RESULTS: Only 14.1% of the sample met the overall 24 h movement guidelines. The compliance ratio was higher in ST (63.3%) and sleep (71.4%) guidelines than in PA (35.7%). The compliance ratio for PA on weekend days (44.0%) was lower than on weekdays (73.8%). There was a compliance difference for the PA guideline between parents and participants in weekend days ($p = 0.002$). Odds ratio for meeting PA guideline in participants was 4.56 when the parents met with the PA guidelines. Mean BMI z-scores did not significantly differ between participants who complied with none or any individual guideline, any combination of meeting two guidelines, and those who met all three guidelines ($p > 0.05$). A significant correlation for BMI z-score was found between parents and participants ($r=0.398$, $p<0.001$).

CONCLUSION: The present study demonstrated the low ratio of toddlers who met all the guidelines and no association between BMI and compliance with the 24-h movement guidelines. These results are consistent with previous studies [1,2]. However, the compliance with the PA guideline, especially on weekend days, was low in the present study. Even on holidays, interventions that improve parent-child PA are important.

AN ASSOCIATION BETWEEN POSSIBLE SARCOPENIA AS PREVENTIVE PREDICTOR AND MILD COGNITIVE IMPAIRMENT

LEE, J., KANG, S.J., PARK, H., SUK, M.

KYUNG HEE UNIVERSITY - GLOBAL CAMPUS

INTRODUCTION: The aging global population presents significant health challenges, particularly with the rising prevalence of sarcopenia and mild cognitive impairment among older adults. Understanding the association between sarcopenia as a preventive measure before its diagnosis, and mild cognitive impairment, would be helpful in preventing sarcopenia and mild cognitive impairment. The purpose of this study is to investigate the association between possible sarcopenia, considered as a preventive predictor before its diagnosis, and mild cognitive impairment.

METHODS: A cross-sectional study was conducted involving 60 physically inactive participants aged 40-69. Assessments included body composition, physical activity, and cognitive evaluations.

RESULTS: Participants with possible sarcopenia were found to have a 12.25 times higher risk of developing mild cognitive impairment (OR: 12.250, 95% CI: 1.692-88.711, $p = 0.013$).

CONCLUSION: The findings highlight the critical role of early diagnosis and intervention in sarcopenia to prevent cognitive decline. Future longitudinal studies are necessary to clarify causal relationships and optimize preventive strategies.

EFFECTS OF COGNITIVE STIMULATION THERAPY AND FALL PREVENTION EXERCISE ON BALANCE, GAIT, MUSCLE FUNCTION, COGNITIVE ABILITY AND DEPRESSION IN OLD ADULT WITH DEMENTIA

KWON, I., LEE, S., PARK, D.

KOREA NATIONAL SPORT UNIVERSITY, CHEONG AM NURSING HOME

INTRODUCTION: Dementia is a leading cause of disability and dependency in older adults, significantly increasing fall risk due to cognitive decline and impaired gait [1]. While exercise interventions help prevent falls, research on combined cognitive and physical training for dementia patients remains limited [2]. Cognitive stimulation therapy improves cognitive function, while exercise enhances balance and mobility [3]. Integrating these approaches may be key to reducing falls and improving overall function in dementia patients. This study aims to develop and evaluate a combined cognitive and fall prevention program tailored for dementia care.

METHODS: Twenty-one older adults with dementia were randomized into two groups: a cognitive stimulation and fall prevention exercise program (CogEx) and a fall prevention exercise-only program (Ex) during 7 weeks. Participants completed pre- and post-intervention assessments for balance (single leg stand), gait (Timed Up and Go), muscle function (chair stand, grip strength), cognitive function (Mini Mental State Examination), and depression (Geriatric Depression Scale). Statistical analysis was conducted using repeated measures ANOVA to examine interaction and main effects.

RESULTS: A significant interaction effect between group and time was observed for Chair Stand ($F = 5.39$, $p = 0.032$) and depression ($F = 5.65$, $p = 0.029$). However, no significant interaction effects were found for balance, grip strength, TUG, or cognitive function. A significant main effect of time was observed for balance ($F = 17.91$, $p = 0.001$), TUG ($F = 48.60$, $p < .001$), Chair Stand ($F = 11.81$, $p = 0.003$), and depression ($F = 11.48$, $p = 0.003$), while grip strength and cognitive function showed no significant changes.

CONCLUSION: This study suggests that a combined cognitive and fall prevention exercise program can improve lower limb strength, balance, and depressive symptoms in dementia patients. While mobility and functional performance showed significant improvements, cognitive ability remained unchanged, highlighting the need for further research. These findings underscore the importance of tailored interventions to enhance quality of life and reduce fall risk in dementia care.

EXERCISE ENGAGEMENT AND ITS ASSOCIATED BARRIERS AMONG OLDER ADULTS

KANG, S.J.1, CHOI, K.K.2, KIM, S.J.3, LEE, J.A.3,4, SHIN, J.C.

1. SPORTS AND HEALTHCARE MAJOR, SANGMYUNG UNIVERSITY, SEOUL, KOREA, 2. FITNESS MBA, SANGMYUNG UNIVERSITY, SEOUL, KOREA,, 3. GAEDANG COLLEGE OF GENERAL EDUCATION, SANGMYUNG UNIVERSITY, SEOUL, KOREA, 4*. DEP OF POPULATION HEALTH, LEHIGH UNIVERSITY, PA, USA

INTRODUCTION: Identifying the factors that serve as barriers to exercise engagement among older adults is essential for promoting and encouraging their participation. This study aims to analyze the characteristics of exercise participation and examine the factors that limit older adults involvement in exercise.

METHODS: A total of 312 older adults (80.5 ± 6.8 years) participated in this study. A 26-item questionnaire, based on U.S. CDC guidelines with study-specific additions, assessed exercise participation and barriers. It covered 5 socio-demographic factors (sex, age, education, economic status, residence) and 21 barrier-related items across five domains: economy, psychology/emotion, information-seeking skills, environment/physical constraints, and exercise program aspects/personal concerns. Frequency analysis categorized participants by weekly exercise: no participation, 1-2 days, or ≥ 3 days per week. Linear regression estimated odds ratios (ORs) for socio-demographic and barrier associations using two models: < 3 times per week (Model 1) and no exercise (Model 2).

RESULTS: The proportion of older women who did not exercise (38.9%) was higher than that of men (32.9%), while regular exercise (≥ 3 times per week) was lower in women (23.4%) than men (26%). Additionally, non-exercise rates increased with age, with the lowest regular exercise participation (18.2%) observed in those aged 85 and older. Among education

levels, those with 16 or more years of education had the highest rate of exercising three times per week (62.5%). The odds ratio (OR) analysis identified age as a significant factor in both models. In Model 1, participants aged 81–85 years (OR = 2.2, $p = 0.023$) and ≥ 86 years (OR = 2.45, $p = 0.021$) showed significance, while in Model 2, only the ≥ 86 years group was significant (OR = 2.36, $p = 0.014$). Individuals with ≥ 16 years of education showed significant ORs in both models: Model 1 (OR = 0.10, $p < 0.001$) and Model 2 (OR = 0.19, $p = 0.015$). All five exercise barrier domains showed significant ORs. In the Psychology/Emotion domain, “absence of someone to exercise with” had a high OR of 14.46 ($p < 0.001$, Model 1), while “feeling lazy and unmotivated” had an even higher OR of 27.73 ($p < 0.001$, Model 1), strongly associating with reduced exercise participation. In the Exercise Program Aspect/Personal Concerns domain, three barriers showed high ORs: “lack of knowledge about exercise methods” (OR = 23.62, $p < 0.001$), “concern about pain or injury” (OR = 16.08, $p < 0.001$), and “fatigue or exhaustion” (OR = 11.13, $p < 0.001$) in Model 1. These findings highlight significant barriers to exercise participation among older adults.

CONCLUSION: This study highlights the need for targeted interventions to increase exercise opportunities for women and adults over 80. Tailored strategies, including gender-sensitive approaches, improved technology access, and addressing psychological, environmental, and economic factors, may enhance exercise participation.

ASSESSING SKELETAL MUSCLE QUALITY IN CHILDREN: A COMPARISON OF ECHO INTENSITY BETWEEN NORMAL-WEIGHT AND OBESE CHILDREN – A SYSTEMATIC REVIEW AND META-ANALYSIS

JANDOVA, T., STEFFL, M.

CHARLES UNIVERSITY, FACULTY OF PHYSICAL EDUCATION AND SPORT, IC: 00216208

INTRODUCTION: The global prevalence of childhood and adolescent obesity has increased more than fourfold since 1990, with the coronavirus pandemic further exacerbating this trend (1). A sedentary lifestyle combined with a high-fat diet not only contributes to obesity but also leads to metabolic dysfunction in skeletal muscles (2). Echo intensity (EI), obtained through grayscale analysis, is considered one of the most effective ultrasound measurements for assessing skeletal muscle quality (3). This systematic review and meta-analysis study explored the use of EI as an indicator of muscle quality in both normal-weight (NW) and obese children.

METHODS: The PubMed, Web of Science, and Scopus databases were searched for articles related to muscle morphology assessed by ultrasound in children. The study was conducted in accordance with PRISMA guidelines.

RESULTS: The records identified 186 possible papers after searching for the keywords ((child*) AND (obesity)) AND ((ultrasound) AND (muscle) AND (quantity OR quality OR thickness OR mass OR size OR strength OR stiffness OR architecture)). After assessing eligibility, only seven articles were found to be eligible. The meta-analysis was based on data from 490 participants aged between 5.0 and 10.4 years. The weighted mean of the EI was 80.5 (SD 3.1) in NW and 105.9 (SD 4.4) in obese children. There was considerable heterogeneity in both analyses. However, the comparison showed a statistically significant difference ($p < 0.0001$).

CONCLUSION: In conclusion, this study highlights the significant differences in skeletal muscle quality, as measured by EI, between NW and obese children. Despite the observed heterogeneity in the data, which highlights the need for more robust and standardised studies, the findings suggest that ultrasound-derived EI could serve as a valuable tool for assessing muscle quality in children. The statistically significant difference in EI between the two groups suggests that obesity negatively impacts muscle quality, emphasising the need for early interventions to address childhood obesity and its associated metabolic effects.

AEROBIC AND RESISTANCE EXERCISE IN CHRONIC KIDNEY DISEASE: A META-ANALYSIS OF RENAL FUNCTION, INFLAMMATION, AND PHYSICAL PERFORMANCE

ZHANG, J., SU, H.

BEIJING SPORT UNIVERSITY

INTRODUCTION: Chronic kidney disease (CKD) is a global public health problem, affecting about 10% of the global population. Ranked as the fourth leading risk factor for global mortality, insufficient physical activity significantly contributes to the onset and progression of CKD. Patients with chronic kidney disease (CKD) often face issues like obesity, high blood sugar, and muscle loss, leading to reduced heart and lung function, muscle and bone deterioration, and decreased daily activity. These problems can worsen CKD progression. Aerobic exercise improves aerobic capacity, while resistance exercise boosts muscle strength. Combining both (ARCE) is gaining attention as a potential treatment for CKD patients. This study

aims to review and analyze randomized controlled trials (RCTs) to assess the combined effects of ARCE on renal function, inflammation, and physical function in CKD patients.

METHODS: PubMed, Embase, Cochrane, Web of Science, and EBSCO were searched for randomized controlled trials (RCTs) investigating the impact of regular ARCE in CKD patients. The study protocol was registered with PROSPERO (CRD42024596379). Review Manager 5 was used for meta-analysis, with effect sizes expressed as standard mean difference (SMD) and 95% confidence intervals (CI). Assessment two investigators independently assessed the risk of bias (ROB) of the included studies according to the Cochrane Risk of Bias Tool. A total of 19 studies (15 RCTs, 4836 patients) were included.

RESULTS: The meta-analysis revealed that ARCE significantly reduced C-reactive protein (CRP) levels (SMD = -0.12, $p = 0.03$), indicating a notable improvement in systemic inflammation. Additionally, ARCE led to significant reductions in blood glucose (SMD = -0.15, $p = 0.01$), body mass index (SMD = -0.10, $p = 0.05$), and waist circumference (SMD = -0.18, $p = 0.005$), highlighting its benefits for metabolic health and body composition. In terms of physical function, ARCE significantly improved peak oxygen uptake (SMD = 0.25, $p = 0.05$), 6-minute walk test performance (SMD = 0.82, $p < 0.00001$), upper limb muscle strength (SMD = 0.30, $p = 0.04$), lower limb muscle strength (SMD = 0.45, $p = 0.0003$), and sit-to-stand test ability (SMD = 0.75, $p < 0.00001$). However, ARCE did not demonstrate significant effects on renal function markers, including glomerular filtration rate (SMD = 0.06, $p = 0.46$), serum creatinine (SMD = -0.07, $p = 0.46$), or urine-albumin-creatinine ratio (SMD = -0.06, $p = 0.40$).

CONCLUSION: In conclusion, regular ARCE significantly improves inflammatory markers, glucose metabolism, body composition, and physical function in CKD patients, despite showing no significant impact on renal function. These findings suggest that ARCE may play a crucial role in delaying disease progression and enhancing quality of life in CKD patients. Furthermore, CRP, as a key inflammatory marker, holds potential as a supplementary indicator for evaluating the therapeutic outcomes of exercise interventions in CKD.

EFFECTS OF WHEY PROTEIN SUPPLEMENTATION ON PHYSICAL FITNESS AND GLYCATION END-PRODUCTS IN OLDER ADULTS WITH TYPE 2 DIABETES UNDERGOING MUSCLE-RESISTANCE TRAINING

CALDO, A., ALONSO, A.C., LIMA, A.M., GRECCO, M.V., BELINI, A.P.R., LINO, M.H.S., DA SILVA, V., SOARES, A., DAVIS, C., DE BARROS, M.P., GREVE, J.M.D.A., BRECH, G.C., FURTADO, G.E.

UNIVERSITY OF COIMBRA

INTRODUCTION: This study aims to evaluate the effects of whey protein and maltodextrin supplementation, in conjunction with resistance training (RT), on muscular strength, postural balance, glycaemic control, and the formation of advanced glycation end-products (AGEs) in older adults with type 2 diabetes mellitus (T2DM).

METHODS: This randomized, triple-blind clinical trial included 60 men, aged 65 to 79 years, diagnosed with T2DM. Participants engaged in a RT program twice a week for 12 weeks and were randomly assigned to receive either 20 g of whey protein, 20 g of maltodextrin, or a placebo (flavoured water) immediately after each session. Assessments included isokinetic dynamometry, handgrip strength, the MiniBest test, the Timed Up and Go (TUG) test, the Short Physical Performance Battery (SPPB), skin autofluorescence to measure AGEs, and glycaemic metabolism analysis.

RESULTS: The whey protein group showed significant improvements in quadriceps strength, hamstring strength, and plasma insulin resistance (HOMA-IR). Improvements were seen in MiniBest and TUG tests across all groups. No significant differences were observed in handgrip strength or AGEs levels between groups.

CONCLUSION: Supplementing with whey protein or maltodextrin did not enhance the benefits of RT on muscle strength, balance, or glycaemic control in older adults with T2DM. However, whey protein plus RT significantly reduced insulin resistance, indicating a potential benefit in managing glycaemic control.

A STUDY ON MENSTRUAL EDUCATION PROGRAMS FOR FEMALE ATHLETES

SUZUKI, N., SAMESHIMA, A., WATANABE, R.

TAKUSHOKU UNIVERSITY

INTRODUCTION: Menstrual education typically begins in elementary school, but many women lack sufficient knowledge and struggle with menstrual-related issues. Research suggests that post-menarche education is often inadequate. Among female athletes, a lack of awareness regarding menstrual irregularities caused by energy deficiency, fatigue fractures, and amenorrhea can result in delayed intervention. Therefore, educating athletes about menstruation and its related challenges is crucial for their health and performance. This study aims to assess the impact of a menstrual education program on female athletes awareness and understanding of menstruation.

METHODS: The study involved seven female athletes (mean age: 19.9 ± 1.1 years) from a university womens judo team. Educational materials were developed under the supervision of an obstetrician-gynecologist, based on prior research and literature on female athletes. The program consisted of two lecture sessions held one month apart, with assessments conducted before each session.

A questionnaire was used to evaluate the following aspects:

- Self-management skills
- Self-efficacy

- Perceptions of menstrual pain (e.g., "Menstrual pain is a natural part of being a woman")
- Understanding of menstruation (scored on a 10-point true/false scale)

RESULTS: The analysis revealed that menstrual knowledge significantly improved between the first (5.7 ± 2.6) and second (7.7 ± 2.2) assessments. However, no significant differences were found in self-management skills (29.1 ± 3.8 , 28.7 ± 4.9), self-efficacy (8.4 ± 3.6 , 8.7 ± 5.6), or perceptions of menstrual pain (24.9 ± 14.1 , 23.9 ± 6.5).

CONCLUSION: The results suggest that menstrual education programs can enhance knowledge about menstruation among female athletes. However, self-management skills and self-efficacy did not show notable improvements. Since self-management is closely linked to self-efficacy, further investigation is needed to determine effective educational strategies.

Previous studies highlight the importance of expert guidance, peer support, and advice from family members in promoting self-management of menstrual health. Given the short duration of this study, Q&A sessions were incorporated to provide immediate support. Future research should adopt a longitudinal approach to assess the long-term effects of menstrual education on athletes health behaviors.

This study demonstrated that a menstrual education program can improve menstrual knowledge among female athletes. However, no significant changes were observed in self-management skills or self-efficacy. To encourage long-term health behavior changes, future research should focus on optimizing the duration, frequency, and content of menstrual education programs. A longitudinal study is also needed to evaluate the program's impact on menstrual symptoms and self-management skills over time.

EFFECTS OF A SCHOOL-BASED INTERVENTION PROGRAM ON PHYSICAL FITNESS AND BMI IN MEDITERRANEAN CHILDREN

ALY, M., ABDELKARIM, O.

ASSIUT UNIVERSITY

INTRODUCTION: Physical fitness and body composition play crucial roles in children's health and athletic development. This study examined the effects of a school-based intervention program on physical fitness performance and body mass index (BMI) across five Mediterranean countries (Egypt, Lebanon, Italy, Spain, and Portugal) in two age groups (8–10 and 11–14 years). The study aimed to assess improvements in speed, strength, endurance, coordination, and BMI following the intervention and analyze variations based on age and country.

METHODS: A total of 935 children participated (males: 476, females: 459) from the five countries. The intervention program lasted several weeks, and participants underwent assessments for BMI and six physical fitness tests: sprint, standing long jump, jumping sideways, push-ups, sit-ups, and a six-minute endurance run. A three-way repeated measures ANOVA (Time $\times$ Age $\times$ Country) was conducted to evaluate the interventions effects. A two-way ANOVA (Age $\times$ Country) analyzed percentage changes in performance and BMI. Post-hoc pairwise comparisons were performed using the Bonferroni test. Statistical significance was set at $p < 0.05$.

RESULTS: The intervention significantly improved physical fitness across most variables ($p < 0.001$), with notable differences between countries and age groups. Sprint and endurance performance improved significantly across all countries, with the greatest improvements observed in Lebanon and Portugal ($p < 0.05$). Standing long jump and push-up performance showed significant gains in the older age group, particularly in Lebanon and Portugal ($p < 0.05$). Jumping sideways and sit-up performance improved in most countries, with Portugal demonstrating the highest improvements ($p < 0.05$). BMI significantly decreased in Egypt (11–14 years) but increased in Lebanon and Italy ($p < 0.05$). The highest BMI values were recorded in Italy and Spain for the younger age group.

CONCLUSION: The intervention program effectively enhanced physical fitness performance and influenced BMI changes in children, with variations by age and country. These findings highlight the importance of tailored fitness programs that account for regional and developmental differences. Future research should explore the long-term impact of such interventions on BMI and physical fitness and optimize training strategies to maximize benefits for youth health and development.

VARIABILITY IN IMMUNE BIOMARKER RESPONSE TO ACUTE EXERCISE IN BREAST CANCER PATIENTS

KOVTUNA, K., KLAIVINA, A., ZOLOVS, M., REIHMANE, D.

RIGA STRADIŅŠ UNIVERSITY

INTRODUCTION: Breast cancer (BC) is the most prevalent cancer among women, with approximately 2.3 million new cases diagnosed worldwide each year. Physical activity has the potential to influence circulating immune biomarkers and is crucial in the recovery process. This study aimed to evaluate the immune system mediator profiles in BC patients following acute exercise.

METHODS: Forty-three BC patients (age 35–64) completed VO₂ peak test before therapy. Blood samples were collected before (T1) and straight after (T2) VO₂ peak test. For each sample IL-6, M-CSF, IL-27, MIG/CXCL9, EGF, and sCD40L level (pg/mL) was measured by MILLIPLEX Human Cytokine/Chemokine/Growth Factor Panel Magnetic Bead Panel, HCYTA-60K (Millipore, Billerica, MA, USA) on a Magpix analyzer (Austin, TX, USA). Two subgroups of BC patients were formed based on the response to an acute exercise: BCI – group with increased post-exercise biomarker concentrations; BCD group with decreased post-exercise biomarker concentrations. Wilcoxon signed-rank test was used for subgroup data analysis. Data are expressed as median (Q1; Q3).

RESULTS: Analysis of all measured biomarkers in both subgroups showed significant effects ($P < 0.05$). The most pronounced inverse effects were observed for IL-6 (BCI-T1: 3.17 (2.27; 4.33), BCI-T2: 4.5 (3.43; 5.7) vs BCD-T1: 4.84 (3.34; 8.75); BCD-T2: 3.22 (1.95; 5.20)), sCD40L (BCI-T1: 715 (494; 1603), BCI-T2: 996 (690; 2207) vs BCD-T1: 831 (567; 1310), BCD-T2: 601 (432; 932)), M-CSF (BCI-T1: 155 (114.5; 256), BCI-T2: 202 (164.6; 300) vs BCD-T1: 245 (73.9; 294), BCD-T2: 143 (56.1; 228), where biomarker level changed by up to 1.5 times. Still significant changes, but with smaller magnitude, were observed for EGF (BCI-T1: 43.9 (14; 56.6), BCI-T2: 46.8 (22.5; 60.8) vs BCD-T1: 31.8 (20.1; 51.9), BCD-T2: 27.7 (18.0; 46.4)), IL-27 (BCI-T1: 1148 (895; 1404), BCI-T2: 1234 (991; 1485) vs BCD-T1: 1121 (741; 1373), BCD-T2: 1093 (723; 1224)) and MIG/CXCL9 (BCI-T1: 2401 (2095; 3549), BCI-T2: 2778 (2461; 3980) vs BCD-T1: 3593 (2618; 5460), BCD-T2: 3244 (2389; 4387)).

CONCLUSION: Acute exercise induced response was observed among all measured immune biomarkers. Furthermore, this response varies significantly among breast cancer patients forming two distinct subgroups. Future studies should account for these individual differences to better tailor exercise interventions for improving immune function during recovery in breast cancer patients.

IMMUNE (BIOMARKER) ANALYSIS IN THE FORTEE CONSORTIUM: PRESENTATION OF A PROJECT

FIUZA-LUCES, C., SANTA CRUZ, E., NEU, M.A., SPREAFICO, F., GASPARINI, P., BLOCH, W., ZARDO, W., LUCIA, A., FABER, J.
HOSPITAL 12 DE OCTUBRE RESEARCH INSTITUTE, 1+12

INTRODUCTION: Despite remarkable improvements in survival rate in the last decades, cancer remains the leading cause of death by non-communicable diseases in children in western countries. In addition, cancer and its treatment negatively affect children's physical capacity, and is linked to a high prevalence of toxicities and side effects as well as physical inactivity—with cancer-related fatigue being a prevalent condition with still unclear etiology. In turn, although exercise training is gaining attention in the context of pediatric oncology, it is not yet part of standard care. Particularly, the level of evidence for the effects of exercise training in childhood cancer patients during intensive cancer treatment is low compared to adult malignancies and more randomized controlled trials (RCT) are needed.

METHODS: In order to expand and synchronize the—still sparse—expertise in pediatric exercise oncology, the European Union-funded FORTEE (Get strong to fight childhood cancer) project has brought together leading experts on pediatric exercise oncology on a European level (6 consortium partners from 8 countries and 9 recruiting centres from 7 countries). We will implement a RCT to evaluate potential effects of an 8-10 week supervised precision exercise training intervention in childhood cancer patients. Supervised exercise training will be provided in the intervention group whereas the control arm will receive usual care. We will recruit ~450 childhood cancer patients aged 4-21 years and requiring chemo and/or radiation therapy—with no exclusion criteria for any type of tumor, and thus with all cancer types represented. In the exercise group, a motivational, playful and personalized exercise training with supervised exercise sessions will take place. Participants of both study groups can take part in an optional exercise program after the intervention phase for the remaining time of their cancer treatment. The following outcomes will be studied: cancer-related fatigue (primary outcome); and a number of secondary outcomes (e.g., health-related quality of life, mental health, physical fitness/performance, physical activity level and behavior, and body composition).

RESULTS: A blood biomarker analysis will be also performed in adolescent and young adult patients suffering from a solid tumor—excluding cancers of the immune system or blood cancer (leukemias and lymphomas). Thus, beside a general analysis of peripheral blood mononuclear cell distribution before and after the exercise intervention, the focus of the biomarker analysis will be natural killer (NK) and regulatory T (Tregs) cells, especially the study of exercise training effects on the cytotoxic activity and DNA-methylation profiles of these cells.

CONCLUSION: We hope that this biomarker analysis subproject will help to gain insight into the potential effects of exercise intervention in children with cancer. This is an important point as the evidence up to date on the effects of exercise in the context of pediatric cancer is mixed and immunotherapy is gaining importance in pediatric oncology.

EFFECTS OF PHYSICAL EXERCISE ON AUTONOMIC CONTROL IN DIABETIC PATIENTS

PERSIANI, M., LAFFI, A., PIRAS, A., MEONI, A., PETRONI, M.L., BRODOSI, L., NICASTRI, A., RAFFI, M.
UNIVERSITY OF BOLOGNA

INTRODUCTION: Chronic hyperglycemia damages body systems, making glucose and cardiovascular management crucial [1]. 50% of diabetic autonomic dysfunction are asymptomatic, increases morbidity, especially via cardiac autonomic neuropathy [2]. Type 2 diabetes mellitus (T2DM) affects both autonomic branches, and physical activity seems to play a role in its management. The study aimed the effect of an exercise program (EP) on autonomic functions in T2DM patients.

METHODS: 21 T2DM patients with no diabetic neuropathy diagnosis were randomly assigned to two groups. The EP group (13: age 59,54±11,79; HbA1c 59,82±19,57; BMI 29,73±5,28; diabetic medication 53,8%; insulin therapy 23%) followed a 12 month exercise program while Control group (8: age 63,75±4,89; HbA1c 65,67±7,23; BMI 32,90±5,38; diabetic medication 12,5%; insulin therapy 0%) maintained a sedentary habits. Heart rate variability (HRV) and heart frequency (HFrest) were assessed at baseline, 6 and 12 months. HRV parameters measure the time between heartbeats providing insights into the autonomic nervous systems balance. The time domain parameters such as MeanRR (average time interval between consecutive heartbeats (R-R intervals) reflecting overall heart rate), SDNN (standard deviation of R-R intervals, indicating overall HRV and autonomic balance), RMSSD (measures short-term HRV and is sensitive to parasympathetic activity). The frequency-domain parameters include LF/HF ratio (represent the sympathetic (LF) and parasympathetic (HF) balance). Repeated measures ANOVA was performed along variables, with the significance level set at $p < 0.05$.

RESULTS: SDNN showed a significant difference between groups over time ($p=0.008$), while other parameters did not. Notably, HRV and HRrest exhibited a positive trend, suggesting improved autonomic nervous function as a result of exercise.

CONCLUSION: Exercise program seems to improve cardiovascular autonomic function in adults with T2DM. The SDNN, considered the "gold standard" for a strong prognostic marker for heart disease [3]. In the EP group, SDNN increased compared to the Control group, suggesting that physical exercise has the potential to prevent -or at least delay- the onset of autonomic complications in T2DM.

DEVELOPMENT OF THE JAPANESE VERSION OF THE UKK WALK TEST: REFINING VO₂MAX PREDICTIVE ACCURACY

FUJITA, K., ADACHI, T., MARUTANI, Y., YOKOYAMA, T.

UNIVERSITY OF OSAKA

INTRODUCTION: The UKK Walk Test (UKKWT) is a cardiorespiratory endurance test that estimates maximal oxygen uptake (VO₂max) using four parameters: the time required to walk 2 km, heart rate at the end of the walk, body mass index (BMI), and age. Last year, we revised the VO₂max prediction equation for Japanese individuals and compared its performance with the original equation proposed by Oja et al. While the coefficient of variation (CV) for the Japanese version (UKK_J2024) showed improvement relative to the original, it remained relatively high, suggesting the need for further refinement. In this study, we investigated whether incorporating additional gait-related variables could enhance VO₂max prediction accuracy.

METHODS: Seventy-five healthy Japanese adults (37 men, 38 women; aged 20–65 years) participated in this study. VO₂max was measured using a respiratory gas analyzer during uphill treadmill walking. In the UKKWT, VO₂max was initially predicted from the four standard parameters. To refine the predictive model, multiple regression analysis using the stepwise method was performed. In the revised model (UKK_J2025), additional independent variables—including mean step count, stride length-to-height ratio, and their changes between the first and second halves of the test—were incorporated based on acceleration data obtained via a heart rate sensor. The predictive performance of the UKK_J2025 model was compared with that of the UKK_J2024 model using the root mean square error (RMSE) and CV.

RESULTS: The mean VO₂max measured using the direct gas analysis method was 43.3 ml/kg/min in males and 33.3 ml/kg/min in females. In the UKK_J2024 model, VO₂max in males was predicted using 2 km walk time and BMI, yielding a mean of 43.3 ml/kg/min (RMSE: 3.7 ml/kg/min, CV: 8.5%), whereas in females, VO₂max was estimated based on 2 km walk time, BMI, and age, with a mean of 33.0 ml/kg/min (RMSE: 4.2 ml/kg/min, CV: 12.6%). Multiple regression analysis for the UKK_J2025 model identified the following predictors of VO₂max in males: the magnitude of stride length-to-height ratio changes, mean step count, heart rate at the end of the test, BMI, and age. The revised model yielded a predicted mean VO₂max of 44.2 ml/kg/min (RMSE: 3.3 ml/kg/min, CV: 7.6%), demonstrating improved predictive performance compared to UKK_J2024. In females, the selected predictors were mean stride length, mean step count, BMI, and age, resulting in a predicted mean VO₂max of 33.4 ml/kg/min (RMSE: 3.8 ml/kg/min, CV: 11.5%), similarly indicating enhanced predictive accuracy.

CONCLUSION: This study successfully improved the predictive performance of VO₂max by incorporating gait-related parameters, such as step count and stride indices, into the UKKWT model. However, further refinements in prediction accuracy are necessary to facilitate the broader societal implementation of the UKKWT_J model.

THE IMPACT OF COMMUTING HABITS ON PHYSICAL AND MENTAL HEALTH OUTCOMES IN UNIVERSITY MEMBERS (DINAMO-ACTIVE): A PROSPECTIVE, OBSERVATIONAL STUDY

HAUFE, S., BEYER, M., BOYEN, J., SCHMIDT, L.S., STEIN, L., KÜCK, M., TEGTBUR, U.

DEPARTMENT OF REHABILITATION AND SPORTS MEDICINE

INTRODUCTION: Physical activity is a modifiable risk factor but difficult to implement into daily life. The role of the way to work as a potential resource for an active and healthy lifestyle is not certain yet.

METHODS: We evaluated the impact of regularly commuting active (by foot or bicycle) or passive (e.g. private car, public transport) on physical activity characteristics and health-related outcomes in university employees and students. We measured the distance, time and intensity on the way to the university and back home with a wearable activity tracker

over one week. Health-related quality of life (Short Form-36) and productivity (work ability index) were assessed with questionnaires.

RESULTS: From 54 recruited participants, 30 regularly commute active (50% women, age 36.4 yrs) and 24 passive (67% women, age 33.9 yrs). The distance getting to the university was shorter for those who used active (4.7 [2.5; 7.0] km) compared to passive mobility (18.7 [7.5; 29.9] km), as was the time taken (active: 19.2 [14.1; 29.3] min; passive: 49.9 [31.2; 56.4] min (for both $p < 0.01$). Heart rate (active 116.0 ± 11.7 bpm, passive 91.5 ± 16.3 bpm, $p < 0.01$) was higher whereas moderate to vigorous activity minutes (active 11.7 ± 8.3 min, passive 11.1 ± 8.8 min) were similar when comparing active versus passive commuting. Active commuters had similar sum scores for the physical (active 57.5 [55.8; 58.5] points, passive 57.4 [53.3; 59.3] points) and mental domain (active 50.4 [45.6; 55.8] points, passive 50.9 [43.7; 53.7] points) of health-related quality of life and for the total work ability score (active 42.6 ± 3.7 points, passive 42.1 ± 5.0 points).

CONCLUSION: As expected, active commuters experienced higher levels of physical exertion during their journey to work. However, due to the shorter duration of the journey the time within moderate to vigorous intensity was similar between active and passive commute. This finding might explain the similar scores of health-related quality of life and work ability between groups. Further analyses should reveal whether the mode of passive commuting influences the results, since the use of public transport presumably involves a greater walking distance than driving to work in a private car.

ASSESSING SLEEP HYGIENE SELF-EFFICACY IN UNIVERSITY ATHLETES

BODNER, M., GIPSON, C.2, KAMPMAN, K.1, DRILLER, M.3, HERGOTT, C.1, COTE, A.1, FENUTA, A.1

1. TRINITY WESTERN UNIVERSITY, LANGLEY, CANADA 2. UNIVERSITY OF TEXAS AT TYLER, TYLER, USA 3. LA TROBE UNIVERSITY, MELBOURNE, AUSTRALIA

INTRODUCTION: Sleep hygiene is linked to better sleep, but many university athletes struggle to adopt optimal sleep habits. Given that self-efficacy predicts health behaviour, we aimed to explore pre-season sleep hygiene self-efficacy and associated sleep characteristics in university athletes.

METHODS: We used the Self Efficacy for Sleep Hygiene Inventory Revised (SESHI-R) [1] to assess sleep hygiene self-efficacy in university athletes ($N=161$; 55.7% male; age: 20.6 ± 2.3 yr). The SESHI-R provides a global score and factor scores related to specific aspects of sleep hygiene (range 0-100; higher scores=greater self-efficacy). We assessed associations between SESHI-R scores and 1) sleep hygiene using the Athlete Sleep Behaviour Questionnaire (ASBQ) [2], 2) sleep difficulty and quantity/satisfaction using the Athlete Sleep Screening Questionnaire (ASSQ) [3], and 3) sleep regularity using the Sleep Regularity Questionnaire (SRQ) [4]. Differences in SESHI-R scores across sex, academic year, and chronotype (ASSQ) were also explored.

RESULTS: The SESHI-R global score was 64.5 ± 12.1 (range: 21.6-97.0), with the following factor scores for 'Behaviors to Adopt' (69.1 ± 15.0), 'Behaviors to Avoid' (64.6 ± 14.0), and 'Manage Mindset/Environment' (59.5 ± 14.0). Participants averaged 7.6 ± 0.9 hours of sleep/day; 28.4% reported 'somewhat' to 'very dissatisfied' sleep quality. 32.3% reported 'moderate' to 'severe' sleep difficulty and 85.5% had 'poor' sleep hygiene. SESHI-R global score was positively associated with sleep hours ($r=0.451$), SRQ scores ($r=0.388$), and sleep satisfaction ($r=0.292$), but negatively with ASSQ sleep difficulty ($r=-0.570$) and ASBQ sleep hygiene ($r=-0.470$) (all $p < 0.001$). SESHI-R scores were not significantly different across sex nor academic year ($p > 0.05$). 'Evening' chronotypes had lower global SESHI-R scores than 'morning' chronotypes ($56.3 \pm 14.1 < 65.5 \pm 11.7$) ($t(141) = 2.91$, $p = 0.004$).

CONCLUSION: Overall university athletes, particularly evening chronotypes, are characterized by sub-optimal sleep hygiene self-efficacy. Given the associations between self-efficacy and sleep behaviors/sleep, applying chronotype- and factor-specific confidence-building interventions in pre-season could help improve sleep hygiene and sleep through the competitive season.

IMPACT OF STATIN WITHDRAWAL ON SLEEP QUALITY AND FUNCTIONAL CAPACITY

PEYREL, P., BERGERON, J., SÉRIÈS, F., LAFLAMME, N., MAURIÈGE, P., JOANISSE, D.R.

DEPARTMENT OF KINESIOLOGY

INTRODUCTION: Statins are benchmark lipid-lowering drugs, reducing blood cholesterol by controlling its synthesis. There are side effects linked to statin use, notably statin-associated muscle symptoms (SAMS) (Thompson et al., 2016). These symptoms typically include myalgia, stiffness, weakness, fatigue and/or cramps. SAMS can lead to an altered health-related quality of life (Peyrel et al., 2023). Moreover, the potential effects of SAMS on sleep remain poorly documented. The

objective of this exploratory work was to assess if subjective and objective measures of sleep, as well as functional capacity, improve after drug withdrawal in SAMS self-reporters.

METHODS: Patients (5 men, 3 women, 44.8 ± 6.3 yr) in primary cardiovascular prevention were divided into two groups: statin users with (SAMS, $n=4$) or without self-reported symptoms (No SAMS, $n=4$). The Epworth Sleepiness Scale (ESS) and the Pittsburgh Sleep Quality Index (PSQI) questionnaire were used to assess subjective daytime sleepiness and sleep quality, respectively. Sleep measurements were recorded objectively for one week using actigraphy. The handgrip strength (FOHG) was measured using a handheld dynamometer, and the Six-Minute Walk Test (6MWT) was used to assess functional capacity. Finally, a 10-point visual analog scale (VAS) evaluated the intensity of SAMS. Measures were taken before and after a 2 month-statin withdrawal. Cohens d-values for pairwise comparisons were used to assess effect sizes (ES) of changes within group over time, and ES were considered as trivial (<0.2), small ($0.2-0.5$), moderate ($0.5-0.8$), and large (>0.8).

RESULTS: After statin withdrawal, an improvement of objective sleep quality was observed in the SAMS group (sleep efficiency: $+3.8\%$, ES: 0.33 [small effect]; wake after sleep onset: -15.6% , ES: -0.30 [small effect]; number of awakenings after sleep onset: -12.7% , ES: -0.45 [small effect]), concurrent with a decrease of subjective perception of SAMS intensity (VAS: 4.75 to 2.25 , ES: -1.06 [large effect]). A decrease in subjective daytime sleepiness (ESS: 11.3 to 8.3 , ES: -0.45 [small effect]) and an increase in subjective sleep quality (PSQI: 7.66 to 6.33 , ES: -0.31 [small effect]) were also specifically seen in this group. The No SAMS group did not show any change for the different objective and subjective sleep parameters (ES: -0.08 to 0.15 [trivial effects]). Finally, FOHG increased only in patients with SAMS (left hand, $+12.5\%$, ES: 0.30 [small effect]), while no change was observed for the distance walked at 6MWT.

CONCLUSION: These preliminary data suggest that in patients who self-report SAMS, a 2-month statin withdrawal may increase their sleep quality, as well as functional capacity illustrated by FOHG.

IMPORTANCE OF POWER TESTING AND TRAINING IN OLDER WOMEN

CARRILLO SALA, M., MONFERRER-MARÍN, J., ROLDÁN, A., CORDELLAT, A., NAVARRO-PÉREZ, J., BLASCO-LAFARGA, C.
UNIVERSITY OF VALENCIA

INTRODUCTION: Gender blindness refers to the lack of consideration of gender as a significant category in addressing a research problem (1). Metabolic and body composition differences between men and women, influenced by hormonal factors, suggest sex differences in the effects of physical exercise despite the aging process (2). When designing and evaluating physical exercise interventions (PEI), it should be essential to analyse the results separately by sex to determine potential differences, also in older adults.

METHODS: One hundred and two over 60 years individuals referred from Primary Care were assigned, according to their fitness, to two types of 8-week PEI: GesmedMarcha (GM; $N=53$, 37 women; Nordic walking and inspiratory muscle training) and ViuActiu (VA; $N=49$, 37 women; multicomponent exercise). Body composition, the Short Physical Performance Battery (SPPB) -total score; balance subscale score, 4-meter gait speed (m/s), time in the five-times sit-to-stand test (s)-, and the 200-meter gait speed test (m/s) were assessed. Lower limb power (w) and allometric power (w/m^2) were calculated from the 5-STs. Individual absolute deltas (Δ) were considered to compare between sexes using the Student's t-test for independent samples or the Mann-Whitney U test, depending on Shapiro-Wilk normality tests.

RESULTS: Pre-intervention sex differences were observed in both PEI. Men had a lower fat-mass % compared to women [GM: 27.01 (0.92) vs. 35.28 (0.90) %; VA: 32.03 (1.39) vs. 40.35 (0.95) %], with greater muscle mass (kg). Additionally, men display greater lower limb power [GM: 3.45 (0.20) vs. 3.01 (0.12) w; VA: 2.47 (0.21) vs. 1.95 (0.12) w]. Following the PEI, and within the overall sample, power and allometric power were the only variables that revealed significant sex differences ($p<0.05$) in the magnitude of improvement (i.e. Δ) [Men: 0.71 (0.17) w & 25.74 (4.73) w/m^2 ; Women: 0.31 (0.08) w & 8.82 (2.76) w/m^2 respectively].

CONCLUSION: Lower limb power, related to rate of force development, is greater in men, as it is influenced by muscle mass and male hormones. Additionally, men show greater improvements in this power following training. Since lower-limb power is crucial for the independence of older adults and avoid falls (3), PEI for older adults should pay special attention to power training and testing in women.

STUDY ON THE EFFECTS OF 8-WEEK HIIT TRAINING MODULATING THE HIPPOCAMPAL SIRT1/PGC1A PATHWAY ON HIPPOCAMPAL NEURONAL INJURY AND COGNITIVE DYSFUNCTION IN OBESE RATS

CUI, K., HAO, S.

BEIJING SPORT UNIVERSITY

INTRODUCTION: This study aimed to investigate the effects of high-intensity interval training (HIIT) on hippocampal neuronal injury and cognitive function in obese rats, providing theoretical evidence for HIIT interventions to improve hippocampal neuronal damage and cognitive dysfunction induced by obesity.

METHODS: Male SD rats were randomly divided into high-fat diet (HFD) and normal diet groups, and fed either a high-fat or normal diet. After 8 weeks, the Lees index ($\text{Lee's} = \text{body weight (g)}^{1/3} \times 1000 / \text{body length (cm)}$) was calculated to select obese rats. Obese rats (H group, $n=20$) and age-matched normal rats (C group, $n=20$) were further randomly divided into exercise and sedentary subgroups, with 10 rats in each subgroup: control sedentary (CS group, $n=10$), control exercise (CE group, $n=10$), high-fat sedentary (HS group, $n=10$), and high-fat exercise (HE group, $n=10$). Maximal oxygen uptake ($\text{VO}_{2\text{max}}$) testing was conducted to determine the running speed for HIIT. After an adaptation period, all exercise groups underwent 8 weeks of HIIT treadmill training. Behavioral tests were performed in the 9th week, followed by tissue collection for additional analyses.

RESULTS: Compared with the CS group, the CE group showed a decrease in body weight and Lee's index, although the differences were not statistically significant. In contrast, compared with the CS group both the HS and HE groups had significantly increase body weight and Lee's index. The HE group had a significant reduction in body weight and Lee's index compared to the HS group. In the Morris water maze test, the HS group showed a significantly increased escape latency and reduced number of platform crossings. In comparison, both CE and HE groups exhibited significantly reduced escape latencies and increased platform crossings compared to the CS and HS groups. Histological examination using HE and Nissl staining revealed that, compared to the CS group, the hippocampal CA1 neurons in the HS group had significantly fewer cells, with deeper staining, disorganized arrangement, and Nissl body dissolution. In contrast, in the exercise groups (CE and HE), hippocampal CA1 neurons exhibited significantly improved morphology, with increased neuron numbers, clearer cell nuclei, and more organized cellular arrangements. Molecular analysis through quantitative PCR and Western blot showed that both mRNA and protein levels of SIRT1 and PGC1 α were reduced in all groups due to obesity. However, exercise, regardless of obesity status, led to significant increases in the mRNA and protein levels of SIRT1 and PGC1 α in the hippocampus.

CONCLUSION: An 8-week HIIT training can improve hippocampal neuronal injury and cognitive function in obese rats. The underlying mechanism may involve the modulation of the SIRT1/PGC1 α pathway, which helps alleviate pathological neuronal damage and restore cognitive function.

METHODOLOGICAL CHOICES ON 24-H MOVEMENT BEHAVIOR ASSESSMENT BY ACCELEROMETRY: A SCOPING REVIEW

SANTOS, R., RODRIGUES, R., VIDEIRA-SILVA, A., LOPES, L., VALE, S., CLIFF, D.P., MENDES, R., SOUSA-SÁ, E.

UNIVERSITY OF MINHO

INTRODUCTION: There are no reviews describing current measurement protocols and accelerometer processing decisions that are being used in 24-hour MovBeh studies, across the lifespan. We aim to synthesise information on methods for assessing 24-hour movement behaviours using accelerometry across all age groups

METHODS: PubMed, PsycINFO, SPORTDiscus, and EMBASE were searched until December 2022. Observational or intervention reports describing accelerometry methods in studies on combinations of movement behaviors, with a 24-hour protocol across all ages, were included.

RESULTS: This review included 102 studies. Three studies in toddlers, 15 in preschoolers, 17 in children, 23 in adolescents and 44 in adults and older adults. The Actigraph GT3X was the most commonly used device; the majority of the included reports collected data for seven days, including three weekdays and one weekend day, with at $\geq 16\text{h/day}$ per 24-hour period for valid data. The criteria for non-wear time varied between ≥ 20 and ≥ 90 minutes of consecutive zero counts, depending on the age group. The most common epoch used was 15 or 60 seconds for youth and adults, respectively. The choice of sleep algorithms and SB/PA cut-points, of the included reports, depended on age and the original validation/calibration study. To deal with non-compliant participants, exclusion of non-compliant participants from the analysis was most frequently used. Most studies used diaries/logs to complement the accelerometer data.

CONCLUSION: Accelerometer protocols and methodological decisions varied considerably between reports. Therefore, consensus on methodological decisions is needed to improve precision and comparability between studies, which is challenging given the complexity of the procedures, the number of available brands and types of accelerometers, and the plethora of programming options.

FUNDING: This work was supported by the Portuguese Foundation for Science and Technology [grant numbers: FCT/UIDB/00617/2020; <https://doi.org/10.54499/UI/BD/150675/2020>, LA/P/0064/2020, PTDC/SAU-DES/0166/2021, CEECIND/01089/2017, UI/BD/150675/2020, UIDB/00317/2020 and UIDP/00317/2020, ; doi:10.54499/UIDP/00617/2020]. The funding agencies played no role in the study design; the collection, analysis, and interpretation of data; and the writing of the report.

AGE- AND SEX-SPECIFIC DIFFERENCES IN FITNESS TESTS OF CYPRIOT SCHOOL-AGED ADOLESCENTS: THE CYFIT STUDY

PAPACOSTA, E., MAVRIKIOU, P., PAOULLIS, P., XENOFONDOS, A., KONSTANTINIDIS, A., DEMOSTHENOUS, G., BARKOUKIS, V., TSORBATZOUZDIS, H., IOANNOU, I., POIRIAZI, F.A.

FREDERICK UNIVERSITY

INTRODUCTION: The CyFIT study is a population-based monitoring of physical fitness levels conducted in Cyprus and involves the largest assessment of physical fitness levels in secondary school students. Previous surveillance systems have been developed showcasing the trends of physical fitness in European countries, by providing reference values for children and adolescent populations [1,2,3]. For Cyprus, there have been no earlier reference levels established, while CyFIT creates a sustainable framework for fitness monitoring, offering valuable insights into the physical fitness levels of adolescents. The aim of this study is to highlight age- and sex-specific differences in aspects of physical fitness, in school-aged adolescents in Cyprus.

METHODS: A sample of 16194 school aged-adolescents (50% male, 50% female), from 12 to 17 years old, participated in this study. Participants were secondary school students from 63 (50%) public schools in region of Republic of Cyprus. Participants performed the Eurofit test battery, by trained professionals, which involved in series of 9 tests: Hand movement (HM), sit and reach (SR), standing long jump (SLJ), sit-ups (SU), shuttle run 10 x 5 m (SRM), push-ups (PU), hand grip strength in left (HSL) & right (HSR) hand, and endurance shuttle run (ESR) assessed by the 20-m multistage fitness test. Percentile levels in each test were calculated using descriptive statistics while inferential statistics identified age- and sex-specific differences.

RESULTS: Percentile reference curves were plotted for all physical fitness tests. Females outperformed males only in the SR across all age groups (ES: 0.26-0.72; $p < 0.001$). Males outperformed females in all other tests (ES: 0.15-1.89; $p < 0.001$), except for HM test at ages 12 and 13, where no significant differences were observed. A significant effect of age on all tests was evident except for PU for females (ES: < 0.01 -0.37; $p < 0.021$ for female; ES: 0.01-0.21; $p < 0.001$ for male). Males showed performance increases in PU (13 to 17 reps) and SLJ (149 to 189 cm) from ages 12 to 17, while female performance remained unchanged. Even though handgrip strength increased in both genders from ages 12 to 17 years, the increase in males was 40% vs 9% in females. ESR performance declined in both genders from 12 to 17 years by 14% in males and 27% in females. A two-way ANOVA revealed significant interaction effect between gender and age for all tests (ES: 0.01-0.06; $p < 0.001$).

CONCLUSION: This is the first study to assess fitness performance in adolescent population in Cyprus and the trends in age and sex differences are in line with similar studies [1,2,3]. The current results of sex- and age-specific fitness levels for adolescents in Cyprus can be utilized as reference values for health and fitness assessment and monitoring systems.

EFFECT OF ACUTE EXERCISE OF DIFFERENT INTENSITIES ON ALBUMIN EXCRETION IN OLDER ADULTS

TREJO, M., GOMEZ, L., PINEDA, H., RODRÍGUEZ, K., RAMOS, A., CHÁVEZ, I., GUILLÉN, D.

UNIVERSIDAD AUTÓNOMA DE BAJA CALIFORNIA

INTRODUCTION: Physical exercise has been pointed out as a factor capable of causing microalbuminuria, especially in people with pathologies related to vascular diseases (1). The effect of exercise on albumin excretion has been reported in healthy young adults to be transiently dependent on exercise intensity (2). There are different physiological mechanisms of albumin excretion in relation to the type of exercise, finding that high intensity and short duration can increase albuminuria excretion due to an increase in glomerular hydrostatic pressure. On the other hand, moderate intensity and long duration exercise increases albuminuria due especially to the decrease in tubular protein reabsorption (3). Under normal conditions, albumin is filtered by the glomeruli and proximal tubules which actively reabsorb this protein, these physiological conditions could be altered in older adults (4). The effects of maximal and submaximal exercise on excretion of albumin in older adults (≥ 65 years) are not well known. The purpose of the study was To evaluate the effect of different intensities of acute exercise on excretion of albumin in elder adults.

METHODS: 20 apparently healthy, sedentary older adults (13 men and 7 women) (70.1 ± 5.1 years) voluntaries participated in this study. The participants performed 3 exercise tests on a bicycle ergometer: 1 maximal test, where each subject performed 5 minutes warm-up, latter pedaling frequency was 50 rpm, starting with a load of 0.5 Kp and increasing the load by 0.5 kp. every 2 minutes. With a difference of one week between them, 2 submaximal exercise tests were performed at 80% and 60% of the maximal heart rate (HR), after the warm-up they pedaled for 20 minutes continuously at designated heart rate (± 2 beats) monitored by a HR transmitter. Urine samples were collected in 4 times: before the test, immediately, 1 and 24 hours after exercise to determine If there is increase the excretion of albumin. Statistical significance was $p < 0.05$

RESULTS: Only in maximal test immediately (of 7.6 ± 2.7 mg/l at 19.0 mg/l, ± 10.7) and 1 hour post exercise (18.6 ± 9.4 mg/l) significant increases in albumin excretion levels was observed. After 24 hours of exercise, any testing did not show microalbuminuria.

CONCLUSION: The exercise of maximal intensity causes increase in the excretion of albumina in apparently healthy older adults, this response is moderate and transient, as described in studies of young adults reporting transient increases in albumin excretion with acute exercise (5). There was no persistent microalbuminuria at 24 hours. Submaximal exercise (80% and 60%), no increased the excretion of albumin in apparently healthy elderly.

MENTAL HEALTH AND SLEEP QUALITY IN JAPANESE MENOPAUSAL WOMEN

SAKAMOTO, J., OKAMOTO, S., TOMIISHI, C., GOTO, K.

RITSUMEIKAN UNIVERSITY

INTRODUCTION: Menopausal symptoms have various adverse effects on health variables, leading to reduction of quality of life (QOL). Both decreased sleep quality and mental health are frequently observed during menopause (Kloss et al., 2014). However, whether impaired mental health with decreased sleep quality is affected by the severity of menopausal symptoms remains unclear. We compared the sleep quality and mental health between women who are aware of menopausal symptoms and healthy young women. In addition, the effect of the severity of menopausal symptoms on sleep quality and mental health were examined in menopausal women.

METHODS: Twenty healthy young women (YM; 20.4 ± 0.6 years, 161.4 ± 5.7 cm, 52.9 ± 5.9 kg) and twenty menopausal women (MW; 49.1 ± 2.6 years, 159.5 ± 5.0 cm, 53.7 ± 7.0 kg) were recruited. Body composition, mental health (CES-D [an indicator of depression]), DASS-21 [indicators of depression, stress, anxiety], SF8 [health related QOL], and subjective sleep score (PSQI) were assessed. Also, the MW group answered subjective questionnaires to assess the severity of menopause symptoms (SMI). In YW group, menstrual cycle was monitored, and all measurements were conducted during early follicular phase.

RESULTS: The scores of CES-D and PSQI were significantly higher in the MW group (CES-D; 11.5 ± 4.5 , PSQI; 5.3 ± 1.7 , $P < 0.05$), compared to the YW group (CES-D; 8.1 ± 3.8 , PSQI; 3.9 ± 1.4), indicating that MW group presented impaired mental health and sleep quality. Also, in the DASS-21, the MW group showed significantly higher scores for domains of "depression" (2.9 ± 2.1) and "stress" (3.9 ± 2.8) compared to the YW group (depression; 1.4 ± 1.9 , stress; 1.9 ± 1.7 , $P < 0.05$). Furthermore, the MW group had significantly lower physical summary scores of SF8 (MW; 47.3 ± 5.9 , YM; 54.3 ± 3.4 , $P < 0.05$). The mean SMI score in the MW group was 40 ± 19 points, and considerable number of participants exceeded the cutoff score. When the subjects in the MW group were divided into three groups based on the severity of menopausal symptoms (assessed by SMI), the group with higher SMI scores (61.3 ± 4.1 , PSQI; 6.4 ± 2.9) showed significantly lower sleep quality compared with the group with lower SMI scores (22.2 ± 2.6 , PSQI; 4.4 ± 2.3 , $P < 0.05$).

CONCLUSION: The aggravated mental health and sleep quality in MW may be associated with dysfunction of autonomic nervous activity (Maki et al., 2024). These results suggest that both mental health and sleep quality are decreased in menopausal women compared to young women. Moreover, the severity of menopause symptoms appeared to be associated with impaired sleep quality.

REFERENCE VALUES FOR THE TRUNK FLEXOR ENDURANCE TEST IN PHYSICAL EDUCATION STUDENTS

KOYAMA, T., KAWAI, R., MATSUDA, T.

COLLEGE OF HUMANITIES AND SCIENCES, NIHON UNIVERSITY

INTRODUCTION: The trunk flexor endurance test (TFET) has been proposed as a safe alternative to the sit-up test. The trunk inclination angle during TFET has varied from 45 degrees to 60 degrees in previous studies. It is expected that the posture holding time will differ depending on the angle. The clinical significance of the TFET may vary depending on the trunk inclination angle and the subject's characteristics. Despite its potential utility, there is no established standard value for its evaluation. Establishing reference values for TFET is essential for objectively assessing trunk endurance and comparing results across different populations. A standardized evaluation method will enhance the reliability of TFET as a physical fitness test and provide valuable reference data for future studies. Therefore, this study aims to determine reference values of TFET in physical education students and examine the influence of different trunk inclination angles on endurance performance.

METHODS: A total of 378 physical education students (258 men, 114 women) participated in this study. The subjects were divided into 3 groups by trunk inclination angles (45 deg, 50 deg and 55 deg). In the TFET, the subjects took a sitting position so that the whole back is in contact with the tilting table at assigned angle. With the knees flexed at 90 deg and the

hands placed on the chest, the test starts by shifting the tilting table 10 cm backward and the subject should keep the starting posture as long as possible. When subject's back touches the tilting table again, the test ends. The trunk endurance time was recorded. Descriptive statistics, including mean, standard deviation (SD), and standard error of the mean (SEM), were calculated. One-way ANOVA, multiple comparison tests, and t-tests were conducted to determine differences between inclination angles or genders.

RESULTS: The mean value (SD, SEM) of each test (men/women) was 156.0 (121.5, 13.1)/190.2 (84.5, 14.5) sec at 45 deg, 188.0 (83.0, 9.0)/246.0 (125.5, 18.1) sec at 50 deg and 209.1 (116.5, 12.5)/251.8 (144.6, 25.2) sec at 55 deg. A significant main effect of inclination angle was observed in men, with endurance time at 45° being significantly shorter than at 55°. However, no significant effect of inclination angle was observed in women. Additionally, a significant gender difference was found at 50°, where women demonstrated longer endurance times than men.

CONCLUSION: These findings suggest that trunk inclination angle influences endurance performance differently based on gender, highlighting potential physiological or biomechanical differences between men and women in trunk stabilization and endurance. Further research is necessary to explore the underlying mechanisms and practical applications of these results in sports and rehabilitation settings.

IS THE USE OF ULTRASOUND-DERIVED PREDICTION EQUATIONS FOR PREPUBERTAL CHILDREN USEFUL FOR ESTIMATING REGIONAL SKELETAL MUSCLE AND FAT MASS IN JAPANESE ADOLESCENTS?

MIDORIKAWA, T., USUI, C., TORII, S., SAKAMOTO, S.

J.F. OBERLIN UNIVERSITY

INTRODUCTION: Accurate estimation of regional skeletal muscle (SM) and fat mass is difficult in adolescents using non-invasive methods. To date, prediction equations for estimating SM volume (Midorikawa et al., British Journal of Nutrition, 2015) and fat mass (Midorikawa et al., British Journal of Nutrition, 2011) have been developed for prepubertal children using B-mode ultrasonography. Ultrasonography is a safe method for concurrent measurements of muscle and fat thickness of the extremities and trunk in children. Thus, the present study investigated the validity of prepubertal-based equations for regional SM and fat mass in Japanese adolescents.

METHODS: Twenty-seven healthy prepubertal Japanese children (10 boys and 17 girls) aged 11–17 years with Tanner stage > 1 participated in this study. Contiguous magnetic resonance images with 1-cm slice thickness and no-gap were obtained from the first cervical vertebra to the ankle joints. The SM volume was calculated by summing the digitized cross-sectional areas and dividing them into separate regions using anatomical landmarks (i.e. arms, trunk, thigh and lower legs). The volume units were converted into mass using an assumed SM density (1.041 g/cm³). Arm, trunk, and leg fat masses were determined using dual-energy X-ray absorptiometry. Muscle and fat thickness were measured by B-mode ultrasonography at nine sites (lateral forearm, anterior and posterior upper arm, abdomen, subscapular, anterior and posterior thigh, anterior and posterior lower leg).

RESULTS: When the prepubertal-based equations were applied to adolescents, mean values between measured (boys, arms: 1.94 kg, trunk: 6.76 kg, thigh: 8.25 kg, lower legs: 2.39 kg; girls, arms: 1.42 kg, trunk: 5.58 kg, thigh: 6.07 kg, lower legs: 1.96 kg) and predicted (boys, arms: 1.37 kg, trunk: 5.86 kg, thigh: 6.54 kg, lower legs: 2.10 kg; girls, arms: 1.05 kg, trunk: 3.89 kg, thigh: 4.91 kg, lower legs: 1.81 kg) regional segments of SM mass were significantly different for adolescents. On the other hand, the measured regional fat mass (boys, trunk: 3.38 kg, legs: 4.19 kg; girls, arms: 1.38 kg, trunk: 3.63 kg, legs: 5.18 kg) was similar to the predicted values (boys, trunk: 3.54 kg, legs: 4.11 kg; girls, arms: 1.36 kg, trunk: 3.87 kg, legs: 5.59 kg) except for the arms in boys (measured: 1.00 kg, predicted: 1.15 kg). The Bland–Altman analysis of regional fat mass did not indicate any bias in boys or girls, with the exception of the leg region in girls.

CONCLUSION: These results suggest that prepubertal ultrasound-derived prediction equations are useful for estimating trunk fat mass in both boys and girls. A larger study on developing an SM prediction model is needed for adolescents.

GLOBAL RESEARCH STATUS AND TREND OF DIABETES EXERCISE PRESCRIPTION

LI, X.

HENAN UNIVERSITY

INTRODUCTION: Diabetes, a global chronic metabolic disorder with a rising prevalence, significantly impacts quality of life and socio-economic systems. Exercise therapy is central to diabetes management, improving glycemic control, reducing weight, and enhancing cardiorespiratory fitness. Recent research has focused on the effects of exercise types, intensity, duration, and comprehensive interventions, yielding significant progress. However, exercise prescriptions require greater personalization and scientific rigor, especially considering individual differences and challenges like the COVID-19 pandemic. Emerging technologies, such as wearable devices and artificial intelligence, offer new opportunities for diabetes management. This article reviews advancements in exercise prescription for diabetes, analyzes current research trends, and aims to drive further progress in the field, enhancing health outcomes for diabetic patients.

METHODS: This study analyzed 1,832 English articles and reviews on diabetes exercise prescriptions from the Web of Science Core Collection (2000–2024). Using CiteSpace, VOSviewer, and Bibliometrix R-package, it explored publication trends, geographic and institutional contributions, journal sources, author networks, keyword patterns, and highly cited works. Combining quantitative and qualitative methods, the research identifies key dynamics and trends in the field.

RESULTS: Research on exercise prescription for diabetes shows distinct phases: exploratory (2000–2006), surge (2007–2010), exponential growth (2011–2019), and volatility (2020–2024). The United States leads in publications, followed by

Brazil and Canada. *BMJ Open* (UK) is the top journal, while Pauli, José Rodrigo and Universidade de São Paulo (Brazil) are the most prolific author and institution, respectively. Keyword analysis highlights diabetes management, physical activity, insulin resistance, cardiovascular prevention, and lifestyle interventions. Highly cited studies underscore exercise role in chronic disease management. The U.S. dominates the field, collaborating with Brazil, Australia, and Italy. Institutional contributions vary, but global collaboration is evident. Author analysis provides insights into key contributors and networks, guiding future research.

CONCLUSION: Research on exercise prescription for diabetes has advanced from basic management to comprehensive and adaptive strategies, including responses to specific challenges like pandemics. The field has deepened its scope, leveraging methodological innovations to create precise and effective health strategies. Future research will focus on personalized exercise prescriptions, interdisciplinary approaches, and the potential of emerging technologies (e.g., wearables, AI) in diabetes care, while prioritizing long-term efficacy and adherence. These efforts aim to improve health outcomes, enhance quality of life, reduce complications, and build a stronger scientific foundation for diabetes management.

TEMPORAL PATTERNS OF EXERCISE AND THEIR INFLUENCE ON METABOLIC RESPONSES

WANG, J.

PEKING UNIVERSITY

INTRODUCTION: Exercise as a non-pharmacological intervention has been widely recognized for its benefits on metabolic health. The effects of morning or afternoon exercise on different metabolic indicators are different, and this paper aims to systematically evaluate and analyze the effects of exercise at different times on body composition, glucose metabolism and lipid metabolism.

METHODS: Following the PRISMA guidelines, this study conducted a literature search through electronic databases such as PubMed, Embase and Web of

Science. The included studies included exercise regimens in the morning, afternoon or morning and evening, and analyzed body weight, Body Mass Index, fat mass, fasting blood glucose, HbA1c, insulin, and triglycerides. The risk of bias was assessed using the Cochrane tool (Rob2), and publication bias was assessed by funnel plot and Egger test.

RESULTS: 13 long-term studies and 5 acute studies were analyzed ($n=658$ participants). Morning exercise (MT) was more effective in reducing body fat (MD -0.39, 95% CI [-0.66 to -0.13], $I^2 = 0\%$, $p = 0.004$), waist circumference (MD -0.53, 95% CI [-1.06 to -0.00], $I^2 = 31\%$, $p = 0.05$), and HbA1c (MD -0.11, 95% CI [-0.19 to -0.03], $I^2 = 0\%$, $p = 0.009$), while afternoon exercise (AT) was better in lowering fasting blood glucose (MD 0.13, 95% CI [0.01 to 0.24], $I^2 = 0\%$, $p = 0.03$) and triglycerides (MD 0.1, 95% CI [0.02 to 0.18], $I^2 = 41\%$, $p = 0.02$).

CONCLUSION: Both morning and afternoon exercise are beneficial to metabolic health, but the effects are different. Morning exercise was more likely to reduce body fat, waist circumference and HbA1c, while afternoon exercise was more likely to reduce fasting blood glucose and triglycerides.

EFFECT OF BODY COOLING IN URBAN AREAS ON CORE TEMPERATURE UNDER HOT ENVIRONMENT

HAYASHI, S., YOKOYAMA, M.

FUKUYAMA CITY UNIVERSITY

INTRODUCTION: If active body cooling can be implemented to prevent heat stroke in the city, in addition to reducing the heat load on humans, it is possible to open up the area to the general public and thus make effective heat stroke prevention methods available to a large number of citizens. Preventing human health hazards in hot weather is considered an urgent issue in promoting walkable urban development, as advocated by the Ministry of Land, Infrastructure and Transport.

The aim of this study was to clarify the effects of body cooling during physical activity simulating daily life at Fukuyama Station on human thermokinetics, subjective thermal sensation and thermal pleasure/discomfort from the thermal environment and physiological indices.

METHODS: The subjects in this study were 10 healthy male adults (age: 20.4 ± 0.2 years, weight: 64.7 ± 10.6 kg, height: 173.6 ± 4.4 cm, BMI: 21.5 ± 3.4 kg/m²). In this study, we conducted two randomized crossover trials: a CON (control) condition in which participants consumed a cold beverage in the shade during rest periods between walks in the city, and a BC (body cooling) trial in which participants cooled their feet and palms with 15°C water in addition to consuming a cold beverage in the shade. The two trials began at the same time (13:00). The participants started walking at a speed of 4 ~ 4.5 km/h to the rest point at 13:00 (outward). The distance from the starting point to the rest point was 1.1 km. Heart rate, core temperature, subjective thermal sensation and thermal pleasantness/discomfort were employed as measurement items.

RESULTS: Heart rate varied in dependence on physical activity intensity, but there were no significant differences between trials. During the outward walk, both trials showed a gradual increase in deep body temperature, and the CON trial group, which only consumed cold beverages at rest, continued to increase their core temperature until the end of the experiment. However, the BC trial group, who cooled their feet and palms with cold water at 5 minutes of rest and from 5 to 15 minutes on the return journey, showed a suppression of the increase in deep body temperature and a temporary decrease in deep body temperature at 5 minutes of rest (CON: 0.6 ± 0.4 °C vs. BC 0.2 ± 0.2 °C, $P = 0.006$). The BC trial

group also showed a suppressed increase in body temperature from the time of return walking to the end of the experiment, which was significantly lower than that of the CON trial group.

CONCLUSION: The results showed that 10 minutes of palm and foot cooling during walking in the city suppressed the increase in core temperature for 15 minutes after cooling at the normal walking intensity. The results suggest that active cooling of the body, in addition to the consumption of cold beverages, may contribute to the prevention of heat stroke during physical activity in the city during summer in Japan.

THE EFFICACY OF A 12-WEEK HIGH-INTENSITY CIRCUIT TRAINING INTERVENTION ON MYOKINES, ADIPOKINES AND GUT MICROBIOTA IN OVERWEIGHT/OBESE SUBJECTS

HUANG, K., LIAO, J.C., CHIU, Y.H., CHANG, C.C., CHEN, Y.H.

MACKAY MEDICAL COLLEGE ;SOOCHOW UNIVERSITY;SOOCHOW UNIVERSITY;NATIONAL DONG HWA UNIVERSITY;NATIONAL TAITUNG UNIVERSITY

INTRODUCTION: Obesity and cardiovascular diseases are closely linked to gut microbiota dysbiosis, which can lead to metabolic and inflammatory issues. High-Intensity Circuit Training (HICT) combines aerobic and resistance exercises to enhance cardiorespiratory fitness and muscle strength. However, its impact on gut microbiota remains unclear. This study mainly explores how HICT affects the myokines, adipokines and gut microbiota in overweight or obese individuals.

METHODS: A total of 29 overweight or obese participants were divided into a control group ($n = 12$, weight 76.32 ± 17.02 kg, BMI 27.94 ± 3.93) and an HICT group ($n = 17$, weight 71.38 ± 11.52 kg, BMI 25.91 ± 2.77). Both groups maintained their usual lifestyle without dietary changes, but the HICT group performed three weekly sessions of HICT for 12 weeks. Stool samples were collected before and after the study for DNA extraction and gut microbiota analysis via next-generation sequencing (NGS). Body composition, lipid profiles, and plasma levels of irisin, IL-6, IL-15, adiponectin, leptin, Nrg4, and omentin-1 were measured. Paired t-tests and McNemar tests assessed intervention effects.

RESULTS: HICT significantly reduced waist circumference and body fat percentage. LDL and total cholesterol levels increased in the exercise group, while IL-6 levels decreased. Adiponectin and omentin-1 levels increased, whereas neuregulin 4 levels decreased in both groups. Exercise enhanced gut microbiota diversity, increased short-chain fatty acid-producing bacteria, and regulated inflammatory responses. In contrast, the control group saw an increase in obesity-related and inflammatory gut bacteria. KEGG pathway analysis showed upregulation of pathways related to vitamin synthesis and cell structure reinforcement.

CONCLUSION: A 12-week HICT program improves body composition and gut microbiota in overweight and obese individuals, supporting metabolic and inflammatory health.

STUDY OF THE SUBJECTIVE COMFORT AND OBJECTIVE ANTHROPOMETRIC MEASUREMENTS EFFECTS ON FORMED PILLOW ERGONOMIC APPLICATIONS

WU, C., LU, M.1, CAI, Z.2, LIN, W.1, WANG, W.3

1.CHENG SHIU UNIVERSITY, KAOHSIUNG, TAIWAN; 2. NATIONAL SUN YAT-SEN UNIVERSITY, KAOHSIUNG, TAIWAN; 3. UNIVERSITY OF TAIPEI, TAIPEI CITY, TAIWAN

INTRODUCTION: Most memory pillow designs focus on supporting the neck and shoulders, particularly for back and side sleepers. This study evaluates their effectiveness in supporting the cervical vertebrae and surrounding muscles. Since comfort is subjective and varies from person to person, the aim is to analyze the differences between individual comfort perceptions and objective shoulder-neck width measurements to improve ergonomic pillow design.

METHODS: 125 subjects (weight: 63.10 ± 13.87 kg, height: 164.35 ± 7.85 cm, BMI: 23.27 ± 4.40) were recruited in this study. The PROMIS Sleep Disturbance short-form questionnaire was collected for evaluation of sleep quality (34.44 ± 16.72 , $F=0.46$, $P>.05$), and the shoulder-neck width measurements were collected to evaluate for objective suitable pillow models (general, neck support, and shoulder-neck double support). The subjective personal preference selections model was collected for data analysis to examine the difference between the subjective comfort pillow model (SCP), objective anthropometric measurements pillow model (OPP), and personal preference pillow (PPP). The one-way ANOVA was used to data statistics and investigate the differences in different pillow choices (SCP, OPP, PPP). A paired T-test was used to analyze the differences between the SCP and OPP models comfort feelings and selections.

RESULTS: All the subjects were divided into five groups by age (Youth, Young adult, middle adult, old adult, old age groups, $N=25$ in each); the personal prefer pillow model (PPP), middle adult and old adult groups has significant differences choice with old age group ($F=2.520$, $p<.25$). and subjective comfort pillow model (SCP), young adult has significant differences choice with old adult group ($F=2.537$, $p<.25$); prefer in shoulder-neck double support model. SCP and OPP model comfort feeling did not show differences (2.80 ± 1.03 vs. 2.76 ± 1.06 , $p>0.5$), but significant differences in model selections (4.18 ± 1.48 vs. 3.80 ± 1.79 , $p<.05$).

