key marker of circadian synchronization, reflecting behavioral, metabolic, and environmental adaptations. Disruptions in CBT rhythms, as seen in shift workers or jetlag, indicate circadian misalignment and can have significant health consequences. Exercise is a potent non-photic zeitgeber that may facilitate circadian realignment, but its role in re-entrainment after abrupt phase shifts remains unclear. This study examined whether voluntary exercise accelerates the re-entrainment of CBT and metabolic rhythms in mice subjected to a 12-hour light-dark cycle inversion (LDI).

METHODS: Fifteen C57BL/6J mice underwent LDI and were divided into sedentary controls (CTRL) and running wheel (RW) groups. CBT was continuously recorded using implanted temperature-monitoring capsules, and metabolic parameters were assessed via metabolic cages.

RESULTS: RW mice exhibited a faster re-entrainment of CBT compared to CTRL mice, with higher Percentage of Rhythm (PR) and Amplitude (AMP) values during early recovery (T2). Interestingly, RW mice initially displayed a greater disruption post-LDI (lower PR at T1), suggesting that unstructured physical activity may act as a conflicting signal, temporarily exacerbating

misalignment. Nevertheless, exercise accelerated recovery, as RW mice achieved a CBT phase peak closer to the new light-dark cycle target. VO_2 rhythms in RW mice also trended toward faster realignment.

CONCLUSION: These findings highlight the dual role of exercise as a zeitgeber, capable of both disrupting and accelerating circadian realignment depending on timing and context. Voluntary exercise may thus serve as an effective intervention to restore circadian synchrony and metabolic homeostasis in individuals experiencing circadian disruption.

ACID-BASE BALANCE DURING ACCLIMATIZATION AT MODERATE ALTITUDES IN ELITE BIATHLETES

NOVÁKOVÁ, M., WORONCZOVÁ, J., ČÍSAROVÁ, K., COKRTOVÁ, K., BOLEK, E.

CASRI - SPORTS RESEARCH INSTITUTE OF THE CZECH ARMED FORCES

INTRODUCTION: The regulation of acid-base balance during the early stages of acclimatization at high altitudes is well studied. During the first 12 hours of acclimatization, arterial pH increases due to hyperventilation and carbon dioxide washout. This respiratory alkalosis is subsequently compensated by renal elimination of bicarbonate ions (HCO_3^-), gradually restoring arterial pH to normal levels. Metabolic compensation is typically completed within 24 hours at low to moderate altitudes. However, data on acid-base status beyond this initial period remain scarce. Moreover, most studies have been conducted in simulated conditions or at higher altitudes, often with non-elite athletes. In this study, we aimed to monitor the acid-base balance of nine top elite biathletes on the third day after arrival at two different moderate natural altitudes and compare it to their acid-base status at low altitude.

METHODS: A group of elite biathletes (5 males, age = 27.4 ± 4.0 years, $VO_{2max} = 69.7 \pm 3.6$ ml/kg/min; 4 females, age = 27.3 ± 3.8 years, $VO_{2max} = 59.2 \pm 3.8$ ml/kg/min) underwent morning arterial blood sampling to assess acid-base balance at low altitude (600 m) and on the third day after arrival at training camps at 1700 m and 2000 m. Additionally, plasma erythropoietin (EPO) concentration was measured 24 hours after ascent.

RESULTS: On the third acclimatization day, no significant differences in acid-base balance were detected between the two altitudes. Although arterial pH remained similar to that at low altitude, other parameters showed significant changes at moderate altitudes. The arterial partial pressure of oxygen (pO_2) was significantly lower at 1700 m (8.62 ± 0.17 kPa, $p < 0.01$) and 2000 m (9.07 ± 0.15 kPa, $p < 0.01$) compared to 600 m (9.95 ± 0.16 kPa). The arterial partial pressure of carbon dioxide (pCO_2) was significantly reduced at 1700 m (3.91 ± 0.08 kPa, $p < 0.01$) and 2000 m (3.96 ± 0.07 kPa, $p < 0.01$) in comparison to 600 m (4.76 ± 0.05 kPa). Blood bicarbonate ion concentration decreased by approximately 15%. Although the available data are limited, a significant negative correlation was found between plasma EPO concentration 24 hours after ascent and the decrease in blood bicarbonate ion concentration on the third day ($r = -0.64$; $p < 0.05$).

CONCLUSION: To our knowledge, this is the first study to monitor acid-base balance at a later stage of acclimatization in elite athletes at training camp venues under natural conditions. No significant differences in acid-base balance were observed between 1700 m and 2000 m. By day three, metabolic compensation was ongoing but insufficient to restore arterial oxygen levels to low-altitude values. Persistently low bicarbonate, a key blood buffer, could impair anaerobic performance in the subsequent days. The correlation between the 24-hour EPO response and the magnitude of metabolic compensation suggests an interconnection between erythropoiesis and acid-base regulation of the hypoxic stress.

THE EXERCISING BODY OVER 300 KM/H: PHYSIOLOGICAL AND ENVIRONMENTAL DEMANDS IN AUTO RACING DRIVERS

BUOITE STELLA, A., FERRARI, A., SOLIMAN, G., TYLER, C.J.

UNIVERSITY OF TRIESTE

INTRODUCTION: There is a common misconception that drivers have a little role in their sport, compared to the importance of their vehicle. Nonetheless, data suggest that usually these athletes compete with heart rates, sweat rates, and gravitation forces that can be compared to those found in other sports, or even in astronauts. Despite motorsports are among the largest spectator sports in the world, and despite the peculiar characteristics of these competitions, only a few studies have investigated the physiological and psychological responses of these athletes, maybe due to the "extreme" contexts where they perform.

METHODS: Electronic databases were searched to retrieve published manuscripts that analyzed cardiovascular, respiratory, metabolic, neuromuscular or environmental parameters in auto racing drivers. All the different auto racing categories were included. Main findings were then extracted and reported. In addition, to provide a novel environmental physiology perspective, environmental and weather data were retrieved from official databases regarding the race day of the Formula 1 (F1) 2023, and a thermal risk map based on the universal thermal climate index (UTCI) was created.