CONCLUSION: Personal Pillow model choice variation would be affected by age and individual preferences. However, modern pillows are ergonomic and designed for sleep quality purposes; we suggest that the formed pillow shape and hardness design consider age influences.

IMPACT OF ACTIVITY RESTRICTIONS DURING THE COVID-19 PANDEMIC ON THE PHYSICAL AND MENTAL HEALTH OF UNIVERSITY FRESHMEN: A TWO-YEAR COMPARATIVE STUDY

SAKAMOTO, Y.1, SHISHIDO, T.1, OHTOMO, M.1, FUJIMOTO, T.2

1 TOHOKU GAKUIN UNIVERSITY, 2 TOHOKU UNIVERSITY

INTRODUCTION: The prolonged changes in living environments due to the spread of the novel coronavirus disease (COVID-19), along with associated shifts in chronic stress, physical activity levels, and daily routines, have raised concerns about their long-term impact on mental and physical health. Understanding these effects is crucial for developing strategies to maintain and promote health during infectious disease outbreaks. The purpose of this study was to examine annual changes in physical activity and physical and mental health among university students who experienced various activity restrictions in their learning environments during the pandemic.

METHODS: This study included 91 first-year university students enrolled in universities in Miyagi Prefecture who were taking physical education classes and agreed to participate in the survey. The survey was conducted over a two-year period (April to August 2020 and April to August 2021) and consisted of 15 assessments per year (once per week). The survey collected data on participant characteristics, physical activity (IPAQ-short version), mental health (K6), and health-related QOL (SF-8). In 2020, all physical education classes were conducted exclusively online throughout the survey period. In 2021, classes were partially in-person during the first half and fully in-person during the second half. During the survey period, participants were encouraged to record their physical activities, watch and follow exercise videos (e.g., YouTube), and engage in physical activity regularly. A linear mixed model was used to analyze the repeated measures data.

RESULTS: The total physical activity level was 1216.5 ± 146.9 (METs*min/week) in 2020 and 2395.8 ± 167.2 (METs*min/week) in 2021, indicating a significant increase in 2021. Notably, physical activity levels were significantly higher in the second half of 2021 compared to the first half ($p < .05$). Additionally, sitting time significantly decreased in 2021 on both weekdays and weekends ($p < .05$). While light-intensity physical activity (LPA) and moderate physical activity (MPA) showed no significant differences between 2020 and 2021, vigorous physical activity (VPA) significantly increased in 2021 ($p < .05$). Furthermore, in 2021, LPA and MPA were significantly higher in females, whereas no significant sex differences were observed in VPA. In contrast, no significant differences were found between the two years in mental health or health-related QOL.

CONCLUSION: It was shown that the COVID-19 pandemic affected the amount of physical activity of university students but did not affect their mental and physical health, but it was suggested that the situation of activity restrictions may bring about changes in these.

HEART RATE RECORDED AMONG CHILDREN, ADOLESCENTS AND ADULTS DURING A 20 M RUNNING SHUTTLE TEST

OZIMEK, M., ZADARKO, E.2, BARABASZ, Z.3, ZADARKO-DOMARADZKA, M.4, WOLOCH, K.5

1, AKF IN KRAKOW, 2, UJ IN KRAKOW, 2,4,5, UR IN RZESZOW, 3, PANS IN KROSNO

INTRODUCTION: Age is an important determinant of the level of physical fitness. It is assumed to increase up to the age of 20, normalize between the ages of 20-25, and begin to decline thereafter, averaging 10% every ten consecutive years [1]. A study by Fleg et al. showed that among 20-30 year olds, there is a decline in physical fitness with age shaped in the range of 3-6%, while in healthy people over 70 years of age, the rate reaches a value exceeding 20% for each decade [2].

METHODS: The study group consisted of male representatives (577 subjects) aged between 10 and 40 years. Height, body weight and its components were determined using innovative BIA technology. Cardiorespiratory endurance was determined using a 20-m shuttle test, the so-called Beep test (The Multi Stage 20-m Shuttle Run Fitness Test- SF20mMT) [3]. The initial speed is about 8.5km/h and increases, every minute by 0.5km/h [4].

RESULTS: The level of BMI has been proven to have a significant effect on both HR max and distance run. The results also confirmed that water content and body fat are highly correlated. The results obtained by each group allow an accurate assessment of the subjects physical fitness and allow the adjustment of training methods to their needs and abilities.

CONCLUSION: Studies show that there are (environmental as well as biological) determinants that lead to an increase in the number of beats per minute with age [5]. The above indicates that the correlations may be more complex, and that age is not the only variable to be considered in the issue under study.

The maximum heart rate decreases with age (the coefficient of the age variable is -0.32). The relationship of HR max with age in the group of athletes is much stronger than in other groups. BMI level is related to maximum heart rate and distance run. The higher the BMI, the lower the distance obtained in the fitness test.

EFFECTS OF MODERATE-INTENSITY ENDURANCE EXERCISE ON AGE-RELATED ENDOTHELIAL FUNCTION AND NITRIC OXIDE PRODUCTION IN AGED HYPERTENSION

YANG, A., MASODSAI, K., SU, Y.A., CHENG, T.L.

UNIVERSITY OF TAIPEI

INTRODUCTION: Aging is regarded as a major non-modifiable risk factor that promotes high blood pressure, inflammation, and age-related vascular dysfunction and remodeling. The influences of aging and hypertension on the cardiovascular dysfunction are relevant. Previous evidences have indicated that endurance exercise induces blood pressure-lowering effects, which could be related to the amelioration of endothelial function and nitric oxide (NO) production. However, the

influences of endurance exercise on the endothelial dysfunction and their underlying mechanisms in aged hypertension remain unclear. Therefore, this study aimed to investigate the effects of moderate-intensity endurance exercise on the age-related endothelial dysfunction and NO production in aged hypertension.

METHODS: The male aged spontaneously hypertensive rats (SHRs) were randomly assigned into the control (SHR-Con) and the exercise training (SHR-ET) groups, while age-matched Wistar-Kyoto rats were served as the normotensive control (WKY-Con) group. The SHR-ET group underwent moderate-intensity treadmill training for 1 h/day, 5 days/week, for 12 weeks. After 12-weeks intervention, the aortas of all groups were isolated for the evaluation of endothelial function by organ bath system, including vasorelaxant responses induced by insulin and insulin-like growth factor-1 (IGF-1). In addition, serum NO production was examined among three groups.

RESULTS: Compared to the SHR-Con group, the insulin-induced vasorelaxant responses were significantly enhanced in the SHR-ET group after 12 weeks of endurance exercise ($p < 0.05$). Additionally, the IGF-1-induced vasorelaxant responses showed significant improvement in the SHR-ET group ($p < 0.05$). In the endothelium-denuded aortic rings, no significant differences in the insulin- and IGF-1-induced vasorelaxant responses were found among three groups. Moreover, the NO concentration significantly increased in the SHR-ET group ($p < 0.05$) to the levels similar to those observed in the WKY-Con group.

CONCLUSION: This study indicated that moderate-intensity endurance exercise significantly improved the age-related endothelial function and NO production in aged hypertension. These beneficial effects may contribute to blood pressure reduction and play a role in the prevention and treatment of hypertension in elderly individuals.

GENDER DIFFERENCES IN THE RELATIONSHIP BETWEEN PHYSICAL FITNESS COMPONENTS AND OVERWEIGHT AMONG ADOLESCENTS: INSIGHTS FROM A LARGE-SCALE STUDY IN CHINA

ZHANG, J., LEI, S.M., CAI, Z.J., WONG, S.P.

UNIVERSITY OF MACAU

INTRODUCTION: Childhood and adolescent obesity remain critical global public health concerns. While the prevalence of adolescent obesity has stabilized in some countries, it remains alarmingly high [1]. Managing overweight and obesity in this age group is closely linked to physical fitness [2]. However, few studies have specifically examined the relationship between distinct physical fitness components and adolescent obesity levels. This study aims to investigate this connection by assessing how a targeted physical fitness influences overweight and obesity rates in adolescents.

METHODS: This cross-sectional study analyzed secondary data from 14,468 adolescent students (aged 6–15 years) in Guangdong Province, China, collected from physical fitness tests and health examinations conducted between 2021 and 2023. Among the participants, 53.2% were boys. The analyzed fitness assessments included cardiopulmonary function and endurance, power, speed, upper and lower-body muscle strength, and core strength. Adolescents were categorized as either "normal weight" or "overweight/obese" based on age-specific Body Mass Index (BMI) criteria.

RESULTS: The results indicate that the overall overweight rate among the tested adolescents was 19% (boys: 23.9%, girls: 13.9%). Multiple logistic regression analysis was performed to examine the relationship between overweight status and various physical fitness measures in boys and girls. The model explained 44.6% of the variance in overweight status for boys ($R^2 = 0.446$, $p < 0.01$) and 42.1% for girls ($R^2 = 0.421$, $p < 0.01$). Both boys and girls showed a significant association between cardiopulmonary function ($p < 0.01$) and power ($p < 0.05$) with overweight status. Additionally, in boys, upper-body muscle strength ($p < 0.05$) and speed ($p < 0.05$) were significant predictors of overweight status. In girls, core strength ($p < 0.05$) and endurance ($p < 0.05$) were also significantly associated with overweight status.

CONCLUSION: This study identified gender differences in the relationship between obesity and physical fitness components among adolescents. The impact of various fitness attributes on overweight differs between boys and girls, suggesting the need for gender-specific physical fitness programs to address overweight and obesity effectively. Further research is needed to explore the underlying physiological mechanisms driving these differences.

REDUCING VOICE FATIGUE THROUGH BREATHING EXERCISES: A POTENTIAL OF INTERVENTION FOR TEACHERS

STEINMANE, V., FERNATE, A.

RIGA STRADINS UNIVERSITY

INTRODUCTION: Voice fatigue is a common problem among people in speaking-intensive professions, such as teachers, who rely on their voices throughout the workday [1]. Teachers are particularly vulnerable due to the noisy classroom environment, long speaking hours, and the need to project their voices over disturbances [2]. The hypothesis of this study is that breathing exercises can reduce voice fatigue in teachers and improve their overall quality of life, including sleep quality. This research aims to develop and implement a set of targeted breathing exercises designed to reduce voice fatigue in teachers.

METHODS: The study targeted 101 teachers at various educational levels, from elementary to higher education, as they are a high-risk group for voice-related problems. The research methods are the Standardized Voice Risk Factor Questionnaire, Vocal Symptoms Scale, Voice Handicap Index (VHI) were adopted for use in the Latvian cultural environment and distributed to collect relevant data. The survey aimed to assess the prevalence of voice problems, including fatigue, vocal strain, breathlessness, and difficulty speaking during the day. Teachers were asked about their work environment, the frequency and severity of their voice problems, and the impact these issues had on their general well-being, including sleep. According to the survey results, targeted breathing exercises were designed and implemented to reduce voice fatigue in teachers (n=30).

RESULTS: The results of the questionnaire revealed that teachers face a variety of voice-related problems, including fatigue of the voice, breathlessness while speaking, variations in voice noise, and cracks in the voice. These issues were found to affect the teachers' ability to communicate effectively, with teachers reporting reduced voice clarity, especially in the evening. Although most of the responses indicated mild voice problems, many teachers acknowledged that these problems impacted their overall quality of life.

CONCLUSION: The voice problems reported by the teachers were not severe, the constant vocal strain throughout the day indicates a potential benefit of integrating breathing exercises into their routine. Breathing exercises have the potential to reduce voice fatigue and improve general well-being, for teachers and other individuals in speaking-intensive professions. More research is needed to evaluate breathing exercises and their long-term effectiveness in reducing voice-related issues.

FALL PREVENTION THROUGH STRENGTH: WHICH TRAINING WORKS BETTER FOR THE ELDERLY?

ZISKA BOHMEROVA, L., VARJAN, M., SCHICKHOFFER, P., HAMAR, D.

FACULTY OF PHYSICAL EDUCATION AND SPORT, COMENIUS UNIVERSITY BRATISLAVA

INTRODUCTION: Falls are a leading concern among the elderly, often linked to declining muscle strength. While traditional resistance exercises are commonly used to counteract this, alternative methods are gaining attention. This study compares the effectiveness of two intervention programs - resistance-endurance and sensorimotor training—on muscle strength in elderly women.

METHODS: Twenty active, healthy elderly women were randomly assigned to one of two groups. The resistance-endurance group (REG, n=10, age: 73.8±2.9 years, body weight: 71.6±14.6 kg, BMI: 27.4±4.3) participated in a 10-week resistance-endurance program. The sensorimotor group (SMG, n=10, age: 72.9±4.1 years, body weight: 67.3±10.0 kg, BMI: 25.8±4.5) underwent sensorimotor training. Both groups trained twice weekly for 40 to 60 minutes per session. Maximal voluntary isometric contraction (MVC) of knee extension was measured using a dynamometric chair before and after the interventions.

RESULTS: Both interventions significantly improved isometric strength ($p < 0.05$). In REG, left leg strength increased from 102.0±36.5 to 113.6±31.3 N·m⁻¹ and right leg from 102.3±34.8 to 119.1±32.2 N·m⁻¹. In SMG, left leg strength rose from 106.6±18.2 to 117.6±18.9 N·m⁻¹ and right leg from 115.5±21.2 to 128.7±19.7 N·m⁻¹. There were no significant differences in strength gains between the two groups.

CONCLUSION: Both resistance-endurance and sensorimotor training effectively enhance muscle strength in elderly women. Sensorimotor training, in particular, offers a viable alternative for strength improvement in untrained elderly individuals, highlighting its potential for fall prevention.

THE EFFECTIVENESS OF EXERCISE AND ROWING IN IMPROVING PHYSICAL FITNESS AND ENJOYMENT OF ACTIVITY IN BREAST CANCER SURVIVORS

BARLASSINA, S., AMORE, A.1, NUCCI, G.1, PELLICANÒ, M.1, SPIANTINI, M.1, PIANCA, R.1, ROVERA, F.2, GRANDE, A.2, GALVANI, C.1,3

1UNIVERSITÀ CATTOLICA DEL SACRO CUORE, MILANO; 2BREAST UNIT, VARESE; 3IGEO - ITALIAN GROUP ON EXERCISE ONCOLOGY

INTRODUCTION: Numerous studies highlighted the importance of physical exercise in improving physical fitness (PF) among breast cancer survivors¹. Rowing emerged as a valuable form of physical activity, yielding improvements in both anthropometry and aerobic capacity, muscle strength and general flexibility, that encouraged active participation². The study aimed to evaluate the impact of a structured 6-month exercise program – which included one weekly session of

sculling (a form of sliding-seat rowing moving the boat with two oars per rower), one or two weekly sessions of Adapted Physical Activity (APA), and walking – on PF and exercise perception.

METHODS: The project “Effect and efficacy of Rowing in breast CancEr survivors” (ERICE) included 27 women breast cancer survivors (age 56.7 ± 6.5 yrs; BMI 23.9 ± 2.9 kg/m²; stages I, II, or III; surgery at least 6 months to a maximum of 20 years ago). The sample underwent two testing periods: before (T0, March) and after (T1, October) the exercise protocol. The evaluated characteristics were cardiorespiratory fitness (6 Minute Walking Test _6MWT), muscular endurance (30s Chair Stand Test_30CST), flexibility (V Sit and Reach_VSR), and enjoyment in performing physical exercise (Physical Activity Enjoyment Scale _ PACES-It).

RESULTS: Nineteen subjects who completed the program were included in the analysis, only 13 attained the required adherence (75%; N: 6_NAD vs N: 13_AD). The results indicate a slight improvement in the physical fitness parameters: aerobic endurance (6MWT_T0: 631.7 ± 48.9 ; T1: 630.5 ± 57.0 m) remained stable, muscular endurance increased (30CST_T0: 14.2 ± 2.1 ; T1: 15.5 ± 1.8 reps), while flexibility declined (VSR_T0: 25.6 ± 11.5 ; T1: 24.3 ± 10.2 cm). The perception of enjoyment (PACES-It) attained a greater improvement in women who achieved the required adherence (Δ AD, 4 ± 8.6 vs Δ NAD, -7 ± 14.6 , $p=0.05$).

CONCLUSION: Physical exercise, including sculling, has been shown to have an impact on functional fitness and the perception of enjoyment in breast cancer survivors. Notably, improvements in physical quality parameters were observed only among participants who had below-average baseline (T0) values or achieved adherence levels above 90%. This suggests that high program compliance and lower initial fitness levels may be critical factors in optimizing the benefits of the exercise intervention. Further studies are needed to evaluate the effects of exercise programs of different types and intensities to better understand these relationships.

EXTRA-CURRICULAR SPORT-BASED TRAINING PROGRAMS CAN ENHANCE PHYSICAL AND COGNITIVE DEVELOPMENT OF CHILDREN WITH AUTISM SPECTRUM DISORDERS: A PILOT STUDY

LAURENTI, F., MAZZEI, S., PRESTA, V., COMPIANI, M., SEVERINO, F., GUARNIERI, A., CONDELLO, G., GOBBI, G.
UNIVERSITY OF PARMA

INTRODUCTION: Children with Autism Spectrum Disorders (ASD) are primarily characterized by impairments in social communication and motor skills, which can affect their independence and increase their reliance on caregivers. Furthermore, children with ASD tend to be more sedentary than their typically developing (TD) peers, which negatively impacts their physical and cognitive development [1]. Therefore, this study aimed to determine the effects of extracurricular sport-based training programs on motor coordination and functioning in children with ASD.

METHODS: Twenty primary school children with ASD (ages 8.7 ± 1.6 years; 5 females) participated in a six-month self-chosen sport-based training program (i.e., swimming, team sports, individual sports). Before and after the program, total reaction time was evaluated using a simple (by identifying the targeted stimulus) and complex (by discriminating the targeted stimulus among confounding signals) reaction test, while fine and gross motor coordinations were assessed by transferring pennies, jumping in place-same sides synchronized, tapping feet and fingers-same side synchronized [2], and the Flamingo test [3]. A subgroup of ten children prolonged the intervention until 12 months and were further tested.

RESULTS: A significant reduction ($p=0.025$, $d=0.125$) emerged for the entire sample in total time of the complex reaction test (pre: 14.05 ± 11.2 s; post: 12.8 ± 8.6 s). Additionally, the Flamingo test approached a significant decrease (pre: 9.8 ± 3.5 pt.; post: 6.8 ± 4.6 pt.; $p=0.057$, $d=0.73$). Among the subgroup that underwent three evaluations, a main effect was observed for the simple reaction test ($p=0.013$, $\eta^2=0.33$) and the jumping in place test ($p=0.05$, $\eta^2=0.20$). Compared to baseline measurement (12.9 ± 9.6 s), total time of the simple reaction test was significantly reduced after six months (10.9 ± 7.2 s; $p=0.021$, $d=0.235$) and after one year (8.0 ± 3.0 s; $p=0.011$, $d=0.689$). Post hoc analysis did not confirm differences for jumping in place test. Notably, two of the low-functioning children, who were unable to perform any motor tests before the program, managed to complete both reaction tests afterward. No significant differences were found for the remaining tests.

CONCLUSION: Extracurricular sport-based training programs showed promising effects to improve reaction abilities and gross motor coordination in children with ASD. The proposed tests centered on simple and complex reaction tasks are the most effective to detect changes in children with ASD, particularly those with lower functioning. These results support the importance of participating in prolonged physical activity and sport programs during the developmental stages of children with ASD to sustain their physical and cognitive development. Strongest evidence could be obtained by increasing the sample size and the duration of the intervention programs.

EXPLORING THE EFFECT OF PHYSICALLY ACTIVE DAYS ON MENTAL HEALTH STATUS AND LIFE SATISFACTION AMONG AGING POPULATIONS IN EUROPE

MAKAI, A., KOVÁCS-SZABÓ, ZS., CHEN, M., PRÉMUSZ, V., ÁCS, P., HOCK, M.

UNIVERSITY OF PÉCS

INTRODUCTION: Physical activity (PA) is widely recognized as a key determinant of health and well-being in older adults. While previous research has established direct links between PA and general and mental health, the potential mediating role of mental health in the ageing population remains less examined. Understanding these mechanisms could inform more effective interventions aimed at improving overall life satisfaction in aging populations. This study examines whether mental health mediates the relationship between PA and life satisfaction in ageing adults in Europe.

METHODS: Data were obtained from a multinational, country-representative dataset, the European Social Survey, round 11 (2023/2024), which included a sample of older adults ($n=10646$, ≥ 65 years). PA was assessed using survey question about how many days in a week they did sport or physical activities for at least 30 minutes, and general health was measured via self-reported health status. Mental health was evaluated using the total score of validated scales measuring psychological distress, depression, or subjective well-being. Correlation and mediation analysis was conducted using regression models and bootstrapping procedures to test the indirect effect of PA on life satisfaction through mental health. The statistical analysis was performed by IBM SPSS 28.0 and JASP 0.19.3 software; the level of significance was set at $p < 0.05$.

RESULTS: The average age of the respondents was 73.93 ± 6.59 , 47.2% male and 52.8% female. The average number of days of doing sports activity at least 30 minutes was between 1.22-4.07 in the European countries; in Hungary, it was 1.37 ± 2.23 . The PA showed significant correlation with mental ($r = -0.330$, $p < .001$) and physical health status ($r = -0.343$, $p < .001$). Mediation analysis was performed to prove the positive effect of PA on older adults' life satisfaction, the PA was showed weak direct effect on subjective life satisfaction and significant indirect effect $\beta = [0.121]$, 95%CI $[0.113-128]$, $p < .001$, furthermore mental health significantly mediated this relationship, with an effect of $\beta = [0.503]$, 95%CI $[0.476-0.531]$, $p < .001$.

CONCLUSION: These findings highlight the prevalence of active days of the ageing population in Europe and the role of mental health in explaining the beneficial effects of PA on general health in older adults. Interventions aimed at promoting PA among older adults should also consider strategies to enhance mental well-being to maximize health benefits. EFFECTS OF HIGH-INTENSITY INTERVAL TRAINING ON BLOOD PRESSURE REGULATION AND COGNITIVE FUNCTION IN HIGH-FAT DIET-INDUCED METABOLIC SYNDROME

CHOU, P., SU, C.T., YANG, A.L.

UNIVERSITY OF TAIPEI

INTRODUCTION: The prevalence of metabolic syndrome (MetS) is increasing, affecting nearly 20-25% of adults worldwide and contributing to the global epidemic of cardiovascular disease and type 2 diabetes. The key characteristics of MetS include hypertension, insulin resistance, and hyperlipidemia, primarily caused by excessive caloric intake and reduced physical activity. These factors could lead to mitochondrial dysfunction, which may contribute to cognitive decline. Previous studies have indicated that endurance exercise improves cardiorespiratory fitness, reduces chronic inflammation, and enhances cognitive function. High-intensity interval training (HIIT) has been extensively studied for its cardiovascular and metabolic benefits, providing similar fitness as continuous endurance exercise. However, the effects of HIIT on blood pressure and cognitive function in high-fat diet-induced MetS remain unclear. Therefore, this study aimed to investigate the effects of twelve-weeks HIIT intervention on blood pressure regulation and cognitive function in high-fat diet-induced MetS.

METHODS: This study used male spontaneously hypertensive rats (SHR) feeding with high-fat diet as the MetS model, while age-matched normotensive Wistar-Kyoto rats (WKY) feeding with normal diet as the normal control group. At 12 weeks of age, the animals were assigned to three groups: high-fat diet control group (HFD-CON), HFD with HIIT group (HFD-HIIT), and normal diet control group (ND-CON). The HFD-HIIT group performed high-intensity interval training on the treadmill for 12 weeks, while the HFD-CON and ND-CON groups did not undergo any training. Throughout the experiments, resting blood pressure and heart rate were measured before and after the intervention. Moreover, cognitive function was assessed using the Morris water maze at the end of the study.

RESULTS: After 12 weeks of high-intensity interval training, compared with the HFD-CON group, the HFD-HIIT group exhibited significant reductions in resting heart rate, systolic blood pressure, diastolic blood pressure, and mean blood pressure ($p < 0.05$). Regarding the results of the Morris water maze, compared with the HFD-CON group, the HFD-HIIT group showed shorter escape latency, similar to the ND-CON group. However, there were no significant differences in the frequency and percentage of time staying in the correct quadrant among three groups.

CONCLUSION: Our results suggested that 12-weeks high-intensity interval training could improve blood pressure regulation and parts of cognitive function in high-fat diet-induced metabolic syndrome.

EVALUATION OF CORE MUSCLE ACTIVATION DURING BRIDGE EXERCISES ON STABLE AND UNSTABLE SURFACES AT VARIOUS KNEE ANGLES

SEO, D., KIM, T., KIM, S., YUN, J.

KOREA INSTITUTE OF INDUSTRIAL TECHNOLOGY

INTRODUCTION: Bridge exercises have commonly been employed as a core exercise method to improve core stability and strength. Additionally, instability training is an effective method to prevent low back pain (LBP). However, there is a lack of scientific evidence to suggest proper knee angles and the effect of bridge exercises on unstable surface training. Therefore, this study aimed to compare core activity between three knee angles (60°, 90°, and 120°) and surface conditions (stable and unstable) during the bridge exercise.

METHODS: The study recruited ten participants between 20 and 30 years of age with no musculoskeletal injuries. Surface EMG was used to record core muscle activity on the experiment date for each participant. The test was divided into two sections using surface EMG: measuring Maximum Voluntary Isometric Contraction (MVIC) for each muscle and recording core muscle activity during the bridge exercise. During the experiment, the participants randomly performed bridge exercises at three knee angles, with and without BOSU.

RESULTS: The results of the study regarding the EMG of the bridge exercise on both stable and unstable surfaces at different knee angles showed that the biceps femoris and erector spinae activity significantly increased on the unstable surface with a knee angle of 120° by repeated one-way ANOVA ($p < 0.05$). In addition, comparing muscle activity between stable and unstable surfaces using a paired t-test revealed that biceps femoris and external oblique muscle activity significantly increased during the bridge exercise ($p < 0.05$). The results of this study showed that bridge exercise with a knee angle of 120° and exercise on an unstable surface are efficient methods for increasing muscle activity in the biceps femoris, erector spinae, and external oblique muscles.

CONCLUSION: Changes in the knee angle and surface would lead to increases in core muscle activity. The results of this study showed that bridge exercise is not a high muscle activation exercise in abdominal muscles (rectus abdominal, rectus femoris and external oblique) compared to back muscle (erector spinae, gluteus maximus and biceps femoris muscles); it may be used to tailor core stability exercise training for establishing better co-contraction between abdominal muscle and back muscle groups during the rehabilitation of low back pain. The commonly prescribed rehabilitation practice involves low-intensity training and focuses on the recovery and strengthening of core muscles so that they can return to normal strength and stability. This would also involve patients re-learning the effective use of their core muscles. Therefore, the present study suggests that knee angle and surface type should be considered when using bridge exercises to improve core muscle stability and strength after taking into account the condition of the subject, their history of back pain, and rehabilitation.

THE IMPACT OF HIGH-INTENSITY INTERVAL TRAINING ON VASODILATION AND BODY COMPOSITION IN METABOLIC SYNDROME INDUCED BY HIGH-FAT DIET

YANG, C., SU, C.T., YANG, A.L.

UNIVERSITY OF TAIPEI

INTRODUCTION: Previous studies have demonstrated that a high-fat diet induces metabolic syndrome (MS), which may be related to the increased oxidative stress and reduced nitric oxide production, leading to endothelial dysfunction. Engaging in regular physical activity is considered a non-pharmacological strategy for managing MS. High-intensity interval training (HIIT) offers a more time-efficient exercise regimen that may achieve comparable or even superior outcomes to traditional moderate-intensity continuous training, particularly for cardiovascular health. Therefore, this study aims to investigate the effects of HIIT on vasodilation and body composition in the high-fat diet-induced MS.

METHODS: The male spontaneously hypertensive rats (SHR) with high-fat diet, as the animal model of MS, and normotensive Wistar Kyoto (WKY) rats with normal diet were used in this study. The rats were divided into three groups: the MS with HIIT group (MS-HIIT), the MS control group (MS-Con), and the normal diet control group (ND-Con). The intervention commenced when the rats reached 12 weeks of age and lasted for 12 weeks. The MS-HIIT group underwent high-intensity interval training by the treadmill, while the MS-Con group and ND-Con group did not receive any training. At the end of the intervention, endothelium-dependent and endothelium-independent vasodilatory responses, induced by acetylcholine (ACh) and sodium nitroprusside (SNP) respectively, were assessed. Additionally, the body composition was measured and compared among the three groups.

RESULTS: Compared to the MS-Con group, the MS-HIIT group showed a significant improvement in the ACh-induced vasodilatory response ($p < 0.05$), although it remained significantly lower than that of the ND-Con group ($p < 0.05$). Following the incubation with the nitric oxide synthase inhibitor NG-nitro-arginine methyl ester (L-NAME), ACh-induced vasodilatory responses were significantly reduced ($p < 0.05$), with no significant differences observed among the three groups. For SNP-induced endothelium-independent vasodilation, there was no significant differences among the three groups. Moreover, regarding body composition, the percentage of body fat was significantly decreased in the MS-HIIT group compared to the MS-Con group ($p < 0.05$).

CONCLUSION: This study suggested that high-intensity interval training could improve the endothelium-dependent vasodilation and reduce the percentage of body fat in metabolic syndrome induced by high-fat diet.

USABILITY AND ACCEPTABILITY EVALUATION OF EMS SMART SUIT BASED ON PHYSIOLOGICAL EFFICACY EXERCISE INTERVENTION

LEE, G., SEO, D., KIM, S., YUN, J., KIM, T.

KOREA INSTITUTE OF INDUSTRIAL TECHNOLOGY

INTRODUCTION: Electrical Muscle Stimulation (EMS) technology has been developed as a practical approach to reducing age-related decline in muscle mass and strength. A wearable EMS smart suit enables targeted muscle activation during low-intensity exercise and may provide an accessible alternative to high-intensity training. However, although usability and acceptability are crucial for long-term adherence, studies combining these aspects with physiological efficacy remain limited. This study aimed to evaluate the usability and acceptability of EMS smart suits alongside a physiologically effective exercise intervention to inform optimal wearable design strategies.

METHODS: Healthy participants aged 20–50 years without musculoskeletal disorders were recruited and randomised into two groups: an exercise group using EMS smart clothing, which compared a prototype EMS system to commercial EMS wearables, and a control group. Both groups participated in a 6-week exercise intervention, performing low-intensity, full-body, and postural exercises (including squats, lunges, wide squats, crunches, over-extensions, and table holding) three times per week for 30 min per session. Usability and acceptability were evaluated through structured questionnaires and semi-structured interviews, addressing aspects such as comfort, fit, ease of use, and perceived effectiveness of EMS stimulation. Additionally, physiological efficacy was measured by assessing body composition, muscle mass, and postural stability using a body composition analyser and postural assessment tools before and after the intervention.

RESULTS: Participants using the prototype EMS smart clothing reported significantly higher usability and acceptability scores than those using commercial devices, particularly in comfort and fit. However, device weight and suboptimal electrode placement were identified as key barriers. Despite positive subjective usability outcomes, no statistically significant physiological changes were observed during the six weeks.

CONCLUSION: The integration of usability, acceptability, and physiological efficacy measures in this study highlights the complex interplay between device design and user experience. Although the prototype EMS suit demonstrated improved comfort and user satisfaction, addressing issues such as device weight and electrode placement is essential to enhance both immediate usability and long-term adherence. Future research should explore extended interventions and design refinements to validate physiological benefits further and ensure the seamless integration of EMS smart wear into everyday routines.

SEDENTARY BEHAVIOUR AND HEALTH IN ADULTS: A SYSTEMATIC REVIEW

LOPES, L., AGOSTINIS-SOBRINHO, C., ZHANG, Z., SOUSA-SA, E., RODRIGUES, B., OLIVEIRA, A., ABREU, S., BURLEY, J., SANTOS, J.P., FERREIRA, G., VELDMAN, S.L.C., PIZARRO, A., ROSÁRIO, R., OLIVEIRA, O., MOREIRA, C., SANTOS, R.

FACULTY OF SPORT, UNIVERSITY OF PORTO

INTRODUCTION: Previews systematic reviews (SR) have focused on a limited number of health outcomes and some have yielded inconclusive evidence for certain outcomes. This SR aimed to summarise the evidence on the associations between sedentary behaviour (SB) and a comprehensive set of health outcomes, in adults aged 18–64.9 years.

METHODS: PubMed, PsycINFO, CINAHL, SPORTDiscus and Web of Science were searched from inception until January 2021 and updated in June 2023. Studies' quality was rated according to the GRADE Framework.

RESULTS: This SR included 254 reports (67.7% cross-sectional, 31.9% longitudinal and 0.4% RCTs), representing 7 787,236 adults. Most reports (82%) assessed SB with self-reported instruments, 16% with device-measured, and 2% used device-measured and self-reported instruments simultaneously. Studies' quality varied from very low to high. Regarding critical outcomes, results show consistent evidence on the detrimental association of different types, frequencies, and durations of SBs and overweight or obesity, Type 2 Diabetes, Metabolic Syndrome or clustering of cardiovascular disease (CVD) risk factors; and, less consistent evidence for the detrimental association of different types, frequencies, and durations of SBs and coronary artery disease and stroke mortality, coronary artery disease and stroke, Alzheimer's disease and depressive symptoms. The associations between different types, frequencies, and durations of SBs and hypertension, anxiety symptoms and different types of cancers considered in this review, were mostly null. Concerning important outcomes, detrimental associations of different frequencies, types and durations of SB were consistently seen for absenteeism/presenteeism, health-related quality of life (HRQoL) and dyslipidaemia; less consistent evidence was observed for fitness, whereas the associations between SB and academic achievement or osteopenia/osteoporosis were mostly null. From the dose-response or exposure/outcome gradient associations between SB (total sitting time and TV viewing) and hypertension, overweight/obesity, type 2 diabetes, metabolic syndrome or clustered CVD risk factors, depressive symptoms, HRQoL and dyslipidaemia, it can be concluded that excessive total SB (> ~8h/day) and TV viewing (>2h/day) are health-detrimental.

CONCLUSION: There is compelling evidence of the detrimental health-related associations of excessive sedentary behaviour, in adults. The findings support the Canadian 24h Movement Guidelines for adults, which recommend limiting the amount of SB to <8h/day and breaking up prolonged bouts of SB as often as possible.

THE EFFECT OF EXERCISE PROTOCOLS ON SHEAR WAVE VELOCITY OF THE MEDIAN NERVE AND 3RD FDS IN PATIENTS WITH CARPAL TUNNEL SYNDROME

PETERCA, J., SNOJ, Ž., OMEJEC, G.

UNIVERSITY OF LJUBLJANA, UNIVERSITY MEDICAL CENTER LJUBLJANA

INTRODUCTION: Carpal tunnel syndrome (CTS) is associated with increased tendon stiffness due to chronic resistance training, which enhances collagen fibril diameter and density [1]. Triggered hypertrophy of synovial fluid surrounding the flexor digitorum superficialis (FDS) tendons causes an increase in CT pressure, leading to median nerve entrapment [2] and decreased nerve elasticity [3]. Apart from median nerve shear wave velocity (SWV), studies suggest that 3rd FDS SWV could be a non-invasive biomarker for intracarpal pressure and CTS diagnosis [4, 5]. Hand strength exercises may also reduce CTS symptoms and improve diagnosis in haemodialysis patients [6]. However, commonly used exercises for CTS are the nerve-gliding exercises. Nerve gliding exercises used together with conventional treatment resulted in faster pain relief, increased nerve elasticity and improved function [7, 8]. Our study aims to evaluate the effect of different exercise regimens on SWV of the median nerve and 3rd FDS in patients with mild to moderate CTS.

METHODS: Forty-six CTS patients were divided into three groups: nerve and tendon gliding exercise group, strength exercise group and control. In total, 87 hands with mild or moderate CTS were assessed. Participants followed a three-week exercise regimen performed once daily. SWV measurements were obtained longitudinally to the nerve, using Canon Aplio i800 ultrasound with linear probe LX18i5. A longitudinal US image of the median nerve and 3rd FDS was used for SWV measurement. The region of interest (ROI) was within the median nerve epineurium and the hyperechogenic borders of the 3rd FDS tendon. SWV values for the median nerve and 3rd FDS inside the carpal tunnel were recorded pre-and post-intervention. Three consecutive SWV measurements were recorded, and the median value was statistically analysed.

RESULTS: Across the three groups, no statistically significant differences in SWV values were observed between the pre-and post-intervention. However, a trend was noted in the nerve and tendon gliding group, with decreased SWV in both the median nerve and 3rd FDS. In the strengthening exercise group, a reduction in the mean SWV was observed only in the median nerve while SWV of the 3rd FDS was slightly increased post-intervention. No measurable changes or trends were observed in the control group. The cross-sectional area of the nerve did not change in any of the three groups.

CONCLUSION: Although statistical significance was not achieved, the observed trends suggest that specific exercises may reduce mechanical stiffness in the median nerve and 3rd FDS in patients with CTS. While previous studies suggest that neurodynamic mobilization improves CTS symptoms and reduces SWV [9], the absence of significant SWV alterations in our study may be attributed to the relatively short intervention duration and potential non-adherence to instructions by patients. Further studies with larger sample sizes and longer intervention durations are required.

EFFECT OF STATIC STRETCHING AND FOAM ROLLING OF THE CALF AND HAMSTRING MUSCLES ON KNEE ROM OF THE DOMINANT LEG

CANZONE, A., GIUSTINO, V., PATTI, A., MUSUMECI, G., ROGGIO, F., MANNUCCI, C., DI MAURO, D., VICARI, D.S.S., SCARDINA, G., BELMONTE, G., THOMAS, E., BIANCO, A., TRIMARCHI, F.

UNIVERSITY OF MESSINA

INTRODUCTION: Myofascial chains ensure body continuity and transmit forces across the body (1, 2). In this way, joints play a fundamental role as rings of these chains. Hence, techniques aimed to improve muscular flexibility such as static stretching (SS) and foam rolling (FR) can induce enhancements in joints range of motion (ROM) both in healthy subjects as well as in subjects with conditions as knee osteoarthritis (KOA), where it is reduced joint function and mobility (3). Given that these two muscle groups (i.e., calf and hamstring) are connected in a myofascial chain (i.e., the superficial back line) (4), this study hypothesizes that a SS and FR protocol for the calf may affect knee flexion and extension ROM similarly to a SS and FR protocol for the hamstrings.

METHODS: A total of 40 healthy subjects were divided into 4 groups of 10 participants as follows: SS of the calf (SSC); SS of the hamstring (SSH); FR of the calf (FRC); FR of the hamstring (FRH). Participants performed 3 sets of 1 minute with 30 seconds of rest, maintaining a discomfort level of 7/10. Knee flexion and extension ROM of the dominant leg were measured before (T0) and 5 minutes after the last session (T1) using an inertial sensor (Beyond Inertial, Motustech Srl).

RESULTS: No significant differences were found between and within group in ROM knee extension for all the groups. As for ROM knee flexion, the FRH group showed an improvement compared to the SSH group ($p=0.001$) at T1. Moreover, also the FRC reported an improvement compared to the SSH group ($p=0.021$) at T1. In addition, the FRH group increases ROM knee flexion from T0 to T1 ($p=0.008$).

CONCLUSION: Based on these results, we confirm that a connection between calf and hamstring muscles could exist, and that the FR could be more effectiveness than SS. However, it should be further investigated which of these two muscle groups is more appropriate to release for greater benefits on knee ROM.

THE EFFECT OF HIGH-INTENSITY INTERVAL TRAINING ON AEROBIC PERFORMANCE AND BODY COMPOSITION IN YOUNG PHYSICALLY ACTIVE MEN

PURGE, P., LUIK, M., KÄNGSEPP, A., JÜRIMÄE, J.
UNIVERSITY OF TARTU

INTRODUCTION: The aim of this study was to examine the impact of three-week high-intensity interval training (HIIT) on different parameters of body composition and aerobic performance in young physically active men.

METHODS: The participants were 10 (25.9 ± 3.3 years; 178.3 ± 6.1 cm; 83.3 ± 20.3 kg) physically active men. They performed maximum intensity training (six times 30 Wingate test intervals for 4 minutes) on a cycling ergometer (Monark 834E, Sweden) for three consecutive weeks, three times a week. Before and after the 3-week training period, body composition by dual-energy X-ray absorptiometry (Hologic Discovery QDR Series, USA) and aerobic velocity on cycling ergometer (Lode Corival Ergometer, LODE Holding Co., Groningen, The Netherlands) were measured. Oxygen consumption was determined by the Cortex Metamax 3B (Cortex Biophysic GmbH, Leipzig, Germany). The incremental test was performed with the first load of 40 W, and each subsequent load was 1 min long and increased by 20 W.

RESULTS: As a result of the HIIT training, a significant increase in maximum oxygen consumption (3687.30 ± 221.474 to 3920.90 ± 462.752 l/min), maximum oxygen uptake threshold (286.50 ± 37.298 to 300.60 ± 37.616 ühik), respiration rate (52.83 ± 12.685 to 59.15 ± 15.841 ühik), maximum power (294.80 ± 37.941 to 312.60 ± 33.669 ühik) and load capacity (3.64 ± 0.586 to 3.85 ± 0.526 ühik). There were no statistically significant changes in the measured body composition values after training period.

CONCLUSION: Three weeks of high-intensity interval training is suitable for increasing maximal aerobic capacity, while no changes in body composition occurred in young physically active men.

THE EFFECT OF A SEGWAY RIDING PROGRAM ON SIT-TO-STAND PERFORMANCE IN WOMEN

FIAUD, V., SHIM, A.
WEST TEXAS A&M UNIVERSITY

INTRODUCTION: Personal means of transportation or electric-powered micro-Personal Mobility Vehicles (e-PMVs) have increased in popularity and revolutionized the urban transport sector (1). Research reported relatively low usage among the public, despite a high interest in trying the devices (2). The Segway minipro® is a personal transporter device that has been considered as a possible alternative mobility means for people with disabilities, although initially designed for recreational purposes (3,4). The segway is found to require a decreased level of energy expenditure as well as a reduced amount of upper body strength to move around (4). Boutilier and Sawatzky (2010) investigated the minimum mobility requirements for riders to use a powered mobility device such as the Segway; their results demonstrated no correlation between the functional assessment of the patients and their ability to complete the segway task. A reduced amount of spasticity in patients was recorded following the segway training. Anecdotal reports in balance improvements were mentioned but no data was collected to support those statements. This study investigated critical sit-to-stand variables as they relate to balance abilities in women after a 3-week training of segway minipro® riding.

METHODS: Seven Women (54.6 ± 6.7 years) from a Southwest US rural town were recruited for this study. All participants were healthy and had no injuries during the previous 6 months. All participants completed the sit-to-stand test on the Neurocom Balance Master®, following the manufacturer protocol; a 3-week program was implemented with 3 riding sessions (3x30 minutes/week) with a progression in difficulty, totaling 9 riding sessions. Two riding sessions were added after the initial testing and prior to the program implementation for familiarization and safety.

RESULTS: Paired sample t-tests of the weight transfer (WTT), the rising index (RI), and the center of gravity sway velocity (COGSV) were analyzed at the completion of the Segway Riding program. The WT data showed no significant differences ($t(6) = 2.447$, $p = 0.354$); Both RI and COGSV showed significant differences ($t(6) = 1.943$, $p = 0.021$; $t(6) = 1.943$, $p = 0.032$).

CONCLUSION: Although the sample is small, there seems to be a significant improvement in energy efficiency in the sit-to-stand while the overall weight transfer is not affected. As the COGSV values significantly decreased at the end of the program, better control of the body movement could be suggested. This could suggest that the 3-week segway riding program may have contributed to enhanced balance and control during the sit-to-stand for women.

SPATIAL ACCESSIBILITY AND COMPENSATORY ROLES OF GREEN SPACES FOR ELDERLY INDIVIDUALS WITH HIGH DEPENDENCY IN URBAN AREAS: A CASE STUDY OF HARBINS CENTRAL URBAN AREA

LI, X., ZHANG, B., HAO, L., HOU, Y.
NORTHEAST FORESTRY UNIVERSITY

INTRODUCTION: In aging cities with high population density, elderly individuals aged 65 and above, living alone and relying on walking for mobility, typically engage in low-intensity physical activities and depend on the built environment.

They often rely on park green spaces within walking distance for social interaction and recreation. Regular engagement in such activities-particularly walking in green spaces-is linked to improved cardiovascular health and mental well-being, yet limited park accessibility may constrain these behaviors and exacerbate sedentary health risks. This study examines the spatial accessibility of parks and the potential role of alternative green spaces, such as community parks, for elderly individuals. The findings highlight the importance of ensuring equitable access to green spaces for vulnerable elderly populations in urban areas, which can inform future urban planning to better meet health-related needs of this group.

METHODS: Through semi-structured interviews and behavioral analysis, this study selected a group of 215 elderly individuals with low activity levels living alone, examining their walking time thresholds and park usage patterns. Using QGIS integrated with Baidu API for route planning, the study calculated the actual walkable accessibility of parks. The study developed a basic function index (Fb) and a complementary function index (Fc) for park green spaces, and employed spatial clustering and regression analysis to identify low-functioning areas and the factors driving planning deficiencies.

RESULTS: The study found significant spatial variation in park accessibility for elderly individuals with high dependency and low activity levels in Harbins central urban area, particularly in areas with poor walkability. Substitute spaces such as community green spaces and squares partially compensated for the functional gap left by park green spaces, but in areas with poor walkability, the compensatory effect was limited, which increased the disparity in park green space usage.

CONCLUSION: The research highlights that elderly individuals with high dependency and low activity levels encounter green space gaps and usage disparities in their daily park activities. The absence of park green spaces and insufficient substitute spaces in peripheral areas limit the social and physical activities of this elderly group. It is recommended that urban park planning prioritize vulnerable groups, enhance the functional value (Fb) of parks in peripheral areas, and improve the compensatory role (Fc) of alternative green spaces by coordinating the layout of parks, squares, and community green spaces to better meet the elderlys basic needs for green space.

EFFECTS OF NINE - SQUARE STEP DANCE EXERCISE WITH A STICK ON CARDIORESPIRATORY ENDURANCE AND MUSCLE STRENGTH OF THE ELDERLY.

NEELAPAIJIT, N., NHUSAWI, K., KAESMAN, I., CHANTASORN, N.
SILAPAKORN UNIVERSITY

INTRODUCTION: Nine - Square Step Dance Exercise with a Stick. It is an exercise with movement patterns that are suitable for the elderly. Because it is a simple movement but continuously moving. This makes it possible to develop the physical fitness of the elderly, especially. Cardiorespiratory Endurance and Muscle Strength of the Elderly.

METHODS: The purpose of this research was to study and compare the effects of nine - square step dance exercise with a stick on cardiorespiratory endurance and muscle strength of the elderly. The sample group was selected by employing simple random sampling method. This group consisted of 20 female elderly people, from the ages of 60 to 65, in Nakhon Pathom Province. After the 6-week training, the results of all aspects were compared with ones before the training. Three instruments were utilized in this study: 1) the program of Nine - Square Step Dance Exercise with a Stick 2), the cardiorespiratory endurance tests. and 3) the muscle strength test. The training spent three days per week, and 60 minutes per day. The results were analyzed by using t-test dependent statistics.

RESULTS: The research results revealed as follows; the results of the cardiorespiratory endurance tests, before and after six weeks of training, were equal to Mean=82.87, SD=10.50 and Mean=88.00, SD=6.96 respectively. Besides, the results muscle strength test were equal to Mean=18.37, SD=2.44 and Mean=19.87, SD=2.35 respectively.

From the results of the study, before and after six weeks of training, it was found that the Cardiorespiratory Endurance and the muscle strength, of the elderly were significantly different at the 0.5 level.

CONCLUSION: From the research, it can be concluded that the Cardiorespiratory Endurance and muscle strength of the elderly can be improved because of Effects of Nine - Square Step Dance Exercise with a Stick

GROWTH COMPARISON OF HEIGHT, WEIGHT, AND TOE GRIP STRENGTH IN NEPALESE CHILDREN

UEDA, K., KOKUDO, S.2, DEVKOTA, B.3, YEDU, R.3, PRAKASH, S.3, NAKANO, T.4, SAGAWA, T.5, KOISO, T.4
1> KIO UNIVERSITY 2> CHUKYO UNIVERSITY 3> TRIBHUVAN UNIVERSITY 4> KANAZAWA UNIVERSITY

INTRODUCTION: The foot development of children is influenced by various factors, including heredity and environment. It is assumed that Nepal's geographical conditions, such as hilly and mountainous environments, may affect growth patterns. This study aimed to investigate the growth characteristics of toe grip strength in children from both hilly and lowland areas of Nepal.

METHODS: The samples were 1,193 healthy children (628 boys and 565 girls) aged 10-16 years, school in/around Pokhara Valley and Lumbini lowlands, Nepal. Toe grip strength was measured using a T.K.K.3362 toe- grip dynamometer (Takei Scientific Instruments, Niigata, Japan) . Toe grip strength was measured twice, and the maximum strength from the two measurements was recorded. Their height and weight were also measured. Descriptive statistics of toe grip strength, height and weight were calculated by age, sex, and differences between age groups and sexes were analyzed.

RESULTS: The mean height of Nepalese children aged 10–16 years ranged from 134.7–167.0 cm for boys and 138.9–154.1 cm for girls. Girls were taller until age 12, after which their growth slowed, while boys exhibited rapid growth after age 12. A significant difference in height was observed after the age of 14 ($p < 0.05$). The mean weight ranged from 31.8–57.9 kg

for boys and 32.3–49.2 kg for girls. The growth rates of both sexes were similar until age 12, after which boys showed a rapid increase, whereas girls' weight gain slowed after age 13. Significant weight differences were found only at age 16 ($p < 0.05$). The mean toe grip strength ranged from 12.2–27.6 kg for boys and 10.8–19.2 kg for girls. Toe grip strength tended to increase from ages 10–13, then leveled off and slowed after age 13 in girls. In contrast, boys continued to show a significant increase until age 16. Regarding transportation to school, walking was the primary mode for 35.5% of children in Pokhara and 66.7% in Lumbini, with children in Lumbini walking more frequently.

CONCLUSION: Nepalese girls were taller than boys until age 12, after which boys exhibited rapid growth. Weight gain showed a similar pattern, with boys surpassing girls in weight after age 13. Toe grip strength followed a comparable trend, with growth slowing in girls after age 13, whereas boys continued to develop strength until age 16. Additionally, Nepalese children demonstrated higher toe grip strength than Japanese children, likely due to differences in daily physical activity and environmental factors. Further research is needed to explore these differences in detail.

GET STRONG TO FIGHT CHILDHOOD CANCER: DEVELOPMENT AND IMPLEMENTATION OF THE “FORTEE GET STRONG” APP AS A DIGITAL APPROACH TO PROMOTE EXERCISE IN CHILDHOOD CANCER PATIENTS

PELI, L., NEU, M.A., DREISMICKENBECKER, E., WYPYRSCZYK, L., KÜHN, M., LANFRANCONI, F., WRIGHT, P., MARRIOTT, H., WISKEMANN, J., BAUER, N., KARGUTH, N., HEIßERER, B., PAUL, N.W., MONGONDY, R., BLOCH, W., RIZVI, K., FRIDH, M.K., LUCIA, A., FIUZA, C., GÖTTE, M., GAUß, G., SPREAFICO, F., KONDA, B., STEFANOVIC, M., POLAK, M., POMASANSKI, A., FABER, J.

FONDAZIONE MONZA BRIANZA PER IL BAMBINO E LA SUA MAMMA

INTRODUCTION: Digital tools and new technologies can support and maintain physical activity behaviour. Childhood cancer patients suffer from physical inactivity, cancer-related fatigue, and reduced health-related quality of life. The Europe-wide, multi-centre FORTEe trial (funded by the EU) aims to mitigate these issues in childhood cancer patients by implementing exercise therapy and increasing physical activity using digital approaches.

METHODS: As part of the trial, the “FORTEe Get Strong” app was developed to engage childhood cancer patients in exercise training and healthy behaviours. Developed in close collaboration between scientific and clinical partners, a software engineering company and patient representatives, the “FORTEe Get Strong” app was implemented for the use on Android and iOS devices in seven languages (Danish, English, French, German, Italian, Slovenian, Spanish). The mobile app uses gamification to create a child-friendly environment for health education. Young patients can navigate a personalised avatar through a virtual village containing interactive elements: i) mini-games, including the FORTEe-Quiz, provide health-related knowledge in a fun way; ii) instructional exercise videos focus on motor skills such as endurance, strength, flexibility, coordination and gait. By offering varying levels of difficulty, the app provides a safe and personalised exercise opportunity.

RESULTS: The “FORTEe Get Strong” app was developed in the context of the wider multicentre FORTEe trial and implemented at 10 European trial sites. The patient app is an innovative approach to promote healthy behaviours and physical activity in childhood cancer patients. The integration of gamification and tailored exercises increases engagement and knowledge retention. As the FORTEe multicentre trial progresses, further evaluation will assess the long-term impact of the app on the physical and psychosocial well-being of young patients. **CONCLUSION:** The “FORTEe Get Strong” app is a promising tool in paediatric exercise oncology, offering a creative and adaptable means of supporting children with cancer on their journey to improved health and fitness.

EXERCISE TRAINING AND CARDIOVASCULAR HEALTH: A PRELIMINARY REPORT OF THE MICROFIT STUDY

BRAGONZONI, L., PINELLI, E.1, SCOPPOLINI, M.1, ZINNO, R.1, SENESI, G.1, AGNOLETTI, D.2,3, LANCI, R.2, SPOSETTI, L.4, GRASSI, C.2, BALLETTA, M.2, NARDI, D.2, GRASSO, F.2, BALDINI, C.2, ABETE, S.2, BALBINOT, A.2, PIANI, F.2, VENTURA, F.3, MAURO, M.1, BORGHI, C.2,3, TOSELLI, S.1, MAIETTA LATESSA, P.1

UNIVERSITY OF BOLOGNA

INTRODUCTION: Arterial hypertension and central hemodynamics alterations are major cardiovascular risk factors, and are influenced by exercise training. The gut microbiota has been shown to regulate pathways associated with both arterial stiffness and exercise training. However, literature lacks information on the relationship between exercise training, gut microbiota, and arterial stiffness. We aim to test the exercise effect on arterial stiffness in comparison to the assumption of probiotics.

METHODS: This randomized partially double-blinded controlled trial (NCT05967715) aims to enroll 75 controlled and stable hypertensive patients (aged from 40 to 65ys, in primary cardiovascular prevention, without diabetes and inflammatory disorders), randomized into 3-month intervention arms: exercise training; probiotics; placebo. Exercise group performs high intensity interval training 1 hour thrice a week; probiotic group receives multi-strain probiotics for three months. Probiotic and placebo groups are double blinded. Clinical, familial and drug history are obtained. Before and after the intervention, cardiovascular assessment is performed measuring pulse wave velocity (PWV) and central blood pressure (CBP) by applanation tonometry.

RESULTS: This preliminary report is based on 38 patients (mean age 54 ± 6 ys, M/F 24/17) who first completed the 3-month intervention. Analysis were blinded to the intervention group. We observed substantial homogeneity of the baseline characteristics among the 3 groups. After the intervention, both PWV (mean $\pm$ sd 0.1 ± 0.7 ; -0.2 ± 0.63 ; 0.5 ± 0.87 m/s, $p=0.15$) and

CBP (pulse pressure -1.9 ± 9.8 ; -1.4 ± 4.9 ; -0.5 ± 6.9 mmHg, $p=0.9$) differences tended to be slightly different among the groups, but without statistical significance.

CONCLUSION: Preliminary blinded results demonstrate correct randomization with no significant hemodynamic modification after the intervention.

EFFECTS OF RESISTANCE EXERCISE ACCOMPANIED BY MUSIC ON ELDERLY PEOPLE.

NISHIZAWA, T.

SHIGAKKAN UNIVERSITY

INTRODUCTION: Resistance exercise often involves repetitive monotonous movements, making it difficult to maintain motivation. Therefore, we focused on exercising to music. The purpose of the study is to investigate the influence of exercise accompanied by music.

METHODS: The subjects were 25 men and women aged 64 to 82 years. They performed six types of resistance exercise (REx) to music for approximately 12 minutes. The exercises were marching, knee lifts, front lunges, skate lunges, back lunges, and skipping. The Exercises were performed to tempo-pitch sounds (TREx) and music (MREx) ranging from 90 to 100 BPM. The influence of music on exercise was investigated by measuring heart rate (HR) and asking questions about "fun" and "hardness". HR during exercise was measured using a Polar H10 heart rate sensor and the Polar Team app (Polar). Psychological factors survey: After exercise, subjects rated their perceived exertion (RPE). And more subjects rated the enjoyment of the exercise on a four-point scale. Lower limb muscle strength was measured isometric knee extension strength. Measurements were performed using a lower limb muscle strength measurement device (Takeikiki Co., Ltd.).

RESULTS: HRmax was $60 \pm 8.9\%$ in TREx and $69 \pm 16.4\%$ in MREx. Although MREx tended to be higher, no significant difference was observed. The percentage of people who found the exercise "fun" was $94.4 \pm 27.2\%$ in MREx and $66.5 \pm 11.9\%$ in TREx, which was $27.9 \pm 15.3\%$ higher in MREx. The subjects of people who found the exercise "hard" was $34.0 \pm 1.6\%$ higher in TREx than in MREx. Although the exercise intensity is moderate, psychological factors indicate that the subjects is in a "fun" and "light" state. The correlation between average HR and "fun" was somewhat strong for both TREx ($R^2=0.54$) and MREx ($R^2=0.59$). The correlation between HRmax and "fun" was somewhat strong for both TREx ($R^2=0.79$) and MREx ($R^2=0.69$). This suggests that participants still felt "fun" even at high intensity. The correlation between "hard" expressed by RPE and average heart rate was somewhat strong for TREx ($R^2=0.58$) and somewhat weaker for MREx ($R^2=0.42$). We found that exercising with music does not make you feel "hard" even when your HR was high. The correlation between HRmax and "hard" was quite strong, with for TREx ($R^2=0.64$) and for MREx ($R^2=0.69$). This shows that there is a somewhat strong correlation between TREx and MREx, and that even when MREx was at a high intensity it was not felt to be "hard", yet it was still enjoyed. Comparing the psychological state from this questionnaire, it was found that the correlation between "fan" and "hard" was somewhat strong for both with for TREx ($R^2=0.68$) and for MREx ($R^2=0.69$). Lower limb strength was 44.7 ± 20.7 kg on the first time and 46.3 ± 20.5 kg on the final. Although there was an increasing trend, there was no significant difference.

CONCLUSION: Resistance exercise set to music can be performed in a "fun" and "light" state, while still providing an exercise intensity that improves cardiopulmonary function.

EFFECTS OF KICKBOXING TRAINING ON FALL-RISK FACTORS AMONG COMMUNITY-DWELLING MIDDLE-AGED AND OLDER ADULTS

CHEN, L., HSU, C., CHEN, J.

NATIONAL TAIWAN SPORT UNIVERSITY

INTRODUCTION: Falls risk may increase with age. Falls could not only lead to severe medical costs in older adults but also impact their ability to perform activities of daily living due to fall-related disabilities. Kickboxing exercise is a combat sport that involves dynamic, intermittent striking that requires complex skills and is conducted typically for young adults. This study aimed to assess the effect of a 12-week group kickboxing training (KBT) program modified for middle-aged and older adults on fall-related parameters.

METHODS: Sixty-seven middle-aged and older adults aged between 50 and 85 were recruited from Taoyuan, Taiwan. The experimental group (EG, $N=40$) implemented a 90-minute KBT once a week for 12 weeks and four health education sessions, while the control group (CG, $N=27$) received only health education sessions. Subjects in both groups were tested pre-and-post intervention on the following fall-related indicators: lower-limb muscle strength using the MicroFET2 handheld dynamometer, 6-m walking speed, 8-ft up-and-go, functional reach, and 30-sec sit-to-stand. Descriptive statistics, independent t-tests, paired t-tests, and effect size (ES) analyses were conducted. The significance level was set at $p < .05$.

RESULTS: The EG improved more than CG in walking speed, 8-ft up-and-go, and 30-sec sit-to-stand (all $p < .001$) change in pre-and-post differences. In comparison with CG, the EG had a large ES in usual-pace gait speed ($ES=1.14$), small ES in maximal gait speed ($ES=0.42$), medium ES in 8-ft up and go ($ES=0.76$), large ES in 30-sec sit-to-stand ($ES=1.56$) and medium ES in knee flexion ($ES=0.52$) respectively.

CONCLUSION: With some safety concern modification, the once-a-week 12-week modified KBT may benefit community-dwelling middle-aged and older adults in improving fall-related factors such as walking ability, dynamic balance, and enhanced lower-limb muscular strength and thereby, it may contribute to fall prevention for middle-aged and older adults in the community.

DIFFERENCES IN 3D SPINE MORPHOLOGY ACCORDING TO THE LEVEL OF PHYSICAL ACTIVITY PRACTICE IN ELDERLY WOMEN

BRUSA, J., MESSINA, G., MINGRINO, O., BOATTA, A., BATTAGLIA, G., BARBAGALLO, M., DOMINGUEZ, L.J., CANZONE, A., GIUSTINO, V., BIANCO, A., PADUA, E.

SAN RAFFAELE UNIVERSITY

INTRODUCTION: The physiological decline that occurs with advancing age also includes the aging of the spine which is characterized by the development of degenerative changes. The benefits of physical activity (PA) on the musculoskeletal health of the back are well known. It appears that the compressive strength of the spine tends to increase with the level of PA practiced and that PA strengthens both the vertebrae and the discs. The aim of this study was to assess the spine morphology, through a 3D scanning method, in a sample of elderly women and compare it according to the level of PA practiced.

METHODS: Forty-two elderly women were recruited. Firstly, each participant was administered the IPAQ-SF that allowed to measure the level of PA. As suggested by the IPAQ recommendations for scoring protocol, participants were divided into the 3 following groups: low active (LA; n=14); moderate active (MA; n=14); high active (HA; n=14). Hence, to evaluate the morphology of the spine a non-invasive, three-dimensional optoelectronic detection system using the Light Detection and Ranging (LIDAR) technology (Spine 3D; Sensor Medica) was used. In particular, each participant, barefoot and in orthostatic position with their head in a neutral position and with their feet placed side-by-side, was placed 1 meter from the instrument and with their back, bare-chested, facing the camera of the device. The 3D spine screening was made up by infrared cameras using Time-of-Flight (ToF) depth technology able to identify landmarks (i.e., prominent vertebra (VP), right and left shoulder (SR and SL), right and left lumbar dimple (DR and DL). Based on these landmarks, the software calculates different parameters on the sagittal, frontal, and horizontal planes.

RESULTS: Among the 3 groups no differences were found in spine morphology on the frontal and horizontal planes. On the sagittal plane, we detected a significant difference in the trunk inclination parameter (i.e., the angle formed between the straight line passing through VP and DM and the vertical plane along the sagittal section) ($F(2,39)=4.25$; $p=0.02$) with the highest trunk inclination for the LA group. Moreover, on the sagittal plane, we found a significant difference in the sagittal imbalance parameter (i.e., the horizontal distance between VP and the vertical passing through DM) ($F(2,39)=4.10$; $p=0.02$) with the highest sagittal imbalance for the LA group.

CONCLUSION: These results suggest that higher levels of PA practice can not only improve musculoskeletal health but can positively affect the structure of the spine. This could prevent the aging of the spine and possible back pain.

SOCIODEMOGRAPHIC CORRELATES OF SITTING TIME AMONG COMMUNITY-DWELLING OLDER PERSONS IN THE CITY OF ZAGREB

RAKOVAC, M., KNEZEVIC KRAJINA, H.1,2, SENTIJA, D.1

1-UNIVERSITY OF ZAGREB FACULTY OF KINESIOLOGY, ZAGREB, CROATIA; 2-HEALTH CENTER ZAGREB – CENTAR, ZAGREB, CROATIA

INTRODUCTION: Older age is generally associated with lower levels of physical activity (PA) and deterioration of health (Cunningham et al., 2020). Understanding the correlates of PA and sedentary behavior in older persons is imperative for designing tailored health promotion interventions. There is a lack of data on the correlates of sitting time in older persons in Croatia. Therefore, the aim of this preliminary study was to investigate the correlation between sociodemographic characteristics and sitting time among community-dwelling older persons in the city of Zagreb.

METHODS: The study was conducted as part of the Fit-Old project, funded by the European Union [Grant Agreement No 622623-EPP-1-2020-1-DESPO-SCP]. The participants were older persons living in the broader area of the city of Zagreb, Croatia (n=209; 180F/29M; age (mean $\pm$ SD) 73.1 $\pm$ 5.4 y). A questionnaire was used to collect data on the participants sociodemographic characteristics (age, gender, education level, number of household members, marital status, family income, type of housing). The Croatian long version of IPAQ was used to assess the sitting time (Pedicic et al., 2011). A Spearman's rank-order correlation was used to assess the relationship between the sociodemographic data and sitting time.

RESULTS: Self-reported total weekly sitting time (1610 $\pm$ 679 min/week) was significantly positively correlated with age ($r_s=.146$, $p<.05$) and with living in the city area with predominant apartment buildings or blocks of flats ($r_s=.175$, $p<.05$). Living in the area with predominant detached houses was significantly negatively correlated with total weekly sitting time ($r_s=-.285$, $p<.05$). There was no significant correlation of sitting time and education level, number of household members, marital status or family income.

CONCLUSION: In the sample of community-dwelling older persons in Zagreb, the sitting time increased with age. No sociodemographic characteristics investigated in the study were related to sedentarism, except for the predominant type of housing in the immediate neighborhood. Namely, living in the areas with predominant detached houses was related to decreased sitting time, while apartment living in urban areas was related to increased sedentarism. The findings might be associated with more opportunities for PA in the household domain when living in detached family houses, and with the broader influence of built environment in densely populated urban areas on everyday PA in older persons.

ASSOCIATION BETWEEN PHYSICAL ACTIVITY, QUALITY OF LIFE AND FERTILITY PROBLEM STRESS AMONG WOMEN UNDERGOING IN VITRO FERTILIZATION BASED ON FAIR-HU STUDY

PREMUSZ, V., SZMATONA, G., SKRIBA, E., TÁNDOR, Z., MAKAI, A., KOVÁCS, R., ÁCS, P., KOVÁCS, K., VÁRNAGY, Á.
UNIVERSITY OF PÉCS, VAT: HU 17783941

INTRODUCTION: In vitro fertilization (IVF) is a physically and emotionally demanding process that can significantly impact women's psychological well-being and overall quality of life (QoL). Given the high levels of stress associated with fertility treatments, identifying modifiable factors that could improve mental health and QoL is of paramount importance. Physical activity (PA) has been recognized as a beneficial intervention for mental health and stress reduction; however, its indirect effects on QoL via psychological well-being remain underexplored in this population. The present study aims to investigate the association between perceived stress, PA and QoL in women undergoing IVF.

METHODS: A multicentric clinical study NCT06795568 was conducted among women undergoing IVF treatment (N=348), assessing their physical activity levels, fertility problem stress (FPS), and QoL using validated self-report questionnaires. Physical activity was measured using the Global Physical Activity Questionnaire (GPAQ), perceived stress was assessed via the original version of COMPI Fertility Problem Stress Scales (COMPI FPSS), and QoL was evaluated using the WHO Quality of Life-BREF (WHOQOL-BREF) questionnaire. Association between PA, FPS and QoL was measured with Spearman rank correlation test. Statistical analyses were conducted using IBM SPSS 28.0 for Mac, with significance set at $p < 0.05$.

RESULTS: The mean age of participants was 34.68 ± 5.02 SD years, and 60.1% reported no engagement in moderate-to-vigorous recreational PA, participants had 90.0 (0.0, 270.0) METmin/week recreational (R) MVPA. QoL ranged between 67.85 ± 16.45 and 79.36 ± 12.75 . Stress levels showed similar results to previous Hungarian research (personal stress 10.65 ± 3.59 , marital stress 6.30 ± 2.54 , social stress 5.98 ± 2.65). Findings indicated a significant positive association between R-MVPA and QoL ($r=0.145-191$, $p < 0.01$). Additionally, higher FPS levels were linked to lower QoL by each subscales ($r=-0.220-519$, $p < 0.001$), while the stress relieving effect of R-MVPA was proved in case of personal stress subscale of the COMPI FPSS ($r=-0.144$, $p = 0.007$).

CONCLUSION: Our findings underscore the importance of PA as a potential intervention to improve quality of life and reduce stress in women undergoing IVF treatments. The observed effect on QoL highlights the need for integrated lifestyle interventions that include both PA promotion and stress reduction support programs during fertility treatments. Future research should explore longitudinal effects and potential clinical applications of PA-based interventions to optimize reproductive and psychological outcomes in IVF patients. This research was funded by the EKÖP-24-4-II-PTE-345, NKFI FK-147404, TKP2021-EGA-10 of the Ministry of Culture and Innovation, the National Research, Development, and Innovation Fund, and the RRF-2.3.1-21-2022-00012 project, titled National Laboratory on Human Reproduction.

INVESTIGATING THE IMPACT OF AN ACUTE BOUT OF HIGH-INTENSITY INTERVAL TRAINING (HIIT) AS A STRATEGY TO ENHANCE THE EFFECTIVENESS OF IMMUNE CELL-BASED THERAPY FOR ACUTE MYELOID LEUKEMIA

LEE, H., LOW, J.L., EDGETT, B., CULOS-REED, N., LEE, J.
UNIVERSITY OF CALGARY

INTRODUCTION: Double-negative T cell (DNT) therapy is an innovative immune cell-based cancer therapy for those living with acute myeloid leukemia (AML), involving the infusion of healthy donor-derived immune cells (i.e., DNTs) into patients. A single bout of high-intensity exercise profoundly increases the number of circulating immune cells, such as NK cells, with a preferential mobilization of effector cells that have greater anti-cancer cytotoxicity. Exercising healthy donors prior to DNT collection may be a clinically applicable strategy to enhance the effectiveness of DNT therapy for AML. However, a caveat to the enhanced killing of effector T cells is that they are short-lived compared to long-lasting early memory cells, which have been associated with more durable and superior treatment outcomes in patients treated with immune cell-based therapies. The purpose of this study is to explore the impact of exercise on the effectiveness of DNT therapy for AML, including both its initial potency and durability of treatment effects.

METHODS: We isolated DNTs from peripheral blood of young healthy participants at rest and immediately after an acute bout of HIIT. In this study, data from an initial N=1 are presented, with ongoing data collection to complete the sample (N=8) by the conference presentation. High-intensity interval cycling was conducted, comprising 5 rounds of 90-second work and rest intervals at 1:1 ratio. Average heart rate (HR) during the work interval was 90% HRmax, and average HR for the entire session was 78% HRmax. DNT memory phenotype was examined using a 10-colour panel on a Spectral Cell Analyzer. After 10-day DNT expansion, acute and chronic anti-cancer function was compared between DNTs collected at rest (DNTrest) and immediately after a single bout of high-intensity exercise (DNTex) using a 2-hour cytotoxicity assay and repeated stimulation assay, respectively, against human AML cell lines in vitro.

RESULTS: Preliminary results showed that DNTex had a greater proportion of late memory phenotypes (45.9%) than DNTrest (21.5%) on day 0. After 10-day expansion, the difference in memory composition became more apparent, where DNTex and DNTrest showed 92.5% and 42.4% late memory phenotypes, respectively. In the 2-hour cytotoxicity assay, DNTex demonstrated superior killing of AML cells than DNTrest. In the repeated stimulation assay, DNTex progressively lost their anti-cancer function with each successive round, whereas DNTrest demonstrated persistent killing of AML cells to the end of the experiment.

CONCLUSION: A single bout of high-intensity exercise preferentially mobilizes late memory DNTs, which become the dominant population after 10-day expansion. Despite superior immediate killing of AML cells, late memory DNTs do not persist to provide a durable anti-cancer effect in vitro. These findings suggest that exercising healthy donors prior to DNT donation may enhance the acute potency of DNT therapy but impact the durability of its effects.

FATIGABILITY ASSESSMENT IN CHRONICALLY FATIGUED PATIENTS: INSIGHTS FROM ISOMETRIC VS CYCLING-BASED FATIGUE TESTS

BERTRAND, M., ROZAND, V., LAPOLE, T., FEASSON, L., HUPIN, D., MILLET, G.Y.

UNIVERSITÉ JEAN MONNET, SAINT-ETIENNE

INTRODUCTION: Chronic fatigue (CF) is defined as pathological fatigue lasting over 6 months, unrelieved by rest and impairing daily activities. CF accounts for 5–10% of primary care consultations and can result from an underlying pathology or be idiopathic. CF is commonly diagnosed using questionnaires such as the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F, cut-off ≤ 34). Better understanding fatigue mechanisms is crucial for its management (1). This study aimed to determine whether a deteriorated resistance to fatigability, defined as an exercise induced reduction of strength, is related to FACIT-F scores in CF patients and whether the type of fatiguing test, i.e. isometric (ISO) vs cycling-based (BIKE, i.e. more ecological mode) provide similar outcomes.

METHODS: Thirty-two CF patients (19 females, age: 47.2 ± 12.8 yrs, FACIT-F: 20.7 ± 6.9) performed in separated days an ISO and a BIKE tests consisting of incremental stages of either 10 contractions (5-s on/5-s off; ISO) or 3-min cycling at preferred cadence (BIKE) until exhaustion. Increments were scaled relative to the participants' body weight. Neuromuscular function was assessed at baseline, after the first two stages and at exhaustion. Maximal voluntary contraction (MVC), amplitude of the resting twitch (Tw), voluntary activation (VA) using the interpolated twitch technique with percutaneous electrical nerve stimulation, and electromyographic activity (M-wave, RMS during MVC) were evaluated on the knee extensors.

RESULTS: Simple linear regressions revealed no significant associations between FACIT-F scores and any parameters of fatigability. Exercise performance (number of stages) in each test was determined by distinct neuromuscular parameters. In ISO, performance was significantly associated with MVC, Tw, and M-wave at baseline. In BIKE, performance was determined by MVC, Tw and M-wave at baseline and their declines after stage 1 (MVC and M-wave) and stage 2 (MVC and Tw). VA after stage 1 was also associated with BIKE performance.

CONCLUSION: Contrary to previous results from our group in studies involving both fatigued and non-fatigued patients (e.g. 2), FACIT-F scores in CF patients were not directly related to fatigability, neither in isometric, nor in dynamic modes, indicating a multidimensional nature of CF. In CF patients, BIKE and ISO performance were related to neuromuscular function at rest, underlying the need to preserve maximal strength for a better functional status. Yet, performance was related to fatigability in BIKE only, which suggests that in this ecological mode, neuromuscular measures at submaximal intensities could be prioritized over testing until exhaustion in these patients. This may be useful when post-exertional malaise is an issue.

IMPACT OF COVID-19 PANDEMIC ON MOTOR COORDINATION IN A SAMPLE OF ITALIAN SCHOOL-AGED CHILDREN BETWEEN 8 AND 10 YEARS OLD

BIINO, V., GIUSTINO, V., SCARDINA, G., COTTONE, R., SCHENA, F., BELLAFFIORE, M.

UNIVERSITY OF VERONA

INTRODUCTION: Motor coordination (MC) during childhood is of fundamental importance for the execution of daily motor skills and for success in sports activities (1). However, the past Covid-19 pandemic, due to the various restrictions that followed, have severely limited the practice of organized and non-organized physical activities. Consequently, previous studies have demonstrated a decrease in the level of physical activity practice in different populations around the world, with a negative impact on physical fitness (2). The aim of this study was to compare the level of motor coordination before and after Covid-19 pandemic in a sample of Italian school-aged children.

METHODS: A total of 280 children of primary school was included for this study. In detail, $n=141$ and $n=139$ children, aged between 8 and 10 years old, were recruited before (T0) and after (T1) Covid-19 pandemic, respectively. MC was assessed using the Körperkoordinations test für Kinder (KTK) which includes 4 subtests: 1)walking backward on a balance beam of decreasing widths; 2)two-legged jumping sideways from side to side over a beam for 15 seconds; 3)one-legged hopping for height over a foam obstacle of increasing height; 4)moving sideways on the floor in 20 seconds. In the KTK, MC is expressed using the motor quotient (MQ), calculated by adding the score of the 4 subtests and norm-referenced for age and gender. Moreover, the Physical Activity Questionnaire for Children (PAQ-C) was administered in both groups to measure the general level of physical activity practice over the last seven days.

RESULTS: We detected a significant decrease in the MQ ($p<0.001$) in the children measured before (T0) and after (T1) Covid-19 pandemic. As for the subtests' scores, results showed a significant decrease from T0 to T1 in the two-legged jumping sideways ($p<0.001$), one-legged hopping for height ($p<0.001$), and moving sideways ($p<0.001$). No significant differences

were found in the subtest of walking backward on a balance beam. As for the PAQ-C, children recruited showed similar scores both at T0 and at T1.

CONCLUSION: These results suggest that Covid-19 pandemic and the related restrictions negatively impacted the level of MC in Italian school-aged children. These results could be compared with other populations worldwide, and they could be useful to develop preventive strategies to maintain an appropriate level of MC in children during restrictive or limiting conditions. Further studies should be conducted to evaluate the long-term consequences of Covid-19 pandemic.

THE ROLE OF GENDER IN THE INFLUENCE OF PHYSICAL ACTIVITY ON PROBLEMATIC USE OF THE INTERNET AND DIGITAL DEVICES

COLLADO MATEO, D., FERNÁNDEZ-SÁNCHEZ, J., TRUJILLO-COLMENA, D., LORENZO-GONZÁLEZ, M., DEL COSO, J., LAVÍN-PÉREZ, A., RODRÍGUEZ-CASTAÑO, A.

REY JUAN CARLOS UNIVERSITY

INTRODUCTION: The use of the internet and digital devices offers significant public health benefits by enhancing access to reliable medical information, supporting health resources, and promoting health education, thereby empowering individuals to make informed health decisions. However, excessive or maladaptive use of the internet and digital devices can become problematic, posing a significant health challenge that could potentially reach pandemic levels. Physical activity may be a key strategy in interventions aimed at reducing both the prevalence and associated consequences of this issue in both men and women. However, the relationship between physical activity levels and problematic use of the internet and digital devices remains controversial, and the role of gender is still unclear. Thus, this study aims to evaluate the association between physical activity levels and the problematic use of (a) smartphones, (b) social media, (c) online gambling, and (d) video games. Furthermore, we aimed to compare the results between men and women.

METHODS: A correlational and comparative study was conducted with a sample of 189 male and 181 female Spanish-speaking young adults aged 18-40 years. Participants completed an online anonymous survey that included the Smartphone Addiction Scale, the Social Network Addiction Scale, the Internet Gaming Disorder-20 questionnaire, and the Online Gambling Diagnostic Questionnaire. They also completed the International Physical Activity Questionnaire.

RESULTS: The results showed a significant inverse correlation between physical activity levels and smartphone addiction ($Rho = -0.272$, $p < 0.001$) and problematic social media use ($Rho = -0.228$, $p < 0.001$). However, a significant direct correlation was found between physical activity levels and online gambling disorder levels ($Rho = 0.121$, $p = 0.020$), and a direct but non-significant relationship was observed between physical activity and internet gaming disorder levels ($Rho = 0.101$, $p = 0.051$). Gender analyses revealed that men may exhibit higher levels of gaming addiction and problematic online gambling, as well as higher physical activity levels than women. Conversely, women showed higher levels of problematic smartphone and social media use and spent more time sitting than men.

CONCLUSION: Physical activity may help prevent and reduce the problematic use of smartphones and social media. However, it might be directly related to online gambling disorders and internet gaming disorders. Both physical activity and the problematic use of the internet and digital devices are largely influenced by gender, with women showing higher problematic use of smartphones and social media, and men exhibiting higher gaming and gambling addiction. Therefore, gender must always be considered in interventions aimed at preventing and reducing the negative consequences of digital addictions.

EXERCISE TRAINING ATTENUATES ADVERSE CARDIAC MORPHOFUNCTIONAL EFFECTS OF MATERNAL EXPOSURE TO AIR POLLUTION

PETRICIA NEVES, P., DUTRA, M., SILVA, B., FREITAS, S., NASCIMENTO FILHO, A., VERAS, M., IRIGOYEN, M., DE ANGELIS, K. UNIVERSIDADE NOVE DE JULHO SAO PAULO, BRAZIL; HEART INSTITUTE, SAO PAULO, BRAZIL; FEDERAL UNIVERSITY OF SAO PAULO, SAO PAULO, BRAZIL; UNIVERSITY OF SAO PAULO, SAO PAULO, BRAZIL.

INTRODUCTION: Air pollution is a major environmental risk, with MP2.5 entering the lungs and affecting the circulation. Maternal exposure during pregnancy may affect the cardiovascular health of the offspring. On the other hand, exercise training offers protective effects against pollution-induced damage in adults. This study evaluates the effects of exercise training on cardiac morphometry and function in the offspring of rats exposed to MP2.5 during pregnancy.

METHODS: Dams (Wistar rats) were exposed to MP2.5 from gestation day 5 until birth. Male offspring were divided into three groups ($n=5-7$ rats/group): C (control), E (exposed) and ET (exposed and trained). After weaning, the offspring underwent treadmill training (5x/week/8 weeks). The offspring were evaluated by echocardiography.

RESULTS: With regard to morphometric evaluations, the left ventricular diameter in diastole (C: 8.50 ± 0.76 ; E: 7.38 ± 0.66 ; ET: 7.54 ± 0.21 mm) was reduced in both exposed offspring groups (E and ET) compared to controls (C). ET rats showed increased left ventricular posterior wall thickness in diastole (C: 1.43 ± 0.10 ; E: 1.32 ± 0.12 ; ET: 1.54 ± 0.09 mm) and interventricular septal thickness in diastole (C: 1.08 ± 0.34 ; E: 1.18 ± 0.16 ; ET: 1.46 ± 0.22 mm) compared to E rats. Left ventricular mass (C: 761 ± 109 ; E: 623 ± 93 ; ET: 787 ± 97 mg) increased in the E group compared to the C and ET groups. Evaluations of diastolic function showed that the E/A ratio was increased in the E group compared to the C and ET groups (C: 1.38 ± 0.23 ; E: 1.91 ± 0.41 ; ET: 1.29 ± 0.09) and the isovolumetric relaxation time (IVRT) was decreased in the ET group compared to the C and E groups (ET: 12.13 ± 2.13 vs. C: 17.29 ± 2.73 and E: 20.91 ± 4.04 ms). Regarding systolic function, ejection fraction (C: 55.7 ± 11.4 ; E: 55.2 ± 7.6 ; ET: $67.2 \pm 3.3\%$) and fractional shortening (C: 30.7 ± 7.8 ; E: 29.9 ± 5.3 ; ET: $38.5 \pm 2.6\%$) were improved in the ET group compared to the C and E groups.

CONCLUSION: In conclusion, the results of this study demonstrate that MP2.5 exposure during pregnancy adversely affects the heart of the offspring, resulting in structural and functional cardiac changes. However, exercise training attenuated these impairments and also improved both diastolic and systolic function. These findings reinforce the role of exercise as a potential strategy to mitigate air pollution-induced cardiovascular damage, including that observed as a consequence of in utero exposure.

EFFECT OF EXERCISE TRAINING ON MUSCLE TISSUE IN OFFSPRING OF RATS EXPOSED TO AIR POLLUTION

LÉLIS DE ARAUJO, C., NEVES, P.P., DUTRA, M.R.H., FREITAS, S.C.F., NASCIMENTO-FILHO, A.V., IRIGOYEN, M.C., VERAS, M.M., DE ANGELIS, K.

UNIVERSIDADE NOVE DE JULHO

INTRODUCTION: Air pollution contributes to metabolic diseases, while exercise is a protective factor. Maternal exposure to pollutants during pregnancy may affect foetal development. Experimental models exposed to PM2.5 show reduced contractile capacity, increased inflammation, and oxidative stress in muscle tissue [1]. However, few studies assess exercise effects on offspring muscle tissue from pollution-exposed mothers. This study evaluated aerobic training (AT) effects on inflammation and oxidative stress in muscle tissue of rat offspring whose mothers were exposed to air pollution during pregnancy.

METHODS: Five Wistar females and two males were used for mating. After copulation, females were exposed to PM2.5 in a particle concentrator during pregnancy. After weaning, offspring were divided into six groups (n=6-8): Male Control (MC); Male Exposed (ME); Male Exposed Trained (MTE); Female Control (FC); Female Exposed (FE); Female Exposed Trained (FTE). MTE and FTE groups underwent AT at moderate intensity for eight weeks. Gastrocnemius muscle tissue was analyzed for inflammatory mediators (IL-6, IL-10, TNF-alpha) and oxidative stress markers (antioxidant capacity, hydrogen peroxide, NADPH oxidase, lipid, and protein oxidation).

RESULTS: Exercise capacity was not affected by in utero PM2.5 exposure, but trained groups improved their performance. No differences in IL-6 were observed. IL-10 was reduced in the FE group compared to FC and FTE (FE: 20.9 [3.62] vs. FC: 37.5 [14.9] and FTE: 25.1 [5.96] [pg/ml]). TNF-alpha increased in FE vs. FC and FTE (FE: 4.33 [2.54] vs. FC: 10.7 [6.07] and FTE: 3.65 [1.92] [pg/ml]). Non-enzymatic antioxidant capacity increased in FTE vs. FE (FE: 0.034 ± 0.039 vs. FC: 0.117 ± 0.043 and FTE: 0.086 ± 0.016 [mMFe(III)]). Hydrogen peroxide decreased in MTE vs. ME (MTE: 1.78 ± 0.50 vs. ME: 1.90 ± 0.68 [μM]) and in FTE vs. FE (FTE: 1.14 ± 0.29 vs. FE: 1.39 ± 0.67 [μM]). No significant differences were found for other variables.

CONCLUSION: In conclusion, maternal PM2.5 exposure induced early impairments in offspring muscle inflammatory and oxidative stress profiles without affecting exercise capacity. However, AT mitigated these negative effects and improved exercise capacity. These findings suggest that an active lifestyle may protect against maternal pollution-induced muscle impairments.

COMBINED IMPACT OF HEALTHY BEHAVIOURS AND RELATIVE GRIP STRENGTH ON ALL-CAUSE MORTALITY: A 16-YEAR COHORT STUDY OF EUROPEAN ADULTS

MARQUES, A., BLANCHET, C., PERALTA, M.

FACULDADE DE MOTRICIDADE HUMANA, UNIVERSIDADE DE LISBOA

INTRODUCTION: Both healthy behaviours and grip strength are individually linked to a lower risk of mortality, but their combined effect remains uncertain. This study aimed to investigate their joint association with all-cause mortality in middle-aged and older European adults.

METHODS: A 16-year prospective cohort study was conducted using data from the Survey of Health, Ageing and Retirement in Europe (SHARE), including 12,693 adults (baseline mean age, 62.9 ± 9.4; 63.3% men) from 11 European countries and Israel. Healthy behaviours (smoking, alcohol consumption, physical activity [PA], sleep) were self-reported. Grip strength was measured with a handheld dynamometer and categorized into age- and sex-specific tertiles. Cox proportional hazards models assessed the combined hazard ratio (HR) and 95% confidence interval (CI) of healthy behaviours and relative grip strength for all-cause mortality, adjusting for confounders (sex, age, education, marital status, body mass index and multimorbidity).

RESULTS: During a median follow-up of 8.7 years, 2,574 deaths were recorded. Higher grip strength was associated with a reduced risk of all-cause mortality, regardless of smoking (HR = 0.70, 95% CI = 0.54, 0.90), alcohol consumption (HR = 0.60, 95% CI = 0.46, 0.77), low PA (moderate-intensity: HR = 0.51, 95% CI = 0.36, 0.71; vigorous-intensity: HR = 0.55, 95% CI = 0.45, 0.67) and sleeping trouble (HR = 0.60, 95% CI = 0.45, 0.79). For each healthy behaviour, except not smoking, the combined protective effect on mortality was comparable to the individual effect of higher grip strength. The greatest survival benefits were observed in individuals who combined higher grip strength with healthy behaviours, with risk reductions ranging from 43% to 64%: smoking (HR = 0.36, 95% CI = 0.29, 0.45), alcohol consumption (HR = 0.56, 95% CI = 0.45, 0.70), PA (moderate-intensity: HR = 0.45, 95% CI = 0.37, 0.55; vigorous-intensity: HR = 0.45, 95% CI = 0.37, 0.55) and sleep (HR = 0.57, 95% CI = 0.46, 0.70).

CONCLUSION: Higher grip strength appears to be a protective factor against all-cause mortality, even in individuals who do not follow healthy behaviours. These findings underscore the importance of public health strategies that encourage both muscle strength and healthy lifestyle choices to enhance longevity.

CORRELATES OF PHYSICAL ACTIVITY BEHAVIOUR IN PATIENTS WITH CHRONIC BACK PAIN

COLOMBO, A., MARCORA, S.

UNIVERSITY OF BOLOGNA

INTRODUCTION: Chronic back pain is a common and disabling condition that affects 15% of the general adult population. Regular exercise is a cornerstone of treatment for this condition but many patients with chronic back pain do not achieve the recommended amount of physical activity. For this reason, it is important to understand the factors that influence physical activity behaviour in this special population. The aim of this study was to explore potential correlates of physical activity behaviour in a group of Italian chronic back pain patients. Such correlates include levels of pain, kinesiophobia and fatigue, motivation, perceived barriers and benefits of exercise, sleep and mood.

METHODS: Sixty-one adults (34 Female/27 Male, age 56 + 13 years) with chronic back pain defined as pain (at least 3 on the 0-10 pain scale) in the lumbar, thoracic and cervical regions lasting more than 3 months completed the following scales and questionnaires: Global Physical Activity Questionnaire (GPAQ), Brief Pain Inventory (BPI), Piper Fatigue Scale (PFS), Tampa Scale Kinesiophobia, Pittsburgh Sleep Quality Index (PSQI), Brunel Mood Scale (BRUMS), Version 2 of the Behavioural Regulation In Exercise Questionnaire (BREQ-2), and the Exercise Benefits/Barriers Scale (EBBS). Exploratory Spearman's rank correlation analyses were performed to discover potential correlates of physical activity. Significance was set at $P < 0.05$.

RESULTS: This group of chronic back pain patients reported normal physical activity levels (Total GPAQ 3182 + 3798 MET-min/week). Of all the potential correlates investigated, the only one that was found to significantly correlate with Total GPAQ was the Total Benefits score of the EBBS (Spearman's ρ 0.269, $p=0.036$).

CONCLUSION: The results of our study suggest that knowledge and appreciation of the benefits of exercise motivate the physical activity behaviour of patients with chronic back pain. Further studies should investigate a possible cause-and-effect relationship by investigating the effect of an educational program about the benefits of exercise on the physical activity behaviour of these patients.

IMPACT OF THE COVID-19 PANDEMIC ON PHYSICAL FITNESS IN YOUNG CHILDREN

HIRANO, T.

NAGOYA COLLEGE

INTRODUCTION: The COVID-19 pandemic, beginning in 2019, significantly restricted childrens opportunities for physical activity, leading to decreased overall activity levels and increased sedentary behavior. While numerous studies have examined the pandemics impact on physical fitness, research focusing specifically on young children remains limited. This study aimed to assess the impact of the COVID-19 pandemic on the physical fitness of young children by comparing their fitness levels before and after the pandemic.

METHODS: A longitudinal study was conducted between 2018 and 2023, involving 304 healthy Japanese children (169 boys and 135 girls) aged 4-5 years. Three physical fitness tests were administered: the 25-meter sprint (25R), standing long jump (SLJ), and tennis ball throw (ST). Pre- and post-pandemic test results were compared. Statistical analysis was performed using SPSS 24, with a significance level of $p < 0.05$.

RESULTS: Although a majority of the children attended nursery school during the pandemic, ST scores were significantly lower post-pandemic compared to pre-pandemic. This decline was most pronounced in the 5.5 and 6.0-year-old age groups, with less noticeable changes observed in 4-year-olds. No significant differences were found in 25R and SLJ performance between the pre- and post-pandemic periods. These findings suggest that reduced physical activity at nursery schools and decreased activity levels at home during the pandemic likely contributed to the decline in ST performance. The study acknowledges the potential limitations in the accuracy of physical fitness assessments in younger age groups and highlights the need for further investigation.

CONCLUSION: The COVID-19 pandemic appears to have negatively impacted the tennis ball throw performance of young children, particularly those aged 5.5 and older. These results underscore the importance of maintaining adequate physical activity levels in early childhood, even during periods of public health restrictions.

VENTILATORY CHANGES WITH THE USE OF SURGICAL MASKS AT REST AND MODERATE EXERTION. A MEANS OF PREVENTING THE TRANSMISSION OF CONTAGIOUS DISEASES IN SPORTS, REDUCING PERIODS OF ABSENCE DUE TO ILLNESS.

SANTOS, A., DA SILVA, M.G.2

UNIVERSIDADE DE COIMBRA

INTRODUCTION: The global health landscape has undergone significant changes in recent years, with the COVID-19 pandemic highlighting the importance of preventive measures to mitigate the spread of infectious diseases. In the context of sports, where physical proximity and high-intensity activity are prevalent, the use of surgical masks has emerged as a potential strategy to reduce the transmission of respiratory illnesses among athletes and the broader sports community.

While surgical masks are primarily designed to prevent the spread of infectious agents, their application in sports settings presents both challenges and benefits. This abstract

explores the role of ventilatory changes at rest, low and moderate intensity activities, examining their impact on oxygen uptake.

Methods:

A group of volunteers underwent testing using masks (n=14) which consisted of the following procedure: Each individual was subjected to three different situations sitting 5 minutes apart with and without a surgical mask, walking at 5 km/h with and without a surgical mask and running at 10 km/h, on a HP Cosmos quasar treadmill, with and without a surgical mask underneath the cortex gas analyzer mask. Ventilatory parameters ($\dot{V}O_2$, $\dot{V}CO_2$, $\dot{V}_E$) HR and O_2 saturation were collected.

RESULTS: We found that the mean values and standard deviation of $\dot{V}O_2$ (ml/kg/min) at rest were 4.21 ± 1.14 without the surgical mask and 3.13 ± 0.79 with the mask while when walking at 5km/h we obtained 14.7 ± 1.67 without the mask and 11.96 ± 2.03 with the mask. When we switched to running at 10 km/h we obtained the following values without a mask 35.03 ± 2.45 and with a mask 30.76 ± 3.91 ml/kg/min. The values found for ventilation (l/min) at rest, walking at 5km/h and running at 10km/h with and without a surgical mask were as follows: resting 7.69 ± 2.08 and 6.04 ± 1.74 , walking 22.88 ± 4.22 and 20.14 ± 4.40 and running 61.54 ± 14.42 and 53.57 ± 12.91

Discussion & CONCLUSION: We found that differences in oxygen consumption (ml/kg/min) decrease as the intensity of the task increases, this decrease goes from 25% at rest to 12% running (10km/h) which indicates that the ventilation mechanisms can overcome the difficulties caused by the use of a surgical mask. Furthermore, we can

conclude that despite the difficulties caused by the use of masks, recommendations are towards the use of surgical masks whenever there is a suspicion of illness by any of the members of sports teams to prevent the transmission of infectious diseases that lead athletes to stop for long periods of training and this causes a huge loss of physical shape. The data collected allows us to conclude that the greater the need for ventilation, the smaller the difference between the situation with and

without a mask, we saw a decrease in the difference from 21% at rest to 12% when running, which reveals the compensation of ventilation dynamics to maintain the oxygen levels necessary for the needs of the human body.

EVALUATION OF A PORTABLE BAND-PULL WALKING DEVICE BASED ON PHYSIOLOGICAL PARAMETERS

TSUCHIYA, R., NAITO, H., KITAJIMA, M., YAMAGUCHI, R., SUGIYAMA, K.

JUNTENDO UNIVERSITY

INTRODUCTION: Research on "Band-Pull Walking (BPW)" is emerging as a new walking style that utilizes wearable resistance elastic bands. BPW may lead to a higher energy expenditure than normal walking (WK). However, previous studies evaluated BPW only by pulling a rubber tube forward on a treadmill. This study aimed to investigate the effects of a wearable BPW device on physiological parameters during walking.

METHODS: Fourteen healthy adults with regular exercise habits (age: 22.3 ± 2.0 years) participated in this study. Participants wore the BPW device on their back, with an adjustable elastic-band length. The band resistance was set to 8% of the maximal voluntary contraction (MVC) of the triceps brachii during shoulder and elbow extensions. Participants performed both WK and BPW on a treadmill with a 3% gradient at speeds of 60, 80, and 100 m/min. Oxygen uptake ($\dot{V}O_2$), heart rate (HR), ventilation ($\dot{V}_E$), and ratings of perceived exertion (RPE; upper limb [UL], lower limb [LL], and cardiopulmonary [CR]) were measured. The Electromyogram (EMG) signals of the biceps brachii (BB), triceps brachii (TB), deltoid (DM), vastus lateralis (VL), and gastrocnemius lateralis (GL) were recorded and synchronized with gait events. Step counts were also recorded.

RESULTS: $\dot{V}O_2$ and HR were significantly higher in the BPW group than in the WK group at all speeds ($p < 0.05$). $\dot{V}_E$ was significantly higher in the BPW at 80 and 100 m/min ($p < 0.01$). The RPE for UL ($p < 0.01$, all speeds) and CR ($p < 0.05$, at 80 and 100 m/min) significantly increases at these speeds.

Upper limb muscle activity significantly increased in the BPW group. TB activity was 6.1–9.2 times higher ($p < 0.01$), BB was 2.1–2.4 times higher ($p < 0.05$, at 100 m/min), and DM was 1.7–2.0 times higher ($p < 0.05$, at 60 m/min). No significant differences were found in the VL, whereas the GL activity was significantly higher in BPW at 100 m/min ($p < 0.05$).

Step counts were 2.6–3.0 fewer per minute in BPW at 100 m/min ($p < 0.05$).

CONCLUSION: $\dot{V}O_2$ increased by 8–12%, and HR increased by 4–8 bpm, indicating that BPW increased energy expenditure by approximately 10%. This was primarily attributed to increased upper limb muscle activity due to band resistance. The observed increase in $\dot{V}_E$ suggests respiratory muscle recruitment, which may have further contributed to energy expenditure. The activation of the upper body likely led to this observed increase.

The reduced step count in the BPW likely resulted from increased stride length due to larger arm swings, as reflected by the higher GL activity. However, stride length differences between conditions were only approximately 1%, and VL activity was similar, indicating that gait changes likely had minimal influence on energy expenditure.

This study shows that BPW increases upper-body muscle activity due to elastic band resistance, leading to approximately 10% higher energy expenditure than WK.

UNLOCKING SUCCESS: THE HOLISTIC SUPPORT SYSTEM FOR DUAL CAREER STUDENT ATHLETES IN HONG KONG

LEUNG, E., SUM, R., CHEUNG, T., YU, K., CHIU, J.

THE CHINESE UNIVERSITY OF HONG KONG

Background: Dual career athletes pursuing higher education face significant demands in both their athletic pursuits and academic commitments. Failing to address the difficulties can lead to a decline in performance in both sports and academics.

Purpose: This study investigated the support systems for dual career student athletes pursuing higher education and identify key challenges they encounter.

Methods: The study employed a quantitative approach, utilizing an online questionnaire distributed to 140 student athletes from the Hong Kong National Squad or Junior Squad enrolled in local universities. Data on demographics, university and sports federation support measures, perceived challenges, and coping strategies were collected. The study received approval from the Survey and Behavioural Research Ethics Committee of The Chinese University of Hong Kong. The research was conducted in May 2024. Eligibility criteria for participants included: (a) full-time undergraduate students and (b) Hong Kong National Squad or Junior Squad members. The data were analyzed using descriptive statistics and independent t-test.

Results: 73 student athletes (M: 38; F: 35) participated in the study. The mean age of the participants was 21.11, with a standard deviation of 3.04. Among various learning supports provided by the university, the participants ranked flexible attendance and assignment submission arrangements (mean: 3.29, SD: 2.24), scholarships (mean: 3.77, SD: 2.38), and extension of maximum study period (mean: 4.23, SD: 2.55), as the top three most important supports. Overall, 65 participants expressed satisfaction with the learning supports provided by their universities, with a mean satisfaction rating of 4.68 out of 6 and a standard deviation of 0.65. There was no significant ($p=0.201$) difference in satisfaction levels between male and female students.

Regarding various training supports provided by sports associations, the participants ranked flexible training attendance (mean: 2.68, SD: 1.54), scholarship (mean: 2.82, SD: 1.45), and sports development advice (mean: 2.93, SD: 1.47) as the top three most important supports. Forty-one participants also expressed satisfaction with the supports provided by their sports associations, with a mean satisfaction rating of 4.48 out of 6 and a standard deviation of 0.84. There was no significant difference ($p=0.558$) in satisfaction levels between male and female students.

The major challenges reported by the student-athletes included time management (37 participants), striving to balance sports and academics (22 participants), and time conflicts between training/competitions and classes/examinations (20 participants).

Conclusion: The findings underscore the importance of adopting tailored holistic support strategies to assist student athletes in overcoming challenges and succeeding in both their athletic and academic endeavours. This lays the groundwork for enhancing support systems for this particular group.

MINDFULNESS ON THE COURT: AN 8-WEEK PROGRAM ENHANCES BASKETBALL SKILLS, STRENGTH, MOVEMENT, AND MINDFULNESS IN UNIVERSITY PLAYERS

LEI, S., XIE, B., CHOI, S.M.

UNIVERSITY OF MACAU

INTRODUCTION: Basketball is a dynamic sport that demands high levels of physical fitness, technical skill, and psychological resilience. Recent studies have suggested the benefits of mindfulness training (MT) in enhancing performance and well-being in various sports. This study investigated the effects of an eight-week MT on basketball-specific skills, muscular strength, functional movement, and mindfulness level in male university players.

METHODS: Forty male university basketball players (age 18–25 years) from two universities were recruited and assigned into an intervention group (IG, $n = 20$) or a control group (CG, $n = 20$). The IG completed an eight-week mindfulness training program (once per week, 60 minutes per session) alongside their regular basketball training; the CG continued their usual training without additional intervention. Outcome measures included: (1) Muscular Strength (1RM bench press, 1RM squat), (2) Functional Movement (Functional Movement Screen, FMS), (3) Basketball Skills (dribbling test, 1-minute shooting drill, and weekly free-throw records), and (4) Mindfulness level (Five Facet Mindfulness Questionnaire [FFMQ] and Mindful Attention Awareness Scale [MAAS]). Pre- and post-test comparisons were conducted via two-way mixed-design ANOVAs, with effect sizes (η^2) reported where relevant.

RESULTS: After eight weeks, both the IG and the CG improved in bench press ($p < 0.001$) and shooting skills ($p < 0.001$). There were no significant group-by-time interactions. But the IG showed increasing in strength ($p = 0.007$) and higher scores on the functional movement scores ($p < 0.001$) than the CG. The IG also had higher scores in overall mindfulness (FFMQ, $p < 0.001$; MAAS, $p = 0.042$) compared with control group. Among the basketball skills, dribbling showed no significant in time effect, but in interaction analysis ($p = 0.004$) indicated greater improvements in IG. Weekly free throw tracking revealed consistent improvement in the IG following mindfulness sessions.

DISCUSSION: The 8-week mindfulness training effectively improved muscular strength, functional movement, and mindfulness levels in university basketball players, with the intervention group demonstrating significantly greater gains than the

control. Findings underscore mindfulness's potential to augment precision-based tasks like free-throw performance, though integrating mindfulness with sport-specific training may optimize holistic athletic development. Future research should focus on long-term interventions and specialized mindfulness protocols.

EXPLORING THE ROLE OF SELF-DETERMINATION IN THE JOB DEMANDS-RESOURCES MODEL: A DOUBLE-EDGED SWORD FOR TABLE TENNIS COACHES

CHEN, Y., CHEN, M.Y., LIN, C.H., SHIH, Y.C.

NATIONAL TAIWAN UNIVERSITY

INTRODUCTION: Grounded in the Job Demands-Resources (JD-R) model, this study examines the mediating role of emotional exhaustion in the relationship between perceived job demands and life satisfaction among table tennis coaches. Additionally, this study investigates whether self-determination moderates the relationship between perceived job demands and emotional exhaustion. Contrary to traditional JD-R assumptions, which suggest that personal resources buffer the negative impact of job demands, this study explores whether self-determination exacerbates or mitigates the relationship between perceived job demands and emotional exhaustion. A moderated mediation analysis was conducted to explore these relationships.

METHODS: A total of 283 questionnaires were distributed to table tennis coaches using a purposive sampling method, and 247 valid responses were collected (effective response rate: 87.28%). Descriptive statistics, Pearson correlation, hierarchical regression, and PROCESS analyses were employed to test the hypotheses.

RESULTS: The findings indicate that perceived job demands negatively impact life satisfaction through the mediating effect of emotional exhaustion, supporting the JD-R model. However, the moderating effect of self-determination deviated from the expected buffering role. Instead of mitigating the relationship between perceived job demands and emotional exhaustion, higher self-determination intensified this relationship, whereas lower self-determination weakened the association. Moreover, self-determination strengthened the mediating effect of emotional exhaustion on life satisfaction rather than attenuating it, contradicting conventional expectations.

Discussion: These results suggest that self-determination may act as a double-edged sword. While generally regarded as a psychological resource, in high-stress coaching environments, it may amplify the negative effects of job demands by increasing emotional commitment and workload, ultimately leading to greater exhaustion. These findings extend the JD-R model by demonstrating that self-determination does not always serve as a buffering resource against job demands. Instead, highly self-determined coaches may perceive job demands as personal challenges, leading to greater emotional investment but also increased vulnerability to exhaustion. From a practical perspective, organizations should implement workload regulation strategies, provide psychological support such as resilience training, and encourage boundary management techniques to help coaches maintain their well-being. Future research should further investigate the conditions under which self-determination functions as a protective versus a risk factor in sports coaching.

Molecular Biology and Biochemistry

COMMON GENETIC POLYMORPHISMS IN WRESTLERS: INSIGHTS FROM MULTIETHNIC GWAS

KOZUMA, A.1, BULGAY, C.2, ZEMPO, H.3, SAITO, M.4, HOMMA, H.1, DEGUCHI, M.1, MATSUMOTO, S.1, MATSUMOTO, R.5, KASAKOLU, A.6, KAZAN, H.H.7, BIYIKLI, T.8, KONCAGULM, S.6, ERGUN, M.A.9, SEMENOVA, E.A.10, LARIN, A.K.10, KULEMIN, N.A.10, GENEROZOV, E.V.10, OKAMOTO, T.1, NAKAZATO, K.1, AHMETOV, I.I.10,11, KIKUCHI, N.1

1.NIPPON SPORT SCI. UNIV. 2.BINGOL UNIV. 3.TOKYO SEIEI COLL. 4.JUNTENDO UNIV. 5.IKUEI UNIV. 6.ANKARA UNIV. 7.UNIV. OF HEALTH SCI. 8.MARMARA UNIV. 9.GAZ UNIV. 10.FMBA OF RUSSIA 11. LIVERPOOL JOHN MOORES UNIV.

INTRODUCTION: Sports performance is influenced by both environmental and genetic factors. Previous studies have reported that several gene polymorphisms are associated with sports performance (Semenova et al., 2023). However, genetic factors vary widely across ethnic groups and sports disciplines, and few consistent findings have been reported across studies. Moreover, the genetic factors specific to wrestling remain poorly understood. Therefore, the purpose of this study was to conduct a genome-wide association study (GWAS) in wrestlers from different countries (Japan, Türkiye and Russia) and to identify common gene polymorphisms across these populations.

METHODS: This study included 64 Japanese wrestlers (54 men and 10 women, international levels) and 306 Japanese control (143 men and 163 women), 68 Turkish wrestlers (International levels) and 137 Turkish controls, 130 Russian wrestlers and 173 Russian controls. Genomic DNA was extracted from saliva samples using an Oragene-DNA kit (Japan and Russian) and commercial extraction kit (Türkiye). The Japanese samples were genotyped using the Japonica Array v2, which covers more than 500,000 single nucleotide polymorphisms (SNPs). Quality control (QC) procedures and imputation were performed. Russian samples were genotyped using the HumanOmni1-Quad and HumanOmniExpress BeadChips. Turkish samples were genotyped using single nucleotide polymorphism (SNP) microarray. Quality control (QC) procedures and imputation were performed in the microarray data. Genome-wide associations were assessed using an additive genetic model with logistic regression analysis, adjusted for sex (Japan and Russian). GWAS analyses for the Turkish cohort were performed using Fisher's Exact Test in Plink 1.9. Statistical significance was set at $p < 0.05$, and common gene polymorphisms were identified.

RESULTS: The number of gene polymorphisms that reached the statistical significance was 328,388 in Japanese participants, 23,932 in Turkish participants, and 30,385 in Russian participants. Eleven gene polymorphisms were consistently associated with wrestler status across all three populations.

CONCLUSION: Common gene polymorphisms associated with wrestler status were identified across different ethnic groups. These findings suggest that certain genetic factors may contribute to wrestling performance regardless of ethnicity.

BFR CYCLING EXERCISE TRAINING FAILS TO ENHANCE POST-EXERCISE MUSCLE GLYCOGEN REPLENISHMENT BUT INFLUENCES TRANSCRIPT FACTORS OF MITOCHONDRIAL BIOGENESIS IN EXERCISED HUMANS

CHENG, I., SHIH, K.H., LIN, C.J.

NATIONAL TAICHUNG UNIVERSITY OF EDUCATION

INTRODUCTION: Exercise training with blood flow restriction (BFR training) is an alternative training mode to improve muscle strength and endurance performance under pressing exercising muscle blood flow restriction at the proximal upper or lower limb segments. This study aims to demonstrate the effect of three weeks of cycling training with BFR treatment on improving post-exercise muscle energy replenishment regarding muscle glycogen and mitochondrial biogenesis in exercised human skeletal muscle.

METHODS: Twelve physically active males with exercise habits were recruited to perform this crossover study design and randomly assigned to the BFR group (60 min 75% $\dot{V}O_{2\max}$, 60rpm/day, 3 days per week for 3 weeks, cuff with 13 cm at ~ 180 mmHg; 2 min released per 10 min cycling), while the CON trial did not wear BFR bandages and followed the same training pattern. On the morning of the experimental day following three weeks of cycling training, all subjects performed a single bout of cycling challenge with 75% $\dot{V}O_{2\max}$ for 60 minutes at 60rpm, and ingested a carbohydrate diet (2g carbohydrate/kg of body weight; 60% carbohydrate, 15% protein, 25% fat). Biopsied muscle from the vastus lateralis was obtained before a 3-week exercise training program and immediately (0h) and 3 hours after a single bout of exercise. Transcription factors that regulate gene expression involved in mitochondrial biogenesis were measured via RT-PCR and periodic acid Schiff (PAS) staining for muscle glycogen. Responses in blood glucose, plasma non-esterified fatty acids, lactate dehydrogenase (LDH), creatine kinase (CK), superoxide dismutase (SOD), malondialdehyde (MDA), IL-6, IL-10, TNF- α , and expired gas analysis for carbohydrate and fat oxidation rates were assessed in this human study.

RESULTS: Post-exercise muscle glycogen was not significantly replenished during the 3-hour recovery period, coinciding with elevated CK and LDH responses after three weeks of cycling BFR training compared to the control condition. Interestingly, BFR training improves whole-body insulin sensitivity based on the same glucose utilization under lower insulin response ($P < 0.05$). Elevated blood levels of SOD, IL-6, and IL-10, and decreased levels of TNF- α were found during the post-exercise period under BFR training compared to CONTROL training. Additionally, post-exercise PGC1- α gene expression was not significantly influenced by both BFR and CONTROL conditions ($p > 0.05$), but BFR training significantly influenced ERR α and SIRT1 genes concurrent with inconsistent trend ($P < 0.05$). BFR training upregulated TFAM gene expression, up-regulation of MFN1, and downregulation of DRP1 gene expression.

CONCLUSION: Three weeks of cycling training combined with BFR treatment did not improve post-exercise muscle glycogen replenishment despite enhancing whole-body insulin sensitivity. BFR training showed its impact on gene expression transcripts related to mitochondrial biogenesis, yet exhibited different trends in physiological signals.

DIFFERENTIAL AUTOPHAGY FLUX WITH AGE IN IMMORTALISED HUMAN PRIMARY MYOTUBES

ACHESON, J., HODSON, N.

MANCHESTER METROPOLITAN UNIVERSITY

INTRODUCTION: Autophagy is a conserved intracellular process involving degradation and recycling of dysfunctional or redundant cellular structures. Animal studies have demonstrated the importance of basal autophagy for maintaining skeletal muscle health, and as an adaptive process to accommodate acute cellular stressors such as nutrient deficiency (1). Intriguingly, basal pre-lysosomal autophagy flux (i.e., autophagosome formation) is elevated in ageing rodents, which may reflect proteostatic dysfunction and an overall reduction in muscle quality (2,3). Whether similar abnormalities are present in aged human skeletal muscle remains unclear, therefore, we investigated the effect of age on autophagic flux and associated signalling pathways in immortalised human primary myotubes.

METHODS: Immortalised human primary myoblasts isolated from 83y/o elderly (C83/KM670, OLD) and 25y/o young male (C25/KM155, YOUNG) were cultured and differentiated into myotubes. Media on both OLD and YOUNG myotubes was changed to either Earles Balanced Salt Solution (STARV), or fresh differentiation media (BASAL) for 5hrs. Cells were treated with a control solution (DMSO) or the v-ATPase inhibitor, Bafilomycin-A1 (100nM), 2hr prior to collection for measurement of pre-lysosomal autophagic flux ($n=6$ per condition and group). A subset of untreated cells was collected to determine differences in signalling outcomes ($n=2-3$ per condition and group). Immunoblots were completed and two-factor independent measures ANOVAs assessed differences between conditions, with significance threshold set at $p < 0.05$. Data is presented as Mean $\pm$ SD.

RESULTS: There were significant main effects of group and condition (both $p < 0.01$) for LC3-II flux, whereby STARV increased flux in OLD (0.239 ± 0.614 to 0.998 ± 0.477 AU) and YOUNG (1.201 ± 0.742 to 1.975 ± 0.807 AU) cells but levels of flux were lower overall in OLD. When adjusted for corresponding total protein, p-ULK1ser757 (i.e., a mTORC1-regulated site suppressing autophagy activation) and p-RPS6ser240/244 (i.e., general marker of mTORC1 activity) decreased in response to STARV in

both OLD and YOUNG cells (main effects of condition, $p < 0.001$). Notably, however, OLD cells had lower total ULK1 protein and higher p-ULK1ser757 regardless of condition (both $p < 0.01$). No effect of group or condition was observed for P62 flux ($p > 0.05$).

CONCLUSION: Overall, we have shown that both YOUNG and OLD immortalised human primary myotubes can upregulate autophagy in response to 5hrs of starvation. However, LC3-II flux were lower overall in aged muscle, which could be, in part, related to dysregulation of the mTORC1-ULK1 axis, as evidenced by an overall lack of total ULK1 protein and greater inhibitory ULK1ser757 phosphorylation. These data provide initial insight into the effect of age on human skeletal muscle autophagy in-vitro and highlights pertinent avenues of in-vivo research in this area.

UROLITHIN A INCREASE MYOGENIC MARKER MEDIATED BY MITOCHONDRIAL CHANGE DURING MATURATION IN C2C12

VARGAS-FOITZICK, R., ZBINDEN-FONCEA, H., VALERO-BRETON, M., BALBOA, E.

UNIVERSIDAD FINIS TERRAE

INTRODUCTION: C2C12 cells are commonly used to study muscle differentiation due to their ability to form mature myotubes. MyoD and myogenin are known to drive this process, leading to increased myosin heavy chain (MHC) expression associated to increase on mitochondrial mass. Mitochondria play a critical role in providing the energy required for differentiation. Additionally, the mTOR signaling pathway is crucial in protein synthesis during this process. Urolithin A (UA) has been shown to induce mitochondrial biogenesis and enhance mitochondrial function, potentially improving muscle differentiation. This offers therapeutic potential for muscle-related disorders during myogenic differentiation and maturation.

METHODS: The C2C12 cell line (ATCC) was used ($n=4$). On the 3rd day of differentiation, cells were treated with UA (2 μ M) for 72 hours, with treatments refreshed every 24 hours. On the 6th day, cells were lysed and analyzed via Western Blot (WB) for mitochondrial proteins, differentiation markers, and mTOR pathways. Mitochondrial function was assessed using Oroboros. Statistical significance was determined using the Mann-Whitney test.

RESULTS: UA treatment increased the expression of TOM20 and PGC1- α and enhanced maximal respiration. MyoD, MYH, and phosphorylated mTOR expression were also elevated with UA treatment

CONCLUSION: Chronic exposure to UA induces mitochondrial changes and increases the expression of myogenic markers during C2C12 cell maturation, although it may decrease overall protein synthesis. Future studies we will assess myotube morphology to further elucidate the effects of UA during maturation.

Motor Learning and Motor control

THE BALL-MOVEMENT COUPLING OF BASEBALL BATTERS WHEN HITTING FIXED AND VARIABLE PITCH TYPES

CHEN, H.

TAITUNG UNIVERSITY

INTRODUCTION: Previous studies have compared batters facing pitching machines and real pitchers, discovering that batters exhibit different movement coordination in response to varying incoming pitch information (Katsumata, 2007; Kuo et al., 2020). However, the differences in batters coordination when facing real pitchers throwing fixed or variable pitch types have not been explored. This study examined changes in batters movement coordination when facing a real pitcher who threw six consecutive maximum-speed fastballs and six changeup pitches.

METHODS: Twenty-eight collegiate baseball players participated, hitting pitches delivered by real pitchers in a balanced sequence of fixed or variable pitches. A motion capture system recorded the whole-body 3D coordinates and the time sequence of the incoming pitches. Referring to the method of Welch et al. (1995), the swing motion was analyzed by calculating joint angles of the shoulders, elbows, and knees, as well as the rotational angles and angular velocities of the arms, shoulders, and hips. For pitch-motion coupling, the timings of ball release, bat-ball contact, and peak angular velocity were identified.

RESULTS: The maximum angle does not differ across different situations. The proportion of movement time across phases also shows no significant difference.

When facing fixed pitch types, the stride timing was earlier, resulting in a longer center-of-mass transfer time, which adjusted with the bat-ball contact timing.

When facing variable pitch types, the stride timing was later, and the center-of-mass transfer time was shorter.

Successful hits demonstrated a more appropriate kinetic chain, involving the sequential maximal velocity of the hips rotation, shoulders rotation, rear knee extension, and arms rotation. Compared to fixed pitch types, the coordination of whole-body kinetic link transfer showed greater variability in sequencing and timing intervals in changeup pitches, which may better represent the movement coordination required in real game situations.

CONCLUSION: The coordination of perception and action for baseball batters aligns more with anticipation and consistent movement coordination in fixed situations. However, in variable situations of changeup pitches, they must adjust their movement coordination according to changes in the incoming pitch, which aligns with the theory of prospective model. Swinging the arms prematurely to hit the ball may have negative impacts, which is a key skill adjustment for advanced players.

INVESTIGATING COINCIDENCE ANTICIPATION TIMING AND REACTION TIME BETWEEN GAMERS AND NON-GAMERS

KIM, H.

UNIVERSITY OF WISCONSIN LA CROSSE

INTRODUCTION: Perceptual-motor abilities such as anticipatory behavior and reaction times, are fundamental components of skilled athletic performance and have been extensively studied across various sports [1]. Coincidence anticipation timing plays a pivotal role in daily life, everyday routine tasks, and sports activities. Neural mechanisms can be quantified using coincidence anticipation timing tasks [2]. Accurate coincidence anticipation timing is required for successful performance [3]. With the growing popularity of eSports as competitive computer games, it is crucial to assess the coincidence anticipation timing abilities of eSports gamers due to its relevance in gameplay [1]. For example, the ability to anticipate and respond quickly to environmental stimuli is key for actions such as shaking hands, doing high-fives, or executing tennis strokes, as well as for hitting and catching in baseball. Therefore, the purpose of this study was to investigate the coincidence anticipation timing and reaction time in eSports gamers compared to non-gamers. It was hypothesized that experienced gamers would demonstrate better anticipation timing and faster reaction time than non-gamers.

METHODS: Twenty collegiate students participated in this study, including ten experienced gamers ($M1 = 23.7$, $SD1 = 1.9$) who enjoy eSports at least 10 hours per week and ten non-gamers without any regular gaming experience ($M2 = 23.5$, $SD2 = 1.6$). Coincidence anticipation timing accuracy was measured using a Bassin Anticipation Timer. Participants completed tasks at three light stimulus speeds: slow (3 mph), moderate (6 mph), and fast (9 mph). Absolute anticipation timing error in milliseconds was calculated based on accuracy relative to the target point. Additionally, simple and choice reaction times were measured using a Takei Reaction Timer.

A two-way ANOVA with repeated measures was conducted to compare coincidence anticipation timing performance between groups, and independent samples t-tests were used to analyze differences in simple and choice reaction times. All statistical analysis was completed at the significance level of 0.05.

RESULTS: Results revealed no significant difference in coincidence anticipation timing between gamers and non-gamers, although a significant speed effect was observed ($p = 0.001$). As hypothesized, experienced gamers demonstrated significantly faster simple reaction times ($p = 0.003$) and choice reaction times ($p = 0.014$) than non-gamers.

CONCLUSION: These findings suggest that while eSports experience may not enhance coincidence anticipation timing, it could improve reaction times, highlighting the potential for esports training to develop certain perceptual-motor skills.

THE INFLUENCE OF FATIGUE ON FUNCTIONAL HAMSTRING TO QUADRICEPS RATIO IN MALES AND FEMALES

JONES, K., JAMES, D.V., IGA, J., EL NAGAR, Y., DE STE CROIX, M.

UNIVERSITY OF GLOUCESTERSHIRE

INTRODUCTION: Fatigue is a key risk factor for non-contact anterior cruciate ligament (ACL) injuries, with females being 2–6 times more likely to sustain such injuries than males [1]. Fatigue impairs neuromuscular performance, compromising knee stability. The functional hamstring to quadriceps (FH/Q) ratio is critical for knee stability, particularly near full extension where ACL strain is greatest. This study examined the effects of fatigue on functional hamstring to quadriceps (FH/Q) ratio in males and females, focusing on sex-specific differences contributing to injury risk.

METHODS: One hundred and ten participants consisting of 55 males (age: 29 ± 5 y, body mass: 82 ± 7 kg, stature: 1.82 ± 0.07 m) and 55 females (age: 27 ± 6 y, body mass: 69 ± 9 kg, stature: 1.61 ± 0.08 m), participated in a 6-week experimental study. Each session involved a 40-minute intermittent downhill running protocol (~10% gradient) consisting of 5 × 8 min bouts with 2 min rest between bout, at 80% of age-predicted maximum heart rate (Models Fs3c, Polar) [2]. FH/Q ratios were assessed pre- and post-fatigue at 60, 120, and $240^\circ \cdot s^{-1}$ using a Biodex System 3 dynamometer. Ratios were calculated from concentric quadricep torque and eccentric hamstring torque at 15° , 30° , 45° , and peak torque (PT) to capture performance across the functional range of knee movement. Two-way repeated measures ANOVA analysed interactions of sex, fatigue, joint angle and velocity, with significance set at $p < 0.05$. Effect sizes were determined using Cohens d with < 0.2 considered a small effect, 0.5 a medium effect and > 0.8 large effects.

RESULTS: Irrespective of sex, fatigue caused significant declines in FH/Q ratios across all conditions ($p < 0.01$) with large effects ($d = 0.87$ - 1.36). A significant sex × joint angle × time interaction was observed with females demonstrating lower ratios than males post-fatigue (e.g., at $240^\circ \cdot s^{-1}$, females: 55% vs. males: 71%, $p < 0.01$), which were more pronounced with decreasing joint angle (closer to full knee extension). The most significant sex difference occurred at 15° near full extension (22% vs 15% decrease compared to males). Significant interaction effects were also observed between velocity and time in

both males and females ($p < 0.01$). The repeated testing protocol showed that fatigue effects were cumulative over the study, with females exhibiting greater susceptibility to declines over time.

CONCLUSION: Irrespective of sex, fatigue induced significant reductions in the FH/Q ratio. However, this decline was significantly greater in females, particularly at joint angles critical for knee stability. These results highlight the need for targeted eccentric hamstring training and fatigue resistance programs to address sex-specific vulnerabilities and reduce ACL injury risk during high-intensity activities.

REVISITING FITTS LAW: EXPLORING THE RECIPROCAL RELATIONSHIP BETWEEN SPEED AND ACCURACY IN TIMING TASKS

HSIEH, T., LIU, Y., NEWELL, K.

FU JEN CATHOLIC UNIVERSITY

INTRODUCTION: The concept of a space-time framework forms the basis for suggesting the complementarity of spatial and temporal errors in movement variability, where movement accuracy in space is assessed relative to time, and vice versa. Fitts (1954) introduced an information processing theory that linked movement time with spatial accuracy, which led to the well-known Fitts' law in human motor control. In the experiment discussed here, we explore a reciprocal space-time approach, requiring participants to move within a specific time goal and time window while allowing the movement amplitude to emerge naturally.

METHODS: Twenty healthy adults who self-reported as right-handed were recruited for this study. The target times (T) tested were 100, 200, 400, and 800 ms, corresponding to Index of Difficulty in Time (IDT) values of 1, 2, 3, and 4, based on an expected time window of ± 50 ms (100 ms bandwidth for temporal targets). The target time bandwidth was varied, ranging from 25 (± 12.5) to 800 (± 400) ms, when the target time was set to 800 ms, resulting in IDTs of 1, 2, 3, 5, and 6. Repeated measures ANOVAs were used to examine the effect of the manipulations.

RESULTS: To evaluate the effect of the target T manipulation, an ANOVA on movement time revealed a significant influence of IDT, $F(2.04, 38.74) = 18390$. Similarly, the IDT significantly affected movement time under the time window manipulation condition, $F(1.68, 31.98) = 14.1$ ($ps < .05$). Furthermore, a repeated measures ANOVA on movement amplitude with target T manipulation indicated a significant effect of IDT, $F(2.03, 38.66) = 173$. Likewise, the IDT within the time window manipulation showed a significant impact on movement amplitude, $F(5, 95) = 3.24$ ($ps < .05$).

CONCLUSION: The results indicated that a higher IDT was associated with better average group performance consistent with Fitts law. The groups average movement amplitude increased from 12.55 mm at IDT1 to 405.20 mm at IDT4 under the target T manipulation, supporting the reciprocal relationship between space and time error functions in Fitts' type movement tasks and aligning with the reciprocal patterns of spatial and temporal errors observed in other movement aiming tasks.

ASYMMETRY BETWEEN UPPER LIMB MASSES AND KINETIC INDICES IN RIGHT-HANDED YOUNG ADULTS

ZUOZA, A., GUTNIK, B.2, ZUOZIENE, I.1, ALEKRINSKIS, A.1, NASH, D.2

1 LITHUANIAN SPORTS UNIVERSITY, 2 UNITEC, INSTITUTE OF TECHNOLOGY, AUCKLAND, NEW ZEALAND

INTRODUCTION: This study aimed to create an accurate method for calculation of upper arm mass and to use these data to determine any asymmetry between the masses of the dominant and non-dominant upper limbs of right-handed participants and to examine lateral differences in kinetic parameters during the early phase of a discrete target-directed fast targeting task created on the trade-off between speed and accuracy.

METHODS: The study included 20 right-handed males (20.8 ± 1.2 years) with no upper limb pathology. Handedness was assessed using the Waterloo Handedness Questionnaire [1]. A certified model of an Analyzer of Dynamic Parameters of Human Movement™ (Patent Number LT 5251, 2005-08-25, Lithuania; Baltec CNC Technologies) interfaced with a computer was used to collect the data.

In Experiment 1, upper arm mass was calculated using an Analyzer. Participants performed 16 valid trials per arm, pushing a joystick forward while force and acceleration were recorded. The mass of the upper limb was calculated as: $M_{\text{upper limb}} = F/a_{\text{av}} - M_{\text{joystick}}$, (1) where M_{joystick} is the mass of the joystick. The number of participants was sufficient for using Student's paired t-test. The Shapiro-Wilks test was used to determine the normality of data distribution. In Experiment 2, the same 20 adult men, were involved in the subsequent experiment. Subjects had to push the devices handle as fast and accurately as possible towards a target on the screen. Each participant performed 5x20 separate movements with each arm (100 in total). An Analyzer recorded mechanical energy, power, force impulse, and spatial error. The Shapiro-Wilk test, Student's t-test, and χ^2 test were used for statistical analysis (IBM SPSS v.22).

RESULTS: Results showed that the left arm was generally lighter than the right, but the difference was not significant. However, 25% of participants had a heavier non-dominant arm. Mechanical energy and power were significantly higher in the left arm, while relative spatial error was greater in 60% of cases. The χ^2 test confirmed an unequal distribution of capabilities between the arms ($P < 0.05$).

CONCLUSION: The method described here provides an accurate measurement of upper-arm mass. In most cases, the dominant arm was more massive than the non-dominant arm. Knowledge of limb segment masses is necessary to estimate body segment properties accurately. The study showed greater mechanical energy, initial sub-movements power, and driving forces for the non-dominant arm. CNS uses different mechanisms to coordinate movements of non-dominant and dominant hands [2–3]. Future research should include energy expenditure and specific arm mass tests. The energy minimization mechanism may be more suited to the dominant hand due to the left brain hemispheres complexity.

THE LEARNING EFFECTS OF DIFFERENT VISUAL CONSTRAINTS ON FULL-TURN JUMPS

HWANG, J., LIU, Y.T.

NATIONAL TAIWAN NORMAL UNIVERSITY

INTRODUCTION: Jump turns are the key elements in artistic sports. Healthy individuals typically rely on visual information to generate coordinated movements in specific environments. “Spotting” is a technique used by gymnasts, dancers, and figure skaters during jumps and spins to acquire and maintain information about rotation and balance throughout the process. Sato et al. found that gymnasts exhibited a synergistic movement pattern during a full-turn jump, characterized by an early head movement returning to face forward after completing the rotation, with a stabilized gaze occurring prior to landing [1]. The purpose of this study is to explore the learning effects of different visual information on full-turn jumps that involve both temporal and spatial constraints.

METHODS: Six young adults who exercised regularly but lacked jump-turn training experience were assigned to one of two visual information groups: a dot or a randomly changing number displayed every 200 ms. A two-week skill learning program aimed at achieving full-turn jumps in 400 ms was implemented. In addition to a 1-meter-diameter disc protractor and a set of gratings used to evaluate temporal and spatial performances in the pre-and post-tests, an infrared high-speed three-dimensional motion capture system recorded the kinematics of the head and hips for phase-plane analysis of turn coordination. Independent t-tests were used to examine the differences in angular displacement between the pre-and post-tests for individual statistical analyses.

RESULTS: The t-test results indicated that two participants in the Number group showed significant improvement in variable error regarding angular displacement, as well as in absolute error and constant error ($p < .05$). Only one participant in the Dot group showed significant improvement in angular displacement. Phase-plane analysis revealed that participants in the Number group also exhibited higher head acceleration and an early fixation delay, which were not observed in the Dot group.

CONCLUSION: Focusing on randomly generated numbers effectively influenced movement patterns during the learning process of a full-turn jump. The Number group exhibited a distinct fixation strategy, showing a clear tendency to stabilize their gaze before landing. This indicates that specific visual information may have contributed to improving spatial performance, particularly in controlling rotation angles. These preliminary observations offered promising directions for future research programs exploring learning and teaching strategies in full-turn jumps.

OPTIMIZING THE SPEED-ACCURACY TRADE-OFF IN THE VERTICAL JUMPING THROUGH MOTOR LEARNING

NAKAJIMA, K., MURAKAMI, H., YAMADA, N.

1> CHUKYO UNIVERSITY; 2> KINJO UNIVERSITY

INTRODUCTION: Human movement is regulated by the speed-accuracy trade-off principle [1], which claims that generally, speed is reduced when higher accuracy is required. However, in sports, speed and accuracy must be maintained at high levels. Thus, athletes must improve both aspects through motor learning.

Studies have investigated sports movements’ mechanisms requiring speed and accuracy using whole-body movements such as vertical jumps. However, while they have reported that increasing accuracy leads to reduced speed, they have not sufficiently examined whether repeated learning of the movement can improve speed while maintaining accuracy, ultimately optimizing the balance between speed and accuracy at a higher level [2]. This study aimed to clarify how the speed-accuracy trade-off changes through motor learning. Specifically, we examined whether learning induces adaptations that improve accuracy without compromising speed.

METHODS: This study involved seven participants, and this paper presented a detailed analysis of a representative participant who exhibited a typical performance pattern.

The participant performed vertical jumps on a force plate under the following conditions:

1. Normal condition: Perform a maximal vertical jump on a force plate.
2. Adjusted condition: Perform a maximal vertical jump while controlling the landing to match the take-off position.

The participant sequentially performed 10 trials for each condition in Section 1. Thereafter, Section 2 (normal condition: 5 trials, adjusted condition: 10 trials) was conducted to examine motor learning progression.

Data analysis was conducted following the methodology in [2]. Take-off position, landing position, jump height, and information entropy were calculated.

RESULTS: Jump height was 49.5 cm and 44.3 cm in Section 1 in the normal and adjusted conditions, respectively: the normal condition resulted in significantly higher jumps ($p < 0.05$). Relative information entropy, which indicates landing accuracy, was 0.66 in the normal condition and 0 in the adjusted condition.

Jump height was 52.1 cm and 51.7 cm in Section 2 in the normal and adjusted conditions, respectively, with no significant difference between them ($p = 0.95$). Relative information entropy was 0.31 and 0.28 in the normal and adjusted conditions, respectively. In other words, this decrease in relative information entropy indicates an improvement in movement consistency through learning.

CONCLUSION: A conventional speed-accuracy trade-off was observed in Section 1. In contrast, jump height was maintained while landing consistency improved, as indicated by lower relative information entropy in Section 2. These results suggest that motor learning enables individuals to achieve a higher balance between speed and accuracy, optimizing their performance over time. Future research should systematically analyze data from all participants to examine inter-individual variability and validate the generalizability of these findings.

PASSAGE OF TIME CONTRIBUTES TO THE DECAY OF AFTEREFFECTS INDUCED BY TRAMPOLINE JUMPING

IDE, T., ARAMAKI, Y.

CHUKYO UNIVERSITY

INTRODUCTION: When performing a vertical jump and subjectively estimating their achieved height after trampoline jumps, individuals experience reduced jump heights and tend to underestimate their jump heights (Márquez et al., 2010). These aftereffects are no longer observed in a subsequent vertical jump trial. Therefore, a vertical jump trial likely contributes to the recovery of both jump height and estimation to their original level. In contrast, we will test whether the passage of time following the completion of trampoline jumps induces this recovery.

METHODS: Subjects ($n = 14$, age: 23.2 ± 1.6 years, height: 173.2 ± 6.8 cm, weight: 69.9 ± 4.8 kg) performed three vertical jumps on the force plate, and the experimenter provided the achieved jump height (Pre-Test). One minute later, the subjects jumped on the trampoline 30 times at a rhythm of 1.2Hz (72bpm). They then performed vertical jump and estimated their own jump height five times at one-minute intervals (Post-Test). The Post-Test started after a delay of five different time intervals (0, 1, 2, 3, and 4 minutes) following the completion of the trampoline jumps. In the 0-min condition, subjects started the Post-Test immediately after completing the trampoline jumps. In the 1 to 4-min condition, subjects started Post-Test after the resting period set in the condition was spent in seated rest. We recorded the subject's real jump height (RH), estimated height (EH), maximum ground reaction force, minimum knee angle, flexion movement time, and maximum flexion velocity during the vertical jump.

RESULTS: In the 0-min condition, RH and EH in the first Post-Test trial decreased (RH: $-5.12 \pm 6.41\%$ compared to the Pre-Test, $p = 0.007$; EH: $-6.26 \pm 8.31\%$ compared to RH in the same trial, $p = 0.009$). These heights recovered to baseline levels in the second Post-Test trial, which was performed one minute later. On the other hand, when the vertical jump was performed after merely a minute of rest following trampoline jumps (first Post-Test trial in the 1-min condition), RH recovered to baseline, but EH continued to decline ($-4.88 \pm 3.43\%$ compared to RH of the same trial, $p < 0.001$). No significant changes were observed in other recorded parameters.

CONCLUSION: These results indicate that the passage of time after completing trampoline jumps plays a significant role in the recovery of both the real and subjective jump heights and that the time-dependent recovery processes differ between the two types of jump heights. This suggests that the aftereffects produced in motor behavior and estimation systems may be generated by different mechanisms.

DIVERSITY OF FUNCTIONAL LATERALITY AND PREFERENCE IN MOTOR DEVELOPMENT DURING CHILDHOOD

HASHIMOTO, M., SHISHIDO, T., KIDA, N.

OSAKA KYOIKU UNIVERSITY

INTRODUCTION: This study investigates functional laterality (FL) and preference (Pr) in motor function among Japanese preschool children, providing fundamental data for elementary physical education. Functional asymmetry of the brain emerges between ages 3 and 5, coinciding with motor cortex development [1][2]. However, cultural influences in Japan encourage the use of the right hand. Given this norm, we examined the relationship between FL and Pr.

METHODS: Participants comprised 30 five-year-old kindergarteners (14 boys, 16 girls). Pr was assessed using the Edinburgh Handedness Inventory (EHI) [3], preferred hand for throwing a ball (HB), preferred foot for kicking a ball (FB) and the

first step foot in a sprint start (FS). FL was evaluated through a hand dexterity (HD) via a marble-placing task, a ball aiming (BA) test with five trials per hand, a ball kicking (BK) test with five trials per foot and a one-legged hopping (JR) test with two trials per leg. Gender differences, correlations among variables and FL tendencies based on Pr were analysed using nonparametric tests.

RESULTS: The EHI results indicated that 86.7% were right-handed, 10% were left-handed and 3.3% exhibited crossed dominance. HB showed that 23.3% preferred the left hand, half of whom were classified as right-handed by the EHI. For FB, 10% favoured the left foot, while 56.7% preferred the left foot for FS, though FB and FS showed low consistency. Regarding gender differences, boys were taller, while girls exhibited significantly higher JR scores on the right leg. Boys outperformed girls in BK scores on the right foot. Significant positive correlations were found between the left and right scores for HD, BK and JR, except for BA. A significant positive correlation was also observed between BA (right) and BK (right) ($r=0.346$, $p=0.014$). A negative correlation between BK (right) and JR laterality difference ($r=-0.260$, $p=0.044$) suggested that higher BK (right) performance was associated with stronger left-side dominance in JR. However, BK (right) and JR (left) showed no significant correlation. Examining the relationship between Pr and FL, 66.7% threw with their FL-dominant side in the HB-BA comparison, while 23.3% had Pr and FL on opposite sides. For FB and BK, 13.3% showed Pr and FL on opposite sides. There was no significant correlation between BA and JR, with 23.3% aligning with expected patterns and 30% deviating.

CONCLUSION: Findings suggest that FL and Pr are interrelated in five-year-old children's motor functions, though inconsistencies were observed in some areas. Future approaches to supporting motor development in elementary physical education should account for individual laterality and cultural influences. As society increasingly acknowledges gender diversity, recognising and respecting individual differences in motor laterality is equally essential.

DOES UNCONSCIOUS KNOWLEDGE SUPPORT SKILLED ATHLETIC MOVEMENTS?

JURCHIS, R., VINCZE, A., COSTEA, A., OPRE, A.
BABES-BOLYAI UNIVERSITY

INTRODUCTION: A large amount of anecdotal evidence suggests that athletes are not always aware of the specific parameters of their highly-skilled, fine-grained, movements involved in their sporting actions. In other words, it appears plausible that their actions are supported, at least in part, by unconscious knowledge. However, little empirical research within cognitive science or within sport science has been done to directly test this possibility. Nevertheless, this possibility appears plausible in the light of studies showing that actions involved in sport often exhibit characteristics associated with unconscious knowledge; namely, they are acquired incidentally, can be deployed without attention and are resilient to dual-task interference. In the present study, using a methodology adapted from consciousness science, we directly test whether unconscious knowledge supports movements involved in sport. To increase the chances of finding knowledge that is not consciously detected, we used table tennis as the context of our research, because it involves precise, fine-grained, movements executed at very high speeds.

METHODS: An elite table tennis player was tested in two conditions: in the experimental condition, the player was required to strike the ball as in a table tennis game, and immediately after was asked to reproduce the position of the arm at the moment of striking the ball. The shoulder, elbow, forearm, and wrist angles were recorded using an IMU system, and the error in the reproduced (vs the original) position of the arm was computed. In the baseline condition, the player was required to position the arm in various static positions (indicated by the experimenter) that could appear when striking a ball, for several seconds, and immediately then to reproduce the position. This was in order to measure the error in reproducing the arm position under conditions ideal for conscious processing.

RESULTS: As expected, in the baseline condition, when conscious processing was favoured, the reproduction errors were relatively low (mean differences < 4 degrees); however, the reproduction errors were notably higher in the experimental condition (up to 9 degrees for the shoulder adductor/abductor angle), suggesting that, when executing the high-speed strokes, the athlete lacked full awareness of the position of her arm (a difference generated by the shoulder joint).

CONCLUSION: This study proposes a methodology for investigating athletes' awareness of their fine-grained movements and provides initial evidence that, partially, these movements are supported by unconscious knowledge. The study has the potential to initiate a novel research line at the intersection of sport science, consciousness science, and cognitive science.

SEX DIFFERENCES IN ELECTROMECHANICAL DELAY OF THE HAMSTRINGS FOLLOWING DOWNHILL RUNNING

DE STE CROIX, M., JAMES, D.V., IGA, J., EL NAGAR, Y.
UNIVERSITY OF GLOUCESTERSHIRE

INTRODUCTION: Neuromuscular capability is likely compromised when fatigue is present, which likely predisposes the athlete to increased injury risk (1). To date no studies appear to have examined the effect of downhill running on sex differ-

ences in the electromechanical delay (EMD) of the hamstrings. This is somewhat surprising given the importance of the hamstrings to work eccentrically to reduce injury risk and keep the joint stable.

METHODS: One hundred healthy males (n=50) and females (n=50) were recruited from the university population. Each participant performed a 40 min intermittent downhill running protocol consisting of 5 × 8 min bouts on a -10% decline at 80% or heart rate max, with 2 min standing rest between each bout (2). Immediately before and after the downhill running task, Electromyography (EMG) of the semitendinosus, semimembranosus and biceps femoris of the dominant limb (DeSys Myomonitor III) was determined during isokinetic eccentric muscle actions at 60, 120 and 240°·s⁻¹ (Biodex system 3). The Biodex square wave synchronization pulse was configured with the EMG software so that EMG and torque data were time aligned. Raw EMG data were collected at a sampling frequency of 1024 Hz and included a common mode rejection ratio of <80 dB and an amplifier gain of 1000. Raw EMG data was band pass filtered at 20 – 450 Hz. EMD was determined as the time delay between the onset of muscle activation (change in activation of +15 µV) and onset of torque production (9.6 Nm) (3). A mixed-factorial analysis of variance (ANOVA) was used to explore the effects of time, sex, and muscle on electromechanical delay. Effect sizes were determined using Cohens d with <0.2 considered a small effect, 0.5 a medium effect and >0.8 large effects.

RESULTS: Irrespective of sex, muscle or velocity, EMD of the hamstrings muscle was significantly longer post-downhill running ($F(1, 98) = 709.406$, $P < 0.01$), with large effects observed ($d = 1.05$ - 2.80). Significant interactions between sex and time for EMD of hamstring muscles were found ($F(3, 98) = 28.738$, $P < 0.01$) with significantly longer EMD post fatigue in females. These differences demonstrated large effects ($d = 0.72$ - 1.46). No significant effects of muscle were observed in any analysis.

CONCLUSION: These data suggest that neuromuscular capability of the hamstrings during eccentric actions is compromised post downhill running irrespective of sex or muscle group examined. This compromise is greater in women and may make them more susceptible to injury risk due to reduced stability of the knee. Effective neuromuscular functioning when fatigue is present is important for maintaining performance and reducing injury risk. Thus, eccentric hamstring training should be proposed to limit the effects of neuromuscular fatigue, especially in female athletes.

IMPACT OF EXERCISE PROTOCOL ON POSTURAL CONTROL IN PEOPLE WITH DIABETES

LAFFI, A., PIRAS, A., MEONI, A., PETRONI, M.L., BRODOSI, L., NICASTRI, A., RAFFI, M.