RESULTS: Nineteen studies were found clearly reporting data regarding the metabolic, cardiovascular and/or thermoregulatory responses to driving. Oxygen consumption during driving has been reported usually being between 22 and 39 mL.kg⁻¹.min⁻¹, and peak heart rate can range from 88 to 197 b.min⁻¹, with a large variability depending on the type of car, competition, speed and circuit, and environmental conditions. In F1 some data suggest that mean heart rate can be 77% of the maximum. Dehydration can further pose a challenge to these athletes, typically exceeding 1 L.h⁻¹. Thermal strain is of particular relevance in this sport, as drivers face increases in core body temperature of 1.7 – 2.5 °C/h⁻¹, in closed cockpit temperature up to 66 °C and physiological strain index (PSI) > 6. On 22 F1 racing events, 7 were classified as "moderate risk", and 1 was at "strong risk".

CONCLUSION: This review supports the definition of the auto racing driver as an athlete competing at high-intensity and in extreme conditions typically characterized by the need of fast and strong neuromuscular responses, the capacity to resist to high accelerations (> 3.5 g), resulting in high metabolic demands, cardiovascular responses, and the necessity to cope

with the increased body temperature and fluid losses. In the context of a changing world, with the challenges posed by global warming and climate change, it might become even more important to promote studies and bring even more sports science and medicine "in the paddock".

CP-PN10 Nutrition and Performance

OMEGA -3 INDEX AND ITS IMPACT ON SELECTED PARAMETERS OF MUSCLE STRENGTH IN ATHLETES – A RANDOMIZED CONTROLLED TRIAL

KLUCZEK, M., TOMCZYK, M.

GDANSK UNIVERSITY OF PHYSICAL EDUCATION AND SPORT

INTRODUCTION: Omega-3 fatty acids, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), are essential nutrients that play a crucial role in modulating inflammation, supporting muscle recovery, and promoting adaptation to physical exercise. The Omega-3 Index (O3I), defined as the percentage of EPA and DHA in erythrocyte membranes relative to total fatty acids, is a reliable marker of the body's omega-3 status. Numerous studies have emphasized the benefits of omega-3 supplementation for muscle repair and inflammation reduction; however, little attention has been given to natural changes in O3I resulting from structured, long-term training interventions, particularly in the context of strength training where adaptive changes in muscle tissue occur.

The aim of this study was to determine the impact of a 12-week strength training intervention on O3I levels in athletes and to examine the relationship between changes in O3I and selected muscle strength parameters. O3I levels were assessed before and after the training intervention to determine whether training adaptations were associated with modifications in O3I that could potentially influence muscle function.

METHODS: In this study, young adults (aged 18–30 years) with less than one year of training experience were randomly assigned to either a training group (n=35) or a control group (n=11). The training group completed 36 sessions over 12 weeks (three sessions per week), while the control group maintained their regular lifestyle without additional training. All participants performed identical exercises with controlled total volume and average intensity to ensure consistency across sessions. A minimum attendance of 90% was required. O3I levels were measured at baseline and after the intervention, and muscle strength was assessed using a Kistler force platform (evaluating peak force, relative peak force, and force at 150, 200, and 250 milliseconds) and the Biodex system (measuring maximum muscle torque of the knee and elbow joints at 95° and 135°).

RESULTS: Results showed that O3I values did not differ significantly between the training and control groups, with both groups exhibiting levels below the recommended optimal range. Changes in O3I after the 12-week strength training intervention were associated with a slight increase in maximum muscle torque in the knee and elbow joints; however, these correlations were relatively weak. No significant changes were observed in other muscle strength parameters.

CONCLUSION: The results indicate that participants in the training group exhibited similar O3I values compared to the non-training group. While there is some correlation between O3I and muscle strength parameters, it is relatively weak and requires further research to better understand the mechanisms underlying this relationship. Additionally, educating athletes on the importance of omega-3 fatty acids and their potential impact on performance and recovery should be emphasized as part of their nutritional guidance.

IMPACT OF MEAL SEQUENCING ON ENERGY METABOLISM, PERFORMANCE, AND RECOVERY IN ENDURANCE ATHLETES IN HOT, HUMID CLIMATES

WANG, B., ZHANG, Q., XU, Q., CUI, X., WANG, J., CHU, Y., TIAN, H., LIN, W., QIU, J., WANG, C.

SHANGHAI RESEARCH INSTITUTE OF SPORTS SCIENCE

INTRODUCTION: Recent studies suggest meal sequencing as an effective way to stabilize postprandial blood glucose and insulin levels. However, its effects on energy metabolism and fatigue recovery in endurance athletes are unknown. This study explores the impact of meal sequencing on endurance athletes in challenging conditions, aiming to improve training and competition strategies.

METHODS: Eleven male cyclists (16±1.45 years, BMI 22.4±1.95) were randomly assigned to either a mixed meal (Mix) or protein/fat before carbohydrate (PFC) pattern, with a 7-day washout. After a 12-hour fast, subjects had breakfast, rested for two hours, cycled for two hours at 70% VO₂max, and completed a 7km sprint in a hot, humid room. Lunch was consumed 30 minutes post-sprint, followed by four hours of rest before re-entering the hot room for an exhaustive cycling at 85% VO₂max. Basal measurements were taken before breakfast. Post-meal glucose was monitored every 15 minutes using the Abbott FreeStyle Libre, and metabolic data were collected every 30 minutes using a cardiopulmonary function tester. During cycling, glucose, heart rate, core temperature, subjective fatigue levels, and gas were collected at regular intervals. Venous blood was drawn immediately, 30 minutes, and 120 minutes post-lunch for NEFA, insulin, and GLP-1 analysis.

RESULTS: Meal sequence did not significantly impact blood glucose levels or AUC between groups, though PFC showed a trend toward higher glucose levels. Key differences emerged at multiple time points: glucose rose faster initially but declined afterward in Mix, while PFC surpassed Mix 45 minutes to one hour post-meal, remaining higher for up to four hours and into cycling. RER and carbohydrate energy supply ratio showed significant interaction effects. Post-7K sprint, PFC trended toward higher carbohydrate energy supply rates, ratio, and RER. At 30 minutes post-lunch (LH30), PFC had a lower RER and higher fat energy supply ratio and rate, though not statistically significant. Insulin levels were significantly higher in Mix immediately post-lunch (LH0), but PFC showed a greater increase at LH120. GLP-1 levels showed no significant differences. PFC had a smaller decrease in NEFA at LH30 compared to Mix. Fatigue indicators and cycling performance revealed no significant differences (7K: Mix 636 ± 55 , PFC 631 ± 26 ; 85% $\text{VO}_{2\text{max}}$: Mix 524 ± 168 , PFC 590 ± 191 seconds), though PFC trended toward longer cycling times at 85% $\text{VO}_{2\text{max}}$, with mixed individual performance outcomes.