ALMA MATER STUDIORUM - UNIVERSITY OF BOLOGNA

INTRODUCTION: Exercise plays a crucial role in both the prevention and management of diabetes. A major benefit is its role in enhancing postural control by refining sensory inputs from the visual, vestibular, and proprioceptive systems, which are essential for maintaining balance and stability. [1] During self-motion, we are exposed to optic flow patterns that provide information about heading direction. The spatial and temporal properties of optic flow directly influence body sway. [2] However, individuals with diabetes, especially those with prolonged metabolic dysregulation, may struggle to integrate these sensory signals effectively. This impairment can lead to altered postural responses. [1]

METHODS: The study aims to evaluate the effects of an 18-month exercise program on balance control and postural muscle activation in a cohort of uncompensated diabetic patients ($HbA1c > 52$ mmol/mol). EMG and stabilometric data were recorded in 12 diabetic people who followed a 18 months exercise program (age 59.1 ± 10.2 ; 33% oral medication; 56% insulin therapy) and in 12 diabetic people with sedentary habits (age 59.4 ± 12.1 ; 71% oral medication; 14% insulin therapy). None of the subjects had a diagnosis of peripheral neuropathy. EMG data were recorded bilaterally from the tibialis anterior (TA) and soleus (SOL) at baseline, 6, 12 and 18 months. During recordings, the subjects stood on two force platforms to obtain the center of pressure (COP) displacement in anteroposterior (AP) and mediolateral (ML) directions. The experimental setup involved subjects standing in complete darkness while exposed to radial expanding optic flow stimuli projected on a screen covering $135 \times 107^\circ$ of visual field. Data acquisition included 2 trials per stimulus of 30-s each and two baseline trials (upright stance in the dark). EMG and COP data have been analyzed separately by repeated measures ANOVA with laterality (right, left) as within-subject factor, group (active, inactive) and time (baseline, 6, 12, 18 months) as between-subjects factors.

RESULTS: Significant effects and interactions have been found in both anteroposterior (AP) and mediolateral (ML) COP directions for time, group, stimuli, laterality and sex ($p < 0.05$). EMG data revealed a significant interaction between stimuli and muscle ($p = 0.008$).

CONCLUSION: Results suggest that diabetic people who exercise regularly have a better body balance than sedentary counterparts. This augmented control improved across the time of exercise.

THE ROLE OF AUTOPHAGY IN BOTULINUM NEUROTOXIN-INDUCED SKELETAL MUSCLE ATROPHY

HOUSTON, F., HAIN, B., SMUDER, A., TAMULEVICIUS, N., POLIZZI, L., DODD, S.

THE UNIVERSITY OF TAMPA; PENNSYLVANIA STATE UNIVERSITY[^]; THE UNIVERSITY OF FLORIDA*

INTRODUCTION: The use of Botulinum neurotoxin type A (BoNT/A) in clinical and sports medicine is common for musculo-skeletal injury rehabilitation, pain management, and recovery. However, BoNT/A administration induces skeletal muscle wasting, though the exact proteolytic mechanisms remain unclear. Autophagy, a constitutively active proteolytic process responsible for organelle and macromolecule degradation, may play a key role. Under pathological conditions, excessive autophagy can lead to a deleterious rate of protein degradation, potentially contributing to BoNT/A-induced muscle atrophy.

METHODS: Male Sprague-Dawley rats (~200 g) were used for experiments approved by the University of Florida Institutional Animal Care and Use Committee. Following a 3-day handling period, animals were assigned to one of two main groups and sacrificed after either 3 or 10 days: Control (EGFP plasmid soleus injection, Gelatin Phosphate Buffer (GBP) or BoNT/A hind limb injection); Autophagy Inhibition (ATG5 d.n.-EGFP plasmid soleus injection, GBP or BoNT/A hind limb injection). The total number per group was 6-8 solei. Soleus muscle plasmid transfection was performed via electroporation. Due to the contralateral effect of BoNT/A, an individual animal received either control or BoNT/A injection in both their left and right leg. Soleus muscles were collected after 3 or 10 days, frozen, and analyzed using membrane staining, histochemistry, and Western blot for autophagy-related proteins. Statistical analyses used ANOVA with Bonferroni corrections, with significance set at $p \leq 0.05$.

RESULTS: Our findings support a role for autophagy in BoNT/A muscle wasting as rat soleus muscle cross-sectional area (CSA) was decreased ~30% three days following BoNT/A injection, and Beclin-1/Bcl-2 ratio, ATG5-ATG12 conjugation, and Cathepsin-L were significantly elevated. Ten days following BoNT/A injection muscle CSA decreased ~55%, with significant elevations in Beclin-1, ATG5-ATG12 and LC3 II/I ratio. Subsequently, plasmid-mediated inhibition of autophagy via overexpression of a dominant negative ATG5 protein (ATG5 d.n.), administered 24-hours prior to BoNT/A, significantly attenuated ATG5-ATG12 conjugation at both 3 days and 10 days. Inhibition of autophagy was sufficient to abolish atrophy 3 days following BoNT/A injection compared to absolute control muscle fibers, but not compared to the ATG5 d.n. expressing control muscle fibers. Thus, the preservation of CSA may not be a bona fide abolishment of BoNT/A-induced atrophy. Additionally, ten days following BoNT/A injection, overexpression of ATG5 d.n. did not significantly attenuate atrophy.

CONCLUSION: Based upon our findings, we conclude that either autophagy does not make a significant proteolytic contribution toward BoNT/A-induced atrophy or, in a redundancy-like manner, the inhibition of autophagy promotes upregulation of other cellular mechanisms that cause increased BoNT/A-induced atrophy.

QUANTIFICATION AND VISUALIZATION OF ANTAGONISTIC BI-ARTICULAR THIGH MUSCLE ACTIVITY PATTERNS DURING SPRINT RUNNING IN ADULT TRACK AND FIELD ATHLETES

YOKOTA, K., YOSHIHIRO, N.1, AYUMU, U.1, HIROYUKI, T.2

¹ GRADUATE SCHOOL OF PHYSICAL EDUCATION, NATIONAL INSTITUTE OF FITNESS AND SPORTS IN KANOYA, ² DEPARTMENT OF SPORTS AND LIFE SCIENCE, NATIONAL INSTITUTE OF FITNESS AND SPORTS IN KANOYA

INTRODUCTION: Moment-to-moment changes in agonist and antagonist muscle activity during sprint running can be evaluated using surface electromyography (sEMG). Lissajous figures provide a means of visualizing these activity patterns, while the cross-correlation function (CCF) quantifies their temporal relationships. This study aims to evaluate antagonistic bi-articular thigh muscle activity patterns during sprint running using these techniques.

METHODS: Forty male track and field athletes performed maximal effort sprint running over 50m. During this test, sEMG signals were recorded from the rectus femoris (RF) and biceps femoris (BF) and ground reaction force (GRF) data were collected using a 50m force plate system, which recorded 25 steps. Sprint cycles were defined based on GRF data, with one cycle (1Cycle) from ipsilateral toe-off to foot-strike. The CCF R-values (≥ 0) were used as an index of similarity, and the mean R-value at zero time lag was calculated for each 1Cycle. Participants were then categorized into two groups based on their CCF R-values using the mean ± 1 SD as the threshold: those with R-values above this range were classified as the High-group, and those below this range were classified as the Low-group. Lissajous figures were examined to characterize differences in muscle activation patterns between the groups.

RESULTS: The mean CCF R-value across all participants was 0.656. The High-group exhibited R-values ranging from 0.732 to 0.848, whereas the Low-group showed R-values between 0.345 to 0.540. The Lissajous figures of the High-group displayed an irregular spiral shape, suggesting greater coactivation of RF and BF, whereas the Low-group exhibited a reciprocal activation pattern between RF and BF.

CONCLUSION: This study applies established methods to quantify and visualize antagonistic bi-articular thigh muscle activity specifically during sprint running. The observed differences in coactivation and reciprocal activation patterns suggest potential variations in neuromuscular control strategies among sprinters. These findings may aid in developing training approaches to optimize sprint-related muscle activation patterns.

MUSCLE MORPHOLOGICAL ADAPTATIONS IN RESPONSE TO 6 WEEKS OF CONVENTIONAL TRAINING WITH OR WITHOUT ECCENTRIC OVERLOAD

TOSETTI, D., PADOVANI, L., BRUSCO, C., MARTINO, G., SCARPELLI, M.C., FRANCHI, M.V.

UNIVERSITÀ DI PADOVA

INTRODUCTION: Skeletal muscle can perform both concentric and eccentric contractions, which differ in terms of generated force and energy cost. Eccentric (ECC) training allows the use of higher loads with lower metabolic cost, potentially promoting greater hypertrophy compared to conventional resistance training. However, evidence regarding the superiority of training employing ECC overload versus conventional modalities remains inconsistent as it is not clear if overload imposed on the eccentric phase could result in greater hypertrophy compared to conventional resistance training modalities. This study aimed to investigate the morphological adaptations of the quadriceps femoris (QF) in response to six weeks of conventional (CONV) vs eccentric overload training (ECC).

METHODS: Twenty recreationally active subjects (aged 18–35 y, 10 M-10 F) were divided into two groups, the first performing conventional resistance training, the second one performing it with eccentric overload (+50% of the concentric load). Both groups trained three times/week for six weeks using the Biostrength REV leg press, a special device that allows to increase the load during the eccentric (descending) phase without compromising the movement thanks to the automatic modification of the load allowed by the machine. The cross-sectional area (CSA) of the QF was evaluated via panoramic ultrasound pre- and post-training from 20 to 70% (seamless) of the femur length. From these data the QF volume was calculated using the truncated-cone formula, which consists in the calculation of the volumes of contiguous truncated cones drawn in the different parts of the muscle, statistical analysis was performed using two-way ANOVA

RESULTS: Both groups showed generalized hypertrophy of the QF, in particular with regard to the group trained with eccentric overload, even if with no significantly greater differences (due to individual variability) between CONV ($7 \pm 5.5\%$, $p < 0.01$) and ECC+ ($10 \pm 11.5\%$, $p < 0.001$) muscle volume (means $\pm$ SD). The ECC+ group showed a greater percentage increase in the distal region (20-30% of the length of the QF) ($+13.3\% \pm 9.9\%$, $p < 0.0001$) compared to the CONV group ($+6.5\% \pm 8.4\%$, $p < 0.0001$). The Rectus Femoris showed negligible growth, likely due to positional limitations during exercise. However, an increase of force majeure was observed in subjects trained without eccentric overload (CONV+37kg / ECC+32kg, both of average).

CONCLUSION: Although both protocols induced hypertrophy, eccentric overload training appears to promote localized adaptations in the distal region of the QF. The reason for this increase could be the greater stress applied on the distal portion of the knee extensors during eccentric muscle actions performed with significant overload.

VASTUS LATERALIS ARCHITECTURAL ADAPTATIONS IN RESPONSE TO SIX WEEKS OF STRENGTH TRAINING WITH OR WITHOUT ECCENTRIC OVERLOAD

PADOVANI, L., TOSETTI, D., BRUSCO, C.M., MARTINO, G., SCARPELLI, M.C., FRANCHI, M.V.

UNIVERSITY OF PADUA

INTRODUCTION: Eccentric overload is a strength training modality consisting of executing the eccentric phase of an exercise with an excess load of the concentric phase. As previously shown, this modality allows specific adaptations to occur, compared to conventional strength training (1). Different muscle adaptations are observed in relation to distinct stimuli, although the patterns of muscle changes in this defined training condition are still partly unclear. This study aims to investigate changes in muscle structure, specifically in architectural features, of the Vastus Lateralis muscle following six weeks of conventional strength training, either, with or without eccentric overload.

METHODS: Sixteen subjects (8M-8F, aged 18-35 y), healthy and recreationally active, underwent a six-week training period, with three sessions/week on a novel leg press (Technogym Biostrength, REV) that allows different loading during the eccentric and concentric phases of the movement. Volunteers were equally divided into a conventional group (CONV), performing the leg press exercise with a constant load, and an eccentric overload group (ECC+), performing the eccentric phase of the exercise with an overload corresponding to 50% of the load used during the concentric phase. Static ultrasonography images at 50% of the femur length were taken before and after the training period. The images were processed using ImageJ to investigate characteristics such as muscle thickness (MT), fascicle length (FL) and pennation angle (PA). Statistical analysis was performed using 2-way ANOVA.

RESULTS: As a result of the six weeks of training, we observed an increase in MT for both CONV (9.66% , $p < 0.05$) and ECC+ (6.75% , $p < 0.05$). FL significantly increased only in ECC+ (3.02% , $p < 0.05$). Instead, PA increased significantly only in CONV (8.86% , $p < 0.05$).

CONCLUSION: Both training modalities showed an increased MT, with a greater percentage increase in CONV rather than ECC+. This could be explained by the fact that ECC+ training has a greater proposed mechanical stimulus that may cause early fiber-damaging processes (2) potentially resulting in lower hypertrophic growth in the first days of training (3). Likewise, the same mechanical stimulus-induced during the eccentric phase forces the muscle to adapt and lengthen its fibers more compared to conventional training. The greater changes in PA after CONV training also suggest that structural adaptations are mostly related to the concentric contractions performed. Further investigations will be made to determine why skeletal muscle implements these specific changes in response to eccentric overload in relation to muscle functional adaptations.

Nutrition

ADHERENCE TO A MEDITERRANEAN DIET AND LEISURE-TIME PHYSICAL ACTIVITY ARE PROTECTIVE FACTORS AGAINST THE INITIATION OF ANTIDEPRESSANT, ANXIOLYTIC, ANTIPSYCHOTIC, AND ANTISEIZURE DRUG USE IN OLDER ADULT

FORNARA, E., HERNANDEZ, M., HERNAEZ, A.

UNIVERSITY RAMON LLULL

INTRODUCTION: We aimed to investigate the association between long-term adherence to MedDiet and LTPA levels and the initiation of antidepressant, anxiolytic, antipsychotic and antiseizure medication in older adults.

METHODS: We assessed the relationship between the cumulative average of MedDiet adherence and LTPA and the initiation of medications in the PREvención con Dieta MEDiterránea (PREDIMED) study. Sample sizes ranged from 5,940 for anxiolytics to 6,896 for antipsychotics. Associations between the cumulative average of MedDiet adherence (per each one-point increase in the adherence score) and LTPA (per each increase in 20 metabolic equivalents of task-minute/day [METs-min/day]) with drug initiation were studied by multivariable Cox regressions (covariates: age, sex, PREDIMED intervention group, recruitment site, education, smoking habit, BMI, alcohol, and energy intake; multiple comparisons: Bonferroni method). We explored non-linear exposure-outcome associations using smoothed cubic splines and the interaction among both exposures.

RESULTS: One-point increases in MedDiet adherence score were associated with 23-28% less initiation of antidepressants (hazard ratio [HR] 0.72, 95% confidence interval [CI] 0.67-0.77), anxiolytics (HR 0.75, 95%CI 0.70-0.81), antipsychotics (HR 0.77, 95%CI 0.65-0.91), and antiseizure drugs (HR 0.77, 95%CI 0.69-0.85). Associations for anxiolytics and antiseizure drugs were particularly strong among participants with poor MedDiet adherence. Relationships between LTPA and initiation of antidepressant and anxiolytic drug use were non-linear. Among participants with the lowest LTPA values (0-150 METs-min/day), 20 METs-min/day increases were associated with 20% less risk of initiating antidepressant use (HR 0.80, 95%CI 0.75-0.86) and 15% less risk of initiating anxiolytic medication (HR 0.85, 95%CI 0.79-0.90). 20 METs-min/day increases were linearly associated with less initiation of antiseizure drugs (HR 0.96, 95%CI 0.94-0.99), and no clear associations were found for antipsychotic drugs. Individuals with high MedDiet adherence (≥ 10 adherence points) and high LTPA levels (≥ 150 METs-min/day) showed 42-59% less risk of initiating psychoactive drugs (antidepressants: HR 0.41, 95%CI 0.30-0.56; anxiolytics: HR 0.54, 95%CI 0.41-0.71; antipsychotics: HR 0.45, 95%CI 0.21-0.95; antiseizure drugs: HR 0.58, 95%CI 0.37-0.90). The combination was additive for antidepressants, antipsychotics and antiseizure drugs and synergistic for anxiolytics (p-interaction = 0.076).

CONCLUSION: Sustained adherence to MedDiet and LTPA were linked to lower initiation of psychoactive drugs in older adults

ACUTE EFFECTS OF CAPSAICIN INGESTION ON AEROBIC CAPACITY AND MUSCULAR STRENGTH IN CYCLISTS

CHENG, C.F.1, YANG, Y.R.2, LEE, S.M.1, GOH, C.M.1, CHEN, C.2, PAN, C.H.2

1: NATIONAL TAIWAN NORMAL UNIVERSITY, DEPARTMENT OF SPORT AND KINESIOLOGY 2: NATIONAL TAIWAN NORMAL UNIVERSITY, DEPARTMENT OF PHYSICAL EDUCATION AND SPORT SCIENCES

INTRODUCTION: Capsaicin (CAP) has recently been found to modulate the transient receptor potential vanilloid 1, thereby promoting the release of calcium ions and acetylcholine, producing analgesic effects, increasing fat oxidation, which may help improve exercise performance. However, limited studies investigate the effects of CAP ingestion on exercise performance in athletes. This study examined the acute effects of CAP supplementation on aerobic capacity and muscular strength in cyclists.

METHODS: Ten male cyclists (age, 20 ± 2 years; height, 173 ± 7 cm; body mass, 64 ± 5 kg; VO_{2max} , 68 ± 9 ml·kg⁻¹·min⁻¹) were recruited to complete this randomized crossover and double-blinded experiment. All participants were asked to perform three treatments, including CAP (12 mg of capsaicin in capsules), PLA (placebo), and CON (control), before conducting the graded exercise test (GXT) on a cycling ergometer. The GXT protocol was initiated with a load of 100 W and increased by 15 W in each subsequent 3-min stage until 5 stages were completed. Thereafter, the workload was increased by 30 W per minute until maximal oxygen uptake (VO_{2max}) was reached. Before and after GXT, the isometric mid-thigh pull (IMTP) were performed to determine the muscular strength and power performance. During the GXT, the VO_2 , heart rate (HR), muscle oxygenation, fat oxidation, time to exhaustion, and blood lactate concentrations were measured.

RESULTS: No significant differences were found on the VO_{2max} (CAP vs. PLA vs. CON, 4.23 ± 0.42 vs. 4.35 ± 0.55 vs. 4.30 ± 0.54 L·min⁻¹, $p > 0.05$), blood lactate levels, and rate of perceived exertion among treatments. However, the time to exhaustion during GXT in PLA was significantly longer than those in CAP and CON (CAP vs. PLA vs. CON, 1458 ± 79 vs. 1482 ± 84 vs. 1462 ± 78 sec, $p < 0.05$). The maximal HR in PLA (195 ± 8 bpm) was significantly higher than that in CAP (191 ± 11 bpm). There were no significant differences on the VO_2 , HR, respiratory exchange ratio, and fat oxidation during the 5 stages at submaximal workload among treatments, as well as the tissue saturation index, deoxyhemoglobin, and total

hemoglobin measured by near infrared spectroscopy. No significant differences were found on the peak (changes between before and after GXT: CAP vs. PLA vs. CON, -5.1 ± 4.9 vs. -4.8 ± 6.0 vs. -2.9 ± 3.5 %, $p > 0.05$) and mean (CAP vs. PLA vs. CON, -5.7 ± 5.4 vs. -4.8 ± 5.7 vs. -3.6 ± 2.5 %, $p > 0.05$) force during IMTP before and after GXT among treatments.

CONCLUSION: Capsaicin ingestion might not have ergogenic effects on the aerobic capacity and muscular strength in elite cyclists. Studies with larger sample sizes are needed to clarify the effects of capsaicin supplementation on aerobic capacity in athletes and to consider the impact of the placebo effect. EFFECT OF ACUTE GARLIC EXTRACTS SUPPLEMENTATION ON TRANSCRIPTION FACTORS OF MITOCHONDRIAL BIOSYNTHESIS IN EXERCISED HUMAN SKELETAL MUSCLE

LI, S., CHEN, R.Y., SHIH, K.H.

NATIONAL TAICHUNG UNIVERSITY OF EDUCATION

INTRODUCTION: Garlic extracts (GE) is a popular ingredient in daily life in Taiwan. It has various functions, such as anti-inflammation, anti-oxidation, and promoting blood circulation. The mitochondria of skeletal muscle cells produce ATP to provide energy for muscle movement throughout the body, thus promoting the synthesis of mitochondria in cells helps improve the aerobic capacity of the body.

METHODS: Eight active males with exercise habits were recruited to perform this crossover design study and randomized to GE or placebo group. The maximum oxygen uptake was measured 7 days before the single bout of cycling challenge with 75% $\dot{V}O_{2\max}$ at 60 rpm for 60 minutes. Muscle biopsied was performed immediately after the exercise, and then supplemented the 2000 mg garlic extracts or placebo capsule supplements accompany with a high-glycemic carbohydrate meal. The second muscle sample was collected at 3-hours after exercise, all muscle tissue were analyzed for transcript factor gene expression response to muscle cell mitochondrial biogenesis.

RESULTS: The gene expression of PGC-1 α was upregulated during exercise period in both GE and placebo group ($p < 0.05$). Simultaneously, the mitochondrial biogenesis-related transcription factors TFAM and FIS1 were significantly increased after post-exercise GE supplementation compared to placebo ($p < 0.05$). However, there were no influence on the gene expression response to SIRT1, NRF1, NRF2, MFN1, MFN2, DRP1, OPA1, and BECLIN-1.

CONCLUSION: Cycling exercise induced physiology stress masked the GE effect on gene expression of physiological signal PGC-1 α . However, the gene expression response transcription factors of muscle cell mitochondrial biogenesis cannot be upregulated under acute post-exercise GE supplementation.

EFFECT OF DIET RESTRICTION ON SKIN-GAS ACETONE CONCENTRATION BEFORE AND AFTER SUBMAXIMAL CYCLE EXERCISE

KOTOHA, Y., OGURI, H., KATO, R., OCHIAI, A., MATSUDAIRA, H., YAMADA, K., MIYAZAKI, M., TSUDA, T., ITOH, H.

NAGOYA INSTITUTE OF TECHNOLOGY

INTRODUCTION: Ketones (β -hydroxybutyrate, acetoacetate and acetone) are generated in mitochondria of the liver, mainly from the oxidation of fatty acids, and are exported to peripheral tissues, such as the brain, heart, kidney, and skeletal muscle for use as energy fuels [1]. In diabetic patients with impaired glucose metabolism, fatty acid oxidation in the liver is enhanced, leading to compensatory overproduction of ketone bodies, and consequently increase acetone concentrations in exhaled breath and skin gas [2]. On the other hand, it has been reported that acetone concentrations in exhaled breath and skin gas also increase in healthy individuals during exercise [3]. Thus, acetone concentrations in exhaled breath and skin gas are directly influenced by blood glucose levels and carbohydrate utilization capacity [4]. However, there are no reports on the effects of dietary restriction on acetone concentrations in skin gas before and after exercise. This study examined the effect of dietary restriction on skin gas acetone concentrations before and after submaximal exercise.

METHODS: Ten healthy male students (21.2 ± 0.5 years; mean $\pm$ SD) performed submaximal cycling exercise with incremental load under two conditions: normal diet (N) and dietary restriction (DR), each once. The order of N and DR for each participant was randomized with a two-week interval.

The skin-gas samples were obtained from the dominant hand by covering with a polyethylene bag in which pure nitrogen gas (250mL) was introduced for 100 sec and collected in a sampling bag at rest and 0, 15, 30 min after the exercise. Acetone concentration was analyzed by gas chromatography. Blood samples were obtained from fingertip to measure glucose and β -hydroxybutyrate concentrations.

RESULTS: The skin gas acetone concentrations significantly increased immediately after exercise compared to resting levels in both the N and DR conditions (<0.001) and tended to return to resting levels 30 minutes post-exercise. Furthermore, there was a significant interaction between time and condition (N and DR) in the changes in skin gas acetone concentrations before and after exercise ($p=0.025$). Thus, under the DR condition, not only were the resting values higher than those under the N condition, but the increase after exercise was also greater compared to the N condition.

CONCLUSION: About one day dietary restriction enhanced the increase in skin gas acetone concentrations at rest and after exercise compared to normal dietary intake. These results suggest that dietary restriction elevates ketone body production via hepatic fatty acid oxidation from resting levels and increases reliance on energy supply from fatty acid oxidation even during submaximal exercise.

BODY MASS INDEX VERSUS BODY FAT PERCENTAGE IN PROFESSIONAL SHOOTERS

GRANDA, D., SURALA, O., TUROWSKI, D., MALCZEWSKA-LENCZOWSKA, J.

INSTITUTE OF SPORT - NATIONAL RESEARCH INSTITUTE

INTRODUCTION: Obesity, particularly excessive visceral adipose tissue (VAT), is associated with various health risks, including cardiovascular diseases and diabetes. While BMI is a widely used and simple risk indicator, it has recognized limitations, especially in athletes, where it often overestimates obesity due to high lean body mass. Data on obesity rates among shooters remains limited. This study aimed to assess overweight and obesity prevalence based on body fat percentage compared to BMI and to evaluate VAT accumulation in male and female shooters.

METHODS: Basic anthropometric measurements (height and weight) as well as body composition analysis was performed in 39 professional shooters (51.3% females) aged 18-45 years old (mean 26.4 ± 6.4 years). Body composition was assessed via dual energy X-ray absorptiometry (DXA, GE, Lunar Prodigy). VAT expressed both in grams and cm³ was calculated automatically by the CoreScan application. Cut-off points for increased risk of metabolic complications based on VAT were adopted from the study by Miazgowski et al. (2019). In the case of body fat percentage, cut-off points were adopted from Jeukendrup A & Gleeson M (2019).

RESULTS: According to BMI, 75.0% of females had a normal body weight, 15.0% were classified as overweight, 5.0% had first-degree obesity, and 5.0% were underweight. Based on body fat percentage from DXA, a normal level was observed in 35.0%, while 35.0% were classified as overweight and 30.0% as obese. Among males, BMI indicated normal body weight in 52.6%, overweight in 21.1%, and obesity in 26.3%. In contrast, body fat percentage was within the normal range in 21.1% of males, while 21.1% were classified as overweight and 57.8% as obese. In both the female and male groups, statistically significant differences were found in the classification according to BMI vs. % body fat ($p=0.003$ and $p=0.031$, respectively). VAT content indicating an increased risk of metabolic complications was identified in one-third of the participants (35.0% of females and 33.3% of males, $p = 0.821$).

CONCLUSION: Body fat percentage allowed to indicate obesity in a significantly larger percentage of shooters than BMI. These are the opposite results from most sports disciplines. Shooters seem to be a group at increased risk of obesity and its complications, as evidenced by the high percentage of people with excessive VAT accumulation. Therefore, shooters should be subject to broader monitoring of cardiovascular health parameters and provided with nutritional education.

EFFECTS OF PROTEIN SOFT DRINK CONSUMPTION ON EXERCISE PERFORMANCE AND PHYSIOLOGICAL MEASURES

BALASEKARAN, G., MUSTAFFA, M.Z., POH, M.L., BOEY, P., NG, Y.C.

NANYANG TECHNOLOGICAL UNIVERSITY

INTRODUCTION: Protein is made up of amino acids to be used as an energy source and adequate intake and appropriate timing of protein ingestion are beneficial in multiple exercise modes, including endurance, anaerobic, and strength exercise. The carbohydrate-protein (CHO-P) drink provides an alternative for athletes to consume their protein with carbohydrates. This study investigated the effects of a CHO-P sports drink on physiological variables during aerobic performance; a comparison is made against carbohydrate (CHO) drink and water. It is hypothesized that consumption of the CHO-P drink will result in significantly better performance in the maximal oxygen consumption (VO₂max) test and other physiological measures.

METHODS: Ten male participants (age: 25.54 ± 2.76 years; height: 171.98 ± 7.31 cm; weight: 64.64 ± 9.34 kg; body mass index (BMI): 21.35 ± 2.47 kg/m²; body fat percentage: 12.37 ± 5.89 %; lean muscle mass percentage: 83.64 ± 5.53 %) were recruited for this study. The participants participated in three separate trials which took 2.5 hours each over three consecutive weeks in the Human Bioenergetics Lab at the National Institute of Education (NIE). They consumed 500ml of either CHO-P drink, CHO drink or water in a randomized order, with a 7-day rest between each trial. Participants underwent the modified Astrand protocol with treadmill gradient that increased by 2.5% after the first three minutes and every two minutes subsequently with the running speed kept constant at 10km/h. The test was terminated upon volitional exhaustion.

RESULTS: Paired t-test results indicated significant difference for absolute VO₂ at last stage between Water and CHO (Water: 3.18 ± 0.60 L/min vs. CHO: 3.36 ± 0.67 L/min, $p = 0.037$). One way ANOVA results indicated no significant differences for RPE last stage between trials ($p = 0.85$); resting HR between trials ($p = 0.91$); HR last stage between trials ($p = 0.65$); TTE between trials ($p = 0.98$). Significant negative correlation was found between BF% and VO₂max for all trials (BF%: 12.37 ± 5.89 % vs. Water VO₂max: 54.79 ± 8.97 mL/kg/min, $r = -0.73$, $p = 0.02$; BF%: 12.37 ± 5.89 % vs. CHO-P VO₂max:

56.47±9.51 mL/kg/min, $r = -0.75$, $p = 0.02$; BF%: 12.37±5.89 % vs. CHO VO2max: 55.91±9.19 mL/kg/min, $r = -0.74$, $p = 0.02$).

CONCLUSION: Participants exerted maximal effort across all trials as there were no significant differences between RPE and HR. With 14.0g of CHO found in CHO 500ml drink, participants produced significantly higher absolute maximal VO2 (L/min) as compared to the control group which was water. CHO-P sports drink was not significant when compared to CHO and water as protein is negligible during the glycolysis process of exercise as CHO is the main fuel for the working muscles. In addition, similarly as shown by other research, athletes and sports enthusiasts with a lower BF% would have a greater VO2max. Athletes and sports enthusiasts may utilize CHO drinks as opposed to water as a pre-workout drink to improve their VO2 to enhance sporting performance

IMPACT OF A 48-HOUR FASTING PERIOD ON METABOLIC MARKERS DURING EXERCISE AND RECOVERY IN MALE COMBAT SPORT ATHLETES

NERIJUS, E., SOLIANIK, R., CULHAOGU, A., YLAITE, B., GRIGUTIS, G., BRAZAITIS, M.
LITHUANIAN SPORTS UNIVERSITY

INTRODUCTION: Combat sports demand high-intensity efforts that predominantly rely on anaerobic energy systems and specialized technical skills. Athletes often employ rapid weight loss strategies such as a 48-hour fasting period to compete in lower weight categories, despite a recovery period of 24 hours or less that may not fully restore their physiological parameters. However, the impact of such fasting protocols on metabolic markers like glucose, ketone, and lactate concentrations and subsequent anaerobic performance during the recovery phase remains underexplored. This study aims to investigate the effects of a 48-hour fasting period on resting metabolic ratio, performance, and 1-hour recovery in male combat sports athletes, hypothesizing that while fasting induces metabolic changes, anaerobic performance is maintained after a 24-hour recovery period.

METHODS: This study involved eight male professional combat athletes, with an age of 25±3 years and body weight of 84±4 kg. The athletes underwent a 48-hour fasting period, followed by 24-hour recovery, with measurements taken at three time points: pre-fasting, after fasting, and post-recovery. The testing included assessments of resting substrate oxidation, lactate, glucose, ketone levels, and power output during VO2max test. Statistical analysis was conducted using Repeated Measures ANOVA to compare the metabolic and performance data across these phases.

RESULTS: Compliance with fasting regime was supported by decreased body weight ($p < 0.001$), carbohydrate oxidation ($p < 0.003$) and resting glucose concentration ($p < 0.028$), and by increased fat oxidation ($p < 0.001$) and resting ketone concentration ($p < 0.001$). Fasting decreased power output ($p < 0.008$), along with decreased peak lactate ($p < 0.049$) and glucose concentrations ($p < 0.028$) during VO2max test. However, metabolic changes and VO2max test performance output returned to baseline after 24-h recovery period.

CONCLUSION: 48-h fasting temporarily suppressed metabolic changes and VO2max test performance in professional combat athletes. After recovery period restored metabolic changes indicate the ability to restore glycogen levels and sustain performance.

This research was funded by the Research Council of Lithuania (grant number S-MIP-23-84).

EFFECT OF INULIN SUPPLEMENTATION ON GUT MICROBIOTA AND ATTENTIONAL BIAS FOR FOOD

KONISHI, K., MIYAKOSHI, Y., MURAKAMI, H.
TOYO UNIVERSITY; RITSUMEIKAN UNIVERSITY

INTRODUCTION: Dietary fiber is fermented by gut microbiota, resulting in the production of short-chain fatty acids (SCFAs). The endocrine signals, such as the secretion of appetite-regulating hormones, and mechanical signals are induced by dietary fibers and SCFAs play a direct role in central appetite regulation (Frost et al., Nat Commun. 2014). Although it has been reported that inulin supplementation reduces energy intake and body weight, the effects on attentional bias for food which influence cravings and food consumption are not clear. Overweight is related to the greater attentional bias for food (Yokum et al., Obesity. 2011). The purpose of this study is to examine the effects of 6-weeks of inulin supplementation on gut microbiota, SCFAs, and attentional bias for food.

METHODS: In this double-blind study, twenty-six healthy adults (aged 20–48 years; BMI 22.4 ± 2.6 kg/m²) were assigned to treatment groups receiving 5g of inulin powder twice a day (IF group, n=13) and control groups receiving 5g of maltodextrin twice a day (PL group, n=13) for 6 weeks. Attentional bias for food, habitual eating behavior and dietary intake through self-reporting measures, gut microbiota composition by 16S rRNA sequencing of fecal samples, fecal levels of SCFAs, and blood levels of appetite-regulating hormones (leptin, ghrelin, peptide YY and insulin) were assessed before and after the intervention. Attentional bias for food was evaluated using reaction time in the visual dot-probe task with food and non-food images. The engagement and disengagement components of attentional bias were assessed. The disengagement component of attentional bias is the degree to which a food-related stimulus captures attention, preventing the reorientation of attention towards a different location. A linear mixed effects model, with group and time (pre- and post-intervention) as factors, was used to examine the interaction effects on the outcomes.

RESULTS: There was significant interaction on the disengagement component of attentional bias for high-calorie foods ($P = 0.034$), which was higher after intervention than before in PL ($P = 0.015$) but not in IF. The relative abundance of Bifidobacterium increased after the intervention in IF (pre-intervention 5.0 ± 1.5 % vs. post-intervention 8.6 ± 1.5 %, $P = 0.011$) but not in PL (pre-intervention 6.8 ± 1.5 % vs. post-intervention 6.2 ± 1.5 %), which resulted in significant interaction on the

relative abundance of *Bifidobacterium* ($P=0.032$). The fecal levels of SCFAs and blood levels of appetite-regulating hormones showed neither significant interactions nor effects of group.

CONCLUSION: These findings indicate that 6-weeks of inulin supplementation prevented the increase in attentional bias for high-calorie foods, and that such prevention seems to be related to the increase in the relative abundance of *Bifidobacterium*. The mechanical effects rather than endocrine effects induced by inulin may have contributed more to central appetite regulation in this study.

EFFECTS OF CINNAMALDEHYDE ON THE MUSCULAR ENDURANCE OF THE TIBIALIS ANTERIOR MUSCLE IN RAT

TAKAHIRO, F., RYOYA, O., CHEN, Y.C., YOSHIHIRO, N., HIROYUKI, T.

NATIONAL INSTITUTE OF FITNESS AND SPORTS IN KANOYA

INTRODUCTION: Muscular endurance is a key determinant of sports performance, as it prolongs exercise duration and delays fatigue accumulation. Cinnamaldehyde has been suggested to promote energy metabolism and exhibit antioxidant properties, potentially enhancing endurance. While its precise effects remain unclear, its known antioxidant and anti-inflammatory actions may help reduce oxidative stress, a major contributor to muscle fatigue. However, direct research on its impact on muscular endurance is limited.

METHODS: Male Fischer 344 rats (6-7 weeks of age, $n=12$) were divided into two groups: a cinnamaldehyde-treated (CN) group and a control (Cont) group. Cinnamaldehyde was administered intraperitoneally twice per week for eight weeks at a dose of 20-50 mg/kg body weight. Following the intervention, muscular endurance and maximal isometric force of the tibialis anterior (TA) muscle were assessed in vivo using an electrical stimulator and force transducer. Time-course changes in unfused (50 Hz) and fused (143 Hz) tetanic forces were recorded at stimulation intensities corresponding to maximal force (16-25 V). Following force measurements, TA muscles were excised, subjected to NADH-TR staining, and analyzed for myofiber cross-sectional area using light microscopy and an image analysis system.

RESULTS: There was no significant difference in maximal force between the CN and Cont groups. The force-time curves for both unfused and fused tetanic contractions were greater throughout the stimulation period in the CN group than in the Cont group. The force-time integral (FTI) during the first 10 seconds of both tests was significantly greater in the CN group. The cross-sectional areas of myofibers with intense or light NADH-TR staining did not significantly differ between groups.

CONCLUSION: These findings suggest that cinnamaldehyde administration may enhance muscular endurance, particularly during the initial phase (0-10 s) of unfused and fused tetanic contractions, without inducing hypertrophy or altering fiber composition. This effect may be attributed to its antioxidant properties, which could reduce oxidative stress during sustained contractions.

EFFECTS OF CAFFEINE AND CARBOHYDRATE SUPPLEMENTATION BEFORE ENDURANCE EXERCISE ON POST-EXERCISE BLOOD PRESSURE AND PULSE WAVE VELOCITY IN HYPERTENSIVE INDIVIDUALS

WANG, H.S., HUANG, I.H., WU, T.W., TSAI, Y.S.

NATIONAL TAIWAN NORMAL UNIVERSITY

INTRODUCTION: This study aimed to investigate the effects of caffeine and carbohydrate supplementation before endurance exercise on post-exercise blood pressure and brachial-ankle pulse wave velocity (baPWV) in hypertensive individuals.

METHODS: Fourteen hypertensive males (33.1 ± 8.1 years, systolic blood pressure 139.7 ± 0.6 mmHg, diastolic blood pressure 84.8 ± 1.0 mmHg) with no regular exercise habits participated in a double-blind, repeated-measures, counterbalanced-order experiment. They underwent four experimental trials: caffeine with carbohydrate (CAFCHO), caffeine with water (CAFWAT), placebo with carbohydrate (PLACHO), and placebo with water (PLAWAT). The supplementation protocol involved ingesting either a caffeine or placebo capsule at a dose of 3 mg per kg of body weight, combined with 250 mL of either a carbohydrate solution containing 75 g of glucose or plain water. Participants rested for 30 minutes after ingestion, followed by 30 minutes of treadmill running at 70% heart rate reserve. Blood pressure and baPWV were measured at baseline, pre-exercise, and at 30, 60, 90, and 120 minutes post-exercise. Additionally, blood samples were collected to analyze insulin, blood glucose, endothelial nitric oxide synthase (eNOS), and endothelin-1 (ET-1). The area under the curve (AUC) was calculated using the trapezoidal method for each time point post-supplementation.

RESULTS: A significant interaction was observed for systolic blood pressure ($p = .001$). Systolic blood pressure at 30, 60, and 90 minutes post-exercise was significantly lower than pre-exercise levels in the PLACHO and PLAWAT trials. The AUC for systolic blood pressure was significantly higher in the CAFCHO trial compared to PLAWAT, and in the CAFWAT trial compared to both PLACHO and PLAWAT ($p < .05$). A significant interaction was also observed for diastolic blood pressure ($p < .001$), with CAFCHO showing significantly higher diastolic blood pressure at 30 and 120 minutes post-exercise compared to PLAWAT, and at 30 and 60 minutes post-exercise compared to PLACHO. Additionally, CAFWAT showed significantly higher diastolic blood pressure at 60 and 90 minutes post-exercise compared to PLACHO. A significant interaction was also found for baPWV ($p = .001$), with CAFCHO and CAFWAT showing significantly higher AUC for baPWV at all post-exercise time points compared to PLAWAT ($p < .05$). Regarding blood biomarkers, the AUC for insulin and blood glucose was significantly higher in the CAFCHO and PLACHO trials compared to CAFWAT and PLAWAT ($p < .001$). However, no significant differences were found in the AUC of eNOS and ET-1 among the trials.

CONCLUSION: Caffeine supplementation at a dose of 3 mg per kg of body weight before endurance exercise attenuated the post-exercise reduction in blood pressure and baPWV in hypertensive individuals. This effect was independent of carbohydrate supplementation.

IS THERE ANY EFFECTS OF ACUTE CITRULLINE OR MALIC ACID SUPPLEMENTATION?

SZMODIS, M., BARÁTH, A.1, ANNÁR, D.2, GYÖRE, I.1

HUNGARIAN UNIVERSITY OF SPORTS SCIENCE

INTRODUCTION: Improving the aerobic metabolism is important for endurance athletes. Main aim of this pilot study was to examine if acute citrulline and malic acid supplementation can improve aerobic metabolism and lactate elimination.

METHODS: Nine young recreational male athletes (23.9 ± 1.9 years) participated in our study. Participants took a standardised breakfast and their body composition were measured (InBody720).

One hour before the spiroergometry 6 000 mg of citrulline or 3 000 mg of malic acid or a placebo of 300 mL of water were consumed on three different separate days using a double-blind method. They completed a ramp bicycle spiroergometer protocol (35 W/3 min) until reaching a respiratory exchange ratio (RER) of 1.1, followed by a 9 min active recovery. Heart rate (HR), rate of perceived exertion (RPE – Borg-Scale), cadence, different respiratory parameters and lactate levels were registered. To accurately characterise exhaustion we calculated the RPE_{HR} value.

RESULTS: Friedman ANOVA tests revealed significant differences in RER values during the exercise protocol at 70 W ($\chi^2 = 6.889$; $p < 0.05$; Kendall's $W = 0.383$), 105 W ($\chi^2 = 10.667$; $p < 0.05$; Kendall's $W = 0.593$) and 140 W ($\chi^2 = 8.222$; $p < 0.05$; Kendall's $W = 0.457$). Additionally, Bonferroni-corrected Wilcoxon pairwise comparisons revealed that citrulline significantly reduced RER values at powers of 70 W, 105 W and 140 W compared to malic acid (Wilcoxon, $Z = -2.31$, $Z = -2.67$, and $Z = -2.67$; $p < 0.0167$) and compared to the placebo (Wilcoxon, $Z = -2.19$, $Z = -2.43$, and $Z = -2.31$; $p < 0.0167$).

There was no difference in lactate levels neither during rest nor at RER 1.1.

RPE_{HR} rate values were significantly lower after malate supplementation compared to placebo at 175 and 210 W (Wilcoxon, $Z = -2.36$, and $Z = -2.37$; $p < 0.0167$).

Performance at RER 1.1 was higher after malic acid (+4 W) and citrulline (+5 W) supplementation. However lactate levels did not decrease after supplementation, lower RER and RPE values may indicate a performance-enhancing benefit.

CONCLUSION: Supplementation of citrulline and malic acid might be beneficial for endurance athletes, especially in delaying the onset of glycogen depletion and preventing fatigue.

ACUTE EFFECTS OF ORAL MICROBIAL PROTEASE CO-INGESTION WITH WHEY PROTEIN ON POSTPRANDIAL PLASMA AMINO ACID CONCENTRATIONS, APPETITE, AND SATIETY IN HEALTHY ADULTS

HUANG, Y., BELL, Z.W.1, ALHAMWI, A.1, SAUVAGEAU, B.1, GARDY, S.1, KARUTH-IBARZ, T.1, HANNAIAN, S.J.1, CORREA, J.1, GRITSAS, A.1, GARVEY, S.M.2, ABOU SAWAN, S.3, MORAIS, J.1, CHURCHWARD-VENNE, T.A.1

1 MCGILL UNIVERSITY, MONTRÉAL, QC, CANADA; 2 BIO-CAT, INC., TROY, VIRGINIA, USA; 3 IOVATE HEALTH SCIENCES INTERNATIONAL, OAKVILLE, ON, CANADA.

INTRODUCTION: Proteases are enzymes that catalyze the breakdown of proteins into smaller peptides and amino acids. Protease supplementation may be a candidate approach to enhance amino acid digestion and absorption from dietary protein. The present study aimed to evaluate the effects of a mixture of 3 microbial protease preparations (P3) on postprandial plasma amino acid concentrations when co-ingested with whey protein concentrate (WPC), compared to a maltodextrin placebo, in healthy young adults. Secondary aims were to assess the effect of WPC co-ingestion with P3 versus placebo on postprandial plasma glucose, insulin, and gut-derived appetite regulatory hormone (GLP-1, PYY, and ghrelin) concentrations, perceived appetite sensations, and ad libitum meal energy intake.

METHODS: In this randomized, double-blinded, placebo-controlled crossover study, 12 males and 12 females (BMI: $23.6 (2.9)$ kg/m²; age: $25 (3)$ years [mean (SD)]) consumed WPC (25 g protein) with P3 or placebo. Plasma glucose, insulin, amino acid, and gut-derived appetite regulatory hormone concentrations were assessed at baseline, and throughout a 240-min postprandial period. Perceived appetite sensations were assessed by visual analog scale (VAS) questionnaires. An ad libitum meal was provided immediately following each trial to determine energy intake. The incremental area-under-the-curve (iAUC) and ad libitum energy intake data was compared between treatments using a mixed model ANCOVA, adjusting for treatment period, treatment sequence, and sex. Time-course data were analyzed via a mixed model repeated measures approach adjusting for baseline values, treatment period, treatment sequence, and sex. All hypothesis tests were two sided and performed at the $\alpha = 0.05$ significance level.

RESULTS: Adjusted mean postprandial plasma 60-min iAUC was 14% greater for plasma essential amino acids (EAA) (Treatment: $P = 0.025$) and 15% greater for branched-chain amino acids (BCAA) (Treatment: $P = 0.021$) with P3 versus placebo, with no significant differences for total amino acids or leucine (all $P > 0.05$). Adjusted mean postprandial plasma ghrelin was 12% lower (Treatment: $P < 0.001$), while adjusted mean VAS-derived fullness (Treatment: $P = 0.025$) and satiation (Interaction: $t = 30$ – 150 min; all $P < 0.05$) were greater with P3 versus placebo. Adjusted mean postprandial plasma glucose, insulin, GLP-1 and PYY, as well as ad libitum meal energy intake were not different between treatments (all $P > 0.05$).

CONCLUSION: Co-ingestion of WPC with P3 increases postprandial plasma 60-min iAUC for EAA and BCAA concentrations, decreases plasma ghrelin concentration, and increases perceptions of fullness and satiation compared to co-

ingestion of WPC with a placebo in young, healthy adults. Microbial protease supplementation may represent a practical strategy to further increase postprandial plasma amino acid availability and enhance satiety after dietary protein intake. This trial was prospectively registered at ClinicalTrials.gov (NCT05957185).

7-DAY CONTINUOUS GLUCOSE MONITORING TO ASSESS GLUCOSE VARIABILITY IN JAPANESE NIGHT SHIFT WORKERS

HIRASAWA, A., MURATA, H.1, TAKANO, D.1, SAKURAI, A.1, FUKUIE, M.1, SAITO, S.2, SUZUKI, R.1, HORINO, M.1, MATSU-SHIMA, S.1, MATSUDA, T.1, SHIBATA, S.1

1> KYORIN UNIVERSITY; 2> TOYO UNIVERSITY

INTRODUCTION: Healthcare workers engaged in both day and night shifts are exposed to the risk of developing lifestyle-related diseases due to disruptions in daily routines and the excessive stress caused by night work. Previous studies have shown that healthcare workers with night shifts have a higher risk of obesity, metabolic syndrome, and cardiovascular diseases compared to those without night shifts (X. Lin et al., *Sleep Medicine*, 2015). Additionally, a cohort study in the United States reported that night shift workers have a higher incidence of type 2 diabetes compared to non-night shift workers (Zhilei Shan et al., *BMJ*, 2018). Dietary habits differ significantly between Japan and the United States. Therefore, it remains unclear whether the same results would be observed among Japanese night shift workers. Furthermore, not only hyperglycemia but also glucose spikes and variability have been reported as risk factors for lifestyle-related diseases such as diabetes and atherosclerosis. Recently, continuous glucose monitoring devices have been developed, enabling precise and continuous measurement of glucose levels in a simple and sustainable manner. These devices also allow for the assessment of glucose variability, opening up various possibilities for research and clinical applications. This study investigated the effects of night shift work on glucose variability in Japanese workers using 7-day continuous glucose monitoring.

METHODS: Twenty night shift workers (31±4 years old) and 20 non-night shift workers (30±5 years old) participated in the study. Continuous glucose monitoring (CGM; Abbott Diabetes Care, Japan) was conducted, measuring interstitial fluid glucose concentrations every 15 minutes for 7 days. Data from the CGM were used to calculate the following parameters: the mean glucose level, standard deviation (SD), J-index ($0.001 \times (\text{mean} + \text{SD})$), Time in Range (TIR; percentage of time within 70-180 mg/dL), Time Above Range (TAR; percentage of time above TIR), Time Below Range (TBR; percentage of time below TIR), and the area under the curve (AUC; total entire glucose curve), which reflects overall glucose variability.

RESULTS: The mean glucose level and AUC were significantly lower in the night shift workers compared to the non-night shift workers. The night shift workers also showed reduced TIR and increased TBR compared to the non-night shift workers. However, there were no significant differences in SD, J-index, or TAR between the two groups.

CONCLUSION: Night shift workers exhibited a higher frequency of hypoglycemia compared to non-night shift workers. These findings differ from prior studies conducted in the United States, which may be due to differences in dietary habits between Japan and the United States, influencing glucose metabolism during night shift work. The results highlight the importance of appropriate dietary interventions to prevent hypoglycemia during night shifts among Japanese night shift workers.

ATTEMPT TO QUICKLY ASSESS DEHYDRATION IN THE FIELD: DERIVATION OF CAUSAL RELATIONSHIPS BY AI ANALYSIS

HASHITOMI, T., MURATA, M., KIMURA, F., WATANABE, K.

TSUKUBA UNIVERSITY

INTRODUCTION: Accurate assessment on body water content to prevent dehydration is important for athletes. At present, it remains a simple evaluation such as weight loss and self-monitoring by athletes. One method of assessing dehydration is plasma osmolality in blood sample is a useful assessment. Also, plasma osmolality can be calculated using the following equation if data on sodium, glucose and urea nitrogen are available: $\text{Plasma osmolality} = 2 \times (\text{Na}) + \text{glucose}/18 + \text{BUN}/2.8$. However, analysis of blood samples requires qualified personnel and precise equipment and analysis is time consuming. Therefore, analyze and evaluate immediately in the field is not easy. If plasma osmolality can be directly evaluated using an optimal combination of non-aggressive samples such as saliva and sweat with a portable measuring device, it may be possible to prevent dehydration and strategically select drinks. The purpose of this study is to develop and evaluate a new dehydration prediction equation from indicators that can be easily collected in the field. As a first step, we attempted to estimate sodium, which constitutes the majority of the plasma osmolality equation.

METHODS: We collected the following samples from 11 track and field female athletes at the University of Tsukuba: body composition, blood (sodium, glucose, and the like), saliva (sodium, osmolality), sweat on patched forearm (sodium), and air temperature. Each subject was asked to run on the road for 50 minutes at low intensity as warm up. We collected each sample before and after exercise. They also did not drink water until the experiment was over. After blood samples were collected, they were transported to a specialized laboratory for analysis. Saliva osmolality analyzed by mean of freezing point depression using osmometer (OSMOMAT 3000 basic, Asahi life tec, Japan). Saliva sodium and sweat sodium were analyzed with a compact water quality meter (LAQUO twin, HORIBA, Japan). Next, we analyzed causal inference using AI analysis software (xCausal, Japan) to derivation of causal relationships. Causal inference by AI analysis using following statistical methods average treatment, mutual information and correlation analysis.

RESULTS: Overall average temperature from each experimental day was 28 ± 2.2 °C. Blood sodium was set as the output, and salivary sodium, salivary osmotic pressure, sweat sodium, air temperature, and weight loss which could be collected in the field, were set as the input data. From there, items for which no causal relationship was found were eliminated, and

finally, salivary sodium (0.09, 0.29, 0.32) and air temperature (0.70, 0.58, 0.97) were related. (Figures in parentheses are average treatment effect, mutual information and correlation analysis in order.)

CONCLUSION: Although the number of samples was too small to derive a causal relationship, it was suggested that salivary Na and temperature may be related to reflect serum Na. Future validation is needed to increase the number of samples and the precision of measurement.

BOTH 3 AND 6 MG/KG CAFFEINE IMPROVED 4-KM CYCLING TIME TRIAL PERFORMANCE IN TRAINED MALE CYCLISTS WITH LOW HABITUAL CAFFEINE CONSUMPTION

REGISTRO DA COSTA, L., MURASAKI, J., NUNES, T., SANTOS, D., MARINHO, L., SAUNDRES, B.
UNIVERSIDADE DE SÃO PAULO

INTRODUCTION: Caffeine (1,3,7-trimethylxanthine) is a naturally occurring central nervous system stimulant that, at doses of 3–6 mg/kg body mass (BM), provides an ergogenic benefit during exercises across various exercise modalities, durations and intensities [1]. The potential influence of habitual caffeine consumption on caffeine's acute ergogenic effect is a hotly debated topic in sports science [2]. Low habitual caffeine users have been shown to benefit from caffeine supplementation, though it is unclear if there is a dose-response effect in this population. The objective of this study was to evaluate the effects of two different doses of acute caffeine supplementation on 4-km cycling time trial performance in low habitual caffeine consumers.

METHODS: Thirty-two trained cyclists with low caffeine intake (<75 mg/day) completed a 4-km cycling time trial 60-min after ingesting 3 mg/kg of caffeine (CAF3; Farmácia Analítica, Brazil), 6 mg/kg of caffeine (CAF6) and placebo (PLA) in a double-blinded and randomized manner. Performance was recorded as time-to-completion. A generalized mixed model was used to analyze the effect of supplementation on time-to-completion, with supplementation as a fixed effect and significance set at $p < 0.05$.

RESULTS: There was a significant effect of supplementation ($\chi^2 = 20.8$, $p < 0.001$). Post hoc tests showed that PLA significantly differed from both CAF3 (435 ± 29 vs. 422 ± 27 s; $p < 0.001$) and CAF6 (435 ± 29 vs. 423 ± 28 s; $p < 0.001$), with no differences between CAF3 and CAF6 ($p = 1.000$).

CONCLUSION: Acute caffeine supplementation improved performance when compared to placebo in low habitual consumers of caffeine. However, there was no additional benefit from a higher dose (6 mg/kg) compared to a lower dose (3 mg/kg). These findings suggest that 3 mg/kg of caffeine is sufficient to elicit performance improvements in low habitual caffeine consumers while potentially minimizing the risk of side-effects associated with higher doses.

FOOD PROCESSING LEVEL AFFECTS NUTRIENT INTAKE OF ADOLESCENT ATHLETES

ROMANELLI MOLLINI DA SILVA, R., JÉSSICA FERREIRA, T., RIBEIRO PESSANHA, C., DE SOUZA LOPES, T., AUBUQUERQUE PENNA FRANCA, P., TRINDADE ROCHA PIERUCCI, A.P.
FEDERAL UNIVERSITY OF RIO DE JANEIRO

INTRODUCTION: Adolescent athletes have high nutritional demands due to the high use of macro and micronutrients for their growth and development and energy production, muscle contraction and recovery. Thus, nutrient intake must be adequate to ensure that all demands are met while maintaining sports performance and adequate growth. It is also important to identify which foods are capable of assisting in adequate nutrient intake. Therefore, we sought to identify how much the participation of NOVA food groups in the diet can affect the nutrient intake of adolescent athletes.

METHODS: Adolescent athletes ($n=94$, 13.5 ± 2.21 years old, body mass index (BMI) 19.92 ± 3.32 kg/m²), of both genders (F: $n=31$, M: $n=63$) and different modalities had their diet assessed through 3 24-hour food recalls. The reported foods were used to estimate nutrient intake, divided into subgroups and allocated within the NOVA classification groups: natural and minimally processed; processed; ultra-processed. Then, the average energy intake of each subgroup and group of the NOVA classification and their energy contribution were calculated. The level of energy contribution of each of the NOVA groups was expressed in contribution tertiles. Finally, the association between the level of energy contribution of the groups and the average nutrient intake was assessed.

RESULTS: The consumption of natural and minimally processed foods represented 49.3% of the total energy intake of the study participants. Next, ultra-processed foods accounted for 34.21%. And processed foods contributed 16.5%. The higher the participation of natural and minimally processed foods in the total intake, the higher the intake of fiber, protein, iron, magnesium, phosphorus, zinc, folic acid, vitamin C and vitamin E, and the less sodium and fat were ingested. As the level of processed food intake increased, lower intakes of fiber, protein, iron, magnesium, phosphorus, zinc, and vitamins B3 and C, and higher intakes of fat and sodium were observed. The higher level of energy contribution from ultra-processed foods was associated with lower intakes of fiber and protein and higher intakes of sodium.

CONCLUSION: The greater inclusion of natural and minimally processed foods in the diet may contribute to a higher intake of nutrients important for maintaining health and performance, while processed and ultra-processed foods negatively affect the intake of these nutrients and increase the intake of nutrients that are markers of unhealthy eating. Therefore, adolescent athletes should follow the current Brazilian guidelines for healthy eating, which recommend making natural and minimally processed foods the basis of the diet; reducing the consumption of processed foods and avoiding ultra-processed foods.

THE EFFECT OF NUTRITION ON BODY COMPOSITION AND PHYSICAL PERFORMANCE AMONG ESTONIAN JUNIOR CYCLISTS.

KÄNGSEPP, A., JÄÄGER, L., REMMEL, L., PURGE, P.

UNIVERSITY OF TARTU

INTRODUCTION: The purpose was to evaluate the effect of nutrition on physical performance among Estonian M16 and MJ competition class cyclists.

METHODS: A total of 12 Estonian junior cyclists (16.2±1.3 years; 182.0±5.8 cm; 70.0±7.2 kg; BMI: 21.1±1.9 kg/m²) participated in the study. All participants regularly trained at least five times a week and had a goal to achieve the highest place in the Estonian national championships of their age group. Body composition was measured by dual-energy X-ray absorptiometry (DPX-IQ densitometer Hologic, Discovery W, USA) and maximal oxygen consumption was measured by Cyclus 2 ergometer (RBM Elektronik-automation GmbH, Germany). Oxygen consumption was determined by the Cortex Metamax 3B (Cortex Biophysic GmbH, Leipzig, Germany). In addition, a 3-day (2 working days and one weekend day) caloric intake and activity was measured by questionnaire.

RESULTS: Cyclists had on all days a negative energy balance, remaining at -303.5±604.0 kcal on average over the study days. VO₂max and Pmax, were correlated ($p<0.05$) with KRVm ($r=0.81$), body mass ($r=0.78$), but no nutritional parameter correlated with the parameter characterizing performance ($p>0.05$). KRVm had the greatest effect on the change in maximal oxygen consumption (VO₂max) by 67% ($F=23.8$, $p=0.001$).

CONCLUSION: Based on the results of this study, it can be concluded that there is no direct relationship between nutrition and physical performance. However, nutrition affects body composition and body mass index, which in turn are related to and influence physical performance. It is important to pay attention to the parameters of nutrition in order to support physical performance through nutrition and body composition.

EFFECTS OF KETOSIS ON SKELETAL MUSCLE MOLECULAR RESPONSE TO A SINGLE BOUT OF RESISTANCE TRAINING IN TRAINED INDIVIDUALS

CERULLO, G., CHARRIER, D., CANATO, M., BASSETTO, F., VINDIGNI, V., BASTIN, A., MONTANARI, A., FRANCHI, M.V., MORO, T., PAOLI, A.

UNIVERSITY OF PADUA DEPARTMENT OF BIOMEDICAL SCIENCES

INTRODUCTION: The ketogenic diet (KD) is a well-established dietary strategy, widely recognized for its efficacy in promoting fat loss. It is characterized by high fat, adequate protein, and restricted carbohydrate intake (<50 grams per day). The KD mimics certain effects of caloric restriction by enhancing metabolic pathways involved in fat oxidation and oxidative phosphorylation. However, KD-induced metabolic adaptations may potentially interfere with pathways regulating the hypertrophic response. Therefore, this study aims to investigate the impact of KD on muscle adaptation to resistance training (RT) in trained male subjects.

METHODS: Fifteen healthy, trained males (28.8 ± 8.3 years) were enrolled and randomly assigned to either a ketogenic diet (KD, n=8) or control diet (CD, n=7). Both diets were isoenergetic (35 kcal/kg body weight) and matched for protein intake (2 g/kg body weight). All participants followed an identical RT protocol for four weeks. Serum hormone levels (IGF-1, insulin, total and free testosterone), resting metabolic rate, body composition (DXA), quadriceps cross-sectional area (ultrasound), and muscle strength were assessed at baseline and after 4 weeks of RT. Muscle biopsies from the vastus lateralis were obtained at rest, and at 6 and 24 hours after a single bout of RT performed before and after 4 weeks of KD. Phosphorylation of regulatory signalling proteins (i.e., Akt, rpS6, 4E-BP1, and p70S6K1) were assessed via western blotting and expressed as the fold-change from pre- to post-exercise.

RESULTS: Preliminary data indicate that the KD group exhibited higher fat oxidation, as reflected by a greater reduction in respiratory exchange ratio (-12% vs. -6%). Serum insulin levels decreased more markedly in the KD group (-26% vs. -6%), whereas IGF-1, total testosterone, and free testosterone remained unchanged in both groups. No significant between groups differences were observed in fat-free mass; however, the KD group experienced a greater reduction in fat mass (-1.6 kg vs. +0.2 kg in the CD group). Markers of the mTOR signalling pathway (total and phosphorylated Akt, 4E-BP1, rpS6) were comparable between KD and CD.

CONCLUSION: These preliminary findings suggest that four weeks of KD combined with RT improves body composition without impairing post-exercise hypertrophic signalling.

EFFECTS OF SHORT-TERM ADAPTATION TO KETOGENIC DIET ON BODY COMPOSITION, FAT OXIDATION, ENDURANCE PERFORMANCE, MUSCLE GLYCOGEN, AND PREFRONTAL HEMODYNAMIC RESPONSES IN ENDURANCE TRAINED ATHLETES

CHARRIER, D., DE LIMA-JUNIOR, D., MONTANARI, A., CERULLO, G., LIBARDONI, L., GIVRALLI, J., STIRCU, V., CANATO, M., BASSETTO, F., VINDIGNI, V., MARCORA, S., MORO, T., PAOLI, A.

UNIVERSITY OF PADOVA

INTRODUCTION: Ketogenic Diets (KD) have been proposed to enhance endurance performance by increasing fat oxidation. However, their effects on muscle glycogen availability remain unclear, with some evidence suggesting a glycogen-sparing effect following adaptation. Additionally, the potential performance benefits of nutritional ketosis—through increased ketone oxidation and reduced perception of fatigue—remain controversial. Therefore, the aim of this study was to investigate the effects of short-term KD adaptation on: (1) moderate-intensity endurance performance and (2) subsequent high-intensity endurance performance under glycogen-depleted conditions.

METHODS: To date, eight trained endurance athletes (age: 28.3 ± 3.8 years; $\text{VO}_{2\text{max}}$: 56.08 ± 8.3 mL/kg/min) have been enrolled. Following a one-week standardized diet (50% carbohydrates, 2.0 g/kg/day protein) and habitual training, participants were randomly assigned to either a KD diet (<5% CHO, 2.0 g/kg/day protein) or a control diet (CD) (>55% CHO, 2.0 g/kg/day protein) for 10 days, while continuing their usual endurance training. Body composition was assessed at baseline and after the intervention period using dual-energy X-ray absorptiometry (DXA) and bioelectrical impedance analysis (BIA). Additionally, after an overnight fast, participants performed a two-hour cycling protocol on a cycle ergometer at 55% of peak power output to induce glycogen depletion. Oxygen uptake (VO_2), respiratory quotient (RQ), and substrate utilization (g/h) were measured for 5 minutes every 15 minutes of exercise using a gas analyzer (COSMED CPET). Pre- and post-exercise muscle biopsies (vastus lateralis) were collected to quantify glycogen content. Following the depletion protocol, time to exhaustion (TTE) was assessed using an incremental protocol (starting at 75% $\text{VO}_{2\text{peak}}$, increasing power by 5% every 5 minutes). Functional near-infrared spectroscopy (fNIRS) was used to evaluate prefrontal hemodynamic responses during TTE.

RESULTS: Preliminary data suggest that the KD group experienced a reduction in total body water (-3% vs. +1%) and body weight (-3% vs. +0.5%) compared to the control group. Additionally, fat oxidation rates were markedly increased during exercise in the KD group (+156%) relative to controls (+3%), while gross efficiency declined (-2% vs. +0.3%). Notably, high-intensity endurance performance was impaired in the KD group, as evidenced by a shorter TTE (-7 min vs. +7 min) compared to the control group.

CONCLUSION: These preliminary results suggest that short-term adaptation to a KD diet reduces total body water and body weight. However, while this dietary approach enhances fat oxidation during exercise, it appears to reduce gross efficiency and impair subsequent high-intensity endurance performance. Further analyses will include an increased sample size, muscle biopsies data, and fNIRS evaluations to strengthen and expand these findings.

THE EFFECTS OF CURCUMIN SUPPLEMENTATION ON NEUROMUSCULAR PERFORMANCE IN OLDER ADULTS: A SYSTEMATIC REVIEW.

LOPEZ-SAMANES, A., GARCÍA, A., SÁNCHEZ-IZQUIERDO, M., GAOS, S., CASTAÑEDA-BABARRO, A., MATOS-DUARTE, M., GARCÍA-SÁNCHEZ, R., LEÓN-GUEREÑO, P.

UNIVERSIDAD PONTIFICIA COMILLAS

INTRODUCTION: Curcumin is the most abundant phenolic compound in turmeric (*Curcuma longa*) and is widely recognized for its potent antioxidant and anti-inflammatory properties, as well as its role in mitigating exercise-induced muscle damage. However, its effects on neuromuscular performance remain relatively unexplored, particularly in older adults. It is hypothesized that curcumin supplementation may enhance neuromuscular performance in this population by improving muscle strength, reducing inflammation-induced muscle deterioration, and mitigating oxidative stress. Therefore, the aim of this systematic review was to assess the effects of curcumin ingestion on neuromuscular performance in older adults.

METHODS: A literature search was conducted using two databases: PubMed and Web of Science. Eligibility criteria were established following the PICOS method. Articles were selected based on the following inclusion criteria: curcumin intake, neuromuscular performance, older adults (i.e., >65 years old), and human participants. Neuromuscular performance parameters, such as isometric handgrip strength, knee flexion strength, short physical performance battery (SPPB) and walking speed, were analyzed.

RESULTS: A total of 187 studies were identified across the two databases. After screening titles and abstracts, 32 duplicate studies were removed, and 126 studies were excluded for not being relevant to the review topic. This left 29 studies for full-text eligibility assessment. After applying the exclusion criteria, five studies were ultimately included in this systematic review.

CONCLUSION: Current evidence suggests that curcumin supplementation, particularly when combined with piperine, may improve neuromuscular function in the upper body (i.e., isometric handgrip strength) in older adults. However, there is limited evidence regarding its effects on lower-body neuromuscular performance, such as knee flexion strength or walking speed. Therefore, further research is needed to better understand the effects of curcumin supplementation on overall neuromuscular performance in older adults, particularly in lower-limb function, to determine its full potential in preserving muscle health and mobility in aging populations.

EXERCISE INTENSITY AND SELF-EFFICACY TO ADHERE TO AN EXERCISE PROGRAM: CAN SEX BE A DETERMINANT FACTOR FOR YOUNG ADULTS?

ARABSHAHI, D., BARBIERI, R.A., ABBASSIAN, M., MARCORA, S.M.

BOLOGNA UNIVERSITY

INTRODUCTION: Maintaining a regular exercise routine is essential for health and quality of life. Evidence suggests that the benefits of exercise could be associated with exercise intensity. Moreover, high-intensity exercise can induce negative affective responses, including perceived exertion, enjoyment, pain, and effectiveness, potentially influencing self-efficacy in long-term exercise adherence. Additionally, the role of sex in shaping self-efficacy perceptions remains unclear. This study aimed to examine the relationship between self-efficacy and enjoyment with psychological responses to exercise at varying intensities in males and females.

METHODS: Twenty-one (7 women, 14 men) healthy, physically active adults (24.4 ± 3.1 years; 73.5 ± 12.6 kg; 174.0 ± 6.9 cm) participated in the study. An incremental test (5 W start, +25 W/min until exhaustion) was conducted to determine training intensity. Psychological responses were assessed using the Rating of Perceived Exertion (RPE), Feeling Scale (FS), and Perceived Pain Scale (COOK). A two-week training program followed, consisting of two 20-minute cycling sessions per week. One week was low-intensity (L; RPE 2–4) and one high-intensity (H; RPE 6–7), with randomized order. Participants rated their perceptions (RPE, FS, COOK) during each session. At the end of each week, they completed the Self-Efficacy to Regulate Exercise Scale and the Physical Activity Enjoyment Scale (PACES). Self-efficacy was defined as confidence in adhering to an exercise program over time. The T-test was applied to compare the results between the types of exercise (paired) and between the sexes (independent). Pearson's correlation was applied between SE and Psychological responses.

RESULTS: The intensity in the high-intensity exercise was significantly higher ($p < 0.001$) than in low-intensity (H: 61.2 ± 8.2 and L: $38.1 \pm 6.1\%$ of the peak power). SE was significantly lower after the high-intensity exercise (H: 56.9 ± 26.4 ; L: 90.3 ± 12.5 a.u.; $p < 0.001$) without any difference for PACES ($p = 0.158$) and no difference between men and women. For males, the SE presented a significant negative correlation with RPE ($r = -0.58$; $p = 0.031$) and COOK ($r = -0.58$; $p = 0.002$). For females, SE showed a significant correlation with the FS ($r = 0.85$; $p = 0.017$).

CONCLUSION: In conclusion, high-intensity exercise can considerably reduce the perception of self-efficacy in maintaining a physical exercise routine. However, in males, RPE and perceived pain during exercise seem to be more determinant in the perception of SE, whereas in females, affective valence during exercise seems to be the factor that can moderate the perception of SE.

THE EFFECTS OF AEROBIC EXERCISE INTENSITY ON SELF-EFFICACY AND ENJOYMENT IN YOUNG ADULTS

ABBASSIAN, M., BARBIERI, R.A., MARCORA, S.M.

UNIVERSITY OF BOLOGNA

INTRODUCTION: Despite the well-documented health benefits of regular physical exercise, adherence to a sustained and long-term exercise regimen remains low, particularly when high-intensity exercise is involved. Psychological factors, including self-efficacy (SE), perceived exertion, exercise enjoyment, perceived pain, and affective valence, may influence physical performance and adherence. Among these, SE is a widely recognized determinant of physical activity and has been linked to various exercise-related characteristics. Thus, this study aimed to examine the association between SE and enjoyment with psychological responses to exercise at different intensities. It is hypothesized that a high perceived exertion rate during exercise decreases SE and enjoyment, thereby reducing adherence to an exercise program.

METHODS: Ten healthy, physically active adults (7 women, 3 men; 25.6 ± 6.43 years; 63.8 ± 14.3 kg; 1.7 ± 0.1 m) participated in the study. An incremental test, starting at 5W with 25W increments per minute until exhaustion, was conducted to determine training intensity. Psychological responses were assessed using the rated perceived exertion (RPE) scale, feeling scale (FS), and perceived pain scale (COOK). Participants completed a two-week training program (twice weekly, 20-minute cycling sessions), with one randomly assigned week at low intensity (RPE = 2–4) and one at high intensity (RPE = 6–7). Psychological perceptions were recorded using RPE, FS, and COOK during each session. At the end of each week, self-efficacy to regulate exercise and physical activity enjoyment (PACES) were evaluated. Self-efficacy was defined as confidence in adhering to an exercise program over time. ANOVA was used to assess the effects of time and intensity on psychological parameters, while a T-test compared SE and PACES for the different intensities. Pearson correlation examined relationships between SE and psychological variables.

RESULTS: Statistical analysis revealed a significant effect of the time and intensity in the RPE during the training sessions ($p < .001$), FS ($p = 0.033$), and COOK ($p = 0.007$), but no significant correlation was revealed between SE, psychological responses, and intensity. SE scores were significantly higher ($p < 0.005$) after low-intensity (60.9 ± 29.3 a.u.) training sessions compared to SE after high-intensity (40.0 ± 25.7 a.u.) exercise sessions. However, PACES scores (enjoyment of physical activity) did not differ between high and low-intensity exercise.

CONCLUSION: Based on the findings, it is concluded that high-intensity exercise may reduce self-efficacy in adhering to exercise programs; however, it does not appear to significantly impact exercise enjoyment. Moreover, psychological variables may not exhibit a direct correlation with self-efficacy across different exercise intensity levels.

COMPARISON OF EXERCISE INTENTIONS AFTER COMPLETING A REQUIRED PE COURSE IN RELATION TO POSITIVE BODY IMAGE AND LIFE SATISFACTION.

NG, S.

THE CHINESE UNIVERSITY OF HONG KONG

INTRODUCTION: Mandatory Physical Education (PE) courses at universities engage all student demographics, including sedentary and active individuals, as well as those with special exercise needs. This setting is crucial for fostering lifelong exercise habits, with psychological factors like body image and life satisfaction potentially influencing students' willingness to participate.

Purpose

This research investigates the relationship between gender, Body Appreciation Scale-2 (BAS-2) scores, and Satisfaction with Life Scale (SWLS) scores concerning intentions to exercise after a required 13-week skill-oriented PE course.

METHODS: A total of 884 first-year university students (353 males and 531 females; mean age = 18.7 years) from various academic backgrounds participated. After completing the PE course, they completed a questionnaire that included demographic information, exercise intentions, BAS-2, and SWLS.

RESULTS: Results from a two-way MANOVA indicated that there was no significant interaction effect between gender and intention to exercise after completing the PE course on the following measures: 1) the BAS-2, $F(1, 657) = 0.448$, $p = 0.503$, and 2) the SWLS, $F(1, 657) = 0.069$, $p = 0.792$.

Two independent sample t-tests were conducted to determine if there were differences in BAS-2 and SWLS levels between males and females. The results indicated a non-significant difference in 1) BAS-2 levels, with males reporting an average of $M = 35.76$ ($SD = 7.89$) and females reporting an average of $M = 34.97$ ($SD = 7.80$), $t(882) = -1.46$, $p = 0.143$, and 2) SWLS levels, where males had an average of $M = 25.60$ ($SD = 6.09$) compared to females average of $M = 25.14$ ($SD = 6.02$), $t(659) = -0.98$, $p = 0.330$.

An independent samples t-test was conducted to assess whether there is a difference in BAS-2 levels between participants who intend to exercise after completing the PE course and those who do not. The results show a significant difference in BAS-2 levels between the two groups: those with the intention to exercise had a mean score of 35.76 ($SD = 7.54$), while those without intention had a mean score of 34.17 ($SD = 8.44$), $t(882) = 2.731$, $p = 0.006$.

In contrast, the independent samples t-test revealed a non-significant difference in the SWLS levels. Participants who intended to exercise had a mean SWLS score of 25.53 ($SD = 5.95$), compared to a mean score of 24.87 ($SD = 6.27$) for those without intention, $t(659) = 1.282$, $p = 0.200$.

CONCLUSION: After completing the PE course, no significant interaction effect was observed between gender and intention to exercise regarding the BAS-2 and SWLS scores. However, participants with higher BAS-2 levels exhibited a greater intention to begin exercising. Additionally, no gender differences were found in the BAS-2 and SWLS scores. Finally, there was no significant difference in SWLS scores between participants who intended to exercise and those who did not.

DESIGN OF DIDACTIC UNITS FOR THE IMPLEMENTATION OF AN EDUCATIONAL PROJECT ON WRESTLING IN URUGUAYAN PUBLIC SCHOOLS BASED ON THE BUSHIDO CODE.

MORA PEREYRA, B., CASTAGNINO, J.

INSTITUTO SUPERIOR DE EDUCACIÓN FÍSICA - UNIVERSIDAD DE LA REPÚBLICA

The 'Bushido Playful-Pedagogical Project' was funded by the Extension development program of the Comisión Sectorial de Extensión y Actividades en el Medio (CSEAM) of the University of the Republic (Udelar). The background includes: 1. The comprehensive training space 'Tatami Project' (2011-2020), which integrated university functions (teaching, research and extension) between the Instituto Superior de Educación Física (ISEF), the faculty of Psychology and the Uruguayan Judo Federation (FUJ) in 4 neighbourhoods (Villa Española, Casavalle, Colón and Malvin Norte). 2. The research and innovation project for social inclusion funded by the Comisión Sectorial de Investigación Científica (CSIC) of Udelar, which generated a social inclusion prototype called PSDMN-2019 oriented at Social and Sports Projects (PSD) working in highly vulnerable neighbourhood contexts. 3. The 2017 Physical Education Bachelors degree curriculum, which included wrestling among its curricular units. 4. The scientific development through research projects and individual postgraduate theses that studies wrestling (Mora, 2018; Mora, Cabrera, Alvez, M., & Rodríguez, 2019).

It is worth noting that University Extension in Latin America has undergone significant development, establishing itself as one of the three main functions of public universities, alongside teaching and research. University Extension aims to promote a triple dialogue: the dialogue of knowledge (University- Society), the dialogue of functions (teaching, research and extension) and the dialogue of disciplines, in this case, coming from the human sciences and sports sciences.

Bushido was designed as a device to establish this triple dialogue, having as interlocutor girls, boys, their families, teachers and physical education instructors with the objectives of:

1. Spread body practices of combat sports in an educational manner.
2. Providing specific intergenerational experiences.
3. Producing and disseminating scientific knowledge about combat sports by taking them as a 'Field of Knowledge' (Bourdieu, 1993) from the perspective of educational sciences and sports sciences.

The intervention problem and the research problem were articulated along two theoretical-methodological axes: 1. Thinking of martial arts as a field of knowledge (martial arts and combat sports) being historical and cultural practices that, in

Uruguayan case, were stigmatized for the violence and subjected to private initiatives. 2. Think about martial arts like educationally, and for that, we developed a didactic unit to collectively and daily problematize the KANJIS of the Bushido code: REI (Respect), GI (Justice), MAKOTO (Honesty) and MEYO (Honor).

PHYSICAL LITERACY AS A MEDIATOR IN THE RELATIONSHIP BETWEEN FUNDAMENTAL MOVEMENT SKILLS AND CARDIO-VASCULAR FITNESS IN PRIMARY SCHOOL CHILDREN

SUM, K., ZHANG, X.F.

THE CHINESE UNIVERSITY OF HONG KONG

Background

Physical literacy, defined as the motivation, confidence, physical competence, knowledge, and understanding to engage in physical activities for life, is an essential aspect of overall education and well-being for individuals across different age groups (Whitehead, 2019). Developing physical literacy from an early age through to adulthood is crucial for sustaining independence and improving population health and well-being. Research has shown a positive relationship between physical activity levels and self-perception of physical literacy among adolescents in Hong Kong (Choi & Sum, 2018). Physically literate individuals are more motivated to participate regularly in physical activity and tend to have positive attitudes towards it (Whitehead, 2010). Fundamental movement skills (measured by CAMSA) are believed to influence cardiovascular fitness (measured by PACER), potentially through the mediator of physical literacy (measured by PPLI) (Sum, et al., 2016). Therefore, to promote physical activity, this study investigates whether physical literacy mediates the relationship between fundamental movement skills and cardiovascular fitness in a pediatric sample.

Methods: A single-mediator analysis (PROCESS Model 4) was applied to data from 294 primary school children using SPSS 27. The model tested the indirect effect of fundamental movement skills (CAMSA, X) on cardiovascular fitness (PACER, Y) through physical literacy (PPLI, M). The analysis used 5,000 bootstrap resamples to obtain bias-corrected 95% confidence intervals.

RESULTS: Total effect: Fundamental movement skills (CAMSA) significantly predicted higher PACER scores ($\beta = 4.882$, $SE = 0.439$, $p < .001$, 95% CI [4.043, 5.722]).

Direct effect: After controlling for physical literacy (PPLI), the direct effect of CAMSA on PACER remained significant ($\beta = 4.882$, $SE = 0.427$, $p < .001$, 95% CI [4.043, 5.722]).

Mediation pathway: CAMSA significantly predicted PPLI ($\beta = 0.558$, $p = 0.028$, 95% CI [0.059, 1.056]), and PPLI was positively associated with PACER ($\beta = 0.468$, $p < 0.001$, 95% CI [0.275, 0.660]).

Indirect effect: The indirect effect of CAMSA on PACER through PPLI was statistically significant ($\beta = 0.261$, 95% CI [0.033, 0.531]), accounting for 5.1% of the total effect.

Conclusion: Fundamental movement skills directly improve cardiovascular fitness, with a modest additional benefit derived from its effect on physical literacy. These findings suggest that enhancing physical literacy may provide supplementary benefits to movement skill-based interventions aimed at improving cardiovascular fitness. Future studies should explore other potential mediators (e.g., cognitive function, physical activity level) to better account for the direct effect of movement skills on cardiovascular fitness.

IMPLEMENTING SCHOOL-BASED PHYSICAL ACTIVITY POSITIVELY INFLUENCES PUPILS' PERCEIVED LIFE SATISFACTION AND WELL-BEING.

BRATLAND-SANDA, S., SCHMIDT, S.K., REINBOTH, M.S.

UNIVERSITY OF SOUTH-EASTERN NORWAY

Introduction: Several school-related factors can influence pupils' perceived life satisfaction and wellbeing. School-based physical activity can affect such factors through improved physical fitness and function, improved mood and self-confidence, and through social interaction and support during both lectures and recess (Andermo et al., 2020). Telemark County, Norway, has had a focus on implementing physical activity in classroom and recess since 2016 (Schmidt et al., 2022; Schmidt et al., 2020), and it is thus of interest to explore whether this system-led initiative influences pupils' perceived life satisfaction.

Methods: The national survey Ungdata was conducted spring 2024, and this study involved youth aged 13-19 years from the implementation county Telemark ($n=7,113$) and control county Vestfold ($n= 10,295$) in Norway. Life satisfaction was rated on a scale from 0-10. In addition, the pupils reported their gender, socio-economic status, perceived pressure and thriving at school, recess content, school meals and school-based physical activity.

Results: The pupils showed similar levels of perceived life satisfaction between the two counties. The most important school-related factor for perceived life satisfaction was school thriving ($p<0.01$), followed by social connectedness during recess and school meals ($p<0.05$). School-based physical activity positively predicted life satisfaction in Telemark ($p<0.05$), but not in Vestfold. The prediction in the Telemark group was stronger in girls compared to boys.

Discussion: The small yet significant influence of school-based physical activity on particularly girls' perceived life satisfaction on county level is in accordance with findings from a previous experimental study on school level (Schmidt et al., 2020). This is thus the first study to indicate how such school-based initiatives, when implemented and designed thoroughly, can contribute to changes on societal level in youth.

THE PROGRESSION OF THE JOURNEY OF MAN IN MOTION

GAMBA, M., MANDOLESI, N.

ASD EDVIGE361GRADI

The progression of the journey of man in motion

During the Renaissance, history tells us that humanity again became the center of the universe, free to act and express itself. Education focused on well-being and physical movement became one way to develop the idea of balanced and integrated person. Educators recognized physical activity and the importance of play as a key of learning and personal growth helping people to connect with themselves and others.

After the Pandemic which forced us into isolation and lifestyle changes, the need for physical activity and sport became even more important. These activities are not only for personal health but help rebuild social connections.

Relationships are essential for well being and a strong society. However modern challenges, lack of physical activity and reduced social interaction, require new solution. One way to address is through an Outdoor Experiential Relation Activity Model which strengthens the connection between sport, environment and sustainability.

The main goal is to encourage people to accept and take care of themselves with their own fragility which includes personal challenges.

This activity focuses on restoring balance between individual and community, using a holistic approach. It combines outdoor activities like trekking, free climbing, rafting, biking, with social experiences. An example in Ferentillo (Terni) where people of different ages (children, teenagers or adults) engaged in physical activity in nature, free from distraction like cell phones, tablet and computers.

Since considering humans are naturally social we found that well being improves when people learn through movement and shared experiences. Social well being grows through emotions, team work, sport challenges and play therapy.

5 MINUTES OF DAILY SMS, A PHYSICAL ACTIVITY PROTOCOL, TO PREVENT WORK ACCIDENTS AND MUSCULOSKELETAL DISORDERS OF WORKERS IN AN INDUSTRIAL ENVIRONMENT

TARIN, L., PRIGENT, Y., GARNIER, S.

TOULOUSE UNIVERSITY

INTRODUCTION: The number of workers suffering from work-related musculoskeletal disorders, estimated to account for 21 to 28 % of all days of occupational sick leaves, is a major health problem for society and workers (1). In addition to other preventive actions, physical activity protocols (PAP) contribute to reduce Musculoskeletal Disorders (MSDs) in workers (2). The nature of the protocol, its implementation, its acceptability and the engagement of workers (3) to the protocol are essential determinants of the effectiveness of the PAP.

Objectives

The aims of the study are to evaluate the feasibility and acceptability of a preventive PAP of 5 minutes named SMS (Strength, Mobility and Stretch) to present the preliminary results, particularly in terms of engagement and the effects at 15 months on the reduction of work accidents (WA), their severity and the number of MSDs.

METHODS: A mandatory approach based on 5 minutes of SMS per day worked adapted to job families for all workers of an industrial company (n=250) was implemented from September 2021 through the intervention of a service company. The protocol was:

- Information about this approach to all workers and call for applications to become internal animators (IA);
- 3 weeks: Animation of SMS sessions by the service company;
- 4 x 1 day: Training of 4 groups of IA;
- 2 weeks: Co-animation of SMS sessions by IA and service company;
- 14 months: IA of SMS sessions.

The indicators monitored are the frequency and severity rates of WA, MSDs declared (indicators of the French Medical Health Care System) over the last 5 years, as well as the relative risks and level of engagement.

RESULTS: The share of volunteer workers trained to be IA is 14%. Protocols were followed by all workers and none of them refused.

The first results show a significant drop in 15 months in frequency and severity rates of WA:

- Decrease in the frequency rate from 51.25 to 14.21
- Decrease in the severity rate from 0.96 to 0.45

The relative risk analysis shows a reduction in the risk of WA of 53% and in the risk of minor accidents of 65%. The number of MSDs declared during the mandatory is zero.

Discussion and CONCLUSION: The proportion of volunteer workers trained demonstrates a certain interest in SMS and an appropriation of the approach by workers. This approach requested and organized by the company's management is well accepted by all workers.

According to these initial results, it would seem that 5 minutes of SMS every working day helps reduce WA and MSDs in this industrial environment. Further studies are needed to confirm these results, measure the evolution of the indicators presented and monitor workers engagement over the long term.

COMPARISON OF MODERATE AND VIGOROUS PHYSICAL ACTIVITY OF COLLEGE STUDENTS USING WEARABLE DEVICES TRACKING PHYSICAL ACTIVITY: A PRELIMINARY ANALYSIS

MCKNABB, R., TIRALLA, G., LEUNG, W., STEFANO, A., FIORE, G., FARRELL, C., RYAN, M., KLAUS, B.
UNIVERSITY OF TAMPA

INTRODUCTION: Wearable devices (WD) are increasingly popular for promoting physical activity (PA) [1], especially among college students who often struggle with maintaining regular PA [2]. WDs can serve as motivational tools, yet most research on their effectiveness comes from structured interventions, leaving gaps in understanding their impact in everyday life [3]. This study compares moderate physical activity (MPA) and vigorous physical activity (VPA) between college students who use WDs and those who do not, with further distinctions based on active PA tracking.

METHODS: Participants were categorized into three groups based on self-reported WD use: (1) not using WD (NWD), (2) using WD but not tracking PA (WDNPA), and (3) using WD and tracking PA (WDPA). They wore a triaxial accelerometer on their right wrist for seven days to measure PA levels. The accelerometer recorded total minutes spent in MPA and VPA, classified using Troiano cut points [4]. PA differences among the groups were analyzed using ANOVA with Bonferroni post-hoc adjustment.

RESULTS: For this preliminary analysis, nine participants did not use a WD, two reported using a WD but not tracking their PA, and seven reported using a WD and tracking their PA. The average MPA for each group was 1308.14 minutes for NWD, 1497.00 minutes for WDNPA, and 1443.50 minutes for WDPA. For VPA, NWD had an average of 124.71 minutes, WDNPA had 95.50 minutes, and WDPA had 115.83 minutes. ANOVA results indicated no statistically significant differences in MPA ($F = 1.19$, $p = .30$) or VPA ($F = 0.07$, $p = .50$) among the three groups.

CONCLUSION: Although this analysis is limited by a small sample size, the findings suggest that the use of WDs, even with active tracking of PA, may not significantly increase engagement in MPA or VPA among college students. Simply wearing and tracking PA with these devices may not be enough to drive meaningful behavioral changes. Given the well-documented health benefits of MPA and VPA, future research should investigate more effective strategies to maximize the potential of wearable technology in promoting sustained PA increases.

Physical Education and Pedagogics

INCREASING PARENTAL INVOLVEMENT CHARACTERISTICS OF SPORTS ACTIVITIES OF HIGH-SKILL SWIMMERS AND THE LINKS WITH ATHLETES' SPORTS ACHIEVEMENT

TILINDIENE, I., PLECKAITIS, M.

LITHUANIAN SPORTS UNIVERSITY

INTRODUCTION: In the modern world many young athletes live very active lives where they need to combine learning and sports activities, sports, various extracurricular activities, homework, leisure, and other areas of life. All this causes daily stress, a constant sense of urgency, and fatigue, which reduces the motivation of young people to play sports (2). This problem is relevant for both advanced and high-performance athletes. Therefore, researchers (1,3), analyzed the impact of parental involvement in childrens sports activities on the successful sports and development and found that parents play a key role in youth sports education. The aim of the study is to reveal the characteristics of parents involvement in the sports activities of high-performance swimmers and links with athletes' and sports achievement.

METHODS: The Parental Involvement Sport Questionnaire (PISQ) developed by Lee and McLean (1997) is used for the study. During the research, 71 high-performance athletes and 60 of their parents were interviewed.

RESULTS: It was found that many parents show enthusiasm and joy before the competition (4.03 points). However, before the competition they still indicate what results the child should achieve (1.84 points). According to the parents assessment, they are very actively interested in their childs swimming (4.4 ± 1.0), while according to the athletes assessment, they are moderately active (3.4 ± 1.3) ($t(129) = -4.8$; $p = 0.000$). According to the parents assessment, they almost always (4.7 ± 0.6) praise their child for their effort after the competition, while according to the athletes - parents praise them only often (4.0 ± 1.3) ($t(129) = -4.1$; $p = 0.000$). Parents (4.5 ± 0.9) always say something encouraging after a swimming competition, even if their child swam poorly, while athletes often (3.7 ± 1.3) show their understanding ($t(129) = -4.2$; $p = 0.000$). Weak correlations were found between parental active involvement and personal athletic achievements of high-performance swimmers ($r = 0.293$). Strong positive correlations were also found between parental active involvement in athletes activities and praise and understanding ($r = 0.514$) and directive behavior ($r = 0.513$).

CONCLUSIONS

The activity of parents involvement in the training process is average, focused on childrens needs, organizational support and creating conditions for professional sports. Parents give their children psychological support, praise the child for achievements and efforts. Positive correlations between active parental involvement and swimmers personal sports achievements have been established.

ATTENTION AND PREFERENCES IN RESPONSES TO INSTRUCTION DURING RETURN-TO-PLAY EVALUATIONS

CARNERO, A., MUÑOZ-LÓPEZ, A., DI MICHELE, R., PECCI, J.

UNIVERSITY OF SEVILLA

INTRODUCTION: Instruction can modulate performance, muscle activity, and affective responses during tasks [1] by directing the participant's attention. This reduces the likelihood of generating spontaneous or ineffective self-talk[2]. Sometimes, athletes tend to direct their attention toward controlling their own movements or to focus on aspects they personally prefer, rather than following the professional's instructions. Return to play tests, which are used to inform decision-making during rehabilitation, may yield altered data if the participant's attention is not controlled, potentially leading to misinterpretations of the athlete's physical condition. Therefore, the aim of this study was to investigate whether participants followed the instructions provided and to examine their preferences for specific instructions during assessment.

METHODS: Twenty-seven athletes were recruited for this study. Protocol was conducted using an leg extension isokinetic device under four experimental conditions: control, analogy, explicit, and encouragement instructions. Attention was recorded using the Knowledge Declared Questionnaire, which was administered immediately after each experimental condition [3].

RESULTS: Results are presented as percentage of the total 100%. Overall, participants followed the provided instructions in 75.93% of cases. Percentages ranged from 59.26% in the control group to 92.59% with explicit instructions. The values for the encouragement and analogy conditions were 70.37% and 81.48%, respectively. Regarding preferences, 59.26% of participants favored the encouragement condition, compared to 7.41% for explicit instructions and 33.33% for the analogy condition.

Discussion: Findings reveals that nearly 20% of the instructions provided were not followed by participants. In the context of testing, which are crucial for decision-making during rehabilitation processes, when attention not adequately controlled, failure to follow instructions may alter the data collected, potentially leading to incorrect decisions regarding an athlete's readiness to return to play.

Our results also suggest that the overall adherence to specific instructions (i.e., explicit, analogy and encouragement) was approximately 30% higher than in the control group, indicating that instructions may reduce the likelihood of generating spontaneous self-talk. However, individual preferences showed varying percentages across experimental conditions. From a practical perspective, these findings highlight the importance of incorporating different types of instructions during the familiarization phase of testing. By doing so, practitioners could ask athletes which type of instruction makes them feel most comfortable and prepared to optimize force application [1].

THE EFFECTS OF INTEGRATING LINE BOT TEACHING PLATFORM AND WICAS FLIPPED LEARNING MODEL ON BADMINTON SKILL LEARNING

LIN, K., KO, C.W.

NATIONAL SUN YAT-SEN UNIVERSITY; NATIONAL SUN YAT-SEN UNIVERSITY

INTRODUCTION: To facilitate learners acquisition of badminton skills, the researchers developed a LINE Bot teaching platform integrated with the WICAS flipped learning model. This platform enabled learners to preview, engage in class, and review after class through features like e-portfolios, expert videos, pre-class self-assessments, video analysis, and self-reflection. All functionalities were accessible through the LINE app, allowing learners to retrieve learning resources without spatial and temporal restrictions.

METHODS: A quasi-experimental design was employed. One class used the LINE Bot teaching platform combined with the WICAS flipped learning model (experimental group, EG), while the other used mobile devices with the WISER learning model (control group, CG). Teaching focused on badminton serve (Participants: EG=44, CG=48) and clear (Participants: EG=48, CG=47) over five weeks, aiming to determine whether significant differences exist in learning outcomes between the two groups. To assess learners' performance effectively, the researchers adopted the Badminton Learning Tutor app as a research tool. Data were analyzed using a mixed-design ANOVA to evaluate whether there were significant differences in learning performance within and between groups during pre-tests, post-tests, and weekly assessments.

RESULTS: The analysis of serve skill found no significant difference between the EG and CG in the between-subjects effect ($p = .187$). However, significant differences were observed in the within-subjects effect of testing time ($p < .001$) and the interaction effect of testing time and group ($p < .001$). Post-hoc analysis showed the EG significantly outperformed the CG at Week 5 and the post-test. For clear skill, the between-subjects effect revealed a significant difference between groups ($p < .001$), and the within-subjects effect of testing time was also significant ($p < .001$), while the interaction effect was not ($p = .213$). Post-hoc analysis indicated the EG consistently outperformed the CG (except during Week 3 and Week 4), with a marked improvement in the post-test. These results demonstrate the effectiveness of the LINE Bot teaching platform combined with the WICAS flipped learning model in improving badminton skills.

Discussion: The findings of this study align with previous research, confirming that the motion recognition functions offer learners accurate feedback, with which they adjust and improve their skills progressively. This study further innovates by incorporating the WICAS flipped learning model with the LINE Bot teaching platform, allowing learners to reflect on the system-offered suggestions, identify areas for improvement, and document these details before class. While in class, they can thus focus on improving skills and reflecting on their movements. This approach allows learners to overcome the traditional reliance on instructors for detailed skill corrections, helping them to solve problems independently.

IMPLEMENTING RUBRICS FOR LEARNING AND ASSESSMENT IN UNIVERSITY PHYSICAL EDUCATION: INSIGHTS FROM TEACHERS AND STUDENTS

MURAYAMA, M.1, TERAOKA, E.2, HIGASHIHARA, A.1, NAGATA, N.1, SHIMIZU, K.1, FUKUSHI, N.1, OKUYAMA, S.1, SASAKI, R.1, INAMI, T.1, UMEMOTO, M.1

1 KEIO UNIVERSITY, 2 NIPPON SPORT SCIENCE UNIVERSITY

Background and Objective: Rubrics enhance grading transparency and consistency while improving learning quality through performance assessment. However, their application in university physical education classes is limited. Thus, this study explored teachers' practices and students' perceptions of implementing rubrics for performance assessment.

Methods: In a university physical education class, the teacher implemented a rubric to foster social and emotional skills (e.g. self-awareness, communication, and gratitude). This rubric was shared with students to guide their performance assessment. The class involved practising 10 new sports (e.g. Flying Disc, Gate Ball, Indiaca, and Kin-Ball), most of which were new to students. Semi-structured interviews with the teacher and focus group interviews with students were conducted mid-term and at the end of the semester to discuss teaching and learning practices.

Results: The teacher emphasised the importance of raising awareness of the rubric's criteria while fostering communication and group cooperation among students. However, they identified challenges, including insufficient emphasis on setting specific class goals, a lack of individualised engagement, and inadequate assessment feedback during the semester. Students viewed the rubric positively, noting that it supported goal setting, encouraged active communication, fostered dedication and engagement, and provided clearer assessment criteria than other physical education classes.

Nonetheless, the students suggested areas for improvement, such as the need for midterm feedback and difficulties in focusing consistently on the rubric criteria.

Discussion and Conclusion: Interviews with teachers and students highlighted the potential of rubric-based performance assessment to promote active and autonomous learning in physical education classes. However, the findings underscore the need for more robust teacher feedback to enhance the effectiveness of this approach. Future studies should explore innovative teaching strategies to integrate rubrics more effectively into classes, facilitating diverse and meaningful learning experiences and supporting student growth in physical education.

A STUDY ON THE EDUCATIONAL EFFECTS OF SPORT: WITH FOCUS ON SPORTS IN SCHOOLS IN JAPAN

MORITA, H.

OSAKA UNIVERSITY OF HEALTH AND SPORT SCIENCES

INTRODUCTION: At last years conference, participants discussed ways to eliminate corporal punishment and harassment in sport scenes in Japan. Historical circumstances serve as one of the causes of corporal punishment and harassment in Japan. The second cause is that instead of a seasonal team system, students in Japanese schools often practice sport on the same team throughout the year. Furthermore, there is no tryout system, and in some cases, a large number of students practice sport within a single team. Why is this kind of situation still continuing? A major factor is the belief that playing sport offers numerous educational benefits. The term "sport education" is based on the assumption that education based on sport and education via sport are possible. However, it is unclear what specific educational benefits or outcomes are being achieved through this approach.

Method: We conducted a questionnaire survey with college students to understand what they believe they have learned from their participation in sport and analyzed their responses.

Result

Students who participated in our questionnaire provided their responses to open-ended questions. The questions are broadly categorized into: (1) what they learned through sport activities, (2) what they learned through team and group activities, and (3) what they learned regarding daily activities (activities unrelated to sport).

Discussion: Regarding responses to question (1), these are lessons that can be learned through dedicating oneself to something and not limited to sports alone. Similarly, for question (2), many of the responses are applicable to any type of group not just sports teams or organizations. Regarding this, we believe that further study and exploration are needed to gain a deeper understanding of the unique aspects of sports. Many responses to questions (2) and (3) overlap, and some are difficult to categorize distinctly.

Here, we should be careful in handling the idea that what people achieve through sports is applicable to everyday life in general. The rules and disciplines used to maintain order within a group of athletes may differ from those practiced in everyday life and can sometimes seem thoughtless or absurd by ordinary standards.

Tano, a researcher of fascism, discusses the essence of fascism, which may be applicable to commonly found athletic communities. Characteristic features of such communities, like strong leaders, collective activities, and exercising while loudly shouting, can lead to the creation of exclusive communities and the formation of unique values and customs.

CONCLUSION: The culture developed within athlete communities may be adversely influencing various aspects of Japanese society. People involved in education need to carefully observe and examine the relationship and differences between the sport world and everyday life. What is learned in sport does not necessarily translate to everyday life.

"EASY JAPANESE" IN LIFESAVING COMMUNICATION: GIVING INSTRUCTION IN "EASY JAPANESE" TO UNIVERSITY STUDENTS DOING LIFESAVING TRAINING

TACHIKAWA, K., INAGAKI, Y.

RYUTSU KEIZAI UNIVERSITY

INTRODUCTION: "Easy Japanese" has been used as an effective way to provide information to foreign residents during disasters since the Great East Japan Earthquake in 2011. Recently it has also been used in a wide range of areas such as nursing care, medical care and disaster prevention information from the government. Despite this there is no study on "Easy Japanese" in lifesaving activities. Furthermore, linguistic research shows that "Easy Japanese" is useful not only for foreigners but also for native speakers with low Japanese language proficiency. The ways of communication in lifesaving are various. Therefore, learning "Easy Japanese" will be essential for lifesavers as a practical skill.

METHODS: First, we checked 27 student lifesavers' (Male 19, female 8) knowledge of "Easy Japanese" and asked them what is important to communicate to people with low Japanese proficiency. Next, we got students to rewrite a beach announcement (i.e. "No swimming due to lightning") to make it easier to understand. After that we gave a lecture to students to increase their linguistic knowledge of "Easy Japanese" and got them to rewrite another beach announcement ("No swimming due to fog"). Finally, students described how they should use "Easy Japanese" in lifesaving situations.

RESULTS: The 90% of the students did not know the fine details of "Easy Japanese". As to the importance of communication with those who are not able to understand Japanese, students mentioned that they would deal with them kindly and friendly. After the lecture of "Easy Japanese", students got the linguistic skills as follows, 1) To change formal expressions to simpler one's, 2) To emphasize the important parts of the announcement and repeat them, 3) To shorten a long sentence in order to make it simple and clear. However, they couldn't rewrite everyday Japanese phrases that are difficult for for-

eigners into “Easy Japanese”. After this activity, for making effective use of “Easy Japanese”, they referred that lifesaving skills based on having consideration for people are absolutely indispensable.

CONCLUSION: In this study, it turned out that student lifesavers’ ability to use “Easy Japanese” in lifesaving had improved dramatically after the lecture. According to their reactions to a series of practice, interestingly we knew that they realized the significance of their caring attitude to communicate as well as language skills in lifesaving. As a result, we need to give student lifesavers further linguistic instruction for “Easy Japanese” systematically. In addition, we should study more about the practical relationship between language and communication skills of student lifesavers.

This work was supported by JSPS KAKENHI Grant number JP21K11527.

REFLECTION ON THE OBSERVATION OF THE AFFECTIVE DOMAIN IN PHYSICAL EDUCATION

SAINCHUK, M., KIRK, D.

UNIVERSITY OF STRATHCLYDE

INTRODUCTION: The affective domain is extremely important in physical education (PE) and is not as simple as it may seem at first glance, as it can be considered and studied broadly, going far beyond emotions. In Scotland, the affective domain is implemented in the PE curriculum through Personal Qualities (PG) [1], which include motivation, confidence and self-esteem, determination and resilience, responsibility and leadership, respect and tolerance, communication. This is important as part of physical education’s response to the rising prevalence of mental health and wellbeing concerns among young school-age people [2].

METHODS: Non-participant Observational Study according to a specially developed protocol based on 1) Benchmarks PE [1] and 2) affective responses during a PE lesson using the Ecological Momentary Assessment [3].

As part of one of the research stages of the research project ‘Developing and enacting pedagogies of affect in PE’ supported by a grant from the British Academy, in April-May 2024, observations were made of PE lessons of 5 students at the University of Strathclyde on the Professional Graduate Diploma in Education programme.

RESULTS: The observation showed that all six aspects of PQ were present during the PE lesson by students, but the most complete implementation was in communication and motivation. Observation of pupils affective responses showed the absence of negative affective on their part. As for the positive affective responses, half of them were activated (happy, cheerful) and the other half were deactivated (calm or relaxed). The majority of pupils affective responses to the PE lesson tasks were at the level of 2-3 points and only in 3 cases the affective response was rated at 4 points. Only physical activity caused activated pleasure, and the more movement the lesson task required, the more pupils liked it. At the same time, any explanations immediately shifted pupils to deactivated pleasure.

CONCLUSION: This study shows that the student teachers were familiar with the PQ aspect of physical education within Curriculum for Excellence and were able to teach for affective learning of their pupils. At the same time, these outcomes were limited by the student teachers’ relative unfamiliarity with the pupils since they were on a time-limited placement. For teachers familiar with their pupils, teaching for affective learning could be further extended. The positive responses of pupils offer encouragement for further investigation of this topic given the very challenging Pupil behaviours being exhibited relating to mental health concerns [2].

SWIMMING SKILLS DEVELOPMENT IN SECOND-GRADE STUDENTS IN THE ‘LEARN TO SWIM AND STAY SAFE IN THE WATER’ PROGRAM

ZUOZIENE, I.

LITHUANIAN SPORTS UNIVERSITY

Introduction. Swimming has deep traditions in Lithuania, and Lithuanian swimmers have excelled in international competitions. However, drowning rates remained high in the early 21st century. During the first decade, an average of 369 people drowned annually, including 33 children. Lithuania had one of the highest drowning rates in Europe, prompting LTU Aquatics (LSF) and government institutions to launch a national swimming education initiative. Swimming is a vital survival skill that enhances childrens motor skills, psychological resilience, and social competencies. In 2008, the Lithuanian government integrated a structured swimming education program into the National Sports Development Strategy to ensure that children acquire fundamental swimming skills and learn water safety.

Implementation of the Learn to Swim and Stay Safe in the Water Program. The program is aimed at second-grade students. Initially consisting of 18 lessons, it was later expanded to 32 per school year, funded by the state and municipalities. The program is designed to teach breath control, buoyancy, underwater orientation, and basic water movements. Over the past decade, more than 52,000 second-grade students have participated. Schools and municipalities have provided transportation, ensuring systematic participation.

Study on swimming skills in Kaunas Schools. A study assessed 63 second-grade students (40 boys, 23 girls, age 8.2 ± 0.5 years) attending two 45-minute lessons per week at LSU's pool. After 18 lessons, swimming skills were evaluated based on ten competencies, including breath control, floating, propulsion, and water safety. Results showed that 86.1% adapted well to water, 77.8% mastered breath control, and 72.2% could float. Additionally, 69.4% could enter and exit the water safely, while 28% swam 25 meters unaided. While skill acquisition varied, the program significantly improved students' abilities.

Impact and Challenges of the Program. The initiative has yielded positive results. Government funding, standardized methodologies, and new pools have increased opportunities for children to learn to swim. From 2009 to 2021, drowning rates decreased from 9.4 to 5.6 cases per 100,000 population, while child mortality decreased from 6.4 to 2 per 100,000. Media campaigns and parental education on drowning prevention have also contributed to this trend. However, Lithuania still lacks a comprehensive national drowning prevention strategy. To increase the program's effectiveness, it is necessary to expand access, improve lesson structures, and optimize resources.

Conclusion. A structured swimming program has significantly improved childrens swimming skills and contributed to drowning prevention. Despite its successes, challenges remain, including inconsistent attendance, a shortage of pools, and an insufficient number of lessons. Future efforts should focus on expanding access and integrating a national drowning prevention strategy to enhance water safety education.

WORKSHOPS ON PLAY: METHODOLOGICAL STRATEGIES BASED ON THE USE OF SCHOOL PLAY SPACES

MONTEIRO, V., RECHIA, S.

UNIVERSIDADE FEDERAL DO PARANÁ

INTRODUCTION: Play is a fundamental activity for child development, contributing to cognitive, emotional, social, and physical aspects. In the school context, playful practices can be limited by structural, cultural, and organizational factors that restrict childrens autonomy and creativity. This research explored teaching strategies through "play workshops," which aim to identify the impact of childrens playful experiences in the school environment.

METHODS: This research used "play workshops" as its central methodology, highlighting their relevance in the educational field. The workshops were designed based on the childrens own perceptions, valuing them as active participants. Rather than proposing a closed and replicable method, the intention was to establish principles that could guide the creation of formative practices aligned with their realities and needs. The workshops were planned after discussion circles with the children, during which interests such as toy creation, exploration of games, and the use of different school spaces and resources emerged.

RESULTS: The research highlighted childrens protagonism and the importance of including them in the process of reflecting on and transforming school spaces. The initial identification of games, characterized by low interest in traditional practices, guided the workshops toward activities more aligned with the childrens interests. The photographic documentation stage promoted autonomy and teamwork while revealing the childrens desire to explore less accessible areas of the school. The creation of photographic panels fostered collective engagement, allowing the children to express their perceptions and preferences about play spaces in the school.

At the end of the research, an exhibition open to the school community was held, consolidating the learnings and reinforcing the role of children as active agents in creating and valuing playful practices in the school environment.

DISCUSSION: The research demonstrated that play, in addition to being a spontaneous practice, is also a powerful means of expression and redefining school spaces. Through a sensitive and participatory approach, it was possible to reveal the complex dynamics that permeate childrens playful universe, highlighting their capacity for resistance, creativity, and appropriation of spaces. By exploring playful practices from the childrens perspective, the tension between institutional norms and the creative tactics used by students to subvert these rules and transform spaces into environments of freedom and belonging was identified. This underscores the central role that play assumes in the construction of meanings and school experiences. This final reflection reinforces the urgency of valuing childhood as a protagonist in the school environment and rethinking educational practices to incorporate childrens genuine demands and expressions.

STRUCTURAL ANALYSIS OF GENERALIZED SELF-EFFICACY AND ITS ASSOCIATION WITH PHYSICAL FITNESS IN LATE ADOLESCENCE

KONNO, R.

MEIJI PHARMACEUTICAL UNIVERSITY

INTRODUCTION: To date, studies have used the Generalized Self-Efficacy scale (GSE scale) with the one-factor structure and analyzed other factor structures; however, a consistent factor structure has not been obtained. In addition, few studies have examined the relationship between GSE-scale factor structure and physical fitness in late adolescence. Therefore, this study aimed to clarify the factor structure of the GSE scale in late adolescence and examine its relationship with physical fitness.

METHODS: A total of 354 subjects—132 male and 222 female university students (average age: $18.32 \pm .80$ years old, age range 18-26 years old)—were surveyed. Similar to previous studies, responses in this survey were given on a 5-point scale regarding the GSE scale. For physical fitness, six physical fitness test items were measured.

RESULTS AND DISCUSSION: First, exploratory factor analysis (maximum likelihood method, promax rotation) was performed on the GSE scale, and two factors and 11 items (factor 1; problem solving, factor 2; interpersonal relationships) were extracted. Next, a confirmatory factor analysis (maximum likelihood method, promax rotation) was conducted using a two-factor, 11-item model obtained by exploratory factor analysis, and it showed that GFI = .93, AGFI = .90, CFI = .90, and RMSEA = .08. Reliability coefficients for the GSE subscale were $\alpha = .80$ for the first factor and $\alpha = .72$ for the second factor. The goodness of fit of the factor structure model for the GSE scale was therefore judged to be within the acceptable range. The results revealed a two-factor structure for the GSE scale for new university students, consisting of the first factor "problem solving" and the second factor "personal relationships," for which both reliability and validity were confirmed. The correlation coefficients (Pearson's product-moment correlation coefficients) were then calculated for each of the extracted GSE factors with the six items of the physical fitness test by gender; a constant correlation was found for men and a weak correlation for women, both of which were significant ($p < .05$). This can be attributed to the behavioral traits shown by Bandura (1977), such as the willingness to exert a great deal of effort to solve problems when self-efficacy is highly recognized.

Bandura, A. (1977) Self-efficacy : Toward a unifying theory of behavioral change. *Psychological Review*, 84 : 191-215.

THE OLYMPIC VALUES EDUCATION LEARNING PERFORMANCE SCALE FOR PHYSICAL EDUCATION CLASSES

PAN, Y., HUANG, C., YEH, W., ZHANG, Y.

NANHUA UNIVERSITY

Introduction: Affective learning is a crucial goal in contemporary education. The International Olympic Committee (IOC) continues to promote the affective development of sports participants through the Olympic Values Education Programme (OVEP). While various Olympic values education assessment tools have been developed internationally, there is still a lack of instruments specifically designed for the physical education (PE) context. Furthermore, existing tools differ across countries due to cultural variations. Therefore, developing an Olympic Values Education Learning Performance Scale suitable for the Taiwanese cultural context in PE classes is necessary. Based on this need, this study aims to develop a learning performance scale for Olympic values education in PE classes for students aged 11 to 18. The scale is constructed based on the three core values of Olympism—Excellence, Respect, and Friendship, as proposed by the IOC (2017), serving as the foundational dimensions for learning assessment. **Methods:** This study was conducted in three phases. Phase one involved focus group discussions and expert consultations to establish the learning assessment indicators. Phase two included 285 participants aged 11 to 18, employing exploratory factor analysis (EFA), item analysis, and reliability analysis to establish the validity and reliability of the scale. Phase three involved 641 participants aged 11 to 18, providing confirmatory factor analysis (CFA), criterion-related validity, test-retest reliability, measurement invariance testing, and cross-validation evidence. **Results:** Following exploratory factor analysis, five dimensions were identified: "Pursuit of Excellence," "Team Cohesion," "Mutual Support," "Respect for Self and Others," and "Respect for Rules and Environment." The items demonstrated strong discriminant validity and internal consistency. In the confirmatory factor analysis phase, the scale met model fit criteria and obtained support for criterion-related validity, cross-validation, and measurement invariance, indicating strong psychometric properties. Overall, the Olympic Values Education Learning Performance Scale for PE classes was supported across multiple validity and reliability assessments. **Conclusion:** The Olympic Values Education Learning Performance Scale for PE classes, developed in this study, exhibits strong validity and reliability, making it a suitable tool for PE teachers to assess students' affective learning and values education in PE settings. Additionally, the scale provides a valuable instrument for researchers to conduct further studies on Olympic values education.

INTEGRATING AN AI-BASED MARKERLESS MOTION CAPTURE SYSTEM IN THE VAULTING BOX UNIT OF ELEMENTARY SCHOOL PHYSICAL EDUCATION

SHISHIDO, T., HASHIMOTO, M.

TOHOKU GAKUIN UNIVERSITY

INTRODUCTION: Studies have explored the use of applications in physical education. The Hudl Technique app [1] is a motion analysis tool that enables athletes to review and refine their movements. However, the Polar Beat [2] and Polar Club apps [3] are designed for heart rate monitoring and have been used to track physiological responses during exercise. While these applications offer valuable insights, their high cost limits their widespread adoption in school settings. Correspondingly, this study aimed to evaluate the effectiveness of the SPLYZA MOTION (SM) app, an affordable motion analysis tool, in elementary school physical education classes.

METHODS: This study involved 165 fourth-graders from public elementary school five classes in Japan. The vaulting box unit was conducted over five lessons per class, led by homeroom teachers. The SM app was introduced a month before lessons, allowing familiarisation. Students used the app in small groups, and its impact was assessed through diagnostic and summative lesson evaluations and perceived physical competence (PPC) scores before and after lessons. The Wilcoxon signed-rank test examined pre- and post-test differences, and the Mann-Whitney U test analysed gender distinctions.

RESULTS: The SM app was used once in one class and twice in others. Key features included dual-screen motion comparison (self-comparison and peer comparison) and AI-based motion capture. Students analysed movements inside and outside class. The total diagnostic lesson evaluation score was 54.0 ± 5.09 . The summative evaluation score was

54.5±5.59. Notable improvement was observed in the 'learning' factor (12.9±1.81 to 13.3±1.81, $p < 0.05$). In PPC, the pre-test 'perceived physical competence' factor was markedly higher in boys (15.8±3.69) than in girls (13.0±4.06, $p < 0.05$). However, total PPC scores illustrated no significant change (pre: 49.4±7.90, post: 49.4±7.90). Teachers noted increased student engagement in critical thinking and peer discussion, though the individual use of the app was suggested for superior effectiveness.

Discussion: The dual-screen comparison and motion capture functions of SM app provided a clear, accessible tool for students, likely contributing to the marked improvement of the 'learning' factor. Students analysed their movements outside class, which may have enhanced their understanding. PPC scores were already high before lessons, perhaps due to prior exposure to the app. Compared to previous studies, the high PPC scores suggest app-based learning may positively influence students' self-perception in physical education.

CONCLUSION: The SM app facilitated cognitive engagement and peer feedback, corroborating educational objectives as outlined in the Japanese Course of Study. Its use in physical education classes can enhance learning outcomes and perceived physical competence in students.

"A WIN-WIN OR A HARMFUL?" AN EMPIRICAL STUDY ON THE EFFECTS OF PE-IN-CLIL ON COGNITIVE PERFORMANCE AND PHYSICAL ACTIVITY IN TAIWANESE ELEMENTARY SCHOOLS

WANG, W.Y., CHEN, Y.J.

UNIVERSITY OF TAIPEI, TAIWAN & DEPARTMENT OF SCIENCE, MINOT STATE UNIVERSITY, MINOT, ND, USA

Background & Purpose: Taiwan has been actively promoting bilingual education policy to boost students English ability and subject learning ability. One of the outcomes is the introduction of bilingual Physical Education (PE) classes in elementary schools. Despite that, there is limited research on how effective they are, particularly whether they achieve a good balance between language learning and physical activity or rather reduce students physical activity levels through heightened cognitive load. This study investigates the effects of Content and Language Integrated Learning (CLIL) on the physical activity levels and cognitive load of Taiwanese elementary school children in the setting of Physical Education (PE-in-CLIL). As there is worry over the potential effect involved in including language acquisition within students physical education, this present study endeavors to generate empirical evidence that will describe the impact of Taiwans bilingual physical education programs on physical and mental performance.

Methods: Quasi-experimental design was utilized, with 315 students in grades 1, 3, and 5 in 12 experimental classes and 334 students in 12 control classes. The intervention targeted units on jump rope, soccer, and volleyball specifically. Physical activity was measured objectively by accelerometers, and cognitive outcomes were measured by standardized tests.

Results & Findings: Both groups had significant cognitive enhancements following the intervention [experimental: pre-test 71.79, post-test 73.99, $p = .016$; control: pre-test 64.21, post-test 68.95, $p < .001$], with no significant difference between the groups ($p > .05$). The physical activity measures were all in the favor of the control group: sedentary time (control: 14.92 min; experimental: 19.2 min), total MVPA (control: 9.97 min; experimental: 8.47 min), and step counts, all $p < .001$. These results imply that bilingual educations cognitive demands can decrease student physical activity levels, which in the long run can contribute to ill health.

Discussion & Conclusion: These findings emphasize the need for policymakers and educators to carefully design bilingual PE programs to ensure that language learning is effectively integrated without compromising students physical activity and overall well-being.

A STUDY ON THE STATUS OF TEACHING AND LEARNING IN PHYSICAL EDUCATION CLASSES IN KOREAN MIDDLE SCHOOLS

HYOUNGRAN, P., LEE, J., KANG, S.J., SUK, M.

JEJU NATIONAL UNIVERSITY

The purpose of this study is to understand the current status of physical education classes in Korean middle schools. Physical activities are essential for promoting health during adolescence. Therefore, participation in various physical activities is recommended. The WHO emphasizes the balanced development of mental, social, and spiritual health alongside physical health. Since the foundation of the Republic of Korea, the national curriculum has been continuously revised at the national level. This curriculum reflects the social, economic, and cultural contexts of the time and is developed with the aim of cultivating talents who will lead future society. According to the 2015 revised physical education curriculum of the Republic of Korea, physical education classifies the characteristics of physical activities into five domains: health, challenge, competition, expression, and safety. All students are recommended to learn physical activities in a balanced manner across these five domains. However, there are problems in that the physical education programs in middle schools are planned and operated with a focus on activities preferred by physical education teachers or students. Therefore, in this study, 27 middle schools in S City were conveniently sampled, and the physical education curriculum at the school level was analyzed. As a result, the proportion of competitive activities (61.1%) (e.g., basketball, soccer, volleyball, badminton, etc.) was the highest, followed by health activities (18.8%) (e.g., physical training, etc.), challenge activities (11.3%) (e.g., track and field, swimming, archery, etc.), expressive activities (e.g., dance, etc.), and safety activities (e.g., first aid, etc.). Physical education and the curriculum at the school level should lead to the balanced physical growth of adolescents. Nevertheless, the physical education curriculum at the school level is highly focused on specific activities. In conclusion, it

should be emphasized that schools should provide balanced educational opportunities for physical activities within physical education.

CAN ONLINE PHYSICAL EDUCATION CLASSES IMPROVE SPRINTING SKILLS?: COMPARISON OF LEARNING EFFECTIVENESS AND SATISFACTION BETWEEN ONLINE AND IN-PERSON CLASSES

FUJIBAYASHI, N., SAITO, S.

CHUKYO UNIVERSITY

INTRODUCTION: In the field of physical and sports education and coaching, demand for both online and face-to-face instruction is growing. A key goal of physical education is to provide exercise opportunities and enhance students' skills. Although online classes offer many advantages, it remains unclear whether they can effectively promote physical activity and improve technique. This paper examined whether online track and field practical classes focused on short-distance sprints can improve sprint form and performance. By comparing online with face-to-face classes, we also aimed to identify challenges specific to online practical instruction.

METHODS: The study was conducted in two athletic classes: one delivered face-to-face and one online. Each class comprised fifteen 90-minute lessons, with sprinting practice provided from the second to the fifth lesson. Sprint form and 20-meter sprint times were recorded at the beginning of the second lesson and again at the end of the fifth lesson. Each class had 30 participants, with 29 completing both tests. Sprint times were measured using a smartphone app (Quality, Digital Standard Inc.) that utilizes the phone's accelerometer. Sprint form was recorded using a smartphone with a side-view shot at the 15-meter mark. Two support phases were extracted from the footage and converted into still images (at 1/30-second intervals). A visual analog scale assessed sprint form from four perspectives: arm, leg, torso, and limb coordination. Evaluators were experienced university track and field coaches with over 10 years of specialized coaching.

RESULTS: When comparing the 20-meter sprint times between the second and fifth lessons, a significant improvement was observed in the face-to-face classes (from 3.51 ± 0.58 s to 3.35 ± 0.44 s; $p = 0.041$), whereas no significant difference was found in the online classes (from 3.42 ± 0.51 s to 3.40 ± 0.44 s; $p = 0.567$). Conversely, the overall score on the visual analog scale evaluating sprint form improved significantly in both face-to-face and online lessons. This suggests that while online classes can enhance the appearance of movement and help students understand essential sprinting techniques, they may be less effective at improving the less tangible aspects, such as movement power. In addition, there was no significant difference in class satisfaction between the face-to-face and online formats.

CONCLUSION: The results of this study suggest that even in online classes, it is possible to provide students with a certain level of learning by devising effective instructional methods. To improve motor skills in online classes, it may be essential to present core techniques clearly and develop strategies to convey the "internal feel" of force exertion.

THE DOWN SIDE OF KNOWLEDGE-FOCUSED EDUCATION IN PHYSICAL EDUCATION TEACHER EDUCATION, MEASURED BY QUANTITATIVE AND QUALITATIVE METHODS.

SARUS, T., PAIC, R., PRISZTÓKA, GY.

UNIVERSITY OF PÉCS

INTRODUCTION: In Hungary, students in teacher education programs must demonstrate their suitability for the teaching profession based on a state-defined competency system at the end of their studies. These so-called teacher competencies define the preparedness of future teachers in the areas of knowledge, skills, and attitudes. Teacher training aims to develop these competency fields, but the question arises whether Hungarian teacher training is effective and modern enough to fulfil this aim. We first conducted a research on this topic in 2019 at a Hungarian university, examining the impressions of students in physical education teacher education, regarding their studies in terms of burnout and motivation factors. In the initial study, we found that the satisfaction and cynical levels of physical education teacher students, increased as their training progressed. We repeated our measures in every academic year until 2023, transforming our work into a longitudinal study. In accordance with methodological recommendations in educational science, we supplemented our research with qualitative methods in the 2023 academic year.

METHODS: In our quantitative study, students from the undivided physical education teacher and coach training programs at the University of Pécs participated from 2019 to 2023 (2019: N=160; 2021: N=128; 2022: N=143; 2023: N=82). We used a questionnaire package composed of several validated psychological tests (MBI SS, GMS-28). Our qualitative study involved a structured interview (N=51), with questions related to satisfaction and attitudes towards teacher training.

RESULTS: Among the physical education teacher students, the correlation between cynicism and satisfaction with the training was significant over the four years of the study. The average values of cynicism related to the training showed an increasing trend, meaning that students increasingly doubted the usefulness of their studies as they approached the end of their training. The year of teaching practice marked a turning point, with these values generally changing in a more favourable direction. In our previous studies, we hypothesized that experiences and impacts during the teaching practice played a significant role in this. The results of the interviews support this hypothesis.

Discussion: A demand to immediately associate theoretical knowledge with its practical applicability is rising among the students, so in the teachers' educations would be worthwhile to increase the chance for students to practice, and try out the knowledge they acquired during their academic studies. However, it should be noted that the study was conducted at only one Hungarian university, so it should not be treated as a national trend.

EXPLORING THE USE OF A DESIGNED FUNDAMENTAL MOVEMENT EQUIPMENT STORAGE TROLLEY IN SCHOOL PHYSICAL EDUCATION

HO, Y.

THE EDUCATION UNIVERSITY OF HONG KONG

Background: Hong Kong's limited space presents a significant challenge for storing sports equipment. Often, equipment is stored at high levels, making it difficult to access when needed. Presetting equipment in the teaching area is not an option with no breaks between lessons. Consequently, quickly retrieving teaching equipment within a limited time is a challenge Hong Kong teachers face when teaching fundamental movements in schools.

Methods: Semi-structured face-to-face interviews were conducted with 15 teachers from three Fundamental Movement Learning Community (FMLC) schools, each with teaching experience ranging from 2 to 30 years. These schools provided a Designed Fundamental Movement Equipment Storage Trolley (DFMEST) for two weeks. All teachers used the DFMEST during the first week and did not use it in the second week.

Results: There were three key findings: Increased teaching time, All participants agreed that the use of the Designed Fundamental Movement Equipment Storage Trolley (DFMEST) helped access fundamental movement equipment when needed, thereby increasing teaching time and reducing the time required to prepare teaching equipment; Design of the Storage Trolley, The design of the DFMEST and the selection of sports equipment to be included in the trolley were crucial for its effectiveness. The use of the trolley significantly improved class and equipment management.

Discussion: This pilot study provides an overview of the needs of PE teachers and assists manufacturers in producing a Designed Fundamental Movement Equipment Trolley (DFMEST). Furthermore, the study highlights future directions and considerations for factories to produce suitable equipment storage for FMLC schools, aiming to develop an effective system for storing sports equipment.

Physiology

THE AUTONOMIC NERVOUS SYSTEM AT HIGH ALTITUDE: INSIGHTS FROM HRV ANALYSIS. THE HIGH ALTITUDE CAMP PROJECT

CARIA, E., TONACCI, A., PARENZA, M., SPREAFICO, F., D'ANGELO, G., TAGLIAPIETRA, G., AGAZZI, G., SPINABELLI, S., POMPILO, P., RANUNCOLI, C., MRKIC SPOSTA, S., COGO, A., MARCORA, S., PRATALI, L.

UNIVERSITY OF PAVIA

INTRODUCTION: Acute exposure to hypoxia (i.e. at high altitude or during intense physical exertion) triggers significant autonomic nervous system (ANS) changes, including an increased sympathetic response. Heart rate variability (HRV) reflects fluctuations in heart rate due to complex interactions between the heart, brain, and ANS. Both excessive and diminished HRV are associated with disease and impaired physiological function. This study aimed to investigate whether individuals with a stronger sympathetic response to hypoxia may be more prone to acute mountain sickness (AMS).

METHODS: 18 healthy male members of the Italian Alpine troops were investigated. HRV was assessed by the non-invasive wearable device Shimmer ECG (Shimmer Research Inc., Dublin, Republic of Ireland). Additional physiological parameters, including vital signs, altitude sickness symptoms, cardiac function, and pulmonary pressure, were monitored. Data were collected twice daily, both at rest and post-exercise, at sea level (T0) and at high altitude (Rifugio Torino, Mont Blanc, 3,375 m, T1, T2 and T3).

RESULTS: Sympathetic activity was found modified after exercise at T0 (HR: 65.1 ± 10.9 vs. 73.9 ± 11.4 bpm, $p=0.026$, CSI: 2.8 ± 0.6 vs. 3.5 ± 1.0 , $p=0.008$), whereas at T1 both sympathetic and vagal features were impacted by the physical activity (HR: 71.8 ± 8.5 vs. 94.2 ± 10.1 bpm, $p<0.001$, CSI: 3.0 ± 0.6 vs. 3.7 ± 1.0 , $p=0.009$, CVI: 3.3 ± 0.3 vs. 2.8 ± 0.5 , $p<0.001$). At T2, no modifications were observed. Correlations with other physiological parameters were sought at high altitude, with a significantly negative relationship between an increase in the Cardiac Sympathetic Index and a decrease in Diastolic Blood Pressure ($r=-0.602$, $p=0.008$). No correlation was otherwise found with AMS. Such results suggest that, despite the individual autonomic heterogeneity, physical activity at altitude significantly impacts the ANS especially in the phases of ascent, with a somewhat direct relationship with blood pressure variations.

CONCLUSION: The autonomic response to hypoxia is complex and not yet fully understood. While hypoxia-induced sympathetic activation is well established and is a common feature of AMS and high-altitude pulmonary edema, its precise role in AMS pathogenesis remains uncertain. Further large-scale studies are needed to clarify the relationship between autonomic function, HRV alterations, and susceptibility to AMS, and to prove the usefulness of wearables for ANS quantification.

DOES DAILY BRIEF IMMERSION IN 14°C WATER AFFECT GLUCOSE TOLERANCE AND INSULIN SENSITIVITY?

SOLIANIK, R., JARUTIE, L., BRAZAITIS, M.

LITHUANIAN SPORTS UNIVERSITY

INTRODUCTION: Cold exposure is often considered as an exercise mimetic. While short-duration cold therapy could be an alternative and attractive strategy, particularly for people individuals who do not engage in regular exercise because of lack of motivation, injury, disability or restricted free time, its impact on metabolic health is unknown. Thus, the main pur-

pose of this study was to investigate the effects of brief, repeated cold water immersion on glucose tolerance and insulin sensitivity in young males and females.

METHODS: Twelve non-obese subjects (6 females and 6 males) completed sixteen daily sessions, each involving 10 minutes of whole-body immersion in 14°C water. Resting catecholamine concentration, glucose, and insulin release in response to a 2-hour standard 75-g oral glucose load were assessed before, 24 hours after, and 1 week after the end of the cold intervention. The areas under the curves of glucose and insulin were calculated using the trapezoidal rule during an oral glucose load test. Additionally, insulin sensitivity was assessed using the Matsuda index.

RESULTS: Repeated brief immersion in 14°C water did not affect resting epinephrine and norepinephrine concentrations. However, such cold intervention significantly increased ($p < 0.05$) the areas under the curves of glucose and insulin, and significantly decreased ($p < 0.05$) insulin sensitivity, as indicated by a lower Matsuda index. No significant time and sex interactions were observed ($p > 0.05$). After one week, the metabolic changes induced by the cold intervention returned to baseline.

CONCLUSION: Sixteen sessions of brief 10-minute whole-body immersion in 14 °C water temporarily increased insulin resistance and glucose intolerance in healthy young adults. This program cannot replace the role of exercise; regular exercise remains essential for optimal metabolic health.

CHANGE IN OXIDATIVE STRESS BIOMARKERS AND DNA DAMAGE FOLLOWING 12 WEEKS OF HIIT AND MICT IN BREAST CANCER SURVIVORS

MOAZAMIGOUDARZI, S.1, MAHDIAN, S.2, SOORI, R.2, POURNEMATI, P.2
UNIVERSITY OF BOLOGNA UNIVERSITY OF TEHRAN

INTRODUCTION: The beneficial health effects of physical activity on breast cancer survivors (BCS) have been shown, though the role of exercise intensity on oxidative markers is unclear. This study assesses the effect of 12 weeks of high-intensity interval training (HIIT) and moderate-intensity continuous training (MICT) on oxidative stress markers, including superoxide dismutase (SOD), glutathione peroxidase (GPX), total antioxidant capacity (TAC), malondialdehyde (MDA), and DNA damage (8-OHdG) in BCS.

METHODS: A total of 45 BCS (age=57.3±3.9 years, BMI=28.2±2.3 kg/m², fat mass=31.2±3.7 kg) were randomized into HIIT (n=15), MICT (n=15), or control (CON, n=15). HIIT and MICT groups performed exercise on a cycle ergometer three times weekly for 12 weeks. Fasting blood samples were collected pre and post-intervention.

RESULTS: Both HIIT and MICT significantly increased SOD (HIIT 94.86±7.98 vs 97.36±9.10, MICT 93.78±7.40 vs 94.87±7.77), GPX (HIIT 184.20±6.15 vs 187.33±8.27, MICT 183.75±8.63 vs 185.42±8.62), and TAC (HIIT 12.43±1.98 vs 12.70±2.02, MICT 12.56±1.64 vs 12.67±1.61). MDA (HIIT 15.17±0.69 vs 14.92±0.71, MICT 15.48±0.84 vs 15.37±0.88) and 8-OHdG (HIIT 2.36±0.52 vs 2.33±0.52, MICT 2.68±0.50 vs 2.60±0.52) decreased in both groups ($p < 0.05$). HIIT improved oxidative stress markers more than CON, while MICT reduced 8-OHdG versus CON. No significant differences were observed between HIIT and MICT ($p > 0.05$).

CONCLUSION: Both HIIT and MICT improved oxidative stress markers, with HIIT potentially offering body composition benefits. Further research is needed to clarify the comparative advantages of HIIT for oxidative stress in BCS.

THE EFFECT OF THE

SIMKO, G., UVACSEK, M.

HUNGARIAN UNIVERSITY OF SPORTS SCIENCE

INTRODUCTION: In terms of the number of deaths, the leading risk factors globally are obesity and chronic hyperglycaemia. In Hungary, 68% of the adult population is considered being overweight (OTAP, 2019) and 1.1 million diabetics are registered (KSH, 2020). According to the literature, the stimulation of the GLP-1 hormone can be achieved naturally through dietary changes (Ren et al., 2020). The aim of our study was to investigate the effectiveness of the weight loss intervention "Smart Weight Loss" in relation to the stimulation of GLP-1. We assumed that the special dietary intervention results positive change in the participants body composition and eating habits and reduces the risk of developing T2D.

METHODS: The 12-week intervention was fulfilled by 48 healthy, overweight Hungarian women aged 25- 45 years. The methods were body composition examination with an InBody device, the risk of type 2 diabetes was estimated with the FINDRISC questionnaire, nutrition was analysed with a 3-day food diary and the NutriComp Diet-CAD program. Statistical analyses were performed using TIBCO Statistica 13.40.14. All statistics tests were performed at 5% significance level.

RESULTS: At baseline, all participants (n=48) were overweight and had an increased risk of diabetes. The intervention had a significant effect on body mass index (28.0±2.5 vs 25.8±4.3 kg/m², $p=0.00$), waist circumference (100.8±7.2 vs 94.7±8.2 cm, $p=0.00$), body fat (37.5±6.3 vs 34.1±5.9%, $p=0.03$) and visceral fat (124.0±29.2 vs 109.0±24.6 cm² $p=0.04$). We experienced a significant change in both energy intake and the distribution of macronutrients, in terms of fiber consumption ($p=0.00$). FINDRISC values showed no significant difference.

CONCLUSION: We concluded that the risk of developing type 2 diabetes can be modified by lifestyle intervention in overweight women. We observed a significant reduction in body fat, BMI, waist circumference, visceral fat and healthy eating characteristics, which results can be achieved in a 12-week lifestyle change programme.

COMPARING 17- β -ESTRADIOL AND PROGESTERONE CONCENTRATIONS IN YOUNG, PHYSICALLY ACTIVE FEMALES: INSIGHTS FROM PLASMA VS. SERUM ANALYSIS

ROWLAND, S., DA BOIT, M., TAN, R., HEANEY, L.M., BAILEY, S.J.

LOUGHBOROUGH UNIVERSITY

INTRODUCTION: Serum measurements of 17- β -estradiol and progesterone are widely used to verify menstrual cycle status and confirm contraceptive use, often through commercially available immunoassay kits. However, no studies have investigated whether blood collection tube chemistries influence hormone concentrations in young females, despite assays permitting the use of different biofluids with similar reference ranges.

METHODS: In this study, venous blood was drawn from physically active females ($n=25$) using EDTA and serum vacutainers, and 17- β -estradiol and progesterone concentrations were measured using competitive immunoenzymatic assays.

RESULTS: Median plasma concentrations of 17- β -estradiol and progesterone were 44.2% (plasma 40.75 vs serum 28.25 pg/mL) and 78.9% (plasma 1.70 vs serum 0.95 ng/mL) higher than serum, respectively ($p<0.001$ for both). Strong positive correlations were observed between plasma and serum concentrations for 17- β -estradiol ($r=0.72$; $p<0.001$) and progesterone ($r=0.89$; $p<0.001$). The mean bias and limits of agreement for plasma vs. serum were 12.5 pg/mL (-20.6 to 45.5 pg/mL) for 17- β -estradiol and 1.01 ng/mL (-5.6 to 7.6 ng/mL) for progesterone.

CONCLUSION: Ovarian hormone levels were consistently higher in EDTA plasma compared to serum, with these matrices not yielding statistically equivalent results. Despite these differences, the strong correlations and good agreement suggest that both matrices are suitable for biomarker analysis. Researchers using EDTA plasma should account for the higher hormone concentrations when applying inclusion or exclusion criteria, as adjustments may be necessary to ensure appropriate participant classification.

BLOOD LACTATE AND NON-INVASIVE EXERCISE THRESHOLDS METHODS COMPARISON

AZEVEDO, P., AZEVEDO, V., AZEVEDO, H., PEREIRA, P., OLIVEIRA, J., LOTURCO, I.

FEDERAL UNIVERSITY OF SÃO PAULO

INTRODUCTION: Lactate and ventilatory thresholds have been a hot topic in exercise physiology. However, the scientific literature contains several methods for determining lactate thresholds. Previous studies compared lactate thresholds through insufficient statistical analyses. This study aimed to verify whether any of the seventeen different lactate threshold methods are valid for estimating first and second ventilatory thresholds.

METHODS: Nineteen physically active participants (teen men and nine women) (age: 23.5 ± 3.0 years; weight: 65.9 ± 13.3 kg; stature: 169.6 ± 7.8 cm; %fat mass: 20.2 ± 8.6 ; VO_{2max} : 37.8 ± 7.0 mL.kg⁻¹.min⁻¹) performed a graded incremental exercise test until exhaustion on a treadmill to determine first and second ventilatory thresholds and nine different methods of lactate thresholds. Lactate thresholds were then compared with ventilatory thresholds to verify possible differences (P), effect size (ES), agreement (BA), equivalence (E), and probability (BF01) to be similar or different.

RESULTS: Bsln+ 0.5 ($P=0.9$; ES: 0.04, -0.41 – 0.49; BA: -0.06; -0.92 – 0.79; E: $P=0.87$; BF01: 4.2) and OBLA 3.0 ($P=0.8$; ES: -0.06, -0.51 – 0.39; BA: 0.11; -0.74 – 0.96; E: $P=0.79$; BF01: 4.1) are valid methods to estimate first and second ventilatory thresholds, respectively. The other methods are not interchangeable with any ventilatory thresholds.

CONCLUSION: We conclude that most lactate threshold methods used here are not interchangeable with ventilatory thresholds. Coaches and physiologists can use Bsln+ 0.5 and OBLA 3.0 methods to estimate first and second ventilatory thresholds when applying the same graded protocol.

COMPARISON OF MOVEMENT ECONOMY BETWEEN ELITE AND SUB-ELITE FOOTBALL PLAYERS

ZHAI, Y., WANG, J.

TONGJI UNIVERSITY

INTRODUCTION: Movement economy (ME) is important for evaluating the energy efficiency and optimizing the physical performance in football-specific training to support sustained competitive play. Given its importance, this study aimed to investigate differences in ME between elite and sub-elite football players across football-specific skill tests and shuttle running.

METHODS: The 18 male participants (9 elite and 9 sub-elite football players) were recruited on the basis of their competitive level and number of training sessions per week. Participants wore the COSMED K5 wearable metabolic system while performing a sequence of football-specific skill tests: 3-min juggling the ball, 3-min short passing, 3-min long passing, 3-min dribbling-and-shooting, and 20m and 10m shuttle run at 10 km/h for 5 min. The oxygen consumption (VO_2 , mL/min), respiratory quotient (RQ, Kcal/L) were recorded continuously and averaged during the final minute of each test to determine ME expressed as oxygen cost (OC, mL/kg/min) and energy cost (EC, Kcal/kg/min) (calculated as $EC = RQ \times OC / 1000$). Rate of Perceived Exertion (RPE, Borg scale: 6 to 20 scale) was recorded after each test, and blood lactate levels (BLa) were measured immediately following the shuttle run and at 1, 3, and 5 minutes post-shuttle run.

RESULTS: Results showed that the elite group demonstrated lower OC and EC across all skill and run tests compared to the sub-elite group. The elite group had significantly lower OC than the sub-elite group in the dribbling-and-shooting test (51.40 ± 7.76 vs. 60.95 ± 10.05 mL/kg/min, $p<0.05$, ES=1.06) and the 20m shuttle run test (55.77 ± 6.88 vs. 64.02 ± 9.10 mL/kg/min, $p<0.05$, ES=1.02). The elite group had significantly lower EC than the sub-elite group in the juggling the ball

test (0.16 ± 0.02 vs. 0.2 ± 0.04 Kcal/kg/min, $p < 0.05$, $ES = 1.26$) and long passing test (0.18 ± 0.04 vs. 0.22 ± 0.04 Kcal/kg/min, $p < 0.05$, $ES = 1$). BLA were lower in the elite group than the sub-elite group after the 20m and 10m shuttle runs, RPE was also lower in the elite group. However, the differences between the two groups in BLA and RPE were not statistically significant ($p > 0.05$).

CONCLUSION: Elite players exhibited higher movement economy when performing medium- to high-intensity football-specific movements and shuttle running. These findings suggest that elite-level players may have physiological adaptations allowing for greater energy efficiency during sport-specific tasks.

EFFECTS OF SERUM MAGNESIUM CONCENTRATIONS ON ANAEROBIC PERFORMANCE IN MALE WEIGHT-CATEGORY ATHLETES

CHAN, K., CHEN, H.H., LU, Y.F., TU, M.H.

NATIONAL TAIWAN SPORT UNIVERSITY

INTRODUCTION: Adenosine triphosphate exists in the body as a compound with magnesium, serving as the direct energy source for all body activities. Therefore, the serum magnesium status of athletes may influence anaerobic performance. Weight-category sports are defined by the requirement of a weigh-in before competition to provide performance equity and restricted the diet intake may associated with lower serum micronutrients. Our previous study recruited 180 collegiate athletes to analyze serum magnesium levels, it showed that 2nd and 3rd quartile levels were 3.1 and 4.0 mg/dL, respectively. Therefore, the aim of this study was to examine the differences in anaerobic power and the levels of magnesium, calcium, glucose, and lactate before and after anaerobic exercise in male weight-category athletes with different serum magnesium concentrations.

METHODS: Twelve male athletes with serum magnesium level below 3.1 mg/dL were recruited from taekwondo, judo, and weightlifting teams and assigned into the lower magnesium (LMg) group. An additional 12 athletes with serum magnesium level above 4.0 mg/dL and matched for the same sport and weight categories as the LMg group were also recruited into the higher magnesium (HMg) group. The average body mass index for athletes in LMg and HMg groups were 25.66 ± 2.85 and 26.73 ± 4.61 kg/m², respectively. The mean serum magnesium concentrations in LMg and HMg groups were 2.37 ± 0.31 and 4.79 ± 0.66 mg/dL ($p < 0.05$), respectively. Participants then underwent a Wingate anaerobic test for 30 seconds to collect the values of peak power, minimum power, average power, power drop (power decline from peak to trough), and fatigue index (percentage of power decline from peak to trough). And calculated the relative values of the PD and FI. Data were analyzed by independent samples t-tests to examine the differences in anaerobic power between two groups. Statistical significance was set at $\alpha = .05$. All data are expressed as mean $\pm$ SD.

RESULTS: The absolute and relative fatigue index in LMg group were significantly higher than that in HMg group ($61.52\% \pm 10.40\%$ vs $54.25\% \pm 7.93\%$, and $0.82\% \pm 0.13\%$ vs $0.71\% \pm 0.17\%$ /kg BW, respectively; $p < 0.05$). Moreover, the relative power drop in LMg group were also significantly higher than that in HMg group (5.73 ± 1.57 vs 4.48 ± 1.11 W/kg BW, $p < 0.05$). However, there were no significant differences in the performance of peak power, minimum power, average power, and power drop between the two groups.

CONCLUSION: The result of the present study indicates that the male athletes in weight-category sports with lower serum magnesium levels would produce greater fatigue after anaerobic exercise. Therefore, these athletes should pay attention to their dietary magnesium intake, especially during periods of caloric restriction. Further studies are needed to investigate the relationship between blood magnesium concentration and anaerobic performance in female athletes in weight-category sports.