CONCLUSION: The PFC meal pattern helps reduce postprandial insulin and glucose fluctuations, enhances fat oxidation for energy, and sustains stable glucose levels over time. This stability may support prolonged energy during exercise and delays fatigue. Furthermore, after exhaustive exercise, this pattern may boost muscle glycogen resynthesis by extending insulin stimulation, enabling rapid recovery and improving subsequent endurance performance.

COMPARATIVE ANALYSIS OF CARBOHYDRATE DELIVERY SPEEDS OF A GLUCOSE-FRUCTOSE ENERGY BAR, A MALTODEXTRIN-BASED GEL, AND GLUCOSE-FRUCTOSE HYDROGEL IN ATHLETES

DEAN, E., OSBOURNE, A., SUBAR, D., HENDRICKSE, P., GAFFNEY, C.

LANCASTER UNIVERSITY

INTRODUCTION: Carbohydrate (CHO) supplementation during exercise is crucial to optimise athletic performance. Energy gels and bars are commonly used to provide rapid CHO by rapid digestion, absorption, and oxidation. While the effects of different sugar compositions – such as simple versus complex sugars and combinations of sugars, such as glucose-fructose – can influence digestion rates, how popular supplements perform in practice is less understood. This study examined the speed of delivery of three popular CHO supplements: a glucose-fructose-based energy bar (Voom Pocket Rocket; VOOM), a maltodextrin-based gel (SIS Go Isotonic; SIS), and a glucose-fructose hydrogel (Maurten Gel 160; MAU).

METHODS: Sixteen healthy male Tier 2 runners, cyclists, and triathletes (mean $\pm$ SD) (aged 23 ± 4.2 years; height 182.03 ± 6.5 cm; weight 79.5 ± 8.3 kg; BMI 23.81 ± 1.2 kg/m²) completed a modified 60-minute oral glucose tolerance test at Lancaster University's Human Performance Laboratory. This preregistered trial (NCT06375577) was approved by Lancaster University Medical School Research Ethics Committee (LMS-24-Dean-1). A baseline blood sample was taken following a 2-hour fast, before providing 45 g of CHO from VOOM, SIS, or MAU. Venous blood samples were taken at 5-minute intervals via antegrade-venous cannulation for 60 minutes for glucose and electrolytes (sodium, potassium, chloride). Substrate utilisation was assessed through indirect calorimetry via the respiratory quotient (RQ). Data were analysed for normality using Shapiro-Wilk. Parametric data was analysed via repeated measures ANOVA, while non-parametric data were analysed using the Friedman test. Significance was defined as $p < 0.05$.

RESULTS: CHO oxidation per 5-minute interval was different between CHO supplements ($p = 0.03$), with VOOM exhibiting greater mean CHO oxidation (2.1 ± 0.3 g·min⁻¹) compared to SIS (1.5 ± 0.4 g·min⁻¹) and MAU (1.7 ± 0.3 g·min⁻¹). Total CHO oxidation was significantly greater in VOOM than SIS (24.6 ± 7.4 g vs 17.8 ± 8.6 g, respectively, $p = 0.01$) but not MAU (MAU 20.1 ± 6.4 g, $p > 0.05$). Conversely, total fat oxidation was suppressed to a greater extent for VOOM than SIS (SIS 9.5 ± 3.4 g, VOOM 7.37 ± 2.29 g, $p = 0.007$) but not MAU (8.45 ± 3.36 g, $p > 0.05$). The mean RQ was greater for VOOM (0.86 ± 0.06) than MAU (0.84 ± 0.07) and SIS (0.83 ± 0.07) ($X^2(38) = 187.8$, $p < 0.0001$). No significant differences were observed in mean peak glucose (VOOM 6.6 ± 1.2 mmol/L, MAU 6.2 ± 1.1 mmol/L, SIS 6.4 ± 1.15 mmol/L) and time to glucose peak (VOOM 31.3 ± 14.0 min, MAU 39.1 ± 12.3 min, SIS 33.1 ± 11.1 min) or in electrolyte levels across supplements ($p > 0.05$).

CONCLUSION: These results suggest that the VOOM glucose-fructose Pocket Rocket delivers CHO as quickly, or perhaps even quicker, than maltodextrin or glucose-fructose energy gels, providing athletes with an effective alternative for carbohydrate supplementation.

PLACEBO EFFECT ON REPEATED SPRINT TRAINING IN HIGHLY TRAINED SWIMMERS IN SPRINT EVENTS.

VALERO MARTINEZ, F.1, GONZÁLEZ-MOHÍNO, F.1, RODRÍGUEZ-BARBERO, S.2, ALDA, A.1, MUÑOZ-DE LA CRUZ, V.1,

SALINERO, J.J.1

UNIVERSIDAD DE CASTILLA LA MANCHA

INTRODUCTION: Caffeine has been shown to enhance swimming performance. Previous meta-analysis has found that caffeine ingestion significantly improved swimming times in both short-distance and moderate-to-long distance events (1). In elite male freestyle swimmers, a moderate dose of caffeine (3 mg/kg) improved repeat-sprint ability, particularly in the middle sprints of a 6x75-m set (2). Interestingly, the placebo effect of caffeine can also contribute to performance improvements in sports. In a recent systematic review anaerobic capacity and endurance performance were improved by the consumption of both, caffeine and placebo perceived as caffeine (3).

METHODS: A randomized, counterbalanced experimental design was used to evaluate the effects of a placebo (PLA), capsule reported as caffeine, versus no intake (CON) in 2 interval sessions separated by 7 days. Six highly trained swimmers participated in this study. Each session consisted of 6x25-m sprints at maximum intensity with 2' of recovery, followed by 50-m all-out. Swimming times, countermovement-jump (CMJ) and subjective effort (RPE) were recorded. Side

effects were assessed via a questionnaire. Statistical analysis (SPSS v28.0) applied t-tests, Wilcoxon tests, and Cohen's d, with significance set at $p < 0.05$.

RESULTS: No significant differences were found in the total time for 6x25-m test (75.1 ± 3.8 vs. 77.0 ± 3.8 , $p = 0.297$, $d = 0.50$), in the average times of each 25-m repetition (12.52 ± 0.6 vs. 12.52 ± 0.8 , $p = 0.987$, $d = 0.006$), and in 50-m times (27.85 ± 1.3 vs. 27.90 ± 1.4 , $p = 0.825$, $d = 0.087$) between PLA and CON conditions. No significant differences ($p > 0.05$) were observed between PLA and CON conditions for RPE POST 25-m (6.83 ± 0.8 vs. 7.17 ± 0.8 , $p = 0.363$, $d = 0.408$) and RPE POST 50-m (7.83 ± 0.8 vs. 8.67 ± 0.5 , $p = 0.093$, $d = 0.848$). Furthermore, there were no significant differences between PLA and CON conditions for the CMJ in the speed loss between the PRE and POST of each session when compared across conditions (2.65 ± 3.0 vs. 5.13 ± 2.33 , $p = 0.072$, $d = 0.826$). No significant differences were found in side effects.

CONCLUSION: In conclusion, the belief of having ingested caffeine did not improve performance in swimmers during 6x25-m sprints with 2 minutes of recovery, followed by a 50-m sprint, CMJ, RPE and side effects. We recommend coaches to incorporate caffeine supplementation into swimmers plans before competitions.

VARIABILITY IN INTERSTITIAL GLUCOSE RESPONSE TO AN ACUTE CHANGE IN ENERGY AVAILABILITY IN ENDURANCE ATHLETES

COX, G., COFFEY, V., BURKE, L., BOWLER, A.

BOND UNIVERSITY

INTRODUCTION: To determine whether an acute change in energy availability (EA) causes perturbations in interstitial glucose in athletes.

METHODS: Using a randomized crossover design, five trained endurance athletes ($n = 3$ men, 26.4 ± 7.5 y, VO_2 max 53.1 ± 4.7 mL·kg⁻¹·min⁻¹), completed a morning high-intensity interval cycling session (AM HIT; 6×5 min @ 85% VO_2 max) and an afternoon steady-state cycling session (PM SS; 80 min @ 63% VO_2 max) under dietary conditions of either (1) high energy availability (HEA: 42.6 ± 3.8 kcal·kg⁻¹ FFM·d⁻¹, 10.0 ± 1.4 g·kg⁻¹·CHO) or (2) low energy availability (LEA: 11.3 ± 2.4 kcal·kg⁻¹ FFM, 5.2 ± 0.3 g·kg⁻¹·CHO) following 3 days of dietary harmonization (DH; 46.1 ± 1.5 kcal·kg⁻¹ FFM·d⁻¹, 8.3 ± 0.6 g·kg⁻¹·CHO). Interstitial glucose data was measured with Freestyle Libre 2 continuous glucose monitors (Abbott Diabetes Care, Chicago IL; CGM's) with 15-min epochs to determine glycemic variability, calculated as mean interstitial glucose (MG), mean amplitude of glycemic excursions (MAGE), and coefficient of variation (CV).

RESULTS: CGM-derived overnight MG was lower during LEA and HEA compared to DH (LEA 4.5 ± 0.3 mmol·L⁻¹ HEA 4.9 ± 0.1 mmol·L⁻¹ vs 5.5 ± 0.4 mmol·L⁻¹; $P = 0.01$, $d > 1.9$). MAGE was lower in the LEA trial compared to HEA, although this was not statistically significant (1.7 ± 0.7 mmol·L⁻¹ vs 2.1 ± 0.3 mmol·L⁻¹, $P = 0.26$, $d = 0.8$).

CONCLUSION: Contrary to our hypothesis, perturbations to overnight glucose variability occurred in both LEA and HEA conditions which may be related to changes in daily training load compared with athletes' habitual training.

MEDITERRANEAN DIET AND ATHLETIC PERFORMANCE IN ELITE AND COMPETITIVE ATHLETES: A SYSTEMATIC REVIEW AND META-ANALYSIS

FIORINI, S., GUGLIELMETTI, M., NERI, L.C.L., CORREALE, L., TAGLIABUE, A., FERRARIS, C.

UNIVERSITY OF PAVIA

INTRODUCTION: Nutrition is a key factor for achieving and maintaining optimal sports performance. Evidence showed that an adequate and individualised dietary pattern able to meet the energy, macro- and micro-nutrient needs of athletes is fundamental to optimising training adaptations, improving performance, preventing illness and injuries and supplying pre-during-post training periods. Mediterranean Diet (MD) has been widely reported to be a model of healthy eating for its contribution to a favourable health status and a better quality of life. Due to its anti-oxidant and anti-inflammatory effects, injury and illness prevention role, vascular and cognitive function enhancement, MD may represent the reference dietary pattern for athletes. This review aimed to investigate whether MD could impact performance in adult elite and competitive athletes from various disciplines.

METHODS: A systematic literature review (PROSPERO: CRD42023459039) was performed based on the PRISMA method. The search was conducted in PubMed/Medline, Scopus, Web of Science, and the Cochrane Library in October 2024. Inclusion criteria: healthy competitive/elite athletes (<18y) performing at least 6 hours/week of physical activity. The risk of bias was assessed using the RoB 2.0 Cochrane tool for randomized-controlled trials, Robins-I tool for non-randomized studies and the Newcastle Ottawa Scale for observational studies. A subgroup meta-analysis was conducted. Data were expressed as standardised mean difference, with a 95% confidence interval, to uniform the units used for different performance outcomes. Random-effects models were applied with $p < 0.05$ considered statistically significant.

RESULTS: Were included 9 studies (192 participants; males 65.6%), published between 2015 and 2023. The article's sample size ranged from 10 to 43 athletes performing different sports (beach handball, canoe polo, CrossFit, football, handball, volleyball, kickboxing, and running). MD adherence was assessed using various tools (KIDMED, MEDAS-14, MDAS), and through monthly phone interviews. Results varied from low to high adherence to the MD. 5 studies reported an MD impact on athletic performance; 80% of these studies reported a positive effect including improvements in anaerobic/aerobic power, explosive strength, and body fat percentage. The meta-analysis showed no significant overall effect of the MD on performance outcomes [SMD 0.00 (CI -0.26; 0.25)].

CONCLUSION: Although some individual studies report positive effects of MD on specific performance parameters, the meta-analysis found no significant overall impact. Nevertheless, the MD may still offer potential benefits for athletes, warranting further investigation. To enhance the reliability of future research, studies should standardise dietary assessment methods and incorporate longer intervention periods to more accurately assess the long-term effects of the MD on athletic performance.