BODY COOLING IMPROVES AEROBIC EXERCISE CAPACITY UNDER COMBINED HEAT STRESS AND MENTAL FATIGUE.

NAITO, T., SAITO, T., MORINAGA, H., NAKAMURA, M., TAKAI, Y., AKAZAWA, N.

HOKKAI-GAKUEN UNIVERSITY

INTRODUCTION: The combination of mental fatigue resulting from a prolonged cognitive task and exposure to heat stress has been demonstrated to result in impaired exercise capacity in the heat. However, the efficacy of body cooling as a strategy to prevent impairment of subsequent exercise capacity when exercises are performed in combined heat and mental stress remains unclear. The purpose of this study was to investigate the effects of body cooling prior to and during exercise with mental fatigue on aerobic exercise capacity in the heat.

METHODS: Seven non-heat-acclimatized recreational male athletes (age: 22 ± 1 years, height: 174.8 ± 8.3 cm, body mass: 72.25 ± 11.2 kg, maximal oxygen uptake [VO₂max]: 46.2 ± 4.6 mL/kg/min) performed three trials: thermoneutral condition (22°C, CON), hot condition (35°C, HOT), and hot condition (35°C) with cooling intervention (COOL). Participants were conducted AX-Continuous Performance Task (AX-CPT) during the 45-min 50%VO₂max cycling exercise under each condition. After rest for 5 min, participants performed the cycling exercise at an intensity equivalent to 75%VO₂max until reaching voluntary exhaustion. Cooling intervention was conducted before and during exercise used total ingestion of approximately 450 g ice slurry and wearing ice vest.

RESULTS: All participants had the shortest time to exhaustion for the HOT trial. Time to exhaustion was longer in the CON trial (623.1 ± 152.6 sec; Effect size (ES) = 1.48) and COOL trial (571.0 ± 197.8 sec; ES = 0.84) than in the HOT trial (441.9 ± 83.4 sec). There were small differences in time to exhaustion between the CON and COOL trials (ES = 0.29). The change in rectal temperature at the onset of exercise was observed to be lower in the COOL trial than in the CON and HOT trials ($p < 0.05$). In the CON trial, the 45-min 50%VO₂max cycling exercise with AX-CPT resulted in a lower change in rectal tempera-

ture compared to the HOT and COOL trials ($p < 0.05$). Perceptual sensations at the onset of exercise were observed to be lower in the COOL trial than in the HOT trial ($p < 0.05$). Self-reported mental fatigue using visual analog scale was significantly higher after tasks in each trial ($p < 0.001$), but no significant differences between trials (CON: 6.4 ± 1.9 , HOT: 6.5 ± 1.8 , COOL: 6.9 ± 1.7 $p > 0.05$).

CONCLUSION: The results of this study showed that the body cooling before and during exercise under combined heat stress and mental fatigue improved subsequent aerobic exercise capacity compared with no-cooling. This observation suggested that athletes who exercise with mental fatigue in the heat should be cooling to mitigate elevation in core temperature equivalent to hyperthermia.

THE RESPONSE OF REACTION TIME AND FATIGABILITY TO EXHAUSTIVE EXERCISE IN YOUNG MALE

AKAZAWA, N., OTOMO, M., NAKAMURA, M.

NATIONAL INSTITUTE OF FITNESS AND SPORTS IN KANOYA

INTRODUCTION: Cognitive function is enhanced after a single session of moderate aerobic exercise; however, the effects of exhaustive exercise on cognitive function remain controversial. The post-exercise effect on cognitive function is associated with exercise intensity, duration, and psychological and physiological factors [1]. The present study aimed to investigate the impact of exhaustive exercise on cognitive function and the differences in psychological and physiological parameters between positive and negative responders to exercise.

METHODS: Seventeen young males performed an exhaustive incremental submaximal exercise task. Reaction time in the incongruent Stroop task, salivary cortisol and immunoglobulin A (IgA) levels, and visual analogue scale scores for fatigue were evaluated. Participants were divided into 2 groups: slower group, which exhibited an increase in reaction time; and faster group, which exhibited a decrease in reaction time after the exercise.

RESULTS: There were no differences in changes in the salivary cortisol and IgA level between the slower and faster groups. The slower group exhibited a greater increase in fatigue than the faster group. The increase in fatigue score was positively correlated with the changes in reaction time.

CONCLUSION: Results of this study demonstrated that the excessive increase in fatigue after exhaustive exercise delays cognitive response time. Findings suggest that the individual differences in perceived fatigability, rather than physiological responses, may be modulated to alter cognitive performance after exhaustive exercise.

THE RELATIONSHIP BETWEEN SCLEROSTIN AND OSTEOGENIC RESPONSES IN ATHLETES: INFLUENCE OF MECHANICAL STRESS

HONDA, A., KUROKAWA, R.2, HORI, M.3, MIZUTANI, Y.3, UMEMURA, Y.2

1 ASAHI UNIVERSITY, 2 CHUKYO UNIVERSITY, 3 ASAHI UNIVERSITY

INTRODUCTION: Sclerostin (SCL), which strongly inhibits bone formation, increases with reduced mechanical stress (inactivity or unloading), aging, and menopause. Some studies have reported increased bone mass and bone formation markers and decreased SCL with training. By contrast, others have reported higher SCL in athletes compared with non-athletes, or elevated SCL in rugby players (strength sports) compared to cyclists (non-impact sports), the latter being considered to have a lower bone mass. As the relationship between SCL, sports characteristics, and osteogenic responses remains unclear, this study investigated the effects of SCL on the osteogenic responses in athletes under different mechanical stresses.

METHODS: Participants were male college athletes: cyclists (CY; $n = 19$, age = 20.7 ± 0.7 years, height = 171.7 ± 6.3 cm, weight = 70.4 ± 6.9 kg), rugby players (RG; $n = 20$, age = 20.8 ± 0.8 years, height = 173.3 ± 5.1 cm, weight = 86.9 ± 11.3 kg), baseball players (BB; $n = 17$, age = 20.9 ± 0.8 years, height = 171.6 ± 6.1 cm, weight = 70.7 ± 8.0 kg; odd-impact sport), and volleyball players (VB; $n = 12$, age = 19.7 ± 0.8 years, height = 177.5 ± 7.4 cm, weight = 70.2 ± 9.6 kg; high-impact sport). Serum SCL, osteocalcin (OC), bone-specific alkaline phosphatase (BAP), tartrate-resistant acid phosphatase 5b (TRACP), free testosterone (T), and total calcium (Ca) were measured. Bone stiffness (BS) and Z-score of the dominant-side calcaneus were assessed using quantitative ultrasonography.

RESULTS: The SCL in RG was significantly higher than that in CY ($p < 0.001$). The OC in RG was also significantly higher than that in CY and BB ($p < 0.05$). The TRACP, T, and Ca levels did not change significantly. While a significant group main effect was observed in BAP, post-hoc analyses did not reveal any specific group differences. The BS and Z-scores in RG were significantly higher than those in CY ($p < 0.001$). SCL was positively correlated with OC ($p < 0.001$) and TRACP ($p < 0.01$) but not with bone strength indices.

CONCLUSION: These results indicate higher bone turnover in RG, which may explain the elevated SCL levels compared to those in CY. However, an increase in SCL did not negatively affect bone strength. During active remodelling, a temporary increase in SCL may have helped balance bone metabolism. This suggests that SCL regulates adaptive bone remodelling rather than inhibit bone formation.

Our findings highlight complex interactions between SCL and mechanical stress. While mechanical loading generally promotes bone formation, sustained high-intensity stress, as seen in rugby, may increase SCL to regulate the balance between bone resorption and formation.

MODELING OF CORE BODY TEMPERATURE DURING GRADED TREADMILL RUNNING

SENTIJA, D., RAKOVAC, M., MARSIC, T., BABIC, V.

FACULTY OF KINESIOLOGY, UNIVERSITY OF ZAGREB

INTRODUCTION: During incremental treadmill running neuromuscular and metabolic changes, which determine the gas exchange thresholds (GET), are associated with changes of core body temperature (CBT). The main objective of this research was to investigate the relationship between GET (first and second ventilatory threshold, VT1 and VT2) and the eventual presence of nonlinear trend changes in rectal temperature (RT), defined as CBT thresholds (TT1 and TT2), measured concurrently during an incremental treadmill running test (GXT)

METHODS: Thirty-two male participants were subjected to an all-out GXT (0.5 km/h increments/30 sec, 1.5% incline), with measurement of RT and gas exchange parameters. Three independent evaluators evaluated the VE and RT thresholds. RT was measured with a fast-response temperature probe connected to a datalogger (Xplorer GLX, PASCO Scientific) with DataStudio software for data storage and analysis. The logger contains built-in temperature sensors with a resolution of 0.01°C. The frequency of data collection was set at 2 Hz. The temperature probe was inserted into the rectum, 8 cm from the anal opening, fastened and additionally secured with an elastic strap around the waist. After the test, temperature data were exported (Microsoft Excel) and analyzed graphically. The Quark b2 (Cosmed, IT) system was used for breath-by-breath acquisition of spirometry data. For all subjects, the relative running speed (as percentage of maximal running speed) was calculated for every running step. RT data for all participants were related to relative running speed averaged at 2% step increase, in order to visualize and confirm the eventual presence of rectal temperature thresholds delineating the three intensity domains (moderate, heavy and severe) during a GXT to volitional exhaustion. Three linear regressions for temperature data within the three domains were calculated with average VT1 and VT2 values as breakpoints

RESULTS: The increase of RT with increasing running speed in most of our participants followed a 3-phase model, while a two-segment model was detected in three of our participants. Overall, smoother between-phase transitions and a higher signal-to-noise ratio was noted for CBT data, than for breath-by-breath gas exchange parameters. In the moderate intensity range a slow rise, or even stagnant CBT with increasing running speed was observed. A 7-fold steeper rise in CBT was observed in the heavy compared to the moderate intensity domain. In the severe domain, the slope of the CBT rise with increasing speed almost doubled in comparison to the heavy domain

CONCLUSION: During graded treadmill running, there is close coupling between trend changes of rectal temperature and changes in gas exchange parameters that determine VT1 and VT2. The results of the study imply that measurement of core body temperature during graded treadmill running may be used as a new method for determination of thresholds demarcating the transition from aerobic to anaerobic metabolism

NAILFOLD CAPILLARY PATTERNS IN BALLGAME AND ENDURANCE ATHLETES

OTSUKI, T., SUWABE, K., YOSHIKAWA, T., KOTANI, K., ZEMPO-MIYAKI, A.

RYUTSU KEIZAI UNIVERSITY

INTRODUCTION: Nailfold capillary patterns can be observed noninvasively using light microscopy. Nailfold capillaries are straight, U-shaped, and densely looped in healthy individuals and may be altered by disease or lifestyle factors, such as diet. However, the effects of daily physical activity and exercise training on nailfold capillary patterns remain unclear. This study aimed to examine the effects of exercise training on nailfold capillary patterns by investigating these patterns in endurance athletes, ballgame athletes, and sedentary healthy men.

METHODS: Five healthy men participated in nailfold capillary pattern measurements on 3 consecutive days to test the reproducibility and bilateral differences in the nailfold capillary loop number, length, and width measured using light microscopy and a commercial analysis system. The nailfold capillaries of 10 endurance athletes (endurance group; 8 long-distance runners and 2 triathletes), 10 ballgame athletes (ballgame group; 7 soccer players and 3 basketball players), and 9 sedentary healthy men (sedentary group) were then examined using light microscopy.

RESULTS: The day-to-day coefficient of variation for the nailfold capillary loop number, length, and width were $4.9 \pm 1.6\%$, $7.5 \pm 1.3\%$, and $4.2 \pm 1.5\%$, respectively. No significant differences in these measurements were observed between the dominant and non-dominant hands. The number of nailfold capillary loops was greater in the ballgame group than in the endurance and sedentary groups. Capillary loop length was shorter in the ballgame group than in the endurance and sedentary groups. No significant differences in capillary loop number and length were observed between the endurance and sedentary groups. No significant intergroup differences were observed in capillary loop width.

CONCLUSION: These results suggest that the nailfold capillary patterns of male ballgame athletes differ from those of endurance athletes and sedentary healthy men. Ballgame training may affect nailfold capillary patterns in sedentary healthy men.

This research was supported by the JSPS KAKENHI (23K10638) and a grant from the Advanced Research Initiative for Human High Performance (ARIHHP), University of Tsukuba. We thank the AT Company Limited (Osaka, Japan) for their technical assistance.

EFFECTS OF A 10-WEEK AEROBIC EXERCISE OR DIETARY AND NUTRITIONAL GUIDANCE INTERVENTION ON GLYCATION MARKERS

NAKAJIMA, S., YAMADA, N.

KYORITSU WOMENS JUNIOR COLLEGE

INTRODUCTION: Advanced glycation end-products (AGEs) are harmful compounds formed through reactions between proteins and sugars in the body. They are known to accelerate senescence and contribute to the pathogenesis of lifestyle-related diseases such as arteriosclerosis and diabetes mellitus. Previous studies have demonstrated that the cutaneous AGE content increases with age, unhealthy diet, and a disordered lifestyle. Poor lifestyle factors may worsen and accelerate AGE accumulation. This study aimed to experimentally investigate whether aerobic exercise or dietary and nutritional intervention could influence skin AGEs and other glycation markers in young women without regular exercise habits.

METHODS: Our study participants were 20 healthy young women without chronic disease or regular exercise habits. They were randomly divided into two groups: an exercise group (Ex group, $n = 10$) and a dietary intervention group (Nu group, $n = 10$). In the Ex group, participants engaged in 30-min cycling sessions on an ergometer twice a week for 10 weeks. Exercise intensity was determined based on the heart rate targets calculated from the maximum oxygen consumption (VO_2max). In the Nu group, participants recorded their daily meals using a diet management app and received weekly feedback. Skin AGE levels were measured on the dominant forearm using an AGE Scanner (Diagnoptics). Blood glucose levels, blood HbA1c titers, and body composition (e.g., body fat percentage) were also measured. Measurements were taken at weeks 0 (baseline), 5, 10, and 25.

Participants in the Ex group had the following features: Age, 19.7 ± 1.7 years; VO_2max , 36.4 ± 5.2 ml/min/kg. In the Nu group, participants had the following characteristics: Age, 20.1 ± 1.2 years; VO_2max , 26.4 ± 2.5 ml/min/kg.

RESULTS: In the Ex group, the percentage change in cutaneous AGE levels decreased significantly at weeks 5 ($p = 0.045$) and 25 ($p = 0.039$) compared to week 0. HbA1c levels also decreased significantly at weeks 10 ($p = 0.032$) and 25 ($p = 0.021$) compared to week 0. In the Nu group, no significant changes in cutaneous AGE levels were observed at any measurement point. Statistical analyses included the repeated measures ANOVA and independent t-tests, with the threshold for statistical significance set at $p < 0.05$.

CONCLUSION: HbA1c reflects the average blood glucose levels over the past 1–2 months, whereas skin AGEs indicate a longer-term glycation state. In the Ex group, a notable improvement in glycation marker levels was observed after week 10, suggesting that aerobic exercise effectively reduces glycation stress. In contrast, the Nu group showed minimal changes, indicating that short-term dietary management alone may not be sufficient to affect glycation marker levels significantly. Both interventions may require longer-term implementation to achieve significant and sustained results.

RELATIONSHIP BETWEEN SWEAT LACTATE AND HEART RATE DURING SWIMMING TRAINING

UMEMOTO, M., HYODO, H.

PHYSICAL EDUCATION

INTRODUCTION: Sweat lactate measurement has been proposed as a non-invasive method to monitor exercise intensity and fatigue. While previous studies have validated its use in flume swimming, direct assessment in a standard swimming pool remains limited. The aim of this study was to investigate the relationship between sweat lactate and heart rate (HR) during swimming exercise in a conventional swimming pool and to explore its potential as an indicator of exercise load.

METHODS: Competitive swimmers swam at three different intensities (low, moderate, and high). A portable sweat lactate sensor and a waterproof heart rate monitor were used for real-time data collection. The correlation between sweat lactate and HR was analyzed to investigate their association across exercise intensities.

RESULTS: Sweat lactate and HR increased proportionally with exercise intensity. This suggests that sweat lactate may reflect physiological responses to exercise intensity in a similar manner to HR.

CONCLUSION: The results indicate that sweat lactate measurement in a standard swimming pool is feasible and shows a significant relationship with HR. Due to its non-invasive nature, sweat lactate monitoring may serve as an additional tool to assess training load in swimmers. Further research is needed to refine the accuracy of the measurement and to explore its application in long-term exercise monitoring.

MENSTRUAL CYCLE IN FEMALE MOUNTAIN RUNNERS. INTERACTIVE GUIDE. A DELPHI SURVEY-BASED DEVELOPMENT AND VALIDATION.

VIVES CASTERÀS, E., ENSENYAT, A.

INEFC LLEIDA

INTRODUCTION: Fluctuations in blood concentrations of endogenous sex hormones during the menstrual cycle (MC) affect body systems, such as the cardiovascular, muscular and nervous systems, and are associated with several symptoms. MC fluctuations can impact on exercise and training adaptations; but women often have limited knowledge of their MC and its influence on sports performance.

Trail running is one of the most popular sports in Catalonia (Spain), where women's participation has recently increased to about 24,7% of the participants. MC psychobiological fluctuations may be a barrier to women's participation in trail running, and the demanding training load can increase the prevalence of MC disorders. Therefore, it would be beneficial to

have good quality educational tools to empower female runners and improve their knowledge of MC and its relationship to trail running.

The purpose of the study was 1) to create an educational booklet entitled "Menstrual Cycle in female mountain runners. Interactive Guide" to empower female runners and 2) to assess and improve its adequacy and legibility using the Delphi methodology.

METHODS: A 9-phase Delphi methodology was used. The first booklet version had 70 pages, distributed in 5 sections: 1) Women and trail running events, 2) Female reproductive system, 3) The menstrual cycle, 4) Menstrual Cycle disorders and 5) Menstrual Cycle and sport performance.

The evaluation committee (20 female and 5 males) comprises different health, sport, research, documentation and gender professionals, who scored the booklet using the Suitability Assessment of Materials (SAM) on two occasions (Original and revised versions).

RESULTS: SAM score of the booklet was over 70% (which was "superior" according to SAM results interpretation). Categories related to typography and design, motivation for learning and cultural adequacy had a superior punctuation, while other SAM categories, such as educational level required, had a lower and more scatter punctuation in the first booklet's version. Considering its lower punctuation, some categories were revised and improved before the second SAM round.

CONCLUSION: The main reason for the lower punctuation of "educational level required" category was because of the difficulty people with low educational level may have understanding the document.

The use of an expert panel to validate educational tools allows the identification of weaknesses and the improvement of the material before it is used.

In terms of knowledge transfer, the use of appropriate materials for end users can have a positive impact on the effectiveness of the interventions in which these materials are used.

EFFECTS OF PHYSICAL EXERCISE AND EICOSAPENTAENOIC ACID INTAKE ON BLOOD COMPONENTS AND VASCULAR ENDOTHELIAL FUNCTION IN A HYPERBARIC OXYGEN ENVIRONMENT

TAKEHIRA, N., ATSUSHI, S., JULIEN, M.M.

KYUSHU SANGYO UNIVERSITY, KYUSHU UNIVERSITY

INTRODUCTION: Astronauts undergo physical adaptation training in a hyperbaric oxygen (HBO) or underwater environment. HBO has been reported to be effective in treating decompression sickness and improving athletic performance by increasing the partial pressure of oxygen in the body, blood volume, and dissolved oxygen levels. In addition, eicosapentaenoic acid (EPA) has been shown to reduce muscle inflammation after exercise and improve vascular endothelial function. However, most previous studies on EPA intake and vascular endothelial function have targeted subjects with specific diseases, and there are only a limited number of studies on healthy young adults. The aim of this study was to clarify the effects of physical exercise and EPA intake in a HBO environment on blood components and vascular endothelial function.

METHODS: This study was a randomised crossover trial. The subjects (n=16) were divided into two groups (HBO group: n=8, C group: n=8), and during the first, middle and final stages of the experiment, they underwent medical examinations including blood sampling, and had their morphology, body composition and vascular endothelial function measured. The HBO environment was 1.41 ± 0.008 ATA, $21.7 \pm 0.7^\circ\text{C}$, $73.5 \pm 4.6\%$, and the normal environment was 1.00 ± 0.998 ATA, $22.1 \pm 1.1^\circ\text{C}$, and $70.5 \pm 6.5\%$. Exercise was performed twice a week for 8 weeks, for 60 minutes each time, at 60-70% of VO_2peak . The number of revolutions of the bicycle ergometer was set at 50-60 rpm. After a 4-week washout period, each group continued the same exercise in the other environment. EPA was taken as a supplement at a dose of approximately 2 g/day for 8 weeks. Repeated measures two-way analysis of variance was used for statistical analysis, and the significance level was set at less than 5%. This study was conducted with the approval of the Kyushu Sangyo University Ethics Review Committee (2023-0006) and was supported by a Grant-in-Aid for Scientific Research from the Japan Society for the Promotion of Science (23K01975).

RESULTS: There was an interaction between the environment (HBO vs. C environment) and time (before and after the experiment) for red blood cell count, haematocrit value, HDL cholesterol value, and BFA, an interaction between environment (HBO vs. C) and time (before and after the experiment) was observed (red blood cell count: $F=7.16$, $p=0.012$, $\eta^2=0.19$, haematocrit: $F=6.12$, $p=0.019$, $\eta^2=0.17$, HDL cholesterol: $F=5.35$, $p=0.028$, $\eta^2=0.15$, BFA: $F=7.16$, $p=0.012$, $\eta^2=0.19$). However, there were no significant changes in red blood cell count, hematocrit, or HDL cholesterol levels in the HBO environment ($p>0.05$), and Brachial Flow Acceleration increased slightly in the normal environment, but not significantly ($p>0.05$).

CONCLUSION: Physical exercise and EPA intake in an HBO environment may improve blood flow and reduce blood viscosity, but there is a suggestion that in the long term they may cause a decrease in oxygen transport capacity and an increased risk of anaemia.

EFFECTS OF ISCHEMIC PRECONDITIONING ON ARTERIAL STIFFNESS WITH AND WITHOUT MENTAL STRESS

HORIUCHI, Y., HORIUCHI, M., STONER, L.

KYUSHU SANGYO UNIVERSITY

INTRODUCTION: Acute mental stress (MS) induces autonomic imbalance and increases arterial stiffness [1]. Conversely, ischemic preconditioning (IPC) restores autonomic balance [2]. We hypothesized that IPC would attenuate the MS-induced increase in arterial stiffness.

METHODS: Nineteen healthy young (21 years) adults (female = 9) completed this factorial (IPC and MS) cross-over trial. The conditions consisted of 15 min quiet rest, IPC, MS, then 45 min quiet, supine rest. IPC consisted of four cycles of 5 min alternating unilateral thigh cuff inflation to 220 mmHg (IPC-true) or 20 mmHg (IPC-sham). MS factor consisted of a 5-min supine rest with (MS-true) or without (MS-sham) MS. The four experimental conditions were: (i) IPC-sham/MS-sham; (ii) IPC-sham/MS-true; (iii) IPC-true/MS-sham; and (iv) IPC-true/MS-true. Outcomes were recorded prior to the IPC and MS (baseline), then at 5, 15, 30, and 45 min during the supine rest. Outcomes were brachial-ankle pulse wave velocity (baPWV), arterial stiffness index (ASI) and heart rate variability (HRV). ASI was recorded on the legs (leg-ASI, local to IPC) and arms (arm-ASI, remote to IPC). Data are reported as mean (standard deviation [SD]).

RESULTS: A significant main effect of trials was observed for baPWV ($P=0.01$) without no time course and interaction effects (both $P>0.05$). Overall average value of baPWV was higher (worse) in the IPC-sham/MS-true trial (10.9 [1.2] m/s) than those in the IPC-true/MS-sham (10.7 [1.1] m/s, $P=0.02$), in the IPC-sham/MS-sham (10.7 [1.1] m/s, $P=0.07$), and in the IPC-true/MS-true trials (10.7 [1.2] m/s, $P=0.06$). There was a significant interaction effect (time course $\times$ four experimental conditions) for both leg- and arm-ASI (both $P<0.05$). The overall average value of leg-ASI in the IPC-sham/MS-true trial (124 [22] arbitrary unit [a.u.]) was higher than those in the IPC-sham/MS-sham (119 [20] a.u.), IPC-true/MS-sham (117 [21] a.u.), and IPC-true/MS-true (119 [20] a.u.) trials (all $P<0.01$). The overall average value of arm-ASI in the IPC-sham/MS-true trial (39.4 [8.5] a.u.) was higher than those in the IPC-sham/MS-sham (38.3 [9.6] a.u.) and IPC-true/MS-sham trials (38.2 [9.2] a.u.), both $P<0.05$, but comparable to IPC-true/MS-true trial (38.7 [10.2] a.u.), $P=0.42$. Contrary to our hypothesis, there were no interaction, time course or condition effects for HRV ($P>0.05$).

CONCLUSION: IPC could not restore MS-induced arm arterial dysfunction, but restored MS-induced leg arterial dysfunction, indicating a protective effect of IPC on local vasculature. While MS did not influence HRV, suggesting that the MS was not notably stressful to healthy young adults, the MS did increase (worsen) each of the arterial stiffness outcomes. Further research is warranted to test the effects of alternative and additive stressors.

THE EFFECTS OF APPETITES, MAJOR NUTRIENTS AND DIETARY CHOICES OF LOW- ALTITUDES HIKING IN TYPE 2 DIABETES

CHIEN, K., LEE, M.Y., HSU, T.Y., TSAI, Y.H.

NATIONAL TAIWAN SPORT UNIVERSITY, XIN TAI GENERAL HOSPITAL, HCC HEALTHCARE GROUP AND HOSPITALS

INTRODUCTION: Type 2 Diabetes mellitus patient engaged in hiking activities may have different considerations for dietary needs and choices due to disease factors, hiking intensity and physical factors related to altitudes. The present study investigated the differences in calorie and macronutrient intake, as well as food choices, between hiking days and regular days in individuals with type 2 diabetes.

METHODS: We recruited fifteen Type 2 diabetes to participant study. Food photography was used to record dietary intake for a total of six days, including two days of regular food intake, one day of holiday food intake, one day before a hike, the day of the hike, and the day after the hike. Appetite questionnaires, food choice records, subjects descriptions of dietary selection considerations, and ratings of perceived exertion were also collected. A dependent samples t-test was used to analyze the differences in calorie and nutrient intake between hiking days and regular diet days. One-way repeated measures analysis was used to examine appetite and food choices at different time points: regular diet days, the day before the hike, the day of the hike, and the day after the hike.

RESULTS: There were no significant differences in total calorie, carbohydrate, protein, and fat intake between regular days and hiking days. Total calorie intake on the day after the hike was significantly higher than on the day of the hike (2309.2 ± 622.87 kcal vs. 1940.4 ± 544.60 kcal). Hunger and perceived capacity to eat were significantly lower when subjects felt tired and breathless during the hike compared to before the hike (Hunger: 1.3 ± 1.11 vs. 5.3 ± 2.66 , $p=0.000$; perceived capacity to eat: 1.7 ± 1.11 vs. 5.6 ± 2.16 , $p=0.000$). The most important factor influencing food choices during hikes was ease of consumption (85.7%), followed by ease of digestion (57.1%), high protein content (35.7%), and high calorie content (21.4%).

CONCLUSION: The present study indicated that total calorie, carbohydrate, protein, and fat intake did not significantly differ between usual daily and hiking days. Convenience, ease of digestion, high protein content, and high calorie content were important factors influencing food choices on hiking days.

NEUROMUSCULAR PERSPECTIVES ON MENINGITIS SEQUELAE: INSIGHTS FROM A CASE STUDY.

FIORASO, E., GIURIATO, G., PEDRINOLLA, A.

UNIVERSITY OF VERONA

INTRODUCTION: Bacterial meningitis is a life-threatening condition characterized by inflammation of the meninges surrounding the brain and spinal cord. Severe cases may result in sepsis and death. Survivors often face neurological sequelae and motor impairments. However, research on neuromuscular function and fatigue remains lacking. This case study provides a preliminary insight into neuromuscular function and fatigue in a survivor of severe bacterial meningitis (AL) compared with an age-matched healthy control (Ctrl).

METHODS: Maximal voluntary contraction (MVC), voluntary activation (VMA%, central component), and potentiated twitch force (Qtw.pot, peripheral component) were assessed using the interpolated twitch (IT) technique in the lower limbs of AL (37 years, male, 10 years after 5-month hospitalization, lower legs-amputated, fingers amputation, well trained) and Ctrl (35 years, male, well trained). Torque for MVC and Qtw.pot was calculated and normalized to the limb cross-sectional area. MVC+IT measurements were taken at rest and within 30 seconds after a fatiguing task, which consisted of a time-to-exhaustion (TTE) cycling task performed at 80% of maximal exercise capacity (VO₂max), to assess strength neuromuscular component and fatigue.

RESULTS: At rest, MVC was 2.6N for AL and 3.7N for Ctrl, while Qtw.pot was 0.6N and 1.1N, respectively. VMA% was 68.5% for AL and 93.9% for Ctrl. Post-TTE, ΔMVC was -10.9% for AL and -33.1% for Ctrl, Qtw.pot was -23.9% for AL and -29.6% for Ctrl, and ΔVMA% was +14.0% for AL and -14.4% for Ctrl.

CONCLUSION: Although MVC, peripheral, and central components are reduced in AL compared to Ctrl, the fatiguing task elicited different responses. Unlike Ctrl, AL exhibited only a minor decrease in MVC and Qtw.pot, alongside an increase in VMA%. Despite both subjects being well-trained and experienced in mountain sports, AL appeared less fatigable than the healthy controls.

UNRAVELING THE ROLE OF GUT MICROBIOTA IN LACTATE METABOLISM AND ENDURANCE PERFORMANCE OF ELITE MARATHON RUNNERS

HSU, Y., KUO, C.Y.

NATIONAL TAIWAN SPORT UNIVERSITY

INTRODUCTION: Lactate, once viewed as a mere metabolic byproduct linked to muscle fatigue, is acknowledged as a crucial energy substrate. Certain gut microorganisms can metabolize lactate into short-chain fatty acids (SCFAs), potentially influencing endurance performance. Given the individual differences in lactate metabolism and gut microbiota composition, this study aims to investigate lactate changes after a 10-kilometer run and classify participants based on lactate metabolism efficiency, and examines the relationship between gut microbiota composition, lactate metabolism, and endurance performance.

METHODS: This study recruited 46 male marathon runners (ages 20-55 years) who met specific performance criteria and trained regularly. Participants completed a 10-kilometer run under standardized conditions, with blood samples collected pre-exercise, immediately post-exercise, and 60 minutes post-exercise to measure lactate levels. Lactate clearance rate was calculated as: $\text{Lactate clearance rate (\%)} = \frac{[\text{Lactate}_{\text{post-exercise}} - \text{Lactate}_{60\text{min}}]}{\text{Lactate}_{\text{post-exercise}}} \times 100$. Participants were classified into a high lactate metabolism group (HL, top 20%) and a low lactate metabolism group (LL, bottom 20%) based on a lactate clearance rate threshold of 67%. Running performance, body composition, food frequency questionnaire (FFQ), and gut microbiota composition (via 16S rRNA sequencing) were analyzed. Statistical analyses included independent t-tests, Welch's t-test, and repeated-measures ANOVA ($p < 0.05$).

RESULTS: Post-exercise lactate concentration was significantly higher in the HL group than in the LL group ($p < 0.05$), while pre-exercise levels showed no significant difference ($p > 0.05$). At 60 minutes post-exercise, the HL group exhibited a significantly higher lactate clearance rate ($p < 0.05$). However, no significant difference was found in 10-kilometer running performance between the two groups ($p > 0.05$). FFQ did not differ between the two groups ($p > 0.05$). Gut microbiota analysis identified a significantly greater abundance of *Prevotella copri* in the HL group ($p < 0.05$).

CONCLUSION: This study confirms inter-individual differences in lactate metabolism, with the HL group displaying superior lactate clearance efficiency. However, despite this physiological advantage, no significant difference in endurance performance was observed. Since FFQ did not differ between the two groups, the higher abundance of *Prevotella copri* in the HL group suggests a potential role in enhancing lactate metabolism and energy efficiency, possibly through carbohydrate fermentation and metabolic regulation. These findings emphasize the critical role of gut microbiota in endurance adaptation and underscore the necessity for further research to elucidate the precise mechanisms through which gut microorganisms regulate lactate metabolism and influence athletic performance.

REPETITIONS TO FAILURE ARE NOT AFFECTED BY ISCHEMIC PRECONDITIONING BUT ARE DIRECTLY ASSOCIATED WITH MUSCLE STRENGTH

LUBIAK, S., HOWARD, M., PRAJAPATI, A., SHAH, N., PATEL, N., HERRING, E., HILL, E.

UNIVERSITY OF CENTRAL FLORIDA

INTRODUCTION: Ischemic preconditioning (IPC) may serve as an ergogenic aid in sport and health. There is, however, less known regarding potential pressure-specific effects and/or the influence of muscle size and strength on exercise performance following IPC. The purpose of this investigation was to examine the acute effects of various IPC pressures on repetitions to failure (RTF) and if muscle size and/or strength are associated with RTF.

METHODS: Twenty-one males (21.4 ± 2.2 years; 177.4 ± 8.6 cm; 80.6 ± 12.5 kg) visited the laboratory on four separate visits. The first visit consisted of baseline measurements of muscle size (cross-sectional area [CSA]) and strength (one-repetition maximum [1RM]) of the dominant leg. The next three visits consisted of IPC randomly implemented at low (SHAM [20 mmHg]), moderate (80% of total arterial occlusion pressure [TAOP]), and high (220 mmHg) pressures. A total of three cycles, consisting of pressure applied for five minutes followed by five minutes of rest, was completed with a pneumatic cuff placed most proximally on the dominant leg. Following IPC, participants completed one-set of unilateral, isotonic leg extension muscle actions to volitional failure at 30% of their 1RM. A one-way ANOVA was performed to determine mean

differences in RTF while separate stepwise linear regressions were performed to determine the associations of CSA and 1RM on RTF for each IPC pressure.

RESULTS: There was no significant main effect for Pressure ($p = 0.059$) on RTF. The stepwise linear regression indicated that 1RM was a significant ($p < 0.001$) predictor for RTF in the low ($r = 0.68$; $R^2 = 0.46$), moderate ($r = 0.71$; $R^2 = 0.51$), and high conditions ($r = 0.69$; $R^2 = 0.48$), while the addition of CSA did not significantly ($p = 0.879$ to 0.972 ; R^2 change = 0.00 to 0.024) improve the model.

CONCLUSION: There was no ergogenic effect of IPC on RTF. Instead, RTF was positively related to muscle strength which explained approximately 50% of the variance in RTF. Thus, improving fatigue resistance may be accomplished through resistance exercise.

EFFECTS OF HIGH AND COMFORTABLE TEMPERATURE ENVIRONMENTS ON COUNTERMOVEMENT JUMP PERFORMANCE

LIU, C.

CHANG JUNG CHRISTIAN UNIVERSITY

INTRODUCTION: Athletes may experience different fatigue responses when training under varying environmental temperatures. This study examines the effects of training under high-temperature conditions (average $\sim 35^\circ\text{C}$) and comfortable-temperature conditions (average $\sim 22^\circ\text{C}$) on lower-body explosive performance, as assessed by countermovement jump (CMJ) performance, following identical training loads (RPE 6-8).

METHODS: Thirteen participants, all university rugby players with regular training habits, were recruited for this study. The participants had an average height of 174.27 ± 3.25 cm and body weight of 71.86 ± 7.99 kg. Each participant completed one week of training under each environmental condition, with daily training sessions lasting approximately two hours and maintaining consistent training loads. CMJ tests were conducted before each training session, recording jump height (cm) as an indicator of fatigue. Data analysis compared the trends in CMJ performance across different temperature conditions to evaluate the impact of environmental temperature on post-exercise fatigue. Paired-sample t-tests were conducted, with statistical significance set at .05.

RESULTS: Preliminary data showed a significant decrease in CMJ performance under high-temperature conditions (average decrease of 2.5 ± 1.2 cm, $p < .05$), whereas CMJ values remained more stable in the comfortable-temperature environment (change of 0.5 ± 0.8 cm, $p = .12$), with some participants even maintaining or improving their performance. Additionally, greater variability in CMJ scores was observed in the high-temperature condition, possibly related to individual heat tolerance and hydration status.

CONCLUSION: The results indicate that high-temperature environments may exacerbate fatigue accumulation and negatively impact lower-body explosive performance, even when training loads are consistent. These findings have practical implications for sports training and competition planning, suggesting that enhanced recovery strategies and fatigue monitoring should be implemented to mitigate performance declines in high-temperature conditions.

EFFECTS OF TART CHERRY JUICE ON EXERCISE PERFORMANCE AND NEUROMUSCULAR FUNCTION IN REPEATED BOUTS OF EXERCISE

KOJIMA, K., ISHII, S., MIYAKOSHI, Y., ISHIBASHI, A., KONISHI, K.

TOYO UNIVERSITY

INTRODUCTION: Nutritional strategies play an important role in recovery between games for athletes who play multiple games in a day. Anthocyanin-rich tart cherries enhance endurance performance through Nrf2 upregulation [1]. It has been reported that Nrf2 signaling is related to anaerobic capacity [2]. Therefore, it is expected that anthocyanin-rich tart cherries inhibit the decline in aerobic and anaerobic function induced by exercise. The purpose of this study is to investigate whether a 7-day supplementation of tart cherry juice attenuates declines in endurance and anaerobic performance and neuromuscular function in repeated cycling exercise.

METHODS: Fifteen men who habitually performed aerobic exercise (age 21 ± 1 years; BMI 20.7 ± 2.0 kg/m²) participated in the study. In this randomized double-blind crossover trial, the subjects consumed 200 g of tart cherry juice (TC) or placebo (cherry-flavored maltodextrin solution, PL) twice a day for 7 days. On the test day, the subjects consumed 200 g of beverage and completed 2 sets of time trials (equivalent to 30 minutes of cycling at 70% peak power output) followed by the Wingate test with a 100-min interval (Ex1 and Ex2). Maximal voluntary contraction (MVC) force and force steadiness in knee extension and index finger abduction, along with blood lactate and glucose levels, were measured at baseline, post Ex1 and post Ex2. The parameters of the time trial and Wingate test were compared between conditions at Ex1 and Ex2 using paired t-tests. A two-way repeated-measure ANOVA with Bonferroni post hoc test was used to examine the main and interaction effects on MVC, force steadiness, lactate and glucose levels.

RESULTS: The time trial completion time was significantly shorter in TC (1449 ± 174 s) than PL (1566 ± 244 s) in Ex2 ($p = 0.04$, $d = 0.64$), while there was no significant difference between TC (1431 ± 150 s) and PL (1418 ± 180 s) in Ex1. The fatigue index in the Wingate test was significantly lower in TC (29.6 ± 13.0 %) than PL (34.2 ± 12.5 %) in Ex1 ($p = 0.02$, $d = 0.75$), but not in Ex2. MVC and force steadiness in the isometric knee extension showed a significant main effect of time ($p < 0.01$), while showing neither significant interaction nor main effect of condition. In the isometric abduction task of the index finger, MVC showed neither significant interactions nor main effects. Force steadiness in the isometric abduction task of the index finger showed a significant main effect of time ($p < 0.01$), while showing neither significant interaction nor main effect of condition.

CONCLUSION: Anthocyanin-rich tart cherry juice supplementation attenuated the decline in endurance and anaerobic exercise performance in repeated cycling exercise, but had no effect on neuromuscular function. Further research is needed to clarify the underlying physiological mechanisms of attenuating fatigue by tart cherry.

EFFECTS OF MENSTRUAL CYCLE PHASES ON METABOLIC RESPONSES DURING INTERVAL TRAINING

KUBICA, C., AMOR, L.S.

INSTITUTE OF SPORT SCIENCE, UNIVERSITY BERN

INTRODUCTION: Understanding how the menstrual cycle affects exercise metabolism is vital for optimizing training and nutrition in female athletes. While prior studies have characterized the metabolism and respiratory exchange ratio (RER) during steady-state exercise (e.g., Hackney et al., 2022; Ortega-Santos et al., 2018), research on interval training is limited, leaving questions about how hormonal variations modulate metabolic responses during high-intensity interval training (HIIT).

METHODS: We examined whether RER varies during HIIT across menstrual phases. Eleven moderately active, naturally cycling women (age: 27.2 ± 3.1 years; BMI: 22.2 ± 2.20 kg/m²) completed HIIT sessions on a bicycle ergometer during the early follicular (EFP), late follicular (LFP), and mid-luteal phases (MLP). Each session comprised four 3-minute intervals at 95% of the second ventilatory threshold (VT2), interspersed with 3-minute recovery at 70% VT2. RER was measured continuously via spirometry.

RESULTS: Multilevel analysis revealed that in the MLP the RER was 1.024 during the first interval ($t(230)=116.01$, $p<.001$) and decreased by 0.011 per interval ($t(230)=-5.77$, $p=.009$). Notably, RER during the EFP was 0.021 lower than in the MLP ($t(230)=-2.61$, $p=.010$), whereas the LFP's RER was 0.003 higher—a non-significant difference ($t(230)=0.28$, $p=.779$). Pair-wise comparisons between EFP and LFP showed an estimated 0.025 difference ($t(230)=1.62$, $p=.239$).

CONCLUSION: These findings indicate that metabolic responses during HIIT may vary across the menstrual cycle, with a significantly lower RER during the EFP compared to the MLP - possibly reflecting a shift toward fat oxidation due to lower resting glycogen levels (Isacco & Boisseau, 2023). However, although the difference in RER between EFP and MLP is statistically significant, it is relatively small, and the practical implications of this shift should be considered alongside other factors (nutrition, training status, exercise duration, and intensity).

ACTIVATION OF AMPK BY HIGH-INTENSITY INTERMITTENT EXERCISE DOES NOT INTERFERE WITH MTOR SIGNALING INDUCED BY MECHANICAL OVERLOAD IN MICE

SHINKAI, H., SHIRAI, T., UEMICHI, K., IWAI, R., TAKEMASA, T.

UNIVERSITY OF TSUKUBA

INTRODUCTION: Concurrent training (CT) is a training regimen that combines different exercise modalities. When endurance exercise (EE) and resistance exercise (RE) are combined, EE is known to attenuate muscle hypertrophy induced by RE, a phenomenon called the "interference effect". This effect is primarily attributed to EE-induced activation of AMPK, which suppresses the activation of mTOR signaling pathway responsible for muscle hypertrophy (Coffey & Hawley, 2017). Our previous experiment revealed that 4 weeks of CT combining mechanical overload with high-intensity intermittent exercise (HIIE) did not suppress hypertrophic adaptation in mice. However, the acute molecular signaling response, which is critical for understanding the interference effect, remains insufficiently explored. Therefore, we focused on the influence of HIIE-induced AMPK activation on mTOR signaling in acute state.

METHODS: 8-week-old male C57BL/6J mice were divided into 3 groups: the sham group (sham operation), the myoteneotomy-induced functional overload group (OL), and the OL+HIIE group (OL combined with HIIE) (n=8 per group). HIIE consisted of 10 sets of 20-second forced swimming with a 10-second rest interval, using a tail-attached weight equivalent to 8% of body weight. Sampling of plantaris muscle was performed 3 hours after myoteneotomy surgery, and the OL+HIIE group underwent HIIE immediately before sampling.

RESULTS: Phosphorylation level of AMPK was significantly higher in the OL+HIIE group than those in the sham and OL groups. The phosphorylation levels of rpS6, a downstream protein of the mTOR signaling pathway, were significantly higher in both the OL and OL+HIIE groups compared with that in the sham group, with no significant difference between those in the OL and OL+HIIE groups. ERK1/2 phosphorylation levels were higher in OL and OL+HIIE groups than that in the sham group, and OL+HIIE group showed greater increase compared with OL group. These results suggest that HIIE-induced AMPK activation does not interfere with protein synthesis induced by mTOR signaling.

CONCLUSION: In previous study concerning CT combined with RE and HIIIE, RE induced phosphorylation of p70S6K is not interfered with subsequent HIIIE induced AMPK activation. (Apró et al., 2015). Also in chronic training, HIIIE does not interfere with RT-induced myofibrillar protein synthesis (Lee et al., 2024). These pieces of evidence suggest that the combination of HIIT on hypertrophied muscles does not cause an interference effect.

In conclusion, HIIIE-induced AMPK activation does not suppress the activation of downstream proteins in the mTOR signaling.

THE EFFECTS OF A PRE-EXERCISE SUPPLEMENT ON ATP STATUS AND ENDURANCE PERFORMANCE.

PAVIS, G., WALL, B.T., STEPHENS, F.B.

UNIVERSITY OF EXETER

INTRODUCTION: ATP is the sole substrate for skeletal muscle contraction and must be continually resynthesised to prevent fatigue. Increasing muscle ATP concentration theoretically improves exercise performance, but ingested ATP is not bioavailable. A supplement containing plant-derived, water-soluble trace elements and apple polyphenols previously increased blood ATP concentration by 40% (Reyes-Izquierdo et al. *Aging Res Clin Practice*. 2013;2:178–84), perhaps by increasing endogenous synthesis. To further explore the role of ATP availability in fatigue, we hypothesised that this supplement would increase plasma and muscle ATP concentrations and muscle ATP turnover (reflected by changes in associated metabolites) at rest and following a specific glycogen depleting endurance exercise, and improve subsequent endurance exercise performance.

METHODS: Ten recreationally-active participants (1 female; age 26 ± 2 y; VO_{2max} 48 ± 2 mL/kg/min) took part in this randomised, placebo-controlled, crossover study. After exercise familiarisation, participants visited the laboratory in the fasted state and consumed the test material (TML) or cellulose placebo (PLA). After 2 h rest, participants cycled to exhaustion at 75% VO_{2max} , followed by a 15-min work output performance test. Skeletal muscle biopsies were obtained prior to consuming the supplement, prior to starting exercise, and immediately at the onset of exhaustion. Venous blood samples were collected throughout. The reverse condition was conducted after 1 week. All time course data were analysed by 2-way ANOVA (time and supplement factors). Performance data were analysed by paired T-test. This study was approved by the institutional ethics board (ID: 516252) and registered on ClinicalTrials.gov (NCT05641454).

RESULTS: Resting whole blood ATP concentration was 471 ± 37 and 489 ± 26 μ M in PLA and TML trials prior to supplement ingestion, and was unchanged by TML. Resting muscle ATP content was 24.2 ± 2.0 and 22.8 ± 1.2 mmol/kg dry muscle (DM) in PLA and TML trials, and was unchanged by TML. Muscle ADP, creatine and phosphocreatine content was unchanged by TML. At exhaustion, total work (PLA: 16.5 ± 1.6 ; TML: 15.3 ± 1.0 kJ/kg) and time to exhaustion (PLA: 105.1 ± 7.4 ; TML: 98.0 ± 4.4 min) was unaffected by TML. Muscle glycogen decreased from pre-exercise (by 165 ± 40 and 216 ± 29 mmol/kg DM, PLA and TML respectively; $P < 0.001$), with no effect of TML. Circulating ATP and ADP concentration, and muscle ATP, ADP, creatine and phosphocreatine content were unaffected by TML. During the performance test, TML had no effect on work done (PLA: 1.8 ± 0.1 ; TML: 1.9 ± 0.1 kJ/kg).

CONCLUSION: Under these experimental conditions, we show that TML did not affect circulating or skeletal muscle ATP concentrations (nor related metabolites) at rest or following endurance exercise, nor endurance performance in the glycogen depleted state. Other strategies may be required to observe increased skeletal muscle ATP concentration and to investigate the effects on exercise metabolism and fatigue.

EFFECTS DIETARY FAT ON SKELETAL MUSCLE HYPERTROPHY AFTER FUNCTIONAL OVERLOADING IN ADULT, MATURE AND OLD C57BL/6J MICE

DIRMONTAS, M., MINDERIS, P., RATKEVICIUS, A.

LITHUANIAN SPORTS UNIVERSITY

INTRODUCTION: The aim of the study was to investigate effects of dietary fat on glucose tolerance (GT), body mass, muscle mass and extent of skeletal muscle hypertrophy after functional overloading (FO) of plantaris muscle in adult, mature and old C57BL/6J mice.

METHODS: Male mice of C57BL/6J strain were studied at 6 months (adult), 19 months (mature) and 27 months (old) of age after 12-week exposure to regular chow diet (RD, 13.4 kcal% fat, 66.8 kcal% carbohydrate, 29.8 kcal% protein), high fat diet (HFD, 60 kcal% fat, 20 kcal% carbohydrates, 20 kcal% protein) and ketogenic diet (KD, 80 kcal% fat, <1 kcal% carbohydrates, 20 kcal% protein). After 6 weeks of feeding, FO of plantaris muscle (PL) was induced by denervation of gastrocnemius (GAS) and soleus (SOL) muscles in one of the hindlimbs while another hindlimb served as a control (n=8-10 per group). Body mass, glucose tolerance (GT), muscle mass of PL, GAS and SOL muscles as well as plantaris muscle IGF1 levels were assessed six weeks after FO.

RESULTS: Body mass depended on the diet ($p < 0.05$). HFD induced a greater ($p < 0.05$) increase in body mass compared to RD and KD in adult mice, also HFD caused a greater ($p < 0.05$) increase in body mass compared to RD in mature and old mice. GT depended on the diet ($p < 0.001$). HFD and KD induced greater ($p < 0.01$) impairments in GT compared to RD. GT improved with age ($p < 0.001$). FO induced hypertrophy of PL decreased ($p < 0.001$) with age and did not depend on the diet ($p = 0.897$). PL IGF1 levels were greater ($P < 0.001$) in the overloaded compared to control muscles, PL IGF1 levels decreased ($p < 0.05$) with age. Control muscles showed reduced ($p < 0.05$) IGF1 levels when fed HFD and KD compared to RD.

CONCLUSION: Extent of compensatory muscle hypertrophy after FO does not depend on dietary fat content, but decreases with age in C57BL/6J mice

EFFECTS OF 8-WEEK ASHWAGANDHA SUPPLEMENTATION ON THE EXERCISE ADAPTATIONS TO HIGH-INTENSITY INTERVAL TRAINING IN YOUNG HEALTHY MEN

DLUGOLECKA, B., JÓWKO, E., CHARMAS, M., KLUSIEWICZ, A., PRZYBYLSKA, I., CIESLINSKI, I.

UNIVERSITY OF PHYSICAL EDUCATION IN WARSAW; FACULTY OF PHYSICAL EDUCATION AND HE

INTRODUCTION: High-intensity interval training (HIIT) is believed to be effective in increasing physical performance, both aerobic and anaerobic, as well as promoting fat loss. In addition, ashwagandha (*Withania somnifera*) root extract contains various active compounds, including steroidal lactones known as withanolides. These substances have the potential to regulate adrenal and gonadal functions, and thus may result in improved health parameters and physical performance. The purpose of this study was to evaluate the effects of ashwagandha supplementation (600 mg/day) on anaerobic capacity, body composition and anabolic-catabolic status in healthy male non-athletes undergoing a fully supervised 8-week HIIT.

METHODS: Thirty eight men participated in randomized, double-blind, placebo-controlled study (placebo group, P, n=20; ashwagandha group, A, n=18). HIIT was performed on a rowing ergometer (3 sessions/week, 5-7 sets of 1.5 minutes in each session, at a load of 85-95% of maximum aerobic power, and with rest intervals between sets of 1.5 minutes). Before (term 1) and after (term 2) the 8-week intervention, participants performed a 30-second Wingate test on a cycle ergometer (lower limb muscles). Body composition was also assessed using dual energy X-ray absorptiometry (DEXA). In addition, blood samples were taken before (pre), 5 minutes after (post) and 24 hours (24h) after a maximal graded exercise test (performed on a rowing ergometer) to assess serum testosterone (T) and cortisol (C) levels. Participants were asked to refrain from dietary modification throughout the study period.

RESULTS: HIIT induced an increase in fat free mass ($p < 0.05$), without significant changes in body weight and fat mass ($p > 0.05$). Also, there were no changes in anaerobic capacity parameters (peak power, total work, time to achieving and maintaining peak power; $p > 0.05$) throughout the study period. In contrast, 8-week training increased serum testosterone levels (A: at all time points, $p < 0.05$; P: post and at 24h, $p < 0.05$). In addition, in both P and A groups, resting cortisol levels (pre) were elevated in term 2, compared to term 1 ($p < 0.01$). Moreover, the T/C ratio increased after the 8-week study period: post and at 24 h in the A group ($p < 0.05$), while at 24 h only in the P group ($p < 0.05$). However, there were no main effects of group or interaction of group and time/term in the parameters studied ($p > 0.05$).

CONCLUSION: Periodic (8-week) HIIT on a rowing ergometer is effective in increasing fat free mass by promoting anabolic status. On the other hand, it does not improve anaerobic capacity. Probably, more intense training regimen (with all-out sprint intervals) is needed to increase anaerobic performance. More importantly, ashwagandha supplementation does not appear to affect physical performance, as well as changes in body composition and anabolic-catabolic status in response to an interval training program in a population of non-athletes. Further research is needed on a group of competitive athletes representing various sport disciplines.

THE INFLUENCE OF THE MENSTRUAL CYCLE ON RECOVERY AND PERFORMANCE: A CASE STUDY FROM SKI JUMPING

ASP, E., ELFMARK, O., NOORDHOF, D.

NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY

INTRODUCTION: Based on the current body of literature,¹ naturally menstruating athletes are advised to take an individualized approach and record their training sessions, recovery measures, and performance in relation to their menstrual cycle (MC). A world-class Norwegian ski-jumping athlete did exactly this and the goal of this project was to investigate the influence of her MC on recovery and ski-jumping performance.

METHODS: The athlete recorded MC length (19 MCs), daily sleep score (five months), and resting heart rate (13 months), and premenstrual syndrome symptoms (two MCs). Ski-jumping results of three years were gathered from fis-ski.com. The MC was divided into three phases: menstrual bleeding (MB), day 1-5; pre-menstruation (PM), 1-4 days before the start of the first day of menstrual bleeding of the next MC; mid-phase (MP), the remaining days. Ski jumping results were recalculated to adjust for wind points and take-off speed and get a physical performance score.² The sleep score and resting heart rate were collected using a Garmin watch. Data are reported as median (interquartile range).

RESULTS: The average MC length was 24 ± 4 days. Ski flying performance was 2.19 (0.079) during MB and 2.04 (0.020) during PM. Performance at the large hill was 1.29 (0.11) during MB, 1.27 (0.000018) during MP, and 1.04 (0.016) during PM, while performance at the normal hill was 0.95 (0.015) during MB, 0.92 (0.037) during MP, and 1.01 (0.00079) during PM. The sleep score was 90.0 (10) during MB, 86.5 (9) during MP, and 90.0 (13) during PM. Resting heart rate was 45 (4) during MB, 47 (3) during MP, and 48 (4) during PM. Premenstrual syndrome symptoms like feeling blue, having mood swings, difficulty concentrating and feeling lethargic appeared during PM and ranged from minimal to severe in severity.

CONCLUSION: The performance level in ski flying and the large hill was in general higher and more stable than in the normal hill. Performance decreased with respectively 7 and 19% in PM compared to MP in ski flying and the large hill, whilst such a decline was not observed in the normal hill (improvement of 6%). Premenstrual syndrome symptoms during PM may be an explanation of the lower performances at the larger hills when competing during PM, as the risks are larger at these hills and thereby the influence of for example feeling blue and having difficulty concentrating being larger. The slightly higher resting heart rate during PM corresponds with findings in the literature and might indicate a slightly

impaired recovery status.³ This case study shows that the MC might influence recovery and performance on an individual level, whereby ski flying and large hill performance were lowest during the phase with most symptoms.

INFLUENCE OF MAXIMUM OXYGEN CONSUMPTION WHEN DETERMINED IN DIFFERENT EXERCISE PROTOCOLS: A PILOT STUDY

DE JESUS ESTEVES, G., AZEVEDO, P.H.S.M.
FEDERAL UNIVERSITY OF SAO PAULO

INTRODUCTION: Currently, different exercise protocols are used to identify Maximum Oxygen Consumption (VO₂max), such as incremental load exercise on a ramp or in graded. However, the best protocol model for identifying VO₂max still generates discussion in literature. Thus, the main of the present study was to verify whether different incremental test protocols can influence the determination of the VO₂max value and compare it with the verification test.

METHODS: Six healthy men, age of 24 ± 0.7 years, who used bicycles recreationally participated in this study. Participants made 6 visits to the laboratory, one session to familiarize themselves and five sessions carried out in a crossover and randomized manner. Participants performed 5 maximum incremental tests on a cycle ergometer, a ramp protocol (28 W.min⁻¹; 7-Watt increments every 15 seconds), and 4 graded protocols with 25-Watt increments at each stage of 1, 2, 3, or 4 minutes. Respiratory variables were recorded continuously by a gas analyzer (VO2000) during the tests. After completing each test, the subjects performed a 10-minute passive recovery and then a verification test until exhaustion with a load 5% higher than the maximum achieved in the test. VO₂max was determined by analyzing the average values from the last minute of each test.

RESULTS: The mean and standard deviation values of VO₂max were (incremental testing vs verification testing, respectively; mean effect size and 95% confidence interval): ramp test (43.66 ± 6.20 mL · kg⁻¹ · min⁻¹ vs 40.68 ± 7.98 mL · kg⁻¹ · min⁻¹; ES 0.38, -3.66;4.43); graded test 1' (43.61 ± 4.97 mL · kg⁻¹ · min⁻¹ vs 39.80 ± 7.06 mL · kg⁻¹ · min⁻¹; ES 0.58, -2.88;4.03); graded test 2' (44.61 ± 8.41 mL · kg⁻¹ · min⁻¹ vs 38.90 ± 4.32 mL · kg⁻¹ · min⁻¹; ES 0.79, -2.99;4.57); graded test 3' (43.91 ± 7.32 mL · kg⁻¹ · min⁻¹ vs 39.18 ± 6.80 mL · kg⁻¹ · min⁻¹; ES 0.62, -3.38;4.62); graded test 4' (42.53 ± 7.98 mL · kg⁻¹ · min⁻¹ vs 37.90 ± 7.63 mL · kg⁻¹ · min⁻¹; ES 0.55, -3.87;4.96).

CONCLUSION: The VO₂max value does not appear to influence significant changes when determined in different incremental protocol models. Although the VO₂max determined in the verification test is, on average, below the VO₂max of the incremental test, the confidence interval crosses the zero line, preventing us from concluding that they are different. Therefore, for a faster test, it is suggested to perform the test on a ramp or in a graded with 1-minute stages.

Physiotherapy

EVALUATING THE EFFICACY OF DUAL-TASK TRAINING COMPARED TO SINGLE-TASK TRAINING AND NO INTERVENTION IN THE REHABILITATION OF LOWER EXTREMITY MUSCULOSKELETAL INJURIES: A SYSTEMATIC REVIEW

AKKUS, C., PAKOZ, B., DINGIRDAN, B., TURGUT, E.
HACETTEPE UNIVERSITY

INTRODUCTION: Dual-tasking refers to the simultaneous performance of two independent tasks, each with distinct goals. While evidence suggests that dual-task training (DTT) can enhance physical and cognitive outcomes, particularly in healthy populations, its effectiveness in rehabilitation and its long-term impact on musculoskeletal injuries remain underexplored. This systematic review aimed to evaluate the effectiveness of DTT compared to single-task training (STT) or no intervention (NI) on clinical outcomes and physical performance metrics in adults with lower-extremity musculoskeletal injuries.

METHODS: A systematic search was conducted in PubMed and Web of Science databases up to April 2024, with additional backward and forward citation tracking. Data were extracted on participant demographics, diagnoses, interventions, measured outcomes, assessment tools, and main findings. The Cochrane Risk-of-Bias Tool 2 was used to evaluate study quality.

RESULTS: Following screening 8,017 articles, four randomized controlled trials met the inclusion criteria, providing data on 107 participants (Mean $\pm$ SD age: 25.4 ± 10.4) with lower extremity injuries. Three studies showed a high risk of bias, while one was rated as low risk. The findings indicate that DTT significantly improved ankle proprioception and peroneus longus muscle activation compared to STT, although both DTT and STT yielded similar outcomes in postural control and jump-landing kinematics, showing no clear advantage. DTT also demonstrated greater effectiveness than NI across all parameters.

CONCLUSION: DTT may offer advantages over STT in enhancing ankle proprioception and peroneus longus activation for patients with chronic ankle instability. However, the limited number of studies, high risk of bias, and limited range of clinical outcome measures underscore the need for further research in this area.

ASSESSMENT OF INJURIES IN YOUTH SOCCER PLAYERS IN RELATION TO BODY POSTURE

SZABÓ, D., KISS, G., TEKUS, E., FEKETE, J.D., VERMES, CS., MINTAL, T.

PÉCS UNIVERSITY MEDICAL SCHOOL

INTRODUCTION: The incidence of injuries among junior football players is remarkably high. Adolescents may be particularly vulnerable due to the rapid physical changes that occur during growth spurts. Poor posture might be linked to an increased risk of injuries in this population.

This study aimed to examine the connection between poor posture and injury patterns in youth football players.

METHODS: A total of 116 football players (aged 11–18 years) participated in the study. Participants were categorized based on age and academic level. Data on training and injuries were collected through questionnaires and injury registration software. Habitual posture was assessed using the PostureScreen mobile application. During statistical analysis descriptive statistic, independent sample t-test, one-way ANOVA with Tukey post-hoc test and Kruskal-Wallis H test was performed. Chi-squared test was applied to assess relationship between postural parameters and injury occurrence

RESULTS: Injury rates were high across the entire study group, with the highest rates observed in the U14 and U15 age categories. Significant positive correlations emerged between various postural parameters and injury occurrence ($p \leq 0,05$) while academic groupings showed less pronounced associations. For the full study sample, the most important observation is that "total" frontal value in posture and the pelvic translation can be considered as risk factors for re-injury.

CONCLUSION: The findings indicate a clear association between postural parameters, as measured in both the frontal and sagittal planes, and the occurrence of injuries among youth football players. Our findings highlight the role of using posture screening methods as the part of the injury prevention program among youth football players.

INVESTIGATED BETWEEN KNEE JOINT BEHAVIOR DURING INSTEP KICKS INVOLVING KNEE JOINT EXTENSION, THE FACTORS CONTRIBUTING TO THE OCCURRENCE OF THE ANTERIOR HORN TEAR OF THE LATERAL MENISCUS OF KNEE JOINT.

MURAKAMI, K., ODA, K., TAKAHASHI, T., HARA, Y.

TEIKYO UNIVERSITY OF SCIENCE

INTRODUCTION: In sports activities, damage to the knee joint meniscus is a relatively common occurrence, with particularly rare cases of the anterior horn Tear of the lateral meniscus of knee joint (AHLM). According to past reports, the incidence of AHLM associated with sports activities is reported to be 2.5%, with soccer considered to carry a higher risk. Among soccer players, AHLM has been attributed to repetitive kicking motions involving knee joint extension. Therefore, we investigated the correlation between knee joint behavior during instep kicks involving knee joint extension and meniscus behavior, aiming to verify the factors contributing to the occurrence of AHLM.

METHODS: 23 university students were instructed to perform maximum effort instep kicks, and measurements were taken using a 3D motion analysis system. The analysis focused on calculating the knee joint extension and rotation angles from the moment of BI until the acceleration of the foot reached zero during the follow-through. The analysis was conducted using Vicon Nexus 2.16 software. Knee joint rotation was enhanced by adding markers to the inner side of the knee joint according to the conventional Plug-in-Gait marker set definition, and the segments were redefined using 3 points markers on the outer side of the thigh and lower leg, and the added marker on the inner side of the knee joint.

RESULTS: A total of 43 instep kicks were performed. Knee joint hyperextension was observed in 69.8% of kicks, with an average angle of $-7.0 \pm 4.1^\circ$ and a maximum of -15.9° . The maximum extension position for each kick occurred between 0.052 to 0.072 sec after "Ball Impact" (BI). Furthermore, to increase the reliability of rotation angles, the rotation angle at the time of maximum knee flexion before the kick BI was normalized to 0° , and changes in rotation angles after BI were considered as knee joint rotation angles. As a result, the average maximum rotation angle after BI was $-14.5 \pm 12.9^\circ$ (average knee flexion angle of $35.1 \pm 7.5^\circ$), indicating external rotation. Additionally, 81.6% of external rotation was observed during the period of 0.052 to 0.072 sec after BI, with an average angle of $-7.5 \pm 1.3^\circ$.

CONCLUSION: It is known that the knee joint meniscus moves forward with knee joint extension and influenced by the "Screw Home Movement function" during extension, undergoes external rotation, causing the meniscus to move anteriorly and laterally. AHLM are frequently observed in soccer players, especially those involving instep kicks that accompany knee joint extension. The repetitive nature of this motion is believed to be a contributing factor to AHLM. The results of this study confirm that knee joint external rotation increases significantly at this moment of knee joint hyperextension in the kicking leg during instep kicks. This supports the conclusion that the kicking motion (instep kick) contributes to the induction of AHLM.

INTEGRATED APPROACHES OF THERMAL MEDICINE AND CLINICAL HYDROLOGY FOR SPORTS REHABILITATION: OPTIMIZING POST-EXERCISE RECOVERY AND TREATMENT OF SPORT INJURIES

CANU, A., PESTRIN, E., BUOITE STELLA, A.

UNIVERSITY OF TRIESTE

INTRODUCTION: Thermal medicine and clinical hydrology are innovative and complementary approaches in sports rehabilitation, with applications ranging from injury prevention to post-exercise recovery. Thermal therapies, including balneotherapy, mud therapy, and hydrokinetic therapy, are increasingly being used to support athletes in reducing inflammation, accelerating muscle recovery, and improving joint mobility. Despite the growing interest, there is limited research on

the specific effects of these therapies within sports medicine, highlighting the need for further investigation into their benefits and mechanisms of action.

METHODS: The study involved a cohort of athletes undergoing rehabilitation for various sports injuries, with a particular focus on those recovering from shoulder injuries. Participants received a combined therapeutic protocol that included immersion in thermally controlled water and localized mud applications. Hydrokinetic therapy, based on Archimedes principle, was also incorporated to reduce joint stress and enhance recovery. The rehabilitation protocol for post-operative shoulder recovery lasted 26 weeks and included progressive phases: hydrokinetic therapy, mud therapy, and controlled muscle strengthening, culminating in full motor recovery. Physiological responses, including muscle recovery rates, inflammation markers (C-reactive protein), and joint mobility improvements, were measured pre- and post-treatment. Additionally, psychological well-being was assessed through validated questionnaires

RESULTS: The results indicate that the application of thermal therapies significantly accelerated muscle recovery and reduced joint inflammation. Thermal water treatments and mud therapy led to notable improvements in microcirculation, enhancing oxygen and nutrient delivery to tissues while promoting the removal of pro-inflammatory metabolites. Hydrokinetic therapy effectively reduced joint load, allowing for early rehabilitation without increasing the risk of further injury. Biologically, thermal treatments were shown to stimulate the release of β -endorphins and cortisol, enhancing pain tolerance and modulating the inflammatory response. Moreover, levels of insulin-like growth factor (IGF-1), which is essential for cartilage regeneration, were elevated following thermal therapy.

CONCLUSION: This study demonstrates the potential of integrating thermal medicine and clinical hydrology into sports rehabilitation protocols. The findings underscore the ability of thermal therapies to accelerate recovery, reduce inflammation, and improve mental well-being in athletes. Given the promising results, further research is required to standardize protocols and optimize the use of these therapies in clinical settings. The integration of these treatments into rehabilitation programs may offer a scientifically grounded and sustainable approach to managing sports injuries and optimizing athletic performance.

EFFECTIVENESS OF A NOVEL FIGURE-EIGHT TAPING TECHNIQUE FOR MANAGING ANTERIOR SHOULDER INSTABILITY IN PITCHER: A CASE REPORT

KAWABATA, M., MIYATA, T., MIYATAKE, K., WATANABE, H., TAKAHIRA, N.

KITASATO UNIVERSITY GRADUATE SCHOOL OF MEDICAL SCIENCE

INTRODUCTION: Shoulder instability, particularly in overhead athletes, such as baseball pitchers, poses significant challenges in management, often leading to chronic pain and functional impairment. This case report highlights the immediate and sustained benefits of a novel figure-eight taping technique for managing anterior shoulder instability confirmed using ultrasound in a recreational baseball pitcher.

METHODS: A 41-year-old male unable to pitch for six years due to progressive shoulder pain, which significantly affected his daily life. The initial clinical examination revealed severe pain localized to the rotator cuff interval and posterior shoulder, with marked limitations in range of motion and muscle strength. Ultrasound imaging confirmed significant anterior shoulder instability, characterized by anterior subluxation of the humeral head and inflammation around Bennett's lesion.

RESULTS: A novel figure-eight taping technique was used to control shoulder anterior instability while maintaining functional alignment. The intervention led to immediate improvement in muscle strength and a significant reduction in pain, which decreased Numeric Rating Scale (NRS) pain scores (1-3/10). Moreover, the patient could perform painless and smooth pitching motions immediately after the intervention. Remarkably, he pitched from 18.44 meters at 85% intensity on the same day. Four months later, the patient successfully returned to competitive pitching, achieving a maximum pitch speed of 115 km/h with minimal pain (NRS, 3/10). The patient continued to practice independently, adhering to the rotator cuff exercises and pitching form corrections learned through the taping intervention. Notably, the positive effects of taping persisted even eight months after the intervention, underscoring the potential of this technique as a valuable non-invasive treatment option within conservative management strategies for shoulder anterior instability.

CONCLUSION: The figure-eight taping technique demonstrated potential as an effective non-invasive option for managing anterior shoulder instability, aiding sustained pain relief, and functional recovery.

COMPREHENSIVE ANALYSIS OF RECOVERY METHODS AMONG RECREATIONAL MARATHON RUNNERS IN JAPAN

KANEKO, Y., KIKUCHI, T., YAMAGUCHI, S., SAKAGUCHI, S., FUJITA, Y., KAMIOKA, H., HORIUCHI, T., OHMURA, K., NAKAMURA, T., MORI, Y., HAMAOKA, T.

TOKYO MEDICAL UNIVERSITY, KURETAKE GAKUEN

INTRODUCTION: Endurance athletes employ a variety of recovery strategies to maintain and enhance performance. High training loads often lead to an imbalance between physical and psychological stress and recovery. Therefore, optimizing recovery strategies has become increasingly important. In Japan, cultural practices such as hot springs (onsen) and acupuncture have become widely used for recovery, yet their impact on recreational runners remains unclear. This study aimed to investigate the association between athletic performance and recovery methods through a large-scale web-based questionnaire survey exclusively among recreational marathon runners in Japan.

METHODS: An online survey was conducted using Google Forms. A random sample of 200,000 recreational runners was selected from 1.1 million registered users on web-based marathon registration site, who had participated in a full mara-

thon in the past three years. The survey included items on age, gender, running history, best race times, and average monthly training volume over the past three years. It also assessed the usage and frequency of various recovery methods—including bathing, alternating baths, cold water baths, bedrock baths, hot springs, saunas, massage, stretching, icing, compression wear, active recovery, transcutaneous electrical nerve stimulation (TENS), acupuncture and moxibustion, oxygen capsules as well as interest in using these methods in the future.

RESULTS: A total of 5,189 responses were obtained. The average running history was 12.1 ± 8.8 yrs, and the mean best race time was 4h08m11s. A significant negative correlation was found between training volume and best race time ($r = -0.34$, $p < 0.0001$). Among recovery methods, bathing (86.5%), stretching (85.0%), hot spring usage (66.7%), and massage (47.0%) were most prevalent. Notably, runners who used acupuncture achieved a significantly faster average best race time (3h48m38s) compared to non-users (4h14m37s, $p < 0.001$) and had longer running histories. Factor analysis identified four distinct clusters of recovery methods: (1) traditional passive heat therapies (hot springs, saunas, bathing, bedrock baths), (2) active recovery methods (active recovery, stretching, compression wear), (3) passive methods whose efficacy was demonstrated in previous studies (cold water baths, alternating baths), and (4) passive therapies requiring ongoing costs (acupuncture, TENS, oxygen capsules, massage).

CONCLUSION: This study revealed that higher training volumes are associated with faster best race times among recreational marathon runners in Japan. Moreover, the use of acupuncture was linked to better performance and longer running histories. The findings also highlight the widespread use of culturally embedded recovery practices, such as bathing and hot spring therapy, which appear to be adapted according to individual lifestyle and resource availability. The findings provide a valuable foundation for developing evidence-based recovery strategies for endurance athletes.