ASSOCIATIONS BETWEEN NUTRITIONAL PROFILE, BODY COMPOSITION, MUSCLE STRENGTH, EXECUTIVE FUNCTIONS AND SPORT PERFORMANCE IN ÉLITE JUDO ATHLETES

CAMPANELLA, M., FERRARI, D., MIGLIACCIO, S., CARDINALI, L., BONAVALONTÀ, V., CURZI, D., GUIDETTI, L., BALDARI, C.
ECAMPUS UNIVERSITY

INTRODUCTION: Judo is a combat sport with weight categories. Many athletes resort to rapid weight loss to gain an advantage against lighter opponents [1]. The consequences are dehydration, decreased strength, aerobic and anaerobic performance [2-3].

This study aimed to assess correlations between national performance ranking, anthropometric measurements, nutritional profile, body composition, muscle strength and executive functions (EFs) in elite judokas.

METHODS: Twenty-seven athletes (14 males and 13 females; age = 19.5 ± 2.0 years) were recruited from Banzai Cortina of Rome. Height, Body Weight (BW) and Body Mass Index (BMI), physical fitness (countermovement jump, handgrip test (HG), dynamic and isometric chin up test) and cognitive functions (Digit Span (DS) and Flanker) were evaluated. Adherence to the Mediterranean Diet (MD) was assessed via questionnaire. Bioimpedance analysis determined nutritional and hydration status, Muscle Mass (MM), Fat Free Mass (FFM) and Total Body Water (TBW).

RESULTS: MD adherence was moderate in both males (7.6 ± 1.8) and females (8.5 ± 1.3). All athletes had normal hydration ($72.7\text{--}74.3\%$), while nutritional values were higher ($p < 0.01$) in males (1136 ± 124 mg 24h/hm) than in females (798 ± 67 mg 24h/hm). In males, MD adherence correlated with age ($r = 0.61$; $p = 0.021$), Flanker reaction time ($r = -0.63$; $p = 0.016$) and DS ($r = 0.53$; $p = 0.049$). Hydration status was related to ranking ($r = -0.56$; $p = 0.045$), BW ($r = 0.63$; $p = 0.016$), BMI ($r = 0.63$; $p = 0.016$), FFM ($r = 0.68$; $p = 0.008$) and MM ($r = 0.71$; $p = 0.005$). Nutritional status correlated with BW ($r = 0.75$; $p = 0.002$), BMI ($r = 0.84$; $p = 0.000$), FFM ($r = 0.87$; $p = 0.000$), TBW ($r = 0.87$; $p = 0.000$), MM ($r = 0.90$; $p = 0.000$) and HG ($r = 0.66$; $p = 0.010$). In females, hydration correlated with ranking ($r = -0.88$; $p = 0.001$), FFM ($r = 0.59$; $p = 0.033$) and MM ($r = 0.71$; $p = 0.006$). Nutritional status was correlated with BW ($r = 0.59$; $p = 0.035$), BMI ($r = 0.58$; $p = 0.038$), FFM ($r = 0.72$; $p = 0.005$), TBW ($r = 0.70$; $p = 0.008$), MM ($r = 0.68$; $p = 0.010$) and DS reaction time ($r = -0.61$; $p = 0.024$). Ranking was correlated with MM ($r = -0.64$; $p = 0.045$) and DS reaction time ($r = 0.64$; $p = 0.047$).

CONCLUSION: Hydration status appears crucial in both male and female elite athletes, correlating with higher national ranking. In males, nutritional status was associated with muscle strength, while MD adherence correlated with EFs. In females, nutritional status and ranking were associated with EFs.

THE IMPACT OF BODY MASS REDUCTION AND NUTRIENT INTAKE ON COMPETITIVE SUCCESS IN ELITE JUDO ATHLETES

SANTOS, D., MURASAKI, J., COSTA, L., FRANCHINI, E.
UNIVERSITY OF SÃO PAULO

INTRODUCTION: In combat sports such as judo, athletes often engage in rapid weight loss (RWL) processes to achieve the lowest possible weight category[1]. Therefore, managing body mass and optimizing nutrition are key elements for achieving competitive success. Thus, this study aimed to investigate the relationship between body mass reduction, nutrient intake, and medal achievement in elite judo athletes.

METHODS: Forty-five elite judo athletes (age: 22.5 ± 2.7 years; judo grade: 1st dan) competing at national and international levels were monitored over a competition. Body mass was measured at 10, 7, and 3 days before weigh-in, on weigh-in day, and competition day. Body mass reduction was calculated from 10 days before weigh-in to weigh-in day, and body mass recovery from weigh-in to competition day. The official weigh-in took place on the evening prior to the competition. Nutrient intake was assessed using 24-hour dietary recalls at 10 and 3 days before weigh-in, and competition day. Inde-

pendent t-tests compared medallists and non-medallists for total body mass reduction and regain, ANOVA two-way with repeated measurements for group and time point comparisons, while logistic regression analyzed the relationship between body mass reduction and medal success.

RESULTS: There were no significant differences between medallists and non-medallists in terms of body mass reduction (medallists = $3.58 \pm 1.81\%$; non-medallists = $3.04 \pm 1.05\%$; $P = 0.297$) and body mass regain (medallists = $3.75 \pm 1.93\%$; non-medallists = $3.98 \pm 1.61\%$; $P = 0.700$). However, logistic regression revealed that a greater body mass reduction from 10 days before weigh-in to weigh-in increased the odds of winning a medal (OR: 1.64; 95%CI: 1.07; 2.51; $P = 0.021$). Protein intake was significantly higher at 10 days before weigh-in compared to other time points ($P < 0.001$). Post-weigh-in, both groups showed increased lipid and carbohydrate intake ($P < 0.001$).

CONCLUSION: Although no significant differences were observed between medallists and non-medallists in body mass reduction or regain, greater body mass reduction prior to weigh-in was associated with an increased likelihood of competitive success, suggesting a potential advantage for athletes who manage their body mass effectively in the lead-up to competition. Additionally, nutritional intake was influenced by RWL strategies. The higher protein ingestion observed 10 days prior to weigh-in could indicate that athletes were prioritizing proper nutrition before starting the RWL. This pattern suggests that closer to the competition athletes were reducing their nutrient intake.

DHA INCORPORATION ATTENUATES THE PHYSIOLOGICAL IMPACT OF ECCENTRIC EXERCISE IN PHYSICALLY TRAINED ADULTS: A 12 WEEK DOUBLE-BLIND PLACEBO CONTROLLED TRIAL

ANTHONY, R., MCLENNAN, P., MACARTNEY, M., SLUYTER, R., ELHAGE, A., SAMPSON, J., MITCHELL, T., PEOPLES, G.
UNIVERSITY OF WOLLONGONG

INTRODUCTION: Recovery from eccentric muscle loading involves a complex integration of perceived muscle soreness and temporary reduction in strength and power. Omega-3 docosahexaenoic acid (DHA) is preferentially incorporated into skeletal muscle (SM) membrane phospholipids and the Omega-3 Index (O3I; %eicosapentaenoic acid+DHA of total erythrocyte fatty acids) serves as an accessible biomarker to reflect SM membrane changes. DHA membrane incorporation promotes the production of pro-resolving molecules, which play a key role in the resolution of inflammation. The aim of this study was to determine if a dietary achievable dose, equivalent to two fatty fish meals per week, of microencapsulated chewable DHA tablets (NuMega™ Ingredients) consumed for 12 weeks, could improve recovery metrics following eccentric loading, underpinned by an increased O3I.

METHODS: Physically trained adults (18-45y) were matched for peak power output (PPO) and supplemented for 12 weeks in a double-blind manner with either oleic acid (control, $n=12$, 33% female) or 715mg/d DHA (DHA, $n=26$, 38% female). At weeks 0 and 12, the O3I was measured and participants performed an eccentric cycling protocol at 30% of PPO to induce muscle damage. Muscle soreness (VAS), countermovement jump height (CMJ-h), peak vertical isometric force (PVIF) and inflammatory cytokines were assessed before, immediately post, 24h and 48h post eccentric cycling. Area under the curve (AUC) was calculated for VAS score, CMJ-h, PVIF and inflammatory cytokines to represent the integrated response over 48 hours. RM-ANOVA was used for O3I and between group effect sizes at week 12 were calculated using Cohen's d. Data presented as mean $\pm$ SD, or mean difference (MD) $\pm$ pooled SD.

RESULTS: O3I was equivalent and low in both groups at week 0 (control, $4.75 \pm 0.87\%$; DHA, $4.89 \pm 0.88\%$, $P=0.622$). At week 12, the Δ O3I was unchanged in the control group, but significantly increased in the DHA group (control, $+0.02 \pm 0.48\%$; DHA, $+2.47 \pm 0.89\%$; $P<0.001$). At week 0, eccentric cycling resulted in both groups experiencing a similar reduction in CMJ-h (control; -169 ± 148 cm*48h, DHA; -173 ± 175 cm*48h) and PVIF (control; -6376 ± 5643 N*48h, DHA; -6814 ± 8656 N*48h). CMJ-h and PVIF were greater within the DHA group at week 12 (CMJ-h, MD= $+61 \pm 102$ cm*48h, $d=0.59$; PVIF, MD= $+2490 \pm 7824$ N*48h, $d=0.32$). VAS was not different between groups at week 0 (control, 163 ± 85 cm*48h; DHA, 164 ± 88 cm*48h). VAS was lower in the DHA group and compared to control at week 12 (MD; -76 ± 81 cm*48h; $d=0.95$). There were significant interaction effects in AUC for TNF- α ($P=0.010$) and IL-10 ($P=0.026$), being lower compared to week 0 in the DHA group at week 12.

CONCLUSION: These findings support the hypothesis that a dietary achievable dose of DHA increases the O3I, reflective of muscle membrane incorporation and can attenuate the physiological impact of eccentric exercise, enhancing performance recovery and modulating inflammation in physically trained adults.

Conventional Print Poster Presentations

EXECUTIVE FUNCTION RESPONSE TO MODERATE-TO-HIGH-INTENSITY ROPE SKIPPING CONTINUOUS TRAINING IN ADOLESCENTS WITH OVERWEIGHT AND OBESE: A RANDOMIZED TRIAL

ZHANG, L., YU, Q.

SHENZHEN UNIVERSITY

Background: Previous studies have shown that high body mass index (BMI) is detrimental to executive function (EF) in children and elderly populations but may be improved by physical activity (PA). However, research on adolescents is lacking. This study examined the correlation between BMI and EF in adolescents and investigated the effects of moderate-to-high-intensity rope skipping (RS) training on EF in adolescents with varying BMIs. Methods: 166 adolescents aged 12–14 years were divided into normal weight, overweight three and obese groups according to BMI. 96 adolescents were assigned to the normal weight control and exercise group (NCG, n=23; NEG, n=23), the overweight control and exercise group (OVCG, n=13; OVEG, n=14), and the obese control and exercise group (OBCG, n=12; OBEG, n=11). Exercise program: moderate-to-high-intensity RS training. Control program: sedentary. Data were recorded for BMI and EF tasks. Results: The average reaction time (RT) of EF tasks in OVG, OBG exceeded NG about 14%, 24% respectively ($P<0.05$) in part one. After exercise intervention, the average BMI in OVEG and OBEG decreased about 10% and 11% ($P<0.05$). The average RT of EF tasks in NEG, OVEG and OBEG decreased about 9%, 14%, 13% respectively ($P<0.05$). Exercise groups have a significant difference with the control groups in the RT of EF tasks ($P<0.05$). Conclusions: The EF is weaker in overweight and obese adolescents than in normal weight adolescents. An 8-week moderate-to-high-intensity RS exercise program can improve EF in adolescents with different BMIs, and the improvement is greater in overweight and obese adolescents.

A 12-WEEK CARDIOVASCULAR EXERCISE PROGRAM ENHANCES BEHAVIORAL AND NEUROELECTRIC MARKERS OF INHIBITORY CONTROL IN SEDENTARY YOUNG ADULTS: A RANDOMIZED CONTROLLED TRIAL

LIGEZA, T., REMISZEWSKI, A., RAJTAR, G., KOMAREK, Z., PALKA, T., MACIEJCZYK, M.

JAGIELLONIAN UNIVERSITY IN KRAKOW

Purpose:

Regular physical exercise may enhance cognitive functions, particularly inhibitory control, yet its effects in healthy but sedentary young adults remain understudied. This study examined how a structured 12-week cardiovascular exercise intervention influences behavioral and neuroelectric markers of inhibitory control in this population.