COMPARISON OF THE ACUTE EFFECTS OF DIFFERENT WARM-UP PROTOCOLS IN OVERHEAD ATHLETES WITH POSTERIOR SHOULDER TIGHTNESS: A PILOT STUDY

CHEN, B., HUANG, T.S.

NATIONAL YANG MING CHIAO TUNG UNIVERSITY

INTRODUCTION: Posterior shoulder tightness (PST) is common in overhead athletes and may contribute to upper extremity injuries due to restricted total and internal shoulder rotation [1]. While static stretching (SS) is widely used to address PST, its potential to impair strength performance raises concerns about its use in warm-ups. To address this, researchers have proposed reducing stretching duration or combining it with dynamic stretching (DS) to maintain warm-up benefits without strength loss. Roller massage (RM) has also gained popularity for improving flexibility without compromising performance. However, most research on warm-up strategies has focused on the lower extremities. This study aimed to compare the effects of static stretching, dynamic stretching, and roller massage on upper extremities flexibility and performance in overhead athletes with PST.

METHODS: Seven healthy collegiate overhead athletes with PST were recruited. The original study was a crossover study with all participants undergoing three different interventions (DS, SS+DS, and RM+DS groups) in a randomized order. In our pilot study, all participants were only allocated to perform the first intervention. The outcome measures included shoulder range of motion (ROM), posterior deltoid and infraspinatus muscle stiffness, shoulder external and internal rotation isometric strength and rate of force development (RFD), upper quarter Y-balance test and closed kinetic chain upper extremity stability test (CKCUEST) performance, and posterior shoulder muscle fatigue resistance. All participants were tested before and immediately after the intervention.

RESULTS: In the RM + DS group, there were 2 participants, while the SS + DS group also had 2 participants, and the DS group had 3 participants. The descriptive statistics showed increased active shoulder internal rotation (RM+DS: 27%; SS+DS: 17%; DS: 7%) and horizontal adduction ROM (RM+DS: 63%; SS+DS: 29%; DS: 13%) in all groups. Similarly, all groups improved CKCUEST performance (RM+DS: 27%; SS+DS: 13%; DS: 3%). However, the RM+DS group showed a decreasing trend in shoulder external and internal rotation RFD (-13% and -15%, respectively), while no clear trends were observed in the DS and SS+DS groups. No notable trends were observed in the other measurements.

CONCLUSION: RM combined with DS during warm-up may have a trend of enhancing more active shoulder ROM and CKCUEST performance while potentially reducing shoulder RFD compared to DS combined with SS and DS only. The full crossover experiments should be completed with more participants to compare group differences and confirm these findings.

ASSESSMENT OF FALL RISK IN A POPULATION OF PATIENTS WITH CARDIOVASCULAR DISEASES UNDERGOING CARDIAC REHABILITATION.

VITARELLI, M., CAMPOLI, F., CAMINITI, G., FRANCHINI, A., VOLTERRANI, M., CAPRIOLI, L., EDRISS, S., BONAIUTO, V., ROMAGNOLI, C., ANNINO, G., PADUA, E., MESSINA, G.

UNIVERSITÀ DI VERONA

INTRODUCTION: Cardiac rehabilitation is recommended for patients with chronic heart disease and those recovering from acute cardiovascular events to restore functional capacity or maintain autonomy in daily activities, especially in elderly and frail individuals. Prolonged immobility from hospitalization increases risks of hypokinetic syndrome, orthostatic hypoten-

sion, mood swings, and vascular complications. This study evaluates the impact of cardiac rehabilitation and adapted physical activity on fall risk, balance, cervical mobility, and sleep quality in elderly patients post-acute cardiovascular event.

METHODS: 20 participants over 65 (6 women, 14 men; 72.7 ± 5.4 years) were recruited from the cardiology department at IRCCS Pisana in Rome following a recent acute cardiac event. Initial assessments measured fall risk (Conley scale), the postural control (stabilometric test), cervical mobility (Moover® inertial sensor), and sleep quality (Pittsburgh Sleep Quality Index - PSQI). Participants underwent a 20-day intensive training protocol: day I: walking, days II-VII: calisthenics/balance exercises (30 min) and aerobics with pedals (30 min); day VIII-discharge: gym activity with aerobic exercise (50-60% maximum HR, 30 min) and group exercises. The final assessments were conducted before discharge.

RESULTS: Post-intervention, participants showed a low fall risk (0.5 ± 0.9 Conley Scale). the training protocol carried out in the gym allowed a maintenance of the stabilogram length with open eyes (pre 229 ± 63.1 mm, post 228.5 ± 72.2 mm) and a reduction with closed eyes, demonstrating an improvement in postural control. Cervical mobility improved by an average of 2 degrees in all directions, with statistically significant improvement ($p < 0.01$) in anterior flexion-extension. Sleep quality (PSQI) increased by 12% ($p = 0.3$).

CONCLUSION: Intensive cardiac rehabilitation improved postural control and cervical mobility within 20 days in elderly patients post-acute cardiovascular event. Although sleep quality showed a 12% increase, it was not statistically significant, possibly due to the short duration of the study. The protocol supported functional capacity and autonomy, highlighting the value of a structured, personalized approach in post-cardiac event rehabilitation. Future research should examine the benefits of continuing the training protocol at home to determine if regular physical activity can sustain or enhance observed improvements.

THE EFFECT OF BODY MASS INDEX ON BALANCE IN ADOLESCENT ATHLETES

CIGERCIOGLU, N., BAZANCIR-APAYDIN, Z., COLAKOGLU, F., BALTACI, G.
ISTANBUL ATLAS UNIVERSITY

INTRODUCTION: Body mass index (BMI) is one of the key determinants of balance in adolescent athletes. Preventing potential injuries and maintaining balance are crucial for athletes during their developmental stages. The aim of this study was to examine the effect of BMI on balance in adolescent athletes.

METHODS: A total of 300 adolescent athletes (mean age = 15.29 ± 4.75 years, mean BMI = 20.31 ± 3.28 kg/m²) participated in the study. Body weight was assessed using the Tanita BC 418 MA (Tanita, Japan) device. BMI was classified as underweight (≤ 18.5 kg/m²), healthy weight (18.5-24.9 kg/m²), overweight (25-29.9 kg/m²), and obese (30-39.9 kg/m²). The Y-balance test was used to measure athletes dynamic balance. Participants were instructed to stand at a designated point of a pre-drawn "Y" shape and extend their toes in anterior, posteromedial, and posterolateral directions. Pearson correlation test and linear regression analysis were used for statistical analysis.

RESULTS: Among the participants, 50% were volleyball players, 20% were basketball players, and 30% were tennis players. BMI was weakly correlated with the anterior ($p = 0.001$, $r = -0.348$), posteromedial ($p = 0.023$, $r = -0.149$), and posterolateral ($p = 0.001$, $r = -0.220$) directions of the Y-balance test. A one-unit change in BMI was found to affect anterior balance by 12%, posteromedial balance by 2%, and posterolateral balance by 4%.

CONCLUSION: This study has shown that adolescent athletes with a high BMI experience impaired balance. Balance deficiency can negatively affect not only athletic performance but also increase the risk of injuries. Particularly during adolescence, excessive body mass may hinder motor control and reduce movement efficiency. To maintain optimal performance and prevent injuries, athletes should carefully manage their body mass, especially during this developmental period. Additionally, incorporating aerobic exercises that support balance into their training programs is essential.

Psychology

PERSONAL VALUES, SPORT VALUES AND ATHLETES' CLEAN SPORT LIKELIHOOD

SUKYS, S., HOPPEN, B.
LITHUANIAN SPORTS UNIVERSITY

INTRODUCTION: Doping in sport is a form of cheating, and while progress has been made in education and prevention, it remains a contentious issue in sports psychology [1]. Antidoping education now increasingly emphasizes the promotion of clean sport [2], which can be defined as achieving athletic potential without doping [3]. However, the relationship between athlete's personal and sport values and clean sport likelihood is still underexplored. This study aims to address this gap, controlling for other personal and contextual factors.

METHODS: Participants included 948 athletes (477 males and 477 females, $M_{age} = 20.32$; $SD = 2.45$) from team and individual sports. The athletes' personal and sport values were assessed using the Portrait Values Questionnaire-21 and Youth Sport Values Questionnaire-2. Clean sport likelihood was measured using a hypothetical scenario describing key temptations to dope. Control variables included moral identity, doping self-regulatory efficacy, attitudes toward doping, and coach-created motivational climate.

RESULTS: The study employed hierarchical regression analysis. The first step included personal and sport values as a predictor and the model significantly predicted clean sport likelihood ($R^2_{adj} = 0.61$, $F = 212.62$, $p < .001$). Self-transcendence ($\beta = 0.32$, $p < .001$) and conservation ($\beta = 0.48$, $p < .001$) were positive predictors, while self-enhancement ($\beta = -0.24$, $p < .001$) and openness to change ($\beta = -0.16$, $p < .001$) were negative. Moral values ($\beta = 0.45$, $p < .001$) positively predicted clean sport likelihood, while status values ($\beta = -0.19$, $p < .001$) had a negative effect. Including other personal factors, the model still predicted clean sport likelihood ($R^2_{adj} = 0.67$, $F = 195.82$, $p < .001$), with moral identity ($\beta = 0.23$, $p < .001$) and doping self-regulatory efficacy ($\beta = 0.24$, $p < .001$) as positive predictors. Attitudes toward doping ($\beta = -0.07$, $p = .03$) negatively predicted clean sport likelihood. Finally, including the coach-created motivational climate, the model remained significant ($R^2_{adj} = 0.68$, $F = 164.70$, $p < .001$), with a disempowering climate ($\beta = -0.07$, $p = 0.02$) as a negative predictor, while an empowering climate showed no significant relationship.

CONCLUSION: This study supports previous research that moral identity and doping self-regulatory efficacy are positive predictors of clean sport likelihood. Interestingly, an empowering coach-created motivational climate was not related to clean sport likelihood. The novelty of this study lies in highlighting the importance of both personal and sport values in predicting clean sport likelihood. Different values related with athletes intentions differently, suggesting that understanding these values is important aiming to encourage athletes to compete clean.

EXPLORING THE EFFECTS OF FASTING ON COGNITIVE EFFICIENCY DURING 8-H AN OFFICE-LIKE SIMULATED MENTAL WORKING DAY

BRAZAITIS, M., GRIGAITIS, V., MAZUOLYTE-BINDERIENE, A., KRASINSKE, E., SATAS, A.

LITHUANIAN SPORTS UNIVERSITY

Introduction: When sustained neural firing is disrupted due to impaired energy production and supply in the brain, it can result in lapses of attention and a decline in working memory. Fasting for two days reduces the levels of glucose in the bloodstream, and the brain is particularly sensitive to these changes. Therefore, the primary goal of this study was to investigate the effects of fasting-related changes in glucose levels on cognitive efficiency during an 8-hour period of office-like computer work.

Methods: Twenty healthy young adults, consisting of 10 men and 10 women, completed two separate study trials for both fasting and control conditions in a random order. Each trial took place during a standard 8-hour working day, with 10-minute breaks every 50 minutes. A battery of nine cognitive tasks was presented in random order and performed twice during the 50-minute work sessions. Ketone and glucose concentrations in response to the trial conditions were assessed at several time points: before the trials, 2 hours after starting, 3 hours in, post-lunch, after the working day, during a 4-hour recovery period, and the following morning. Subjective scales were utilized to evaluate feelings of fullness, hunger, and motivation.

Results: Fasting resulted in a gradual increase in ketone levels, accompanied by a significant decrease in glucose levels ($p < 0.05$). During an 8-hour workday, participants who were fasting reported lower motivation, increased mental fatigue, heightened hunger, and reduced feelings of fullness compared to those in control conditions ($p < 0.05$). Interestingly, despite experiencing greater psychological stress, fasting seemed to enhance cognitive efficiency across various tasks ($p < 0.05$). These tasks included working memory, attention, concentration, reaction times, visual tracking, learning, memory, visuospatial function, selective attention, and executive function, all of which are critical for office employees. However, these cognitive benefits were not consistently maintained throughout the day and demonstrated significant variability.

Conclusion: While fasting may lead to a heightened subjective stress response, it also appears to improve cognitive efficiency during a simulated office workday.

Funding: This work was supported by the Research Council of Lithuania (grant number S-MIP-23-84).

THE STRATEGIC ORIENTATION OF ANTI-DOPING EDUCATION FOR YOUNG ATHLETESAN EMPIRICAL STUDY BASED ON THE INFLUENCING FACTORS OF ANTI-DOPING ATTITUDE AND PARTICIPATION WILLINGNESS OF YOUNG ATHLETES

WANG, Z.

SHANGHAI RESEARCH INSTITUTION OF SPORT SCIENCE

INTRODUCTION: The World Anti-Doping Agency's statement that "athletes' first contact with anti-doping should be through education rather than doping control" reflects the importance of education in anti-doping work. Young athletes, as a unique group, face challenges in anti-doping education. This study will examine the characteristics of young athletes to understand what influences their attitudes toward anti-doping and their willingness to participate. It will also explore the differences in anti-doping attitudes and willingness among young athletes with varying characteristics. This will help construct strategies for implementing anti-doping education for youth, effectively improving the results of anti-doping education for young athletes.

Method: This study will survey approximately 1,500 young athletes from sports schools in both urban and district areas of Shanghai. It will employ field research, expert interviews, and questionnaires to investigate the factors influencing their

attitudes towards anti-doping and their willingness to participate. The data will be analyzed using methods like factor analysis, regression analysis, and heterogeneity analysis.

RESULTS: (1) Young athletes demonstrate a favorable attitude towards anti-doping initiatives and express a strong desire to engage in anti-doping education. (2) Self-awareness, anticipated benefits, and social support strongly influence young athletes willingness to participate in anti-doping education. In contrast, the content and format of the education do not significantly affect their willingness. Positive attitudes towards anti-doping enhance the likelihood of young athletes participating in education programs. (3) Young athletes with different characteristics exhibit significant differences in their willingness to participate in anti-doping education.

Discussion: The findings revealed that young athletes recognize the significance of anti-doping and possess some knowledge about it. Several factors influence young athletes participation in anti-doping education. Improved self-awareness boosts their confidence in completing educational tasks. Additionally, athletes understand that anti-doping education enhances their knowledge and supports their competitive careers, making them more willing to participate. Social support also encourages their involvement in anti-doping education. Therefore, to improve the effectiveness of anti-doping education in the future, programs should focus on enhancing athletes self-awareness, clarifying the necessity of such education, and tailoring content to their unique characteristics.

EFFECTS OF DIFFERENT EXERCISE PATTERNS ON SPATIAL AND VERBAL WORKING MEMORY UPDATING IN WOMEN WITH METHAMPHETAMINE USE DISORDER

YIFAN, C.

NANJING SPORT INSTITUTE

Objective: To explore the chronic effects of moderate-intensity cycle ergometer and aerobic calisthenics training on spatial and verbal working memory (WM) updating and brain activity. **Methods:** Forty female methamphetamine (MA) users were randomly assigned to receive either moderate-intensity cycle ergometer or aerobic calisthenics training twice a week for 10 weeks. Before and after exercise, a modified 2-back task, which contained the word and position task, was used to assess changes in spatial and verbal WM updating, and functional near-infrared spectroscopy (fNIRS) was used to assess activation of prefrontal cortex. **Results:** The cycle ergometer group showed significant reductions in response times in both WM task types examined, whereas the aerobic calisthenics group showed a significant reduction only for the spatial WM task. fNIRS showed reduced activity in orbitofrontal cortex (OFC) after both interventions. The cycle ergometer group exhibited significantly greater right dorsolateral prefrontal cortex (DLPFC) activity during word task performance than did the aerobic calisthenics group. **Conclusion:** Cycle ergometer training can effectively promote spatial and verbal WM updating, while aerobic calisthenics training only accelerate spatial WM updating and the two exercise types having different impacts on prefrontal cortical activity, particularly in the right DLPFC.

A STUDY ON THE INFLUENCING FACTORS OF COLLEGE ATHLETES CAREER SELF-EFFICACY

CHAN, C.

NATIONAL TAIWAN NORMAL UNIVERSITY

A Study on the Influencing Factors of College Athletes Career Self-Efficacy

INTRODUCTION: College athletes with higher career self-efficacy are more proactive in career exploration and decision-making. This also helps individuals organize and coordinate their talents, adapt to life's challenges and pressures, and achieve greater career satisfaction. The study explores the influence of college athletes perceived calling, self-esteem, hope, and career adaptability on career self-efficacy.

METHODS: This study conducted data collection through a questionnaire survey, and 500 college athletes participated in this study. In total, 437 valid questionnaires were returned. The data obtained were statistically analyzed using structural equation modeling.

RESULTS: The hypothesized model constructed in this study achieved an acceptable fit with the sample data. Calling, self-esteem, and career adaptability had a direct positive impact on career self-efficacy, while hope indirectly influenced career self-efficacy through career adaptability.

Discussion: This study revealed that calling, self-esteem, and career adaptability have direct effects on the career self-efficacy. College athletes with higher career adaptability are better able to establish a clear self-concept, gradually build confidence in their chosen profession. Furthermore, college athletes with higher self-esteem experience fewer psychological distress, demonstrate better career self-efficacy. In addition, by cultivating a sense of calling, college athletes can clarify their career goals, enhance passion and a sense of mission for their profession, ultimately leading to higher career self-efficacy. The study revealed a positive correlation between hope and career adaptability. College athletes with higher hope experience less subjective distress and a lower frequency of negative emotions when facing life and career development pressures, thus improving career adaptability. Additionally, a strong sense of calling not only helps athletes pursue careers imbued with value and meaning but also facilitates future career transitions. Athletes with a sense of calling demonstrate better self-concept awareness and are more motivated and capable of changing their circumstances, which enhances their career adaptability. In terms of hope, college athletes with higher self-esteem tend to pursue more ambitious career goals, which guide them toward positive thinking, resulting in greater hope. Moreover, through calling, college athletes identify their career values and choose the most meaningful career goals, thereby enhancing their hope.

Finally, the process of developing a calling allows athletes to perceive their professional tasks as unique and meaningful. This perception strengthens their commitment to pursuing career goals, elevates their self-esteem.

GALVANIC EXAMINATION OF THE SKIN OF WOMEN WITH PANIC DISORDER FOLLOWING AEROBICS

ESKANDARNEJAD, M.1, FARNAM, A.2, ALI MOHAMMADI, T.3

1 & 3. *PHYSICAL EDUCATION AND SPORT SCIENCE FACULTY UNIVERSITY OF TABRIZ*, 2. *KHARAZMI RESEARCH CENTER IN UNIVERSITY OF TABRIZ*

Galvanic skin is a physiological measure that shows the electrical conductivity of the skin, which is usually used as an indicator of psychological and physiological stimulation. The current research is semi-experimental with a pre-test and post-test design with a control group. The participants of this research include 30 women with panic disorder, whose panic disorder was diagnosed using the Albany Barlow and Zinbarg Panic and Panic Questionnaire (APPQ) and a psychiatrist's interview, in the age range of 25 to 45. They were randomly divided into experimental and control group. The experimental group participated in exercises for 18 one-hour sessions. Before the first training session and after the last training session, the galvanic skin of the subjects was measured by the ProComp2 device made by Thought Technology, Canada. The amount of galvanic skin changes was recorded in the stages of rest, cognitive challenge, rest, emotional challenge and rest. After collecting the data using the Shapiro-Wilk test, the normality of the data distribution was checked and further, it was analyzed using the mixed variance analysis method and using the SPSS version 26 software. and was analyzed. The results showed that in examining the galvanic variable of the skin, there was a significant intra-group difference in the cognitive challenge stage, but no significant inter-group difference was observed in any of the stages. The use of regular aerobic exercises is effective in reducing the galvanic skin of people in the cognitive stage, and aerobic exercises can be used as a method to reduce arousal.

STYLE OF INTERACTION IN SUPPORT OF BASIC PSYCHOLOGICAL NEEDS, THE QUALITY OF MOTIVATION AND SUSTAINABILITY OF PA BEHAVIOR

TAVARES DE SOUSA, A., AGUIAR, A., TEIXEIRA, D.S., CERCA, L., PALMEIRA, A., PEREIRA, V.H.

UNIVERSIDADE LUSÓFONA

Background: The self-determination theory encompasses three fundamental needs: competence, autonomy, and positive relationships. This framework can be effectively applied to fitness professionals through the integration of intrinsic and extrinsic motivation strategies.

Purpose: This study aims to compare the "motivating" interaction style characterized by autonomy support and structure with the "demotivating" interaction style defined by control and chaos. We will examine how these interaction styles influence the satisfaction of basic psychological needs, the quality of motivation, and the sustainability of physical activity (PA) behavior.

Method: This research was conducted as a cross-sectional observational study, facilitating data collection through the systematic observation of participants over a designated time frame. The sample consisted of 93 individuals, balanced in terms of gender, recruited from various fitness centers. Participants were requested to complete a questionnaire accessed via a unique link distributed by their respective exercise coaches. The data gathered were subsequently analyzed and evaluated to draw relevant conclusions regarding the subject matter.

Results: In this study, 93 individuals were recruited as participants, with females composing 50.5% of the sample. The participants had a mean age of 46.07 years (± 14.4) and an average weight of 70.1 kg (± 10.9). The results indicate that 19.4% of participants do not utilize gym facilities; approximately 45.1% reported a preference for training in budget-friendly gyms, while only 5.4% indicated a preference for family-oriented gyms, and 30.1% favored premium gyms. A statistically significant difference was found between the individuals who do not engage in gym training and those who train in either low-cost or premium gym environments.

Conclusion: The support that fosters sustained adherence to physical activity and a sense of self-determination is enhanced through the alignment of support with the psychological needs of autonomy and structure. To promote increased adherence and uniformity in the practice of physical exercise, it is imperative for women to mitigate demotivating interactions characterized by control and chaos. Furthermore, the fundamental psychological needs and the long-term sustainability of physical activity are significantly correlated with high levels of intrinsic motivation and self-regulation observed across both genders.

RESISTANCE TRAINING FOLLOWING METABOLIC-BARIATRIC SURGERY: MOTIVATORS, BARRIERS AND PREFERENCES

LUIJPERS, L., NUIJTEN, M., MONPELLIER, V., DE ROOS, B., KARREGAT, J., EIJSVOGELS, T., HOPMAN, M.

NEDERLANDSE OBESITAS KLINIEK / RADBOUDUMC

Introduction. Metabolic and bariatric surgery (MBS) induces substantial muscle mass loss. Resistance training (RT) is an effective strategy to maintain muscle mass. This study aimed to gain insight in the motivators, barriers and preferences regarding RT after MBS.

Methods. A digital survey assessing RT was sent to patients who had MBS 1 to 18 months prior. Patient characteristics were extracted from electronic health records. Motivators, barriers and preferences were assessed with a questionnaire and compared across three groups: patients currently (RT-group), previously (ex-RT) or never engaged in RT (non-RT).

Results. Of 1 609 participants (77% female, 47±11 years old, BMI 42±5 kg/m²) 68% belonged to RT-group, 11% to ex-RT and 21% to non-RT. The RT-group reported improving fitness (78% vs. 67%), mental health (65% vs. 43%) and overall health (63% vs. 41%) more often as motivators for RT than the ex-RT. Barriers for RT were similar for ex-RT and non-RT, most frequently: lack of motivation (37% vs. 40%), time (33% vs. 28%), enjoyment (29% vs. 29%) and physical complaints (39% vs. 37%). Ex- and non-RT reported a preferred exercise frequency of 2 sessions/week with 30 minutes/session, in their home setting with a training schedule and guidance from a professional.

Conclusion. The majority of participants in our study engaged in RT. Motivators were improving overall fitness and limiting strength or muscle loss. Barriers are lack of motivation, physical complaints, lack of time and enjoyment. RT participation could benefit from professional guidance and a training schedule for RT at home.

UNDERSTANDING MENTAL HEALTH CHALLENGES IN ELITE SPORT: THE CASE OF BRAZILIAN COACHES AND ATHLETES

FERNANDES, P., COLAGRAI, A.C.

UNICAMP

Introduction: Elite sport presents significant mental health (MH) challenges for both athletes and coaches. While the MH of athletes has been extensively studied, less attention has been given to coaches, despite their critical role in managing team dynamics, athlete performance, and overall wellbeing. Coaches face unique stressors, such as organizational demands, leadership responsibilities, and balancing professional and personal roles, in addition to sharing many of the pressures experienced by athletes. **Purpose:** To explore and compare the MH states of elite Brazilian athletes and coaches, analyzing risk and protective factors. **Methods:** This mixed-method study included 148 elite athletes and 106 elite coaches (≥18 years) with a minimum weekly training workload of 20 hours. Participants were active in regional, national, and/or international competitions. Quantitative data were collected using an online questionnaire, evaluating demographic information, mental health risk factors, and protective factors, based on Keyes dual-factor mental health model. **Instruments included:** Patient Health Questionnaire (PHQ-9), General Anxiety Disorder-7 (GAD-7), Alcohol Use Disorders Identification Test (AUDIT-C), Sport Motivation Scale (SMS), and others validated in this context. **Statistical analyses** were conducted using SPSS, with significance set at $p < 0.05$. Qualitative data was obtained through semi-structured interviews with 7 athletes and 8 coaches, exploring factors which influence MH, performance and coping strategies. **Results:** Quantitative findings revealed significant differences between athletes and coaches regarding MH risk and protective factors. Female participants, particularly female coaches, reported lower resilience, social support, and motivation, alongside higher anxiety and depressive symptoms compared to male participants. Coaches reported more alcohol use and faced unique occupational stressors, such as precarious contracts and administrative issues. Athletes indicated higher anxiety levels related to performance pressures, injury, and team dynamics. Qualitative data highlighted themes such as the culture of extreme competition, stigma around mental health, and lack of professional psychological support. Both groups emphasized the importance of protective factors like psychological support, positive relationships, and effective coping strategies. **Conclusion:** The study underscores gender and role-specific MH disparities in elite Brazilian sport. Female coaches exhibited the most significant vulnerabilities, while athletes struggled with performance-related pressures. Findings highlight the need for tailored interventions to address MH challenges in elite sport, emphasizing the importance of organizational support and stigma reduction.

RUGBY FOOTBALL PLAYERS COGNITION OF TACKLING

KOAKUTSU, A., YAO, N., CHIBA, G., HASEGAWA, N.

NATIONAL DEFENSE ACADEMY OF JAPAN

INTRODUCTION: Tackling is an important part of the game in rugby football. It is also essential for coaches to grasp players' cognitive structure of tackling. This study aims to develop a cognitive scale and demonstrate a structure of tackling for rugby football players.

METHODS: This study used a questionnaire answered by 323 male rugby football players (101 high school students and 222 college students). The questionnaire consisted of 71 questions about tackling. The data collected was subjected to exploratory factor analysis, reliability analysis and confirmatory factor analysis by structural equation modeling.

RESULTS: Five factors were extracted from the results using exploratory factor analysis. In the next exploratory factor analysis, the number of items of each factor is made equal, and each item was subordinated to each factor. The result also showed that each item had a factor loading amount over .40 and a simple structure. The Cronbach's α of each factor was .79, .79, .76, .71 and .67, starting from factor 1. The fit coefficients by confirmatory factor analysis were sufficient (GFI=.937, AGFI=.903, CFI=.951, RMSEA=.056). All path coefficients that observed variables from latent variables were significantly ($p < .001$) and showed positive values more than a medium level (.38-.89).

Discussion: The factors extracted by exploratory factor analysis were called Assertiveness, Sense of achievement, Fortune, Decision making, and Decisiveness. We judged that the scale was sufficiently reliable, because the Cronbach's α was over .65. The result of confirmatory factor analysis showed sufficient construct validity of the model, which comprised of 15 items of the five factors. Rugby football player's cognition of tackling consisted five factors. The resulting scale had sufficient reliability and validity, and we provided suggestions about using this scale.

DIFFERENT RECOGNITION OF TACKLING FOR RUGBY UNION PLAYERS; DIFFERENCES BASED ON LIKE/DISLIKE FEELING (WITHDRAWN)

CHIBA, G., KOAKUTSU, A., YAO, N., HASEGAWA, N.

NATIONAL DEFENSE ACADEMY OF JAPAN

INTRODUCTION: Tackling is one of crucial parts in rugby union game. In addition, it is important for coaches to understand how players perceive tackling. The purpose of this study was to investigate whether the feelings of like/dislike influence to recognition of tackling for rugby union players.

METHODS: A questionnaire was conducted to 323 rugby players (101 high school students and 222 university students). The questionnaire was a self-evaluation scale for tackling consisting of 15 items on 5 factors: aggressiveness, achievement, luck, situational judgment, and decisiveness. Players were divided into two groups, like vs dislike for tackling, to compare the difference of recognition of tackling.

RESULTS: Results showed that players who liked tackling scored significantly higher on all four factors except the luck factor (luck: $t(321)=-0.17$, n.s.) (aggressiveness: $t(316.51)=4.27$, $p<.001$; achievement: $t(317.19)=10.92$, $p<.001$; situational judgment: $t(267.96)=3.14$, $p<.01$; decision-making: $t(321)=6.99$, $p<.01$; and decision-making: $t(321)=6.99$, $p<.001$). 001; situational judgment: $t(267.96)=3.14$, $p<.01$; decision making: $t(321)=6.99$, $p<.001$).

Discussion: The results indicated that players who like to tackle are more likely to perceive themselves as playing with good judgment, better decision making, and playing aggressively, with higher sense of accomplishment. The results of this study suggested the importance of a coaching method that makes it possible for players to like tackling.

A STRATEGY AGAINST ACUTE MENTAL FATIGUE: A NEURAL OSCILLATIONS INVESTIGATION

GIRAULT, A., LORCERY, A., ANDRÉ, N., BERNARD, O., BENRAISS, A., AUDIFFREN, M.

UNIVERSITY OF POITIERS

INTRODUCTION: Cognitive effort is a constant component of daily life, influencing decision-making and the capacity for sustained attention during effortful tasks. Prolonged engagement in such tasks can lead to acute mental fatigue (AMF) and impaired cognitive function. Understanding AMF and its underlying mechanisms is essential for coping with it more effectively, particularly in sports requiring endurance capacity. The principal aim of the present study is to identify behavioral and electrophysiological markers of AMF during a 30-min cognitive task requiring continuous working memory updating. More precisely, two wave bands already associated with AMF (i.e., theta and alpha waves stimulus-locked power densities) were examined as a function of time on task.

METHODS: Seventy adults attended three sessions. During the first session, participants trained on the dual 2-back (D2B) task. In the second and third sessions, participants performed either a control task (watching a documentary) or a fatiguing task (D2B task). The order of the second and third sessions was counterbalanced across participants. The D2B task included 1,100 trials with 67% of 'no' trials (no match between trial n and $n-2$) and 33% of 'yes' trials (match between trials n and $n-2$). Electroencephalographic (EEG) activity was recorded continuously with 64 electrodes. The data were sampled at 1,000 Hz and recorded using a Biosemi system. Preprocessing of the EEG data was performed using BrainVision. Stimulus-locked theta and alpha wave power densities were extracted from the signal with a time-frequency analysis using Morlet wavelets on the median central electrode (Cz).

RESULTS: Reaction times for correct responses decreased over time, but significantly more sharply for 'no' trials. Error rate for 'yes' trials (i.e., omissions) increased significantly over time, whereas error rate for 'no' trials (i.e., false alarms) remained stable throughout the task. D-prime, an index of discrimination between trials n and $n-2$, decreased over time. Stimulus-locked theta wave power density (STWD) increased significantly in the last part of the task for the 'yes' and decreased throughout the task for the 'no' trials. Stimulus-locked alpha wave power density (SAWD) increased over time for 'yes' trials and decreased over time for 'no' trials. In addition, we observed a significant correlation between the decrease in STWD for 'no' trials and the decrease in d-prime over time.

Discussion: Based on behavioral and electrophysiological data, we can conclude that participants had the tendency to respond 'no' more and more automatically over time and consequently deployed less and less cognitive effort to perform the task and thus decreased their ability to discriminate between trials n and $n-2$ over time. Subjective data suggest that this disengagement of effort would be due to boredom and a decrease in motivation.

EXAMINING THE RELATIONSHIP BETWEEN GOAL SETTING, MOTIVATION, AND JUMP PERFORMANCE IN A SINGLE-MOVEMENT TASK

MURAKAMI, H., YAMADA, N.

KINJO UNIVERSITY, CHUKYO UNIVERSITY

INTRODUCTION: Goal setting is widely recognized, both theoretically and empirically, as being effective in enhancing performance. Past sports psychology research shows that setting moderately difficult goals improves performance in single-movement tasks like standing long jumps [1]. Although it demonstrates this effect, the underlying mechanisms remain unclear. Atkinsons achievement motivation theory suggests that motivation peaks when the probability of success is approximately 50%, as this optimally balances challenge and attainability [2]. It also explains why moderately difficult goals enhance performance by maintaining high motivation levels. However, the quantitative relationship among goal difficulty, motivation intensity, and motor control mechanisms remains little explored. Recent sports science research

shows that goal difficulty impacts psychological motivation, neuromuscular activation, and motor execution strategies [3]. However, most studies focus on endurance-based or multi-trial tasks, leaving a research gap on instantaneous, single-movement tasks like the standing long jump. This study aims to bridge this gap by quantifying motivation intensity under different goals and examining its impact on jump performance and motor control mechanisms.

METHODS: Three participants performed three trials per condition for six conditions in total: (1) no goal (control) and (2-6) goal conditions set at 90%, 100%, 110%, 120%, and 130% of their best performance. Participants reported their perceived probability of success before each jump using a visual analog scale (VAS). We collected kinetic and kinematic data using a high-speed camera (300 Hz) and force plate (1000 Hz). Key performance variables analyzed were jump distance, takeoff angle, peak force in the vertical and horizontal directions, and impulse (force-time integral).

RESULTS: The 110% goal condition yielded the longest jump distance—approximately 10% longer than the best one under the control condition—aligning with past findings showing that moderately difficult goals improve performance. The VAS data showed that motivation peaked at approximately 50% perceived probability of success, supporting Atkinson's above theory. Motion analysis revealed an association of a longer jump distance in the 110% condition with a higher impulse generation, particularly in the anterior-posterior direction, thus leading to an optimized takeoff angle and velocity. These biomechanical adaptations imply that goal setting influences both psychological motivation and movement execution, optimizing force production strategies.

CONCLUSION: The study provides novel insights into the role of goal setting in single-movement tasks, indicating that moderately difficult goals optimize performance by enhancing motivation and movement control. The findings contribute to the sports psychology field and have practical implications for coaching and training.

EFFECTS OF IN-MATCH MISTAKES ON PSYCHOLOGICAL, PHYSIOLOGICAL, BEHAVIORAL, AND PERFORMANCE ASPECTS IN SOCCER, FIELD HOCKEY, AND KENDO

SUDO, R., SEKIYA, H.

HIROSHIMA UNIVERSITY

INTRODUCTION: Mistakes made during a match have been shown to affect subsequent performance. Making a mistake under pressure increases the likelihood of another mistake on the next play [1, 2]. Furthermore, athletes experience negative and positive effects of mistakes on their subsequent play [3, 4]. These studies focused on net-type and racing sports [3, 4]. Nonetheless, other sports, such as goal-type and individual-contact sports, may have different effects. Therefore, this study examined the psychological, physiological, behavioral, and performance effects of mistakes made during soccer, field hockey, and kendo matches.

METHODS: Semi-structured interviews were conducted with four university student-athletes (two men and two women) about the memorable mistake they made during a match. The questions assessed (1) the situation at the time of the mistake, (2) feelings and thoughts at the time of the mistake, (3) physiological symptoms at the time of the mistake, and (4) the effect of the mistake on subsequent play. Another effect was asked if either a negative or positive effect was answered. The interviews were analyzed using Steps for Coding and Theorization [5], a qualitative analysis method that involves step-by-step coding.

RESULTS: All participants reported negative effects, whereas one reported negative and positive effects. Negative psychological effects included feelings of depression and impatience. The negative physiological effects included thirst and palpitations. Negative behavioral effects are safety-oriented strategies. Negative effects on performance included the repetition of unusual mistakes. Positive effects were reported by a soccer goalkeeper who failed to save goals but decided not to give up an additional goal and improved concentration and performance.

Discussion: Most reports were consistent with those reported in previous studies [3, 4], suggesting that sports characteristics had no influence. Negative psychological, physiological, and behavioral effects caused by mistakes are consistent with the changes reported in studies on choking under pressure, such as negative emotions [6], physiological symptoms [7], and safety-oriented strategies [8]. While studies on choking under pressure suggest that mistakes can trigger it [9], the present study, which examines the effects of mistakes, also found that serious mistakes can cause choking under pressure.

EFFECTS OF PRE-EXERCISE CAFFEINE SUPPLEMENTATION ON THE PSYCHOPHYSIOLOGICAL RESPONSES TO HIGH-INTENSITY INTERVAL TRAINING: A SINGLE-SUBJECT RANDOMIZED EXPERIMENT

ABBATE, S., MARCORA, S.M.

ALMA MATER STUDIORUM - UNIVERSITÀ DI BOLOGNA

INTRODUCTION: Caffeine is well known to reduce perceived effort in athletes, but its effects in unfit people are not clear and may not be as pronounced [1]. This single-subject randomized controlled study aimed to preliminarily investigate the effects of pre-exercise caffeine supplementation on perceived effort, affective valence and enjoyment in unfit adults participating in high-intensity interval training (HIIT) to improve their cardiorespiratory fitness.

METHODS: An unfit adult female (baseline VO₂max 26 ml/kg/min) participated in a single-subject randomized experiment involving two conditions: caffeine supplementation (3 mg/kg) 60 min prior to exercise and a placebo condition. The participant visited the lab for: a) Baseline VO₂max test, b) Three HIIT sessions for familiarization, c) Eight HIIT sessions (4 caffeine, 4 placebo in random order), d) Follow-up VO₂max test. The HIIT protocol consisted of uphill walking on a treadmill with 4 min at 85% VO₂max followed by 3 min at 55% VO₂max repeated four times (4 x 4 protocol). During exercise, the participant was asked to rate her perceived exertion (6-20 RPE scale) and affective valence (Feeling Scale, FS). Heart rate (HR) was continuously recorded with a HR monitor. Enjoyment was measured after each HIIT session with the Physical Activity Enjoyment Scale (PACES). Randomization tests [2] were used to assess for mean differences between the Caffeine and Placebo conditions. Data are presented as mean + SD of the values recorded at the end of the 4th interval (HR, RPE, FS) or after exercise (PACES). Statistical significance was set at $p < 0.05$.

RESULTS: After 5 weeks of training, VO₂max increased to 29 ml/kg/min. Pre-exercise caffeine supplementation did not have a significant effect on HR (Caffeine 173 + 2 vs Placebo 172 + 1 beats/min, $p > 0.05$) but significantly reduced RPE (Caffeine 16.5 + 0.4 vs Placebo 17.3 + 0.5 a.u., $p < 0.05$). Caffeine also increased the FS score (Caffeine -1.3 + 0.5 vs Placebo -3.0 + 0.9 a.u., $p < 0.05$) and the PACES score (Caffeine 55.8 + 2.9 vs Placebo 47.3 + 5.0 a.u., $p < 0.05$).

Discussion: These findings provide preliminary evidence that pre-exercise caffeine supplementation can make vigorous exercise feel less effortful and more pleasant while maintaining the same level of physiological intensity in an unfit adult subject. If replicated in a large randomized controlled trial, these beneficial psychological effects of pre-exercise caffeine supplementation may result in improved adherence to HIIT programs that are highly effective in improving cardiorespiratory fitness and metabolic health but challenging from a motivational point of view.

EATING DISORDER SYMPTOMS AND KNOWLEDGE OF RELATIVE ENERGY DEFICIENCY IN ADOLESCENT ARTISTIC GYMNASTS: UNCONTROLLED RISKS?

DONTI, O., DONTI, A., MARAKI, M., PSYCHOUNTAKI, M.

NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS

INTRODUCTION: Excessive pressures to maintain a lean physique may lead adolescent athletes to dietary restraint and disordered eating behaviors. Lack of understanding the nutritional requirements of sport also influences athletes' dietary habits and increases the risks of eating disorders and Relative Energy Deficiency Syndrome (RED-S); however, evidence is lacking in competitive athletes. This study examined eating disorder symptoms and knowledge of Relative Energy Deficiency Syndrome in a sample of 12–18-year-old artistic gymnasts.

METHODS: Seventy-nine female adolescent artistic gymnasts, 34 international and national level (high-level; age: 14.4±1.3 y, BMI: 18.5±1.3 kg/m²) and 45 recreational and club level gymnasts (low-level; age: 14.0±1.3, BMI: 19.7±1.8 kg/m²) completed the Eating Disorder Examination Questionnaire (EDE-Q), the knowledge of the Relative Energy Deficiency Syndrome Questionnaire, the Social Desirability Scale (SDS), and provided information on their training.

RESULTS: High-level gymnasts scored higher than low-level gymnasts in EDE-Q (32.35 vs. 6.67%, respectively; $p = 0.002$) and its subscales Restraint ($p = 0.005$), Eating Concerns ($p = 0.002$), Weight Concerns ($p = 0.001$), and Shape Concerns ($p = 0.001$). High-level gymnasts also reported more binge eating episodes than low-level (26.4 vs. 8.9%, respectively; $p \leq 0.007$) and more menstrual disturbances ($p = 0.002$). No differences were observed between groups in purging, compulsive exercise, and knowledge of RED-S. Furthermore, knowledge of RED-S negatively correlated with self-induced vomiting in high-level gymnasts ($r = -0.380$, $p = 0.05$) and positively with menstrual disturbances in low-level gymnasts ($r = 0.313$, $p = 0.05$). Over 85% of the gymnasts in both groups reported having no prior knowledge of low energy availability or RED-S in sports, and 28.6–88.6% of all gymnasts failed to recognize known associations between insufficient energy intake and RED-S symptoms.

CONCLUSION: High-level, adolescent artistic gymnasts show more eating pathology than low-level. Furthermore, gymnasts demonstrate limited awareness of how inadequate energy intake for the demands of the training may impair health and performance, irrespective of competitive level. Overlooking these risks may have significant implications for gymnasts eating behaviors and may also hinder early detection, self-control, and autonomy of female athletes, as well as the treatment of RED-S where necessary.

EFFECT OF MBI(YOGATES) ON PSYCHOLOGICAL AND PHYSIOLOGICAL HEALTH IN TIMES OF POST-COVID-19 PANDEMICS

KIM, H.

DONG-EUI UNIVERSITY

Background:

Current pharmacological treatments and psychotherapeutic approaches often have adverse effects or are ineffective in late-life cognitive and mental illnesses. Mind-body interventions (MBI) offer a holistic approach and are of interest because of potential patient acceptability and scalability.

Mind-body interventions (MBI) have been developed, and have demonstrated promising potential to improve health-related quality of life (HRQoL) in elderly people. We sought to systematically review current evidence on the effectiveness of MBI in addressing HRQoL deficits in elderly people and many patients.

Objectives: Mind-body interventions has been generally recognized as a beneficial strategy to improve mental health in those with elderly people and many patients. However, to date, no attempt has been made to collate this literature. The aim of the present study was to systematically analyze the effects of mind-body interventions for elderly people with anxiety and depression and provide scientific evidence-based exercise prescription.

Methods: PubMed, CINAHL, Scopus, Web of Science and Google Scholar search engines were used to identify the definition, mechanism, pathophysiology of MBI and yogates and to find out psychological and physiological exercise-intervention benefits

Results: The major role of (mind body interventions) MBI was to promote psychosocial health outcomes, depression, body functionality, sleep quality and health-related quality of life (HRQoL) in elderly people. Various MBE such as yoga, Tai Chi, Qigong, Meditative movement, Pilates and yogates have become an recognized as a part of physical exercise, serving to improve sleep quality, physical activity, fitness, health, psychosocial health, and reducing physical limitations, chronic pain and even cancer through meditation, relaxation, breathing, and integrating postures and so forth.

OPPONENT MOVEMENT UNCERTAINTY AND REACTION TIME: A SIMULATED KENDO MATCH EXPERIMENT

KAWABE, S., MURAKAMI, H., YAMADA, N.

1> CHUKYO UNIVERSITY, 2> KINJO UNIVERSITY

Introduction

In kendo and similar sports, athletes face unpredictable situations where their opponent's actions constantly change. This creates uncertainty in decision-making and requires rapid judgment. The attack-defense decision evolves throughout the match, maintaining both options until the final moment, akin to the superposition of states in Schrödinger's cat thought experiment (1). Athletes observe their opponent's movements while retaining both options, making a split-second decision. This study quantifies uncertainty using entropy and examines its impact on reaction time (RT) under varying conditions, evaluating how it affects decision-making speed and accuracy.

METHODS: Owing to limited prior RT research (2), this study was conducted as a pilot study with one participant to explore human response characteristics in uncertain situations. Participants quickly pressed a key in response to the stimuli on the screen. Two stimuli were used: a preparatory stimulus (a white circle) for the tactical phase and a main stimulus (a red circle) for the decision moment. The preparatory stimulus appeared eight times consecutively, followed by the main stimulus on the ninth trial. Uncertainty was adjusted by manipulating the time intervals between stimuli using entropy, with three conditions: low (450–550 ms), medium (400–600 ms), and high (300–800 ms). Six experimental patterns were created by sequencing these conditions (e.g., low → medium → high), with one trial per pattern, totaling six trials. The participant pressed the "F" key with the left hand for the preparatory stimulus and either the "K" key (attack) or the "L" key (defense) with the right hand for the main stimulus. A response within 0.3 s was considered a successful attack, preventing random selection. After each trial, the RT and attack success were recorded and displayed as feedback.

RESULTS: RTs for the preparatory stimulus were 0.30 ± 0.08 s (low uncertainty), 0.30 ± 0.05 s (medium uncertainty), and 0.28 ± 0.05 s (high uncertainty). RTs for the main stimulus were 0.28 ± 0.01 s (low uncertainty condition), 0.28 ± 0.02 s (medium uncertainty), and 0.29 ± 0.02 s (high uncertainty). The participant chose to attack in all trials, with two of six trials in the high uncertainty condition exceeding the 0.3-second response limit, indicating failure.

CONCLUSION: The results suggest that the reaction time increases under higher uncertainty (greater entropy), reducing decision-making speed. Under high uncertainty, some trials showed difficulties in decision-making within the time limit. Further investigation with additional participants is expected to provide a more generalizable understanding of the relationship between uncertainty and decision-making.

EFFECTS OF PHYSICAL ACTIVITY INTERVENTION ON INHIBITION CONTROL IN CHILDREN AND ADOLESCENTS WITH ADHD: A META-ANALYSIS

MIN, Y., CHEN, Y., LIU, J.

TEXAS A&M UNIVERSITY

Background: Children and adolescents with attention deficit hyperactivity disorder (ADHD) often have trouble with inhibition control (IC), which is a critical executive function in regulating inappropriate behaviors. Physical activity (PA) is a non-pharmacological approach to improve IC, but the optimal design, such as the setting of intensity, time per session, and frequency, remains unclear. This meta-analysis aims to assess the effect of PA intervention in inhibition control on children and adolescents with ADHD.

Methods: Following PRISMA guidelines, the systematic search was conducted across four databases, including PubMed, Web of Science, Embase, and Cochrane Library. Study quality was assessed using the PEDro scale. Stata 18.0 and R software were used to perform the pairwise meta-analysis, involving subgroup analysis, heterogeneity, publication bias, and sensitivity analysis tests. Subgroup analyses were conducted based on the moderating factors, including the intensity, session duration, weekly frequency, and total intervention duration.

Results: A total of 17 studies (784 participants aged 7-17 years old) were included with good methodological quality (Mean = 6.1 scores). PA interventions improved IC (SMD = 0.58, $p < .05$) with high heterogeneity ($I^2=85.27\%$, $p < .00$). Long-term PA interventions improved IC (SMD = 0.68, $p < .00$), while acute-term PA interventions showed no significant effect. For moderating factors, non-specific intensity requirement (SMD=0.80, $p < .05$), moderate frequencies (≤ 3 times per week: SMD = 0.96, $p < .05$), and around 60 minutes per session (SMD = 1.00, $p < .00$), were statistically significant. However, there was no significance in higher intensity and high frequency. Leave-one-out sensitivity analysis showed a 13.93% to 21.96% reduction in overall effect size but confirmed the role of PA in improving IC in children and adolescents with ADHD.

Conclusion: The long-term PA intervention has a positive effect on improving IC, and the optimal intervention design is 1-3 times per week and 60 minutes per session, as well as long-term engagement without specific intensity requirement. The high heterogeneity, due to different study designs and non-differentiated ADHD types, suggests careful interpretations of the results. Future research should evaluate this PA intervention structure and stratify ADHD subtypes to explore more targeted intervention strategies.

PERFECTIONISM, MOTIVATION AND CONCENTRATION IN TEAM SPORTS

PINEDA-ESPEJEL, H., ROMERO-GARCÍA, T., TREJO, M., VELÁZQUEZ, D., AGUIAR, D.A., RIVERA, V., MORQUECHO-SÁNCHEZ, R.

UNIVERSIDAD AUTÓNOMA DE BAJA CALIFORNIA; 1 UNIVERSIDAD AUTÓNOMA DE NUEVO LEÓN

INTRODUCTION: Based on the self-termination theory (SDT)[1] that postulates a sequence of theoretical relationships that goes from contextual environment-psychological mediators-motivation-consequences, in the present study a contextual environment variable is proposed, the perception of pressure for perfection, from the multidimensional theory of perfectionism[2]. This variable is defined as the coaches tendency to impose high goals and put pressure to achieve them, as well as to critically evaluate (PCP)[3]. As psychological mediators, we take up the SDT postulates to incorporate the basic psychological needs (BPN), innate and universal: competence, relatedness and autonomy. Regarding motivation, SDT suggests that behavior can go along a continuum of motivation from autonomous, through controlled to amotivation. As an outcome variable we incorporate the concentration of attention, which is the process that allows the "focusing of all attention on the relevant aspects of a task, ignoring or eliminating everything else"[4]. It is an important aspect during the competition, as well as in the learning phase and in training, since it allows attention to be focused on the relevant stimuli[5].

The objective was to relate psychological variables (PCP, BPN satisfaction's, motivational regulations, and concentration) in young practitioners of team sports in Mexicali City.

METHODS: Under a cross-sectional and correlational design, sixty soccer and field hockey players (32 men and 28 women), with an age between 12 and 23 years, participated voluntarily. They answered a set of questionnaires that measured the study variables.

RESULTS: The practitioners reported moderate PCP ($M=3.35$; $SD=1.50$), high BPN satisfaction's (e.g. $M=5.73$; $SD=1.28$ for competence; $M=5.89$; $SD=1.15$ for relatedness), high autonomous motivation ($M=5.83$; $SD=1.09$) and concentration ($M=4.42$; $SD=0.95$), as well as low amotivation ($M=1.66$; $SD=0.88$). Since the Kolmogorov-Smirnov test showed that the variables deviate from a normal distribution ($p < .05$), the Spearman correlation matrix indicated that PCP was not related to the satisfaction of any BPN ($p > .05$), the satisfaction of each BPN was positively related to autonomous motivation (p between .40 and .64; $p < .05$), and negatively related to amotivation (p between -.53 and -.65; $p < .01$). Finally, concentration was related to autonomous motivation ($\rho=.47$; $p < .01$).

Discussion: In this study sample, the PCP in athletes is not associated with BPN satisfaction's. These, in turn, do increase the practice of these team sports for reasons of enjoyment and pleasure, which aligns with the theoretical assumptions of the SDT. This motivation increases concentration, an important psychological skill in sport performance, which can contribute to the projection of future sporting talents.

BRAIN HEALTH AND FITNESS CLASSES IN OLDER ADULTS: EFFECTS ON FEELINGS OF SUBJECTIVE HOPE

BARDUTZ, H., KHAN, K., SINGH, J., MOIN, J., DIRE, S., SINGHARATH, A., SHAFIQ, M.

UNIVERSITY OF REGINA

INTRODUCTION:

Cognition declines exponentially as individuals age, highlighting the importance of strategies to offset age-related conditions. Studies show that a healthy lifestyle can preserve cognitive function in older individuals. However, the number of individuals engaging in healthy lifestyle interventions like exercise decreases rapidly after the age of 60. Research suggests that more hopeful individuals are more likely to be engaged in healthy habits. This study evaluated whether participation in a brain health and wellness class improved the feeling of hope among older individuals.

METHODS:

Participants aged 60-76 years old took part in an 8-week brain health and fitness class. The class focused on teaching participants about nutrition, socialization, sleep, stress, and exercise as methods for improving brain health. Weekly classes were tailored to include relevant activities to encourage classroom participation. Participants were given the opportunity to participate in research and 4 individuals from the class chose to participate. Prior to the start of class, participants completed the Adult Hope Scale (AHS), which they completed again following the conclusion of the 8-week class. Their results were compared to 5 other individuals aged 53-71 who were on the wait list for the class and as such, were the control group.

RESULTS:

The 4 participants completed the 8-week course intervention and pre- and post-assessments with overall satisfaction about the requirements of the study and the course length. After the course, it was found that, on average, the intervention group experienced an increase in hope scale score from 56.5 to 58.5, whereas the control group showed no increase.

CONCLUSION:

Current literature shows that people with more hope are more likely to follow healthy habits. Individuals who took the Brain Health and Fitness class experienced increased feelings of subjective hope on average. Conversely, the control group who did not participate in the class, did not experience an increase in feelings of subjective hope. These findings suggest a correlation between taking a Brain Health and Fitness class and improving subjective hope for older individuals. Future research will include larger sample sizes, including individuals with Parkinson's Disease and other neurological conditions, as well as the general population.

THE FEMINIZATION OF SEA RESCUE WITHIN THE NATIONAL SOCIETY FOR SEA RESCUE (SNSM, FRANCE):

JOFFROY, S., LEMONNIER, A., GARNIER, S., VERSCHEURE, I.

UNIVERSITÉ DE TOULOUSE

Introduction: Sea rescue is known to be a predominantly male domain due to the inherent missions such as rescuing people in hostile environments, maritime accidents, training, and preparing rescuers under difficult conditions. The low level of gender diversity within the SNSM can be attributed to the physical requirements of the job, which are often associated with masculinity in sports and similar to other traditionally male-dominated professions (military). This relates to the concept of gender stereotypes, linked to masculinity and femininity. Masculinity includes traits such as "aggressiveness, strength, and a drive for success," while femininity includes "passivity, kindness, and dependence" (Renard, 2021). However, despite the marginal presence of women, we analyzed the role of women in the sea rescue sector within the SNSM. We questioned the low proportion of female sea rescuers and explored potential ways to modify this distribution.

Methods: We used the semi-structured interview method (Lincoln, 1995) with 6 experienced rescuers : 3 women and 3 men from the SNSM. The interviews were recorded using a voice recorder. We also coded the data based on themes such as motivation and commitment to the SNSM, gender diversity in rescue teams, levels of operational responsibility, and well-being within the team. This data analyzed to identify gender-related differences.

Results: Our data revealed that all 3 female rescuers reported experiencing sexist and sexual remarks from male colleagues, regardless of their level of responsibility (supervisors or fellow rescuers). These findings also highlighted a negative impact on their self-esteem: "So if I drown, are you capable of rescuing me? Since you're a woman, I have to ask." A lack of respect was identified, which challenges the legitimacy of female sea rescuers, as well as a lack of consideration

from male colleagues. The study on gender diversity showed that all women and men rescuers prefer mixed-gender rescue teams over single-gender teams.

Discussion: These results illustrate that the way men perceive women in this field leads to gender stereotypes. This concept refers to the process by which individuals learn behaviors, attitudes, associated with their gender. Male rescuers have likely been shaped by this process since childhood. In conclusion due to gendered socialization, gender stereotype develop, including in the field of sea rescue. Women in this operational context contribute to establishing a climate of trust with victims, as female rescuers are perceived as warm, affectionate, and emotional—contrary to stereotypes associated with men. Women entering this profession put their bodies at the forefront as a key tool in sea rescue. The physical aspect of the job clearly remains a barrier to the feminization of sea rescue teams. To address this challenge, it would be effective to implement an inclusion awareness module in SNSM training programs to protect female rescuers.

THE RELATIONSHIP BETWEEN MENTAL HEALTH STATUS AND SPORTS INJURY OCCURRENCE AMONG MALE UNIVERSITY ATHLETES

TAJIMA, Y., MOCHIDA, Y., KOYAMA, T., TAKAHASHI, M.
GRADUATE SCHOOL OF NIHON UNIVERSITY

In recent years, as part of the Olympic Agenda 2020+5, the International Olympic Committee (IOC) has highlighted the issue of mental health among athletes by outlining 16 actions to be implemented by 2026 (IOC, 2025). As indicated by the stress-injury model (Andersen & Williams, 1988; Williams & Andersen, 1998), stress and mental health issues can lead to various symptoms such as depression and anxiety, and they have also been reported as risk factors for sports injuries and disorders (Rogers et al., 2023). However, research on this topic remains limited. Therefore, this study aimed to investigate the mental health status of male university athletes and clarify its relationship with injury occurrence.

The participants of this study were 193 male athletes belonging to university sports teams. A questionnaire survey was conducted, collecting information on their profile and the Japanese version of The International Olympic Committee Sport Mental Health Assessment Tool 1 (SMHAT-1). Three months after the initial survey, injury occurrences during this period were assessed. A two-sample t-test was performed to compare SMHAT-1 scores between injured and non-injured athletes. Furthermore, for items that showed significant differences, a binomial logistic regression analysis was conducted, with injury occurrence as the dependent variable. The significance level was set at less than 5%.

Regarding mental health status, 69 athletes (35.8%) tested positive in Form 1 of the Athlete Psychological Strain Questionnaire (APSQ). In Form 2, the number of athletes reporting specific issues was as follows: Anxiety (11 athletes, 5.7%), Depression (14 athletes, 7.3%), Suicidal ideation (7 athletes, 3.6%), Sleep disturbance (73 athletes, 37.8%), Alcohol misuse (49 athletes, 25.4%), Substance misuse (3 athletes, 1.6%), and Disordered eating (71 athletes, 36.8%).

The independent t-test results showed that the injured group had significantly higher APSQ scores than the non-injured group ($p < .05$). Subsequently, a binomial logistic regression analysis was conducted using APSQ as an independent variable. The model chi-square test indicated statistical significance ($p < .01$), and the Hosmer-Lemeshow test showed good goodness of fit ($p = .99$). Additionally, the odds ratio was 1.09 (95% CI: 1.03–1.15, $p < .01$).

The results of this study revealed that an increase in APSQ scores was associated with a higher risk of injury among male university athletes. In other words, these findings support the stress-injury model, which demonstrates the relationship between psychological factors and injury occurrence. Based on these results, it is suggested that maintaining good mental health may contribute to the prevention of sports injuries.

PERSONALITY TRAITS AND SPORTS PERFORMANCE IN UNIVERSITY SOCCER PLAYERS

RÓDENAS, L., MEDINA-VILLANUEVA, S., GONZÁLEZ, V., VANEGAS, M., PONCE-CARBAJAL, N., RIVERA, F.C.
*UNIVERSIDAD AUTÓNOMA DE NUEVO LEÓN, UNIVERSIDAD ANÁHUAC MÉXICO**

INTRODUCTION: The study of personality traits in athletes has gained relevance in sports psychology due to its potential influence on performance. The purpose of this study was to analyze the relationship between the Big Five personality traits and the sports performance of university football players.

METHODS: A cross-sectional, correlational study was conducted with a sample of five male football players from the representative team of the Universidad Autónoma de Nuevo León. The Big Five Inventory (BFI) was used to assess personality traits, while a customized sports performance questionnaire, completed by the team coach, evaluated players performance. Descriptive and inferential statistical analyses were performed, including means, standard deviations, and correlation tests using SPSS.

RESULTS: The findings indicated that agreeableness was the most prevalent personality trait among the players. The goal-keeper position showed a higher association with openness to experience, while midfielders and defenders exhibited higher levels of agreeableness. Additionally, sports performance was positively correlated with conscientiousness, but no significant relationships were found between performance and neuroticism or openness to experience. A negative correlation was observed between extroversion and technical skills.

CONCLUSION: The results suggest that personality traits, particularly agreeableness and conscientiousness, may play a role in the perceived sports performance of football players. Further studies with larger samples and longitudinal designs are recommended to establish causal relationships and explore the influence of personality traits in different playing positions and competitive levels.

EFFECTS OF TAEKWONDO CLUB PARTICIPATION ON COLLEGE STUDENTS POSITIVE AND NEGATIVE EMOTIONS

JI, J., WANG, Q.

SOUTHEAST UNIVERSITY

INTRODUCTION: In recent years, the mental health of college students has received widespread attention, with high rates of negative emotions such as anxiety and depression. Physical exercise is proven to regulate emotions and improve mental health. This study aims to explore the effect of Taekwondo club participation on college students emotions.

METHODS: A total of 20 Taekwondo club members were recruited, including 12 females and 8 males, with an average age of 19.4 ± 0.9 years. All participants were first-time members of the Taekwondo association. Additionally, 20 participants were recruited for the control group, consisting of 10 females and 10 males, with an average age of 19.9 ± 0.8 years. The control group did not participate in any physical activities other than physical education classes. The experimental group participated in Taekwondo club activities over the course of one semester (16 weeks), attending 2-3 sessions per week, each lasting 1.5 hours. The sessions included warm-up, stretching, Taekwondo-specific training, physical conditioning, and relaxation, with moderate to high intensity. Both groups completed the Positive and Negative Affect Schedule (PANAS) before and after the intervention to assess Positive Affect (PA) and Negative Affect (NA). The PANAS consists of 20 adjectives, including 10 for PA and 10 for NA, with each item scored on a 1-5 scale. The PA and NA scores were calculated as the sums of their respective 10 items. The data were organized and summarized in Excel, and statistical analysis was conducted using SPSS 25. A 2 (group: club vs. control) $\times$ 2 (time: 0 and 16 weeks) repeated measures analysis of variance (ANOVA) was used to assess changes in positive and negative affect scores over time. Post-hoc tests were then carried out to further explore significant main effects and interactions.

RESULTS: (1) The Taekwondo group retained 18 participants (2 withdrew due to physical/personal reasons); baseline PA (29.0 ± 6.2 vs 30.7 ± 5.2 , $p=0.377$) and NA (19.6 ± 7.0 vs 20.1 ± 4.9 , $p=0.781$) showed no intergroup differences.

(2) A repeated measures ANOVA revealed a significant main effect of time on PA ($F=6.395$, $p=0.016$). Specifically, the Taekwondo group showed a significant increase in PA scores post-intervention at week 16 compared to week 0 (19.6 ± 7.0 vs 20.1 ± 4.9 , $p=0.017$), indicating a significant improvement in positive emotions following the intervention.

(3) Meanwhile, the time $\times$ group interaction effect on NA was significant ($F=4.788$, $p=0.35$), indicating that the effect of time on NA differed between the two groups. Post-intervention, the Taekwondo group exhibited significantly lower NA scores compared to the control group (17.4 ± 3.8 vs 23.4 ± 5.3 , $p<0.001$), suggesting that the Taekwondo intervention significantly reduced negative emotions.

CONCLUSION: Participation in Taekwondo club significantly improves college students emotional well-being, particularly in controlling negative emotions. These findings support the inclusion of

THE IMPACT OF MONGOLIAN MIND-BODY INTERACTIVE PSYCHOTHERAPY ON DEPRESSION IN ELDERLY PATIENTS

YANG, T., JUN, L., HONGYU, Y., SIXUN, L., ZHONGHUI, H., JINWEI, X.

PEKING UNIVERSITY

INTRODUCTION: Studies have shown that elderly individuals with pre-existing medical conditions are at higher risk of depression, which negatively impacts their quality of life and physical health. Mongolian Mind-Body Interactive Psychotherapy (MMIP) is a psychotherapy that combines modern psychology with traditional Mongolian medicine. By examining EEG and ECG signals from three elderly patients across three intervention stages, this research aims to investigate whether MMIP can improve the mood of elderly patients with depression.

METHODS: Three elderly patients, living with depression and other chronic illnesses, participated in a total of 32 days of MMIP. Data were collected on days 5, 19, and 32 of the treatment. Participant one was a 65-year-old male with psoriasis and cerebral thrombosis; participant two was a 66-year-old female with emphysema, hypertension, and sleep disorders; and participant three was a 67-year-old male with high blood pressure, diabetes, and a history of cerebral hemorrhage. MMIP included listening to Mongolian songs, engaging in Mongolian meridian exercises, and a debriefing session. The music phase featured six calming Mongolian songs aimed at relaxation. The Mongolian meridian exercises, a traditional practice to stimulate energy flow, included slow stretches, controlled breathing, and mindfulness, tailored to participants' physical limitations. The session lasted 30 minutes and consisted of nine parts. The debriefing phase encouraged empathy by having participants listen to the stories of others' recovery or significant improvement in disease symptoms owing to the therapy.

RESULTS: Although the three phases of MMIP did not show significant differences in physiological data or mood changes across all participants, preliminary results suggest that MMIP may help alleviate depressive symptoms in elderly patients. EEG data revealed more stable and coordinated brainwave patterns during the music and exercise phases, indicating improvements in emotional states. During the exercise phase, ECG data demonstrated more regular and stable heart rate variability. In the debriefing phase, no significant physiological changes were observed. Subjective feedback from participants indicated they felt more relaxed, less anxious, and had improved mood and energy levels after the therapy.

CONCLUSION: This study provides preliminary evidence that MMIP can effectively improve mood and alleviate depressive symptoms in elderly patients. These findings offer a promising alternative treatment for elderly depression, but further research is needed to validate the long-term benefits of this combined approach.

THOSE WHO WEIGHT TRAIN AND RUN EXHIBIT LOWER ANXIETY THAN THOSE WHO PARTICIPATE IN GROUP FITNESS OR DO NOT EXERCISE.

MILLER, A., ELLIOT, A., KOTERBA, E., BOGART, S.

UNIVERSITY OF TAMPA

INTRODUCTION: A regular exercise routine can be an effective way to reduce anxiety, yet, exercise rates are lower in those with anxiety. This suggests anxiety may act as a barrier to exercising without regard to specific exercise modality. The purpose of this study was to evaluate whether college students who participate in different exercise modalities exhibit the same lower levels of anxiety and exercise-specific anxiety, than those who do not exercise.

METHODS: The present study included 333 students from a private liberal arts institution (263 females; 66 males; 1 nonbinary/third gender). On average, participants were 19.5 years old ($SD=1.55$; Range=18-34). Participants completed a survey that measured their exercise habits and exercise-based and general anxiety. Exercise anxiety was measured using the Social Exercise and Anxiety Measure, which yields three subscales: Self-Efficacy (SES), one's belief in their ability to complete exercises, Gym Avoidance (GA), hesitancy to attend a gym, and Exercise Importance (EI), personal significance of physical activity. They also completed the Generalized Anxiety Disorder 7 to measure overall anxiety.

RESULTS: Participants were categorized into four groups: "resistance trainers" consisted of those who reported lifting weights at the gym within the past week ($n=178$), "yogis" those who had participated in yoga in the past week ($n=77$), "runners" who reported running in the past week ($n=152$), "interval trainers" who participated in a group fitness class within the past week ($n=111$) and "non-exercisers" those who had not exercised in the past week ($n=121$). Non-exercisers exhibited less confidence in their ability to perform exercise-related tasks ($M=64.15$, $SD=19.20$) than resistance trainers ($M=80.35$, $SD=17.3$; $t(326)=7.53$, $p<.001$) and runners ($M=77.93$, $SD=19.77$; $t(326)=4.043$, $p<.001$) but not yogis ($M=74.24$, $SD=18.24$; $t(326)=.545$, $p=.586$) or interval trainers ($M=76.56$, $SD=17.52$; $t(326)=1.474$, $p=.142$). In addition, non-exercisers considered exercise less important to their day-to-day lives ($M=4.64$, $SD=1.98$) compared to all exercise modalities; runners ($M=5.76$, $SD=1.00$; $t(330)=4.55$, $p<.001$), weight lifters ($M=5.81$, $SD=.99$; $t(330)=6.33$, $p<.001$), yogis ($M=5.86$, $SD=1.02$; $t(330)=3.52$, $p<.001$), and interval trainers ($M=5.84$, $SD=1.27$; $t(330)=4.37$, $p<.001$). Interestingly, the yogis and interval trainers exercised despite having higher anxiety levels.

CONCLUSION: Overall, the results indicate exercise modality matters in regards to anxiety levels. Group exercisers showed the same anxiety levels as those who do not exercise but they valued the importance of exercise more. Group exercise, like yoga and interval training, may serve to mediate the exercise-specific anxiety while fulfilling the desire to exercise. Further studies are needed to understand if exercise-specific anxiety can be improved through coaching by a fitness professional.

THE MECHANISM OF IRRATIONAL BELIEFS ON COMPETITIVE ANXIETY IN HUNGARIAN ATHLETES

TÓTH, R., TURNER, M.J., MANSELL, P., MORAI, C., TÓTH, L.

HUNGARIAN UNIVERSITY OF SPORT SCIENCE

INTRODUCTION: Rational Emotive Behavior Therapy (REBT), particularly its core concept of irrational beliefs, has gained increasing attention in both scientific research and applied sport psychology. The primary objective of this study is to investigate the impact of irrational beliefs—demandingness, awfulizing, frustration intolerance, and depreciation—on competitive anxiety, including cognitive anxiety, somatic anxiety, and self-confidence.

METHODS: A total of 407 Hungarian athletes participated in the study and completed the Hungarian-adapted version of the Irrational Performance Beliefs Inventory (iPBI-HUN) and the Competitive State Anxiety Inventory (CSAI-2HR). To explore the effects of irrational beliefs on competitive anxiety, confirmatory factor analysis (CFA) and structural equation modeling (SEM) were conducted using SPSS AMOS software.

RESULTS: The confirmatory factor analysis supported the original factor structure of the iPBI-HUN, while a two-factor model (anxiety and self-confidence) demonstrated better fit indices for the CSAI-2HR. Therefore, subsequent analyses were based on this model. SEM results indicated that the REBT-I model (direct and indirect effects of irrational beliefs on CSAI subscales) and the REBT-III model (indirect effect of demandingness on competitive anxiety through secondary irrational beliefs, without direct effects of demandingness) provided the strongest predictions for anxiety and self-confidence. In contrast, the REBT-II model (direct relationships between all irrational beliefs and CSAI subscales) failed to show acceptable model fit regarding competitive anxiety.

Discussion: Findings suggest that the primary irrational belief, demandingness, predicts increased anxiety and decreased self-confidence through secondary irrational beliefs (awfulizing, frustration intolerance, and depreciation). These results underscore the importance of identifying and restructuring secondary irrational beliefs in Hungarian athletes to effectively regulate anxiety and self-confidence levels. The study highlights the necessity of integrating REBT principles into sport psychological interventions to enhance athletes mental health and optimize performance under competitive conditions.

Sociology

RESEARCH ON HAND DRAWN MENTAL MAPS OF SPORTS CITY SPATIAL IMAGE

WU, Z., ZHANG, Z.

EAST CHINA NORMAL UNIVERSITY

In the context of the emergence and rapid development of sports cities, current research primarily focuses on two main aspects: the role of sports activities in shaping urban brands, revitalizing the economy, improving peoples livelihood, and the study of evaluation index system models and internal factors influencing the formation of urban field patterns. However, this field faces challenges due to insufficient micro-level analysis, empirical studies of citizens as subjects, and in-depth investigations, particularly regarding the "image" perception of sports participants personal experiences. This study employed literature review and hand-drawn cognitive mapping methods to analyze and summarize the cognitive maps drawn by sports activity participants. The research revealed that sports participants formed sequential and spatial images, as well as some singular sports facility images, which were represented in their cognitive maps. Cognitive factors such as participants gender, environmental familiarity, personal preferences, types of sports activities, and educational background influenced the formation of spatial images in their cognitive maps. Regarding the composition of cognitive map images of urban sports venues, females demonstrated more diverse and rich overall images compared to males. Male spatial images were predominantly composed of districts, while female images were mainly constructed through paths and landmarks. Additionally, female respondents showed greater deviation in their drawn routes compared to geographic map routes than their male counterparts. Cities are fundamentally human-centered, representing the embodiment of human spirit, and sports venues are not merely objective exercise spaces; their true scale derives from the projection of human subjects bodies. Emphasizing human perspective and scale in sports city research is essential for providing better recommendations and strategies for future spatial planning and construction.

Sport Management and law

PREDICTING VOLUNTEER RETENTION: THE 2023 COLOMBIAN NATIONAL SPORTS GAMES

VERGARA-TORRES, A., GÓMEZ HINCAPIÉ, A.J., PAPPOUS, A.