METHODS: Sedentary young adults were randomized into an exercise group ($n = 32$) or a passive control group ($n = 30$). The intervention consisted of 6 weeks of moderate-intensity continuous exercise (MCE) followed by 6 weeks of moderate-to high-intensity interval exercise (MHIE) on a cycling ergometer. Inhibitory control was assessed at baseline (pre-test), mid-intervention (mid-test), and post-intervention (post-test) using a modified flanker task with EEG recordings. Key outcomes included response time (RT) and event-related potentials (N2 and P3b components).

RESULTS: The exercise group showed progressive RT reductions in incongruent trials at all time points (pre-to-mid, mid-to-post, pre-to-post) without accuracy loss. The control group exhibited RT reductions only from pre- to post-test but with decreased accuracy. EEG data revealed that the exercise group demonstrated decreased N2 amplitudes and faster P3b latencies from mid- to post-test during incongruent trials, indicating improved neural efficiency. In contrast, the control group showed increased N2 amplitudes during congruent trials at pre-to-mid and pre-to-post assessments.

Conclusions:

A structured cardiovascular exercise program combining MCE and MHIE enhances both behavioral and neuroelectric markers of inhibitory control in sedentary young adults. These findings suggest that tailored exercise programs can serve as an effective, accessible strategy for improving cognitive function in populations at risk of sedentary-related cognitive decline.

GREATER MOTOR COMPETENCE AND ENHANCED INHIBITORY CONTROL DEVELOPMENT IN CHILDREN WITH ADHD: A NEUROELECTRIC STUDY

CHUEH, T., TSAI, Y., WU, J., CHU, C., WU, C., HUNG, T.

UNIVERSITY OF TAIPEI

INTRODUCTION: Neurocognitive deficits, especially inhibitory control processing, are common developmental challenges in children with attention-deficit/hyperactivity disorder (ADHD). Although previous studies have suggested that greater motor competence (MC) is associated with better inhibitory control on both behavioral and neuroelectric levels in children with ADHD, some limitations exist. Therefore, this study aimed to examine whether higher MC is associated with improved neurocognitive development in children with ADHD, as indexed by behavioral and neuroelectric indices of inhibitory control in a well-designed study.

METHODS: Sixty children with ADHD were divided into high MC ($n = 30$) and low MC ($n = 30$) groups, based on the median total composite scores from the Bruininks-Oseretsky Test of Motor Proficiency. Forty-four typically developing (TD) children

were recruited as the healthy control. The Stroop task was administered to assess inhibitory control while electroencephalography was recorded to derive P3 component.

RESULTS:

The TD children group demonstrated higher accuracy rate (AR), shorter reaction time (RT), and greater P3 amplitude relative to the Low MC ADHD group. However, the TD children group had higher AR compared to the High MC ADHD group, with no significant differences in RT and P3 amplitude. Further, the High MC ADHD group demonstrated shorter RT and greater P3 amplitude regardless of congruency compared to the Low MC ADHD group while accounting for intelligence quotient and aerobic fitness.

CONCLUSION: Superior MC in children with ADHD is associated with favorable neurocognitive development, as evidenced not only by the association of MC with enhanced inhibitory control performance and increased P3 amplitude but also by that such neurocognitive performance is comparable to those of TD children. These findings suggest that enhanced MC plays a role in mitigating typically developmental neurocognitive deficits associated with ADHD.

SUPPORTING TEACHERS' WELL-BEING BY [RE]-LEARNING HOW TO BREATHE.

PERREAULT-IMBEAULT, E., STOLOFF, S., SALAMÉRO, E.

UNIVERSITÉ DU QUÉBEC À TROIS-RIVIÈRES

Faced with increasing tensions, compassion fatigue is a threat to many professionals, particularly teachers. This research studied the stress factors identified in the scientific literature, as in work overload and lack of support, which contribute to the increased risk of burnout in the educational sector. Based on the socio-emotional competencies framework, the integration of emotional regulation strategies, such as conscious breathing, appears to be a key strategy to improving self-awareness and self-regulation. For this purpose, a training program on breathing techniques, entitled Zen Breathing, was offered to primary and secondary school teachers in Quebec, including physical education teachers (PE). The aim of this research was to document the implementation of a training program focusing on these breathing techniques. This exploratory qualitative study was carried out with PE teachers (n = 7) and a trainer responsible for implementing this training program. A thematic analysis was conducted on the corpus combining a survey on PE teachers appreciation of the Zen Breathing training, training artefacts, the trainers logbook and an individual interview with a participant. The initial results shed light on the trainers action model in terms of intentions, planning strategies, and actions or interventions during training. In addition, the results allow to corroborate or compare the trainers impressions to those of PE teachers by analyzing the artifacts and the participants comments. This research project has enabled a better understanding of the facilitators and obstacles involved in implementing a program of this kind.

MINDFUL TENNIS: IMPACT OF A 7-WEEK INTERVENTION ON PERFORMANCE AND MENTAL STATE IN COLLEGIATE PLAYERS

FEI, F., LEI, S.M., CHOI, S.M.

UNIVERSITY OF MACAU

INTRODUCTION: Maintaining steady psychological state is crucial for achieving and sustaining athletic performance. While mindfulness training has been shown to enhance psychological well-being and performance, its integration into sports training programs remains under-explored with limited research on its impact in collegiate tennis. This study aimed to examine the effect of a 7-week mindfulness-based intervention on psychological state and tennis performance among college-level tennis players.

METHODS: Sixty second-year collegiate tennis players in Yunnan, China, were randomly assigned to an experimental group (n=30) or a control group (n=30). Both groups participated in a 7-week structured tennis training program. The experimental group additionally received Mindfulness Sports Training, which included 30-minute mindfulness-based sessions and two 15-minute integrated tennis skills practices on the training court. Assessments were conducted before, immediately after, and 4 weeks post-intervention. Psychological measures included the Five Facet Mindfulness Questionnaire, Acceptance and Action Questionnaire, Sport Competition Anxiety Test, and Mindfulness Attention Awareness Scale. Standardised tennis skill tests were administered at each assessment. Descriptive statistics, normality tests, independent t-tests, two-way repeated-measures ANOVAs, and Pearson correlations were used for data analysis.

RESULTS: After 7 weeks of training and at the 4-week follow-up, the experimental group exhibited significantly greater improvements than the control group on mindfulness ($p < 0.001$, $\eta^2 = 0.798$), psychological flexibility ($p < 0.001$, $\eta^2 = 0.705$), competition anxiety state ($p < 0.001$, $\eta^2 = 0.766$), and character concentration ($p < 0.001$, $\eta^2 = 0.684$). In terms of tennis performance, the experimental group showed greater improvement in forehand/backhand ($p < 0.001$, $\eta^2 = 0.808$), serving ($p < 0.001$, $\eta^2 = 0.825$), and net volleys ($p < 0.001$, $\eta^2 = 0.805$). Although the control group also improved in tennis skills, they did not demonstrate significant changes in psychological measures. Correlation analyses revealed significant positive relationships between overall mindfulness level and character concentration, as well as between overall mindfulness and psychological flexibility, and between forehand/backhand and net volley performance.

CONCLUSION: The improvements in mindfulness, psychological flexibility, and reduced competition anxiety appear to contribute to better on-court performance, illustrating the interconnected nature of mental and physical training. Future studies could explore the underlying mechanisms in other athletic contexts, investigate longer-term effects on competitive outcomes, and consider how different sports or skill levels might benefit from similar mindfulness interventions.

SELF-DETERMINATION, HAPPINESS, AND PHYSICAL TRAINING IN STROKE SURVIVORS WITH APHASIA: A HOLISTIC APPROACH TO REHABILITATION

LEMYRE, P., BIEL, M.

NORWEGIAN SCHOOL OF SPORT SCIENCES

Background: Stroke survivors with aphasia face significant challenges in communication, leading to difficulties in social interaction, emotional well-being, and independence. While physical rehabilitation and speech therapy are commonly prioritized in stroke recovery, psychological factors such as self-determination and happiness play a crucial role in improving motivation, emotional resilience, and engagement in therapy. This highlights the need for a holistic rehabilitation approach that integrates both physical and psychological aspects of recovery.

Objective: This study explores the role of self-determination, happiness, and physical training in the rehabilitation process of stroke survivors with aphasia. It aims to assess how combining psychological factors, such as fostering self-determination and promoting happiness, with physical training can enhance both communication skills and overall recovery outcomes.

Methods: Stroke survivors with aphasia will participate in a rehabilitation program that integrates physical exercises with psychological techniques aimed at enhancing self-determination and happiness. The program will include autonomy-supportive strategies, motivational techniques, and physical exercises designed to improve mobility and communication. Interviews are conducted to evaluate improvements in motivation, happiness, communication abilities, and overall rehabilitation outcomes.

Results: Preliminary findings suggest that participants who experience higher levels of self-determination and happiness, in addition to physical training, show significant improvements in communication abilities, increased motivation, and greater engagement in rehabilitation. These factors contribute to better emotional well-being and more sustained participation in therapy, leading to enhanced recovery outcomes.

Conclusion: A holistic rehabilitation approach that combines self-determination, happiness, and physical training is essential for maximizing recovery in stroke survivors with aphasia. By addressing both the emotional and physical aspects of recovery, this approach enhances motivation, communication abilities, and overall quality of life, supporting comprehensive rehabilitation and long-term recovery for stroke survivors.

THE INFLUENCE OF PSYCHOLOGICAL SKILLS AND STRATEGIES ON COMPETITIVE PERFORMANCE IN SWIMMING

STUCKE, C.

OTTO-VON-GUERCKE-UNIVERSITY

INTRODUCTION: A long-term and systematic psychological training program can significantly contribute to the positive development of young athletes. Ideally, this training should commence during the youth and junior stages. The German Swimming Federation has developed a sports psychology training program specifically for the junior sector, aimed at supporting long-term athletic development. This study examines which psychological skills and strategies have a decisive impact on competitive performance.

Method: Between 2021 and 2024, a total of 34 female and 37 male athletes, with an average age of 16.3 years ($SD=1.25$), participated in sports psychology training and diagnostics as part of four annual training camps for the junior national team. To assess psychological skills and strategies, the Test of Performance Strategies (TOPS-D) was employed [1]. This test evaluates the use of self-talk, emotional control, automaticity, goal-setting, imagery, activation, and relaxation in both training (T) and competition (C). Additionally, negative thinking in competition and attentional control in training were assessed. Competitive performance was measured using the Rudolph Table, which allows for an age-appropriate and discipline-specific performance evaluation in swimming [2].

RESULTS: The findings indicate that young swimmers utilize psychological skills and strategies as frequently as reported in existing literature [1]. However, self-talk (T) ($p=.003$) and imagery (C) ($p=.004$) were used significantly more frequently, whereas attentional control ($p=.012$) was used less frequently than in the comparative sample. Emotional control, goal-setting, imagery, activation, and relaxation were significantly more prevalent during competitions (all: $p<.001$). With the exception of emotional control (T), imagery (T), and relaxation (C), no gender-specific differences were observed. However, these three psychological skills and strategies were significantly more frequently employed by male swimmers ($p=.011$ –

$p=.033$). Stepwise regression analysis identified the following factors as influencing competitive performance (Rudolph points – $F(1,58)=3.844$, $p=.004$, $R^2=.182$): Goal-setting (C) ($b=.434$, $p=.002$), Self-talk (T) ($b=.288$, $p=.021$), Emotional control (C) ($b=.239$, $p=.050$), Automaticity (C) ($b=-.187$, $p=.115$) and Imagery (C) ($b=-.221$, $p=.125$).

CONCLUSION: Psychological skills and strategies are primarily applied by young swimmers during competitions. Athletes who practiced self-talk during training and implemented effective goal-setting and emotional control during competitions demonstrated superior performance outcomes. Conversely, excessive cognitive engagement and imagery during competitions had a negative impact on performance. Based on these findings, the content of the sports psychology training program should be reviewed and adjusted as necessary.

TRAINING PSYCHOLOGICAL SKILLS: EFFICACY AND ASSESSMENT OF A NONCLINICAL PSYCHOLOGICAL SPORTS COACHING E-INTERVENTION FOR YOUNG ELITE ATHLETES

BONETTI, R., CRETZAZ VON ROTEN, F., HAUW, D.

UNIL

Given the critical role of psychological skills in the development of young athletes and the current emphasis on digital and sustainable innovations, the rise of accessible e-interventions is unsurprising. Indeed, the significance of psychological skills as fundamental attributes of high performance in sports has been well documented (e.g., Birrer & Morgan, 2010; Brown & Fletcher, 2017; Weinberg & Gould, 2023). Solid acquisition of these skills may contribute to more effective learning and optimized development opportunities, aligning with principles of knowledge transfer and long-term sustainability in athlete development.