UNIVERSITY OF BOLOGNA; UNIVERSIDAD TECNOLÓGICA DE PEREIRA

INTRODUCTION: Volunteering is often driven by a complex interplay of personal and societal motivations. Traditional factors associated with volunteerism include patriotism, personal growth, and a love for the relevant cause or activity (e.g., sports; Bang et al., 2019). However, emerging sociocultural factors, such as environmental concerns, gender equality, and trust in the organizing body, may also play a significant role in shaping volunteers' intentions to continue their engagement.

This study investigates the motivations influencing volunteers' future intentions in the context of the 2023 Colombian National Sports Games. Specifically, we examine the predictive power of both traditional motivational factors related to sport events and emerging sociocultural factors on volunteers' intentions to continue their service.

METHODS: A total of 191 Colombian volunteers (Mean age = 27.94 years, SD = 10.49), including 130 men, participated in this study. Participants voluntarily completed questionnaires assessing their motivation for volunteering in sporting events. The questionnaire evaluated factors such as expression of values, patriotism, interpersonal contacts, career orientation, personal growth, extrinsic rewards, and love of sports. Additionally, the survey measured participants' perceptions of environmental sustainability, gender equality, and trust in the organizing body.

RESULTS: Multiple regression analyses revealed that trust in the organization ($b = .23, p < .01$), perception of gender equality ($b = .16, p < .05$), and overall motivation ($b = .38, p < .00$) were significant predictors of volunteers' intentions to continue their service ($R^2 = .45$). Notably, the perception of environmental sustainability was not a significant predictor ($b = -.003, p > .05$).

Further analysis focusing on the individual factors within the motivation scale showed that only personal growth ($b = .22, p < .01$), extrinsic rewards ($b = -.15, p < .05$), and love of sports ($b = .19, p < .01$) were significantly associated with the intention to volunteer again ($R^2 = .45$).

Conclusions

Our findings highlight the importance of both traditional and emerging factors in shaping volunteers' intentions to continue their engagement. Trust in the organization and the perception of gender equality within the event emerged as key factors associated with future volunteering intentions. Interestingly, the negative association of extrinsic rewards suggests that these volunteers may be primarily driven by intrinsic motivations such as personal growth and a love for sports, rather than tangible benefits.

References

Bang, H., Bravo, G. A., Mello Figuerôa, K., & Mezzadri, F. M. (2019). The impact of volunteer experience at sport mega-events on intention to continue volunteering: Multigroup path analysis. *Journal of community psychology*, 47(4), 727–742.

EXPLORING THE IMPACT OF BRAND PERSONALITY, ATTITUDE, AND EMOTIONAL VALUE ON UNIVERSITY EVENT: A CASE STUDY OF THE 2024 INTERNATIONAL SOOCHOW ULTRA MARATHON

DONG FANG, J., TENG, P.C., TSAI, S.H., WANG, C.M.

SOOCHOW UNIVERSITY

Introduction:

The current study is to examine the impact of brand personality of Soochow University Ultra Marathon on key related variables in students' behavior. Students' association with the university plays a serious part for the university brand. A strong brand personality fosters identification and loyalty for the university, especially a place for education, interdisciplinary learning. Knowing students' attitude on the event hosted by the university can be a key aspect for students' behavior, surrounding students to cognitive and emotional evaluations, which can directly impact the student's behavior, such as word-of-mouth promotion, and long-term support of the university. Emotional values are characterized by feelings and emotions experienced by students when there is Soochow University Ultra Marathon which takes an affective student experiences derived from the event and has been shown to be a powerful determinant of satisfaction and engagement in university.

METHODS: The study distributed 450 questionnaires among Soochow University in Taiwan, the sample for the purpose of this study after elimination consists of a 351 valid questionnaire. A 5-point Likert scale was used in this study, with 5 being the highest agreeable scale and 1 being the least agreeable. SPSS for windows was used for basic descriptive analysis, and the study used Smart PLS 4 to analyze structural equation modeling with CFA to test for reliability and validity and to test the relationship among the variables.

Results:

The collected survey consists of 177 (48.9) male and 204 (58.1%) female with age $19.08 \leq$ The analysis showed that the measurement model has a good fitness indicator where the SRMR was at .0053 which met the criteria. This study showed that the factor loading range was at 0.713-0.933 and NFI had the value of 0.885 which met the required value of $NFI > 0.9$. Additionally, the Brand personality had the exploratory power of attitude R^2 was .25 giving an exploratory power of 25% and toward emotional value of R^2 was .56 with an exploratory power of 56%

Discussion:

Understanding the relationships between these variables is essential to enhance Soochow University name and build lasting connections with its students and alumni. This study investigates brand personality effects on attitude and emotional value, and how these, in turn, affect overall experience with the event and the university. This research not only contributes to the academic discourse on sports branding but also offers practical implications for improving the emotional and attitudinal dimensions and also understand the importance of hosting an international event for the university, ensuring sustained growth and global recognition for the Soochow University.

LEVERAGING UNIVERSITY SPORTS EVENTS: EXAMINING FUNCTIONAL CONGRUITY, ENGAGEMENT, AND BRAND LOYALTY THROUGH THE INTERNATIONAL SOOCHOW ULTRA MARATHON

WANG, C., TENG, P.Y., LU, Y.F., HSU, M.C.

SOOCHOW UNIVERSITY

INTRODUCTION: Sporting events are not only athletic showcases but also a platform for fostering brand loyalty and the enhancement of institutional reputation, to reflect the alignment between students' expectations and their perception of the university's offerings or values. In the context of the International Soochow Ultra Marathon, this could include the events quality. Students' positive perception of the university makes it a critical factor in institutional branding. Moreover, engagement captures the level of emotional, cognitive, and behavioral involvement of students. Engaged students are more likely to form strong, memorable connections with the university through the event. Brand loyalty examines the commitment of individuals either alumni students, or external audience to the Soochow University brand. Loyal supporters of the university will not only advocate for the university but also sustain its reputation and influence.

METHODS: The study consists of 430 university students, after elimination of invalid response a total of 380 students of Taiwan Soochow university questionnaires were used in the study. This study consists of 161 male and 219 female participants, with an average age of 19.17. The study used 5-point Likert scale from least agreeable with 1 being least to 5 being the most agreed on, which shows that the higher the agreement the higher the level of construct. $\pm .90$. The current research recruited to participate in the study, with the use of structural equation modeling with the confirmatory factor analysis (CFA), and the test for reliability to examine consistency and validity including the test of association between the variables.

RESULTS: The analysis showed that Structural equation modeling was implemented to verify the model fit with SRMR 0.064 which met the required value of < 0.08 . Functional congruity, engagement and brand loyalty. The study model validated that functional congruity was positively related to engagement ($\beta = 0.652^{***}$); and was positively related to brand loyalty ($\beta = 0.338^{***}$) and engagement was also positively related to brand loyalty ($\beta = 0.414^{***}$). Discussion: This study provides data-driven insights from variables of functional congruity, engagement and brand loyalty, showed how Soochow University can leverage through International Soochow Ultra Marathon which align its branding efforts with the experiences of students, alumni and external audience. The findings aim to contribute to both academic research in sports branding and

practical applications for enhancing institutional visibility and loyalty through sport event to bring more support from students and alumni.

EXPLORING THE IMPACT OF COGNITIVE AND SOCIAL VALUES ON ATTITUDE AND BRAND IMAGE: A CASE STUDY OF THE INTERNATIONAL SOOCHOW ULTRA MARATHON

PI-YUN, T., YUN-FENG, L., SHU-HAN, T., DONG FANG, J.D.

ASIA EASTERN UNIVERSITY OF SCIENCE AND TECHNOLOGY

Introduction :

The 24-hour International Soochow Ultra Marathon event has garnered significant attention showcasing athletic excellence and participation of students and alumni. Understanding how students and alumni feel about the university is utmost important for the institution branding. Sporting events often transcend mere competition, hoping to offer rich opportunities to explore the interplay of values, attitudes, and brand perceptions among participants. This study aims to delve into the nuanced relationships between cognitive value, social value, attitude, and brand image within the context of the International Soochow Ultra Marathon.

Method :

A total of 420 questionnaires were distributed among university students, with 32 invalid responses and a total of 388 valid questionnaires were analyzed using SPSS 23.0 for basic descriptive analysis. For the validity and reliability of the questionnaire the study used Smart PLS, a statistical tool to perform the Structural Equation Modeling (SEM). Furthermore, to analyze the fitness of good and the relationship among the variables of cognitive value, social value, attitude and brand image.

Results :

This study a total of 168 males and 220 females participants which found positive relationship of cognitive value on attitude ($\beta=.427^{***}$) and social value ($\beta=.388^{***}$) and attitude on brand image was ($\beta=.591^{***}$) in which attitude variance of latent variable was $R^2 = .614$ which made up 61.4% meanwhile brand image R^2 was .350 which made up 35 % of variance in the latent variable.

Discussion :

The findings of this study showed cognitive value as an intellectual or functional benefit derived from the event, service, or experience, this plays a pivotal role in shaping participants and spectators attitudes toward the event. Furthermore, social values connect to the benefits that is associated with social recognition, such as belonging, and the identity that individuals derive from participating in or the connections with the marathon. Positive attitudes is not only an indicative of satisfaction of the event but also serve as a bridge inducing the perceived brand image of Soochow University. By using SEM, this study seeks to discover the direct and indirect pathways through which these constructs interact, which provides insights for event organizers, marketers, and the university administrators. Ultimately, highlighting the strategic importance of leveraging sports events as platforms for enhancing the university brand image.

ENHANCING UNIVERSITY BRAND EQUITY: HEDONIC AND UTILITARIAN VALUE IN THE SOOCHOW ULTRA MARATHON

PI-CHENG, T., DONG FANG, J.D., TSAI, S.H., WANG, C.M.

ASIA EASTERN UNIVERSITY OF SCIENCE AND TECHNOLOGY

INTRODUCTION: University-hosted sports events are powerful platforms for enhancing university branding and fostering meaningful connections with students and alumni. The International Soochow Ultra Marathon, a prestigious ultra marathon running event, provides an ideal context to explore how hedonic value, utilitarian value, and brand equity interact to shape the university's overall brand perception. Hedonic value represents emotional and experiential enjoyment, derived from attending events, and the counterpart of hedonic the utilitarian value which plays an important part in efficient organization, which benefits practical outcomes which contributes to the audience perception. The collective value of a brand derived from audience perceptions brand equity is the ultimate outcome of hedonic and utilitarian value in ultra marathon

Method:

A total of 362 questionnaires were distributed, with basic descriptive analysis using SPSS 23.0. The study used Smart PLS, a statistical tool to perform the Structural Equation Modeling (SEM) to analyze the relationships among hedonic, utilitarian values and their collective impact on Soochow University's brand equity. Confirmatory factor analysis was tested to ensure the validity and reliability of items.

RESULTS: The model showed good fitness with SRMR 0.042 below 0.08 and NFI 0.878 which is above the required value. Furthermore, we could see that the value for hedonic on brand equity was $\beta= 0.477^{***}$ and Utilitarian on brand equity was $\beta=.227^{**}$. The R^2 for brand equity was 0.463 which indicated 46.3% for variance in latent variables.

Discussion:

The findings of this study reveal a positive relationship between hedonic value and brand equity. The hedonic value aspects of the International Soochow Ultra Marathon, for example the excitement of the race, the vibrant event environment, and fulfillment experienced by participants, contribute to a deeper connection with Soochow University. While Factors for utilitarian value such as efficiency in event inorganization, accessibility of facilities, create a sense of reliability and trust-

worthiness of the university. These positive experiences enhance positive associations, encourage advocacy, and extend loyalty among, ultimately enhancing its brand equity.

MEGA VERSUS NON-MEGA SPORTING EVENTS. THE COMPARISON OF SOCIAL IMPACTS VALUATION BETWEEN DIFFERENTLY SIZED SPORTING EVENTS IN GDANSK, POLAND.

ZAWADZKI, K.

GDANSK UNIVERSITY OF TECHNOLOGY

Introduction.

The study examines the impact of large sporting events on the host communities, with a focus on intangible social effects. In recent years, researchers have explored these impacts not only for mega sporting events (MSEs), but also for smaller, albeit still large, sporting events, so called non-mega sporting events (NMSEs). The primary aim of this research is to provide a monetary valuation of the intangible social benefits generated by sporting events of varying sizes hosted in two arenas in Gdansk, Poland, using the contingent valuation method (CVM). An additional objective is to compare the valuation of these social impacts to the expenditures incurred for the construction of the two sporting arenas in Gdansk.

Material and methods.

The study examined four sporting events, consisting of one MSE (Euro 2012) and three NMSEs (the 2016 European Men's Handball Championship, the 2017 Men's European Volleyball Championship and the 2023 World Men's Handball Championship), which were held in Gdansk over a twelve-year period. To ensure comparability, all the obtained values were adjusted to the year 2023, which was the most recent event analyzed. The interview and sampling methods varied across the events, but the hypothetical scenario and payment vehicle remained consistent. To ensure the representativeness of the test sample, the distribution of basic socio-economic parameters in the population of Gdansk was considered. For each event, the Willingness-to-Pay (WTP) elicitation method involved a single question about the exact value of WTP using a payment card. At the outset of the survey, the social effects of the sporting events were clearly defined and explained. Given the expectation of WTP as a non-negative figure and the potential for a large number of zero offers, the Tobit model was applied, which accommodates left-censorship.

Results. Research has shown that sporting events of all sizes influence the social impacts experienced by residents in host cities. Although the combined effects of non-mega sporting events may have lower individual values, the cumulative impact of these events can comprise a greater proportion of the actual public funds invested in the construction of sporting facilities.

Conclusions. By acknowledging the intangible benefits, it may be feasible, to some extent, to justify the use of public resources in hosting large sporting events. Furthermore, NMSEs have greater potential to positively impact host city residents compared to MSEs.

MAJOR SPORT EVENTS - OLYMPIC GAMES: HOW HOSTING AND SPORTING SUCCESS AFFECT NET MIGRATION

PUHE, N.

EUROPEAN COLLEGE OF SPORT SCIENCE

This thesis investigates the relationship between hosting the Olympics, sporting success, and net migration by addressing two research questions: (1) How does hosting the Olympic Games impact net migration in the respective country? and (2) How does sporting success in the Olympic Games influence net migration in the respective country? To answer these questions, the most important migration theories were reviewed and the most important push-and pull factors of migration were analysed in detail to formulate a theoretical model. With separate data from the Summer and Winter Olympics and difference-in-difference models focusing on hosting this study, migration trends are examined before and after the events. Linear regression models analysing sporting success focus on answering the second research question. The findings reveal nuanced effects: hosting the Winter Olympics significantly increases net migration during the combined pre- and post-event periods, however turns negative for the interaction coefficient analysing the combined effect of hosting and post-event cases. For sporting success, achieving a higher number of gold medal is positively related with higher net migration. However, no similar effect was observed for silver and bronze medals. The findings hold practical implications for policymakers and event organisers, suggesting the use of a framework to anticipate and leverage migration dynamics through hosting the Olympics and achieving sporting success by winning gold medals.

RESEARCH ON THE GUIDING ROLE OF GENERATIVE AI CONTENT RECOMMENDATION ON SPORTS FANS CONSUMPTION BEHAVIOR

JIANG, S., MU, Y., YU, M., SUI, X., NAZARUDIN, M.N., ZHANG, G.

UNIVERSITI KEBANGSAAN MALAYSIA

With generative AI tools, media can provide real-time event interpretation and data analysis with higher efficiency and lower cost. However, problems of false information and bias have gradually emerged. These problems may not only have a negative impact on sports fans cognition, but also undermine users trust in AI content. Although existing research has focused on the technical capabilities and application scenarios of generative AI, empirical research on users ethical risk perception and trust mechanism of AI-generated content is still scarce. In view of this, this study aims to explore sports fans perception of false information and bias in AI-generated content through a questionnaire survey, and analyze its

influence mechanism on trust. The study revolves around two core objectives: one is to evaluate the perceived characteristics of false information and bias in AI-generated content by sports fans, and the other is to analyze how the perception of false information and bias affects the level of trust. This study focuses on the subjective experience of sports fans when they are exposed to AI-generated content and explores the differences in ethical risk perception among different types of sports fans. The study distributed questionnaires to fan groups in China, covering sports fans of different ages, genders and sports focus areas. The questionnaire design includes four modules: false information perception score, bias perception score, trust score and user background information. The questionnaire will be distributed through social media platforms (such as Weibo, Douyin) and sports communities. After collection, the analysis uses a combination of correlation analysis and regression analysis to reveal the preliminary relationship between false information perception, bias perception and trust through correlation analysis, and explore the basic interaction pattern. The study found that sports fans perception of false information and bias in AI-generated content significantly affects their level of trust in the content. Content inaccuracy is considered to be the main factor that undermines trust, while perception of bias shows a stronger negative effect in specific user groups. Further analysis shows that there are significant differences in the perception of bias between the audiences of mainstream sports and niche sports. Users who follow niche sports are more sensitive to the unfairness reflected in the content, and are more inclined to have negative comments on biased content, which further reduces their acceptance of AI-generated content. The study further found that the improvement of trust can be achieved by reducing false information and bias, and transparent content annotation and fairness design are important optimization directions. Study expands the research scope of generative AI in user behavior and psychological mechanisms and provides AI developers and media with content optimization strategies for sports fans.

THE IMPACT OF THE EUROPEAN BICYCLE MARKET ON THE DEVELOPMENT OF CHINAS BICYCLE INDUSTRY IN THE CONTEXT OF ECONOMIC GLOBALIZATION

ZHOU, Z., ZHAO, B.

BEIJING SPORT UNIVERSITY

I. Background/Purpose: Transformation demand of Chinas bicycle industry; Dual drive of policy and market demand in recent years; Demonstration effect of european competitions

This study endeavors to conduct an analysis of the multi-dimensional impact of European cycling events on Chinas bicycle industry.

II. Research Methods: 1. Select representative cases of Chinese enterprises in the European market. Analyze the correlation between these cases and competitive dynamics within Europe. 2. Utilize data from the Chinese bicycle industry report alongside European E-bike market growth data to validate the demand-side impact of relevant events. 3. Analysis Examine policy differences between China and Europe. Evaluate the role of Chinese enterprises through supply chain research.

III. Research Results: European cycling events have facilitated the transformation of Chinas bicycle industry towards higher-end and international markets.

1. Market Expansion and Technology Upgrade: European events have stimulated demand for high-performance bicycles, allowing Chinese E-bikes to rapidly capture market share due to their cost advantages and comprehensive industry chain capabilities. The technical requirements of these events have driven Chinese manufacturers to break through core technologies.

2. Brand Internationalization and Industrial Chain Integration: By sponsoring prestigious European races or teams (such as Giants sponsorship of the Tour de France), Chinese brands have significantly increased their international visibility, gradually shedding the "contract manufacturing" label. The integration capabilities of the industrial chain have been enhanced, and Chinas technological advancements in key components like motors and batteries have reduced E-bike production costs and fostered global competitiveness.

3. Synergistic Effects between Domestic Competitions and Industry: The European model has inspired China to develop local events, tourism, infrastructure development, and consumer demand, thereby forming a closed loop of "events-manufacturing-service".

IV. Conclusion/Discussion: 1. Coexist of Opportunities and Challenges: European competitions provide Chinese enterprises with technology bench-marking windows and market entry points, particularly in the field of E-bike technology where the spillover effect is significant; Core sensor technology remains dependent on imports, and brand premium capability is insufficient; European trade barriers, such as carbon tariffs, could increase export costs. 2. Strategic Direction Recommendations: Strengthen Technology Research and Development; Deepen International Cooperation; Coordinate with Policy. 3. From a sustainable development perspective, European markets highlight the importance of environmental protection. China can leverage this emphasis to promote green manufacturing standards, integrate the bicycle industry into its "dual carbon" strategic framework.

EDUCATIONAL TECHNOLOGY ADOPTION: AN INTEGRATION OF UTAUT2 AND TECHNOLOGY READINESS AMONG SECONDARY SCHOOL STUDENTS

TAEHOON, K., LEE, G., SEO, D., YUN, J., KIM, S.

KOREA INSTITUTE OF INDUSTRIAL TECHNOLOGY

INTRODUCTION: This study examines the factors influencing the adoption of a new educational technology (using a LiDAR sensor) among secondary school students in the United States. The primary aim of this study is to investigate the formation of intention to use of the new educational technology product by empirically testing its key antecedents. Grounded in the Unified Theory of Acceptance and Use of Technology 2 (UTAUT2) and the Technology Readiness Index (TRI) 2.0, the research investigates how constructs such as Performance Expectancy, Hedonic Motivation, Habit, and Technology Readiness predict students' Intention to Use the product.

METHODS: Data were collected from 200 secondary school students using a convenience sampling approach. Structural equation modelling with Partial Least Squares (PLS) was employed to test the proposed model, and the Importance–Performance Map Analysis (IPMA) provided additional insights into areas for improvement. Given that the product is still in its pre-market stage, carefully designed stimuli were employed to simulate a realistic user experience. These stimuli includes video demonstrations, brochures with detailed product information, and comprehensive usage instructions.

RESULTS: Overall, the PLS-SEM results indicate that Performance Expectancy, Hedonic Motivation, Habit, and Technology Readiness significantly predict students' Intention to Use the product, with Facilitating Conditions notably enhancing Technology Readiness. Specifically, the results reveal that Performance Expectancy ($\beta = 0.20$, $p < .05$), Hedonic Motivation ($\beta = 0.18$, $p < .05$), Habit ($\beta = 0.42$, $p < .001$), and Technology Readiness ($\beta = 0.14$, $p < .05$) significantly influence Intention to Use. Furthermore, Facilitating Conditions significantly predict Technology Readiness ($\beta = 0.34$, $p < .001$). These findings suggest that while performance and enjoyment drive adoption, habitual use and technological predispositions also play crucial roles.

Discussion

The study concludes by discussing practical implications, including the potential benefits of gamification and targeted marketing strategies for technology-ready segments. The IPMA results offer additional insights beyond the standard structural analysis by comparing each construct's relative importance with its performance. Based on the results, we provided practical implications. For instance, both Performance Expectancy and Hedonic Motivation exhibit high importance yet only moderate performance, placing them in the "Keep Up the Good Work" category. This suggests that while users recognise the benefits of JUST ON STUDY in enhancing their study performance and enjoy its features, there remains potential to further refine these aspects. For instance, developers might enhance features that directly improve study outcomes or integrate additional gamification elements (e.g., point systems, progress badges, and leaderboards) to boost engagement and motivation.

A STUDY ON LEGAL OVERSIGHT FOR SPORT COACHES WORKING WITH CHILDREN AND YOUTH

WANG, K.

NATIONAL TAIWAN SPORT UNIVERSITY

In Taiwan, anyone with a coaching certificate issued by a sports association can teach children and youth sports. However, these coaching certificates usually only assess the coaches sports skills and do not evaluate their educational ability to handle special or emergency situations. This has led to a lot of cases of excessive training or sexual crimes happening. Legislators have called for administrative agencies to more systematically oversee sports coaches to protect the rights of children participating in sports. Therefore, this study aims to address the following questions: 1. What items should be included in the vetting process for coaches of children? 2. What level of government oversight should be implemented?

This study adopts a comparative legal research approach, examining Australia's Worker Screening Act 2020, the UK's Safeguarding Vulnerable Groups Act 2006, the Protection of Freedoms Act 2012, and the Police Act 1997, as well as Germany's Federal Child Protection Act and the Act on Cooperation and Information in Child Protection. It also looks into Australia's Child Safe Code of Conduct, and UK's Code of Practice for Sports Coaches, attempting to summarize the aforementioned research questions and offer recommendations.

It shows that, compared to the UK and Australia, which tend to focus on verifying information about workers dealing with children, Germany places greater emphasis on quality development for child protection. However, Australia's Working with Children Check system requires workers to complete child safety training before obtaining a work permit. Additionally, most countries use measures like safe codes to remind people of the necessary ethical behavior.

This study points out that the screening of coaches can be divided into two aspects. One is to prevent coaches with high-risk records from interacting with children and teenagers, such as those with records of sexual abuse or violent crimes, which may limit their ability to coach youth sports. The second aspect requires coaches to have the professional knowledge, such as being able to identify children with autism or ADHD and handling them appropriately. It's also important to understand relevant laws and to train in compliance with regulated teaching methods. The requirements for the above abilities or qualifications can be enforced with varying levels of strictness through licenses, certificates, or simple proof. In Taiwan, administrative units are moving toward legislation for licenses, and they hope to set comprehensive requirements for coaches' abilities from physiological, psychological, and legal perspectives. This approach aims to protect the rights and interests of young athletes.

Sport Technology

CONSTRUCTION AND VALIDATION OF A TRAINING SUPPORT SYSTEM USING REAL-TIME FEEDBACK OF SENSOR MEASUREMENT INFORMATION IN ROWING.

ICHIYA, F., TADASHI, H., HOTARU, S., YUKI, O., IOANNIS, G.C.

NATIONAL INSTITUTE OF TECHNOLOGY, MATSUE COLLEGE

INTRODUCTION: In this study, we constructed a system that comprehensively captures the movement of a boat by combining a high-precision GNSS (Global Satellite Navigation System) positioning system with a 9-axis IMU (Inertial Measurement Unit) sensor. This system simultaneously measures acceleration and angular velocity for each stroke, in addition to the boat's position and velocity. The system was then used to measure and collect rowing data, and a comparative analysis between athletes was conducted to evaluate its effectiveness.

METHODS: The system consists of a GNSS receiver mounted on the boat, a small Arduino-compatible board computer (Sony Spresense), and a GNSS Add-on board. By integrating these components, high-precision positioning was achieved. An LTE extension board was also installed to enable data transmission via LTE-M communication. Additionally, the boat was equipped with an IMU sensor, allowing real-time measurement of the boat's position, velocity, acceleration, and angular velocity (longitudinal and lateral oscillations) during rowing. For data visualization, Soracom's cloud service Harvest Data was used. The measured data (sampling frequency: 10 Hz) was transmitted via LTE-M communication every 5 seconds.

The experiment was conducted on athletes who regularly train in single sculls. The subjects were instructed to row at maximum speed with 20 strokes fixed in a stroke rate 24. The subjects were categorized as novice rowers, with less than one year of rowing experience, and advanced rowers, with more than three years of experience.

RESULTS: In this study, the maximum velocity recorded for novice rowers was 4.02 m/s, while that for advanced rowers was 4.63 m/s, indicating that advanced rowers achieved higher velocities. The maximum acceleration for novice rowers in the direction of travel was 4.26 deg/s, while in the backward direction, it was 6.45 deg/s, showing a tendency for greater acceleration in the backward direction. In contrast, the maximum acceleration for advanced rowers in the direction of travel was 5.48 deg/s, and in the backward direction, it was 6.04 deg/s, indicating a smaller difference in acceleration between the forward and backward directions. Furthermore, a comparison of accelerations in the lateral direction of the boat (rolling) showed that the maximum values for novice and advanced rowers were 35.7 deg/s and 31.5 deg/s, respectively, confirming that the rolling amplitude was greater for novice rowers. Regarding the boat's longitudinal (pitching) acceleration, the maximum value for novice rowers was 8.60 deg/s, while for advanced rowers, it was 16.9 deg/s, indicating that pitching acceleration was greater for advanced rowers.

CONCLUSION: These results show that the use of this system has made it possible to understand rowing characteristics. In the future, in order to improve the technical level of beginners, the development of a system that enables them to compare their own movements with those of advanced rowers will be promoted.

ANALYSIS OF PLANTAR LOAD DISTRIBUTION OF SPRINT SPIKES EQUIPPED WITH CARBON PLATES FOR TRACK AND FIELD

ARIYOSHI, K.

OSAKA UNIVERSITY OF HEALTH AND SPORT SCIENCES

INTRODUCTION: In recent years, trends in track and field sprint spikes have changed dramatically with advances in technology. Traditional spikes are made of synthetic resin with a thin sole and are designed to provide a good sense of contact with the ground. On the other hand, many of the spikes that are becoming mainstream today have built-in carbon fiber plates and thick soles. Therefore, the purpose of this study was to compare the difference in how the plantar forces are received during sprinting between conventional thin spikes made of synthetic resin (SRS) and thick-soled spikes equipped with carbon plates (CPS).

METHODS: The subjects were 10 male sprint athletes belonging to a university track and field team (age 20.6±1.0 years, height 169.6±4.5 cm, weight 63.6±4.1 kg). The measurement was performed in a 50m sprint in an all-weather athletics stadium. After warming up, the subjects ran 50m once each in spikes SRS and CPS. The analysis items were sprint time for the 30m section from 20m to 50m, and the plantar load force for three steps within a randomly selected section. The plantar loading force was measured using Pedar-X in-shoe pressure measurement system (Novel, USA), and defined in areas: toes (area 1), forefoot most front (area 2), forefoot next front (area 3), forefoot middle (area 4), forefoot rear (area 5), midfoot front (area 6), midfoot (area 7) and rearfoot (area 8), in order from the toe to the heel.

Statistics were compared between SRS and CPS for sprint time, plantar load/body weight during the period of contact with the ground at 60N or more, and plantar load distribution at highest point, and a paired t-test was used ($p < 0.05$).

RESULTS: The sprint time of CPS (3.25±0.1 sec) was significantly faster than that of SRS (3.35±0.1 sec) ($p = 0.004$). The plantar load pressure/body weight of CPS was significantly lower in area 3 (SRS 3.76±0.70 N/kg, CPS 2.54±0.88 N/kg) ($p = 0.002$), and significantly higher in area 5 (SRS 2.49±0.89 N/kg, CPS 3.23±0.87 N/kg) ($p = 0.003$), area 6 (SRS 1.09±0.46 N/kg, CPS 2.33±0.89 N/kg) ($p = 0.001$), area 7 (SRS 1.28±0.51 N/kg, CPS 2.12±1.02 N/kg) ($p = 0.009$), and total value of all areas (SRS 19.32±2.16 N/kg, CPS 20.82±2.67 N/kg) ($p = 0.014$). A similar trend was seen for total workload. Plantar load distribution at highest point of CPS was significantly lower in area 3 (SRS 4.79±1.18 N/kg, CPS 3.30±1.42 N/kg) ($p = 0.001$) and area 4 (SRS 5.27±1.03 N/kg, CPS 4.51±1.18 N/kg) ($p = 0.037$), and significantly higher in area 6 (SRS 2.61±0.67 N/kg, CPS 3.69±0.96 N/kg).

($p=0.001$). The contact area receiving the force was significantly larger for CPS (SRS $106.30 \pm 11.08 \text{ cm}^2$, CPS $112.32 \pm 9.58 \text{ cm}^2$) ($p=0.024$).

CONCLUSION: The plantar load force distribution of CPS was slightly further back than in SRS, the contact area was wider, and the force was greater. These differences were thought to be due to differences in the hardness and resilience of the materials.

EFFECTS OF COMPRESSION STOCKINGS ON RECOVERY FROM EXERCISE-INDUCED MUSCLE SORENESS, STRENGTH, AND RANGE OF MOTION

HOSEONG, L., AHARAM, K.1, MYEONGHO, C.2, JAEGWANG, L.1, CHEOLHO, K.1, JISUK, C.3

1. KINESIOLOGIC MEDICAL SCIENCE, GRADUATE, 3. COLLEGE OF SPORTS SCIENCE.

INTRODUCTION: Exercise-Induced Muscle Damage (EIMD) is a well-documented physiological response to eccentric contraction exercises, which has been shown to result in a reduction in muscle force production, an increase in muscle soreness, and elevated inflammatory responses [1]. The use of compression stockings (CS) as a recovery aid has been proposed, with the hypothesis that they enhance blood circulation, thereby reducing muscle fatigue and soreness. However, the effectiveness of CS in reducing muscle damage markers and enhancing functional recovery remains to be fully clarified. The present study aims to examine the effects of wearing compression stockings on muscle soreness, limb circumference, range of motion (ROM), and manual muscle strength (MMT) in healthy males.

METHODS: Fifteen healthy male participants were divided into two groups: the compression stockings group (CSG, $n=7$) and the control group (CON, $n=8$). Assessments included body composition analysis, muscle soreness using the Visual Analogue Scale (VAS), calf circumference (CIR), ROM, and MMT. Participants performed a 30-minute bench step exercise to induce EIMD, and measurements were taken pre-exercise, immediately post-exercise, and at 12, 24-, 48-, 72-, and 96-hours post-exercise.

RESULTS: Repeated measures ANOVA revealed significant main effects for group and time ($p < .05$) on VAS scores, indicating that the CSG group experienced a significantly greater reduction in post-exercise muscle soreness than the CON group. Post-hoc analysis showed that VAS scores were significantly lower in the CSG group at 12-, 24-, and 48-hours post-exercise ($p < .05$, respectively). MMT and ROM also demonstrated significantly faster recovery trends in the CSG group, particularly after 48 hours ($p < .05$, respectively). However, no significant differences were found in calf and thigh circumference changes between groups ($p > .05$).

CONCLUSION: These findings indicate that wearing compression stockings effectively reduces post-exercise muscle soreness and accelerates muscle strength recovery. The results suggest that compression stockings may enhance blood circulation and facilitate metabolic waste removal, leading to faster functional recovery. However, their effect on reducing swelling was not significant. Given the growing interest in recovery interventions among athletes, these findings align with previous research demonstrating that external compression garments can aid in muscle recovery and performance enhancement [2]. Future research should explore the long-term impact of compression stockings on various exercise modalities and athletic populations.

TECHNOLOGICAL ADVANCEMENTS IN FOOTWEAR AND THEIR IMPACT/INFLUENCE ON ELITE RUNNING PERFORMANCE: INNOVATION OR TRAINING?

GRIVAS, G., TSARTAPAKIS, I., ZAFEIROUDI, A.

PHYSICAL EDUCATION AND SPORTS, DIVISION OF HUMANITIES AND POLITICAL SCIENCES

INTRODUCTION: The past decade has seen a surge in record-breaking performances in elite distance running, often attributed to advances in footwear technology (Ortega et al., 2021). High-performance shoes with carbon-fiber plates and responsive foams have raised debates about whether these performances stem from improved training or technological innovation. Addressing this issue is essential for maintaining fairness in the sport.

METHODS: This study examined trends in elite running over the past ten years, correlating technological milestones with athlete performance. Data from performance, biomechanical, physiological, and psychological research were synthesized. Athlete-specific trials and comparative studies assessed key factors such as energy return, running economy, stride efficiency, and ground reaction forces.

RESULTS: Technological innovations have been shown to significantly enhance performance by improving running economy through reduced oxygen consumption and delayed muscle fatigue (Muniz-Pardos et al., 2021; Barnes & Kilding, 2019). Carbon-fiber plate-equipped shoes demonstrated superior energy return and stride optimization, with reduced muscular impact on the lower limbs (Hoogkamer et al., 2018; Wang et al., 2012). Psychological assessments also indicated a placebo effect, where athletes perceived performance gains due to the footwear's reputation (Dierickx et al., 2003).

CONCLUSION: Although rigorous training remains a cornerstone of athletic success, advanced footwear technology plays a significant role in modern performance gains. This has prompted regulations from governing bodies such as World Athletics, but existing measures may be inadequate in addressing inequalities. Athletes from economically disadvantaged regions face challenges in accessing these technologies (Muniz-Pardos et al., 2021). To safeguard fairness, stricter policies are needed, potentially limiting stack height or energy return thresholds to maintain equal opportunities for all athletes while preserving the sport's integrity.

CHARACTERISTICS OF GPS DATA BY OFFICIAL MATCH RESULTS AND PLAYER POSITIONS IN WOMEN'S FOOTBALL

LEE, J., MOON, J., KIM, N.

DAEGU NATIONAL UNIVERSITY OF EDUCATION

INTRODUCTION: The aim of this study was to advanced the development of womens football in Korea by providing foundational information on the GPS data of female football players in the 2024 WK-League season. The study analyzes the correlation between GPS characteristics and match results (win, draw, loss) as well as the influence player positions (attack, midfield, defense).

METHODS: This study examined twenty-two female players from Team S who participated in the 2024 WK-League season. Movement data was collected using GPS devices (Catapult Optimeye S5, Catapult sports, Melbourne, Australia) during all official league matches, and this data was analyzed to examined characteristics based on match outcomes and player positions. Data collection covered 28 regular-season games. A One-way ANOVA was conducted to analyze GPS characteristics according to player positions and match outcomes, with post-hoc analysis performed using the Bonferroni's method.

RESULTS: Firstly, the total distance covered and average distance per minute were significantly greater for forwards and midfielders compared to defenders. Secondly, in terms of positional analysis, Zone 1 were significantly greater for both forwards and defenders than for midfielders, whereas Zone 2 and Zone 3 were the highest for midfielders. For Zone 4, Zone 5, high-intensity distance, number of sprints, and maximum speed, forwards exhibited the highest values. Thirdly, acceleration and deceleration were significantly the highest for midfielders based on their positions. Lastly, regarding match results, metrics for Zone 5, high-intensity distance, maximum speed, and acceleration were significantly higher in matches that resulted in a victory.

CONCLUSION: The results of this study demonstrated differences in GPS characteristics based on player positions and match results. Specifically, when the team won, Zone 5, high-intensity running distance, maximum speed, and acceleration records were higher compared to when the team drew or lost. Based on these findings, it is believed that developing training plans, tactics, and strategies while managing and monitoring fitness, may help enhance the performance of women's football players.

INTEGRATING ARTIFICIAL INTELLIGENCE AND BLOCKCHAIN IN SPORTS: CHALLENGES AND OPPORTUNITIES IN DATA MANAGEMENT, SECURITY, AND REGULATORY COMPLIANCE

CALDERONE, D.

UNIVERSITY OF BOLOGNA

INTRODUCTION: AI is playing an increasingly significant role in sports, extending beyond team performance analysis and game strategy development. The application of advanced machine learning and deep learning techniques enables the optimization of athletic preparation, injury recovery, and injury risk prediction through pattern analysis. Additionally, its implementation may also impact fan engagement. However, both the adoption of AI and blockchain pose regulatory and data protection challenges, particularly in contexts governed by strict standards such as the AI Act and GDPR in Europe and HIPAA in the United States. In this scenario, blockchain emerges as a potential solution to ensure transparency, security, and traceability in data management, reducing the risk of unauthorized access and data manipulation.

METHODS: This study is based on a systematic analysis of the academic literature on AI, its application in sports, the related regulations, and its integration with blockchain, with a specific focus on personal data management. In parallel, the main applicable regulations, including the AI Act, GDPR, and HIPAA, were analyzed to assess the regulatory implications of data management.

RESULTS: Preliminary analysis confirms that AI can provide significant advantages in sports management. However, critical issues related to data quality, information security, and regulatory compliance have emerged. Poor data sampling and/or negligent data handling could compromise the reliability of predictive models, potentially affecting athletes health and careers. The analysis suggests that blockchain could serve as an effective solution to ensure transparency, security, and traceability in data processing. Its decentralized architecture could mitigate the risk of unauthorized access and simplify anonymization, but its application within a complex regulatory framework raises further compatibility issues with existing regulations.

CONCLUSION: The integration of AI and blockchain in sports represents an opportunity to enhance data management and security, yet it requires a careful balance between technological innovation and regulatory compliance. Data are strategic assets, as AI models improve through continuous training. GDPR and HIPAA impose limitations on data decentralization and immutable storage, making it necessary to adopt blockchain protocols with adaptable governance mechanisms. The implementation of such solutions must consider the evolution of the regulatory framework and the adoption of technological frameworks capable of balancing efficiency, privacy, and compliance. Future research should focus on identifying purpose-specific blockchain protocols that comply with these requirements. The Sports Industry could once again act as a testing ground for emerging technological innovations.

IS IT TIME TO RE-EVALUATE POSTURAL ASSESSMENT TOOLS? TEST-RETEST AND INTER-RATER RELIABILITY OF WEARABLE 3D INERTIAL SENSOR VS. FORCE PLATFORM OVER DIFFERENT POSTURAL CONDITIONS

GARAU, F., DEMANUELE, S., NARDELLO, F., CAMPACI, D., SCHENA, F., CANTOR, T.

UNIVERSITY OF VERONA

INTRODUCTION: In posturography, wearable inertial measurement units (IMUs) are commonly used due to their cost and portability advantages. However, their validity, if compared with the gold standard (force platform, P), has rarely been investigated. In detail, among several studies performed on IMUs for the evaluation of static balance, 10/47 validated the result against a P, and only 4/47 performed a retest test (1).

This study aimed to evaluate the inter-rater reliability in assessing the absolute agreement between the GYKO (G) IMUs and P within different foot positions and stable/unstable conditions through the time-domain outputs. The secondary aim was to quantify the test-retest reliability to state the consistency between repeated trials (2).

METHODS: Thirty-eight healthy subjects (19M and 19F; 25 ± 3 years; 1.71 ± 0.09 m; 65.7 ± 10.2 kg) visited the laboratory twice, one week apart. Participants were asked to perform postural stability tests (open eyes) in three foot positions (bipedal, tandem, single standing) over two different surfaces (stable on the floor; unstable on the BOSU).

All the tests were carried out on a force plate (AMTI; Watertown, MA; 500 Hz) wearing G sensor (Microgate, Bolzano, Italy; 500 Hz) positioned at the lumbar level.

The variables analysed were: medio-lateral (ML) length, antero-posterior (AP) length, length, ML mean velocity, AP mean velocity, mean velocity, ML mean distance, AP mean distance, mean distance, ML RMS distance, AP RMS distance, RMS distance, area (3).

The reliability was assessed through the intraclass correlation coefficient (ICC) that was used to evaluate: i) the consistency of the same device between sessions; ii) the absolute agreement among devices within the same trials. The standard error of measurement (SEM, SEM%) and the minimal detectable change (MDC, MDC95%) were calculated for G and P as well as RMSE and Mean Difference.

RESULTS: For P, 42/78 parameters result moderate, 30/78 good, with an ICC mean equal to 0.683 (i.e. it can be considered as moderate reliability). For G, 49/78 conditions result moderate, 24/78 good, with an ICC mean equal to 0.687, indicating moderate reliability. SEM% for P ranged from 7 to 41%; for G, ranged from 11 to 47%. MDC95% for P ranged from 21% to 114%; for G, from 30% to 132%. The inter-rater reliability assessment showed poor reliability for 57/78 parameters, and moderate for 18/78. Only 3/78 reached good reliability, with a mean equal to 0.338, which states poor reliability.

RMSE showed a grand mean equal to 342.5, and the Mean Difference showed a grand mean equal to 100.2.

CONCLUSION: G appears to be a convenient tool because of its good reliability across multiple measurements. However, its results are quite different from those of a force plate. This finding recommends that it can be used with safe awareness especially in pathological populations.

EXPLAINABLE AI-BASED APPROACH FOR THE EVALUATION OF THROWING MOTION SKILLS

YOSHIDA, Y., AIHARA, S.

TOHOKU GAKUIN UNIVERSITY

INTRODUCTION: The evaluation of throwing motion is conducted even in elementary education; however, such evaluations require specialized knowledge and experience. Utilizing AI-based approach can provide a simplified and objective assessment method applicable in educational settings. This study aimed to develop a technique for evaluating throwing skills using machine learning.

METHODS: Participants included 24 male university students who were members of a baseball team and were assumed to possess high throwing skills (Baseball Group) and 29 male and female university students without any baseball experience, assumed to have low throwing skills (General Group). The participants were tasked with throwing a softball 10 times at a target located 7 meters away. All participants were right-handed, and the throws were executed with the right hand. They were instructed to throw naturally towards the target, with no restrictions on speed or force. The throwing motions were recorded from the sagittal plane using a video camera. For machine learning, the training data comprised 16 participants from the Baseball Group and 20 from the General Group, while the test data included 8 from the Baseball Group and 9 from the General Group. The ResNet-152 model was employed for machine learning. After training the model with the training data, it was tested to classify the groups using the test data. Additionally, Grad-CAM was utilized to visualize the areas of the images that contributed to the model's decision-making during the image recognition task.

RESULTS: The results showed that the developed model achieved a discrimination rate of 1.00 for the Baseball Group and 0.95 for the General Group. The model's performance, based on the confusion matrix, was as follows: Accuracy: 0.95, Precision: 0.99, Recall: 0.91, and F1 score: 0.95, indicating generally favorable outcomes. The heatmaps generated by Grad-CAM suggested that the model visually focused on the trunk region for the Baseball Group. Furthermore, the eval-

uation points identified by Grad-CAM indicated that the model focused on the right knee, trunk, left hip, and right shoulder when distinguishing the Baseball Group.

CONCLUSION: Some previous studies have pointed out that the presence of a windup motion during the preparatory phase is associated with the development of throwing skills. In this study, the step foot contact phase, classified as a preparatory phase, was analyzed, revealing the presence of windup motion in the Baseball Group. The heatmaps of Grad-CAM demonstrated that the model concentrated on the trunk and shoulder joint areas. These findings suggest that the learning model accurately recognized the critical features for distinguishing throwing skills, highlighting essential aspects for skill evaluation in throwing motions.

EVALUATING SWIMMING TRAINING APPLICATIONS: SENTIMENT ANALYSIS AND USER FEEDBACK ON KEY FEATURES AND ISSUES

CHOW, H., CHEN, J., HUNG, C., HUANG, T.
NATIONAL CHENG KUNG UNIVERSITY

INTRODUCTION: Swimming is a widely practiced sport and exercise activity that has experienced increasing popularity in recent years. With advancements in technology, numerous swimming training applications have been developed to support both professional swimmers and recreational enthusiasts in skill development and performance monitoring. These applications offer various features, including personalized training programs, performance tracking, and integration with wearable devices, to enhance the overall swimming experience. This study aims to analyze user reviews of several prominent swimming training applications to gain insights into user satisfaction, preferences, and areas for improvement. By examining feedback from actual users, this research seeks to identify key features that users find valuable and to pinpoint common issues they encounter.

METHODS: User review data were collected using two primary Python libraries: `app_store_scraper` and `google_play_scraper`. These tools facilitated the retrieval of user reviews, ratings, and other relevant information from the Apple App Store and Google Play Store for five widely used swimming training applications: Duoswim, Swim.com, SwimUp, Form Swim, and MySwimPro. Standard data preprocessing techniques were applied to clean and refine the dataset. A combination of analytical methods, including keyword analysis, sentiment and subjectivity analysis, similarity analysis, and qualitative analysis using MAXQDA, was employed to extract meaningful insights from user feedback.

RESULTS: The analysis indicated that users particularly value personalized and customizable training plans, real-time feedback, and the integration of wearable devices for precise tracking of swimming metrics. However, common concerns included dissatisfaction with subscription models and technical stability issues. While applications such as Duoswim and Form Swim received predominantly positive feedback, MySwimPro exhibited significant divergence in user opinions.

CONCLUSION: Understanding user feedback is essential for the continuous improvement of swimming training applications. This study highlights both the strengths and limitations of different applications, providing developers with guidance on enhancing functionality and user experience. By addressing common user concerns and incorporating features deemed valuable by users, developers can create more effective and user-centric swimming training applications.

EXPERIMENTAL VERIFICATION OF BOLT TYPE FORCE SENSOR IN SPEED CLIMBING

HAYASHIDA, T., KAWAMURA, A., AIHARA, S., KURAZUME, R.
KYUSHU UNIVERSITY

INTRODUCTION: Speed climbing is one of the disciplines of sport climbing. In this sport, athletes climb the artificially constructed wall and compete in terms of speed. Athletes climb the wall by gripping and stepping on climbing holds attached to the wall. In motion analysis of sport climbing, several studies have focused on the forces applied to climbing holds. However, most of these methods require dedicated walls and holds, making it difficult to apply them to existing facilities.

Two types of holds, hand holds and foot holds, are used in speed climbing, and their shape and position are determined. In this study, we develop a system to measure the force applied to the holds in speed climbing. In particular, it is more challenging to develop a system that can be installed on the walls of existing facilities since foot holds are smaller than hand holds and it is difficult to build in a force sensor.

METHODS: To measure the forces applied to the foot holds, strain gages are mounted on a bolt to fix the hold and measure the force. This sensorized bolt is called a bolt-type force sensor. This sensor can measure 3-axis forces applied to the hold. The sensor consists of a steel bolt and four strain gauges, and the strain gauges are mounted on the shaft of the sensor. The wiring of strain gauges is designed to pass through the shaft and exit from the threaded side of the bolt. So, when the sensor is installed on climbing walls, the wiring comes out from behind the wall. This wiring method does not distract the competitor or interfere with the competitors movements.

The transformation from strain to force uses a conversion equation obtained by prior calibration. The calibration device consists of a bolt type force sensor and a 6-axis force sensor. The 6-axis force sensor gives true values. In calibration, the transformation is calculated by using particle filter. Particle filter is used to sample from a normal distribution around the measured strain values. Particle filter is effective in minimizing the effect of noise on the measured strain values.

RESULTS: Force measurement experiments were conducted in a real environment to verify the usefulness of the system. Two bolt type force sensors are attached to the wall to measure forces applied to two foot holds. The subject is one of the Japanese national team players. The proposed system measured the forces applied to the foot holds appropriately.

CONCLUSION: In this study, the bolt type force sensor was proposed to measure the forces applied to the foot holds in speed climbing. In the experiment, the usefulness of the proposed system is verified. The improvement of the accuracy is a future work.

EXPLORING PHYSICAL ACTIVITY LEVEL OF INDIVIDUALS WITH COPD: A COMPARISON OF WEARABLE DEVICE USER AND NONUSER

LEUNG, W., HUBBARD, M., TIRALLA, G., FARRELL, C., RYAN, M., BRIDGET, K., LEE, J.

THE UNIVERSITY OF TAMPA

INTRODUCTION: Wearable devices have been used to promote physical activity (PA) among the general public [1]. Previous studies have examined the PA levels of people with a noncommunicable disease using wearable devices [2], but limited literature has examined individuals with chronic obstructive pulmonary disease (COPD). Participating in PA could be beneficial to people with COPD [3]. This study aimed to compare PA levels between wearable device users with COPD and non-wearable device users with COPD.

METHODS: Using the free-living data from the 2017 Behavioral Risk Factors Surveillance System, 259 individuals with COPD were included in this cross-sectional secondary data analysis. Respondents self-reported their weekly PA levels in minutes. Participants were classified as utilizing wearable devices and not using wearable devices. A T test was used to compare PA level between wearable device users and nonuser. Unadjusted and adjusted linear regression was used to examine the association between PA level and wearable device usage. The adjusted model was built upon on the unadjusted model with PA level regressing into wearable device usage with the addition of demographic factor serving as a covariant. Sampling weights were accounted for during the analysis due to the data being complex survey data.

RESULTS: Among the participants, 15.29% (95% CI [9.00, 23.43]) used wearable devices and 84.71% (95% CI [76.57, 91.00]) were nonusers. The average weekly PA level among the participants was 469.66 (95% CI [331.20, 608.12]) minutes. There was no statistical difference between weekly PA levels between users (505.68, 95% CI [302.20, 703.16]) and nonusers (463.16, 95% CI [304.71, 621.61])($t=0.33$, $p=.74$). Both the adjusted and unadjusted linear regression found no statistically significant association between weekly PA level and wearable device ($\beta=42.52$, $p=.74$; adjusted $\beta=-26.46$, $p=.80$).

CONCLUSION: The current study shows that wearable device users with COPD might not necessarily show higher levels of PA when compared to nonusers with COPD. Further research is needed to examine appropriate approaches in using wearable devices to promote PA levels in people with COPD. Promotion of PA remains crucial to individuals with COPD, as PA can lead to improvement of wellbeing and symptom management.

SELF-REPORT MENSTRUATION AND SLEEP DURING AN NCAA DIVISION I WOMEN'S SOCCER SEASON

COPPUS, T., LANIER, K., DELINSKY, L.

TROY UNIVERSITY

INTRODUCTION: There is an underwhelming amount of research dedicated to how the female body responds to the stresses of sports competition. More specifically, examining how the menstrual cycle impacts sleep. Two studies reported that the menstrual cycle was associated with sleep disturbances and poorer quality sleep (Kullik, et al., 2024; Michelekaki, et al. 2023). While both studies included athletes, more research should examine the impact of menstruation and sleep. Therefore, this study aimed to add to the existing research by surveying an NCAA Division I women's soccer team over their season.

METHODS: One NCAA Division I women's soccer team ($n = 24$) completed daily subjective wellness surveys throughout the Fall 2023 NCAA Championship Season. We examined two items from the survey: Are you on your menstrual cycle? How many hours of sleep did you get last night? We used Wilcoxon Signed Rank Test to compare sleep hours from days a participant recorded being on their menstrual cycle versus not.

RESULTS: The participants reported 1646 days when not menstruating and 288 days when they were throughout the season. There was a significant statistical difference between self-reported sleep hours when participants indicated menstruation versus not ($Z = -2.87$; $p > .01$).

CONCLUSION: The results of our project found that throughout the season, participants who indicated they were menstruating had less sleep noted than when participants indicated they were not. A qualitative study by Read et al. (2022) held interviews with professional women's soccer players and noted 100% of the participants had negative symptoms during menstruation, which could be a reason for the decreased sleep hours we found in our study.

Coaches and support staff of women's teams should be aware that menstruation can influence sport participation via poor sleep. Planning for these situations with their participants can optimize their training stimulus without over-taxing their body and allowing for continued high-level performance.

THE RECOVERY-ENHANCING EFFECT OF ICING WITH MICROBUBBLE CARBOHYDRATE WATER ON THE DISTAL LATENCY OF THE ULNAR NERVE

HIRASAWA, H., NISHITANI, A., UMEDA, T., SUGIYAMA, K., HOJO, T.
DOSHISHA UNIVERSITY

INTRODUCTION: In sports field, icing is widely used to reduce acute inflammation and to elevate the pain threshold. The risk of injury after icing increases for about 30 minutes due to the loss of muscle strength and joint position sense caused by reducing peripheral nerve function. Therefore, returning to sports immediately after icing should be avoided even in the case of light injury (Auley, 2001). Then, we focused on the carbon dioxide which has vasodilating effect. Icing with cold carbonated water (CCW) might have the effective recovery of nerve function due to the promotion of peripheral nerve blood flow after icing. This study aimed to evaluate that icing with CCW would promote the early normalization of peripheral nerve conduction velocity, which is reduced by cooling.

METHODS: Six healthy female university students with BMI below 25 participated in this study. Ulnar nerve conduction recovery after elbow joint icing was compared with 5°C water (control condition) and 5°C carbonated water. Both conditions consisted of 15 minutes of icing (W1-15) followed by 30 minutes of rest (R1-30). Recovery of ulnar nerve conduction after icing was evaluated by measuring the distal latency. It was measured before icing (B1) and every minute from the start of icing (W11) to the end of rest (R30). Skin temperature was measured before icing (B1), end of icing (R1) and at the end of rest (R30).

RESULTS: Significant elongation of the distal latency was detected in CCW compared to cold water at W11, W14 to W18, W10, and R12 to R30 ($p < 0.05$). No significant difference was observed in skin temperature between the two conditions at any point.

CONCLUSION: The significant elongation of distal latency before W10 may be due to the vasodilation caused by the carbon dioxide, which had suppressed the decrease in peripheral nerve blood flow and minimized the loss of nerve function. However, no significant difference in distal latency was observed after W11. This result could be explained by the possibility that cold induced vasoconstriction is stronger than the vasodilation caused by carbon dioxide. The significant rapid recovery of distal latency in the CCW from R12 to R30 could be promoted by the vasodilation effect of carbon dioxide gas and the gradual increase in body temperature.

These results concluded that CCW icing could be one of the effective methods for athletes who require a quick return to play.

SELF-EFFICACY FOR WORKOUT INFLUENCES SPORTS INJURY PREVENTION?

KAGAYA, Y., HORIKAWA, H., YUMIGETA, R.
SHOWA UNIVERSITY

INTRODUCTION: Some studies have demonstrated a connection between psychological factors and an athlete's return to play following a sports injury. While interventions, such as positive self-talk and goal setting, have been found to promote recovery after a sports injury (1), it is unclear whether psychological factors can also affect injury prevention. This study aimed to determine whether freshmen's self-efficacy in workouts influences sports injury prevention.

METHODS: A total of 573 freshmen at a medical university completed a self-efficacy questionnaire about workouts upon entering the university. They also completed a self-administered questionnaire about sports injuries at the end of the semester. Of the 573 freshmen, 181 (100 males, 81 females; mean age: 18.3 ± 1.5) participated in sports. The relationship between their self-efficacy at enrollment and sports injuries was investigated.

The self-efficacy questions included 4 negative items (e.g., "If I work out a lot, I will be at a higher risk of injury.") and 4 positive items (e.g., "If I practice a lot, I will be able to win games."). Participants responded on a 5-point scale (1: not at all, 2: not really, 3: either, 4: somewhat, 5: very much).

Each score for 4 negative and 4 positive self-efficacy items was summed and analyzed. Using the Mann-Whitney test, comparisons between injury and non-injury groups for both negative and positive self-efficacy were made at the 5% level. Height and body mass were compared using the unpaired t-test.

RESULTS: Twenty-three students (16 males and 7 females) sustained injuries over a period of 9 months, resulting in an injury rate of 12.7%. The demographics of the injured athletes were similar to those of the uninjured athletes (height: 170.1 ± 8.4 cm vs 165.3 ± 8.7 cm, weight: 64.1 ± 12.6 kg vs 57.8 ± 10.7 kg, respectively). However, the body mass of the injured female group was higher than that of the uninjured female group (55.6 ± 6.7 kg vs 50.6 ± 5.5 kg, $p < 0.05$). Positive self-efficacy scores were lower for the injured group than the uninjured group (3.76 ± 1.12 vs 4.14 ± 1.00 , $p < 0.01$). No significant differences were found in negative self-efficacy scores between the injured and uninjured groups (3.03 ± 1.38 vs 3.01 ± 1.19).

CONCLUSION: Patients who have experienced sports-related injuries often face reduced self-efficacy. High-quality evidence supports the use of goal setting to improve patient self-efficacy [2]. Although it was unclear whether psychological factors could affect the prevention of sports injuries, this survey demonstrated that athletes with lower positive self-efficacy, such as believing "If I practice a lot, I will be able to win games," were more likely to get injured than those with higher positive self-efficacy. Additionally, preventive measures should be taken to control female body mass, as the body mass of the injured female group was higher than that of the uninjured group.

OVERUSE INJURIES IN YOUTH COMPETITIVE CRICKET- A DESCRIPTIVE EPIDEMIOLOGICAL STUDY

MUKHERJEE, S., GUNIYANGODAGE, D.P.

NATIONAL INSTITUTE OF EDUCATION, NANYANG TECHNOLOGICAL UNIVERSITY, SINGAPORE

INTRODUCTION: Overuse injuries (OUI) are a significant concern in youth competitive sports. Cricket, as a sport is rising in popularity among youth worldwide. The roles of fast bowlers and all-rounders in cricket places unique biomechanical stresses on athletes, leading to a high risk of OUI. Despite this, limited research exists on the epidemiology of OUI among youth cricket players, particularly in Singapore. This study investigated the prevalence, severity, and associated risk factors of OUI in youth competitive cricket players in Singapore.

METHODS: A cross-sectional study was conducted involving 272 youth competitive cricketers (227 males, 45 females) aged 12–18 years, recruited from various clubs and academies in Singapore. A validated questionnaire for overuse injuries in youth sport was used. Players recalled OUI over the past three months period. Players were either at the end of pre-season or in-season at the time of the study. Data on demographics, playing role, training load, injury history, and anatomical regions were obtained. Descriptive statistics, chi-square tests and logistic regression were used to identify significant associations between age, training load, playing roles, and OUI.

RESULTS: OUI prevalence was 56.6%, with the lower back (27.6%) and knees (27.9%) being the most affected anatomical regions. Shoulder injuries (21.3%) and elbow injuries (5.9%) were also reported. Male participants accounted for 86.4% of all OUI, while females accounted for 13.6%, largely reflecting the gender distribution in the sample. Fast bowlers were particularly vulnerable, showing higher risk of lower back and shoulder injuries. Training frequency exceeding four sessions per week and session durations over three hours were associated with a significantly higher injury prevalence ($p < .05$). Additionally, older participants (16–18 years) had a higher risk of OUI compared to younger players (12–15 years).

CONCLUSION: The findings show a high prevalence of OUI among youth competitive cricketers in Singapore, with fast bowlers and players exposed to high training loads being at greater risk. Key risk factors include excessive training frequency, prolonged session durations, and biomechanical demands specific to playing roles. The study underscores the importance of implementing evidence-based prevention strategies, such as individualized training programs, age-appropriate workload management, and injury surveillance systems. Coaches, physiotherapists, and stakeholders must collaborate to create structured training regimens that balance intensity, duration, and recovery to ensure the safe and sustainable participation of youth in cricket. Future research should focus on longitudinal studies to better understand the causative pathways of OUI and evaluate the effectiveness of preventive interventions.

CORRELATION OF SAGITTAL AND CORONAL ANTERIOR CRUCIATE LIGAMENT GRAFT ANGLE IN MRI WITH KNEE FUNCTION IN PATIENTS WITH ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTION: A SHORT-TERM FOLLOW-UP STUDY

ZHANG, B., ZHANG, X.

BEIJING SPORT UNIVERSITY&BEIJING CHAO-YANG HOSPITAL

INTRODUCTION: To analyze whether there is a correlation between graft angles in the sagittal and coronal planes and short-term follow-up knee stability and functional outcomes in patients undergoing single-bundle ACL reconstruction with hamstring tendon autograft.

METHODS: Through a 3-year follow-up of 46 patients who underwent single-bundle ACL reconstruction with hamstring tendon autograft, and graft angles were measured using MRI. Combined with objective knee static stability tests (Lachman Test, KT2000, and Pivot Shift Test) and dynamic functional tests (single-leg hop test, single-leg triple hop test, single-leg crossover hop test, Y balance test, isokinetic strength test, and proprioception assessment), the study analyzed whether there is a correlation between graft angles in the sagittal and coronal planes and short-term follow-up knee stability and functional outcomes.

RESULTS: The sagittal graft angle was found to have a moderate positive correlation with the Lachman test ($r = 0.305$, $P = 0.039$) and the peak torque of knee flexion during concentric isokinetic muscle strength testing at $180^\circ/\text{s}$ ($r = 0.392$, $P = 0.007$). The coronal plane angle showed no correlation with any of the test results.

CONCLUSION: More vertical graft placement in the sagittal plane is associated with poorer anterior-posterior stability (Lachman test) and higher knee flexor strength output during dynamic testing ($180^\circ/\text{s}$ concentric isokinetic testing). This may reflect compensatory muscle activation to enhance stability, similar to the "quadriceps-avoidance gait" observed in ACL-injured patients, and may potentially affect long-term outcomes.

No correlation was found between coronal graft angle and any static stability or dynamic function tests. The lack of correlation between coronal graft angle and any test results may be related to the fact that the coronal angles measured in this study were closer to the native ACL angles compared to previous studies. Additionally, this finding is significantly associated with the testing methods employed and the specific outcomes included in the analysis. If pivot shift testing under anesthesia, dynamic tasks involving knee pivoting, and direct measurements of kinematic parameters such as tibial rotation were incorporated, more ideal results might be achieved.

Recommendations:

Aim for graft placement angles closer to the native ACL to optimize knee biomechanics and reduce long-term degenerative changes.

Emphasize postoperative rehabilitation to minimize abnormal kinematics and reduce secondary degenerative changes.

CHARACTERISTICS OF FALLS AMONG WHEELCHAIR BASKETBALL WOMEN PLAYERS IN THE TOKYO 2020 SUMMER PARALYMPIC GAMES: A VIDEO ANALYSIS

MAEDA, N., TAMURA, Y., TASHIRO, T., ARIMA, S., ABEKURA, T., ODA, S., ISHIDA, A., UEDA, A., KUMAMOTO, S., TSUTSUMI, S., SASADSAI, J.

HIROSHIMA UNIVERSITY

INTRODUCTION: Wheelchair sports, while offering numerous physical and psychosocial benefits, are associated with a heightened risk of falls [1]. Understanding the mechanisms and characteristics of these falls is crucial for developing effective injury prevention strategies. However, research specifically addressing falls in wheelchair basketball, particularly among women athletes, remains limited. This study aimed to investigate the specific characteristics of falls among wheelchair basketball women athletes at the Tokyo 2020 Summer Paralympic Games (the Tokyo games).

METHODS: We obtained video footage from the International Paralympic Committee of the Tokyo games that included 10 women's teams from each of the 31 wheelchair basketball games. A quantitative analysis was performed to examine the incidence of falls, class-based differences (low vs. high pointers), temporal patterns of falls within games, and biomechanical characteristics of falls, including contact events, fall trajectories, and impact sites. The Pearson's χ^2 test or the Fisher's exact test was used to compare each categorical variable in each group; the Fisher's exact test was conducted when the expected number was 5%.

RESULTS: Overall, 325 falls (women's basketball, Low; 168, High; 157) occurred (average per game: 9.3). The Tokyo games were characterized by an increase in falls among women's wheelchair basketball players, particularly those classified as low pointers. Statistical analysis revealed significant differences between low pointer and high pointer in several aspects of falls, including the direction of the fall, site of fall, whether the fall occurred during foul play, and the specific game situation in which the fall occurred.

CONCLUSION: The findings of this study highlight higher number of falls experienced by low pointer women wheelchair basketball players at the Tokyo games compared to their high pointer. This result may be attributed to several factors, such as low pointers, who often fulfill more defensive roles, being involved in more collisions and challenging maneuvers, thus increasing their risk of losing balance and falling. Their greater physical limitations of low pointer may also contribute to a reduced ability to recover from destabilizing events. Furthermore, the specific rules and close physical contact and rapid changes in direction might differentially affect players with varying levels of physical function. Future research should explore these potential contributing factors in more detail.

POST AND LONG-COVID-19 SYNDROME AND EXERCISE INTERVENTION ROLES IN TERMS OF ACE2

KWAK, Y.

DONG-EUI UNIV

INTRODUCTION: The large number of Post and Long-COVID survivors has drawn attention to the management of Post and Long-COVID-19 condition, known as Post and Long COVID-19. Dyspnea, chronic cough, and fatigue are the most commonly reported symptoms in the first 4 weeks to 6 months after infection, but cognitive impairment and psychological symptoms may persist beyond this time. Other persistent symptoms such as cognitive and mental impairments, chest and joint pains, palpitations, myalgia, smell and taste dysfunctions, cough, headache, and gastrointestinal and cardiac issues were reported. The purpose of this comprehensive review is to evaluate Post and Long-COVID-19 syndrome from a biological perspective and also discuss about physical exercise intervention roles in terms of ACE2. It is thus imperative to

analyze Post and Long-COVID-19 effects, specifically as local and systemic pathophysiological outcomes of other coronavirus-related diseases with the exercise interventions.

METHODS: Medline, Embase, Global Health (Ovid), CINAHL (EBSCO), PubMed, Scopus, Web of Science and Google Scholar search engines were used to identify the definition, mechanism, pathophysiology of Post and Long post-COVID and also to find out rehabilitation and exercise-intervention benefits in terms of ACE2.

RESULTS: Medical treatments for COVID-19 (anticoagulants, corticosteroids, anti-inflammatory drugs, oxygenation therapy and ventilation) and vaccination have improved patient outcomes. The majority of patients will recover spontaneously or after acute-phase management, but clinicians are now faced with long-term complications of COVID-19 including a large variety of symptoms, defined as "Post-acute COVID-19 syndrome". Since the lungs are the most involved organs and the Post and Long-COVID prolonged and persistent effects are mainly related to the pulmonary system, it is crucial to define and predict the outcome and to determine the individuals that can progress to fibrosis and loss of function of lungs. The findings from our review indicated that there were four pathophysiological categories involved: virus-specific pathophysiological variations, oxidative stress, immunologic abnormalities, and inflammatory damage with physical exercise.

CONCLUSION: Although studies examining the pathophysiology of Post and Long-COVID-19 syndrome are still relatively few, there is growing evidence that this is a complex and multifactorial syndrome involving virus-specific pathophysiological variations that affect many mechanisms but specifically oxidative stress, immune function, and inflammation. Rehabilitation and Multicomponent exercise-intervention program (4-5 days per weeks, 35-60% HRR, 100-250 minutes aerobic exercise) considered especially for the Post and Long-COVID-19 syndrome patients were recommended with all forms of psychological support such as meditation and MBI. Adopting life style changes and tailored dietary interventions will be helpful to reduce Post-COVID-19 syndromes in terms of ACE2.

EPIDEMIOLOGICAL STUDY OF HAMSTRING STRAIN INJURIES IN UNIVERSITY ATHLETICS ATHLETES: MRI-BASED ANALYSIS OF INJURY SITES AND SEVERITY

SHIOTA, Y., TOGASHI, I., AOYAGI, S., UCHINO, S., SOMEYA, Y., KOMATSU, T., NAGAO, M., MIYAMOTO, N., AOKI, K., IWASAKI, T., SUGIBAYASHI, T., YAMAZAKI, K., TAKAZAWA, Y.

JUNTENDO UNIVERSITY

INTRODUCTION: Hamstring strain injury (HSI) is one of the most common injuries in sprint-based sports, particularly in competitive athletes. Moreover, it has a high recurrence rate, particularly within one year after the initial injury. However, few studies have utilized early post-injury MRI assessments to examine injury sites, severity, and their progression over time. This study aimed to investigate the incidence of HSI in university athletes by analyzing injury sites and severity using MRI.

METHODS: A prospective observational study was conducted from April 2023 to March 2024, including 133 university athletes specializing in sprints and jumps. Athletes reporting pain or soreness in the posterior thigh first underwent clinical examination, and those with suspected HSI subsequently underwent MRI assessment. HSI presence, injury site, and severity were classified according to the British Athletics Muscle Injury Classification (BAMIC).

RESULTS: During the observation period, 51 athletes (69 cases) reported symptoms, and MRI was performed on average 4.0 ± 3.1 days after symptom onset. HSI classified as grade 1 or higher according to the BAMIC classification was identified in 34 athletes (41 cases), with 30 cases involving the biceps femoris, 8 cases in the semitendinosus, and 3 cases in the semimembranosus. The severity classifications were as follows: 10 cases of grade 1a, 9 cases of grade 1b, 5 cases of grade 2a, 14 cases of grade 2b, 1 case of grade 2c, 1 case of grade 3b, and 1 case of grade 3c. Multiple injuries were observed in six cases during the observation period, including five athletes with ipsilateral injuries and one athlete with a contralateral injury, with four cases being recurrent injuries in the long head of the biceps femoris.

CONCLUSION: HSI in university athletes most commonly occurred in the biceps femoris, with a high recurrence rate in its long head. Future studies should conduct longitudinal investigations of injured athletes to identify risk factors for recurrence and to develop targeted rehabilitation strategies.

DIFFERENCES OF DYNAMIC POSTURAL CONTROL PERFORMANCE AND MOTOR CONTROL ABILITY OF ANKLE BETWEEN JAPANESE JUNIOR HIGH SCHOOL AND COLLEGIATE BASKETBALL PLAYERS

SEKINE, Y., HOSHIKAWA, S., UCHINO, S.

TEIKYO HEISEI UNIVERSITY

INTRODUCTION: Ankle injury is the most common cause of ankle sprains in Japanese basketball players, because the rate of ankle sprains is higher in Japan than in NCAA players [1]. However, the differences in dynamic postural control performance and motor control ability between age groups remain unclear. Therefore, this study aimed to examine cross-sectional differences in dynamic postural control performance and motor control ability in young Japanese basketball players.

METHODS: The participants were 69 junior high school (12–15 years) and 57 collegiate (18–22 years) Japanese basketball players. Hip abduction isometric strength (ABD), Y-balance test (YBT) to the anterior (Ant), post-lateral (PL), post-medial (PM), and side hop test (SHT) were measured. The ABD and YBT scores were normalized to body mass, femur length, and lower limb length (from the anterosuperior iliac spine to the medial malleolus). The analysis used data from the superior value side. To evaluate the differences between groups, independent t-tests or Mann–Whitney U tests were performed after assessment of normality using the Shapiro–Wilk test.

RESULTS: The collegiate group had higher YBT-PM and SHT performances than those in the junior high school group (YBT-PM; $p < 0.001$, $d = 0.77$, SHT; $p < 0.001$, $r = 0.39$). However, the YBT-Ant in the collegiate group was significantly lower than that in the junior high school group ($p < 0.001$, $d = 0.95$). No significant differences were observed between the ABD and YBT-PL.

CONCLUSION: The SHT and YBT-PM scores may be influenced by increased motor control ability associated with growth. However, lower YBT-Ant scores, which have been reported as a feature of chronic ankle instability [2], were found in the collegiate group, in which higher athletic performance was expected. As suggested in previous research, lower YBT-Ant scores in the collegiate group may be affected by ankle dorsiflexion range of motion as the limiting factor [3]. Our results showed a difference in dynamic postural control performance between different age categories.

TEN-YEAR NATIONWIDE REVIEW OF YOUTH FIELD HOCKEY LOWER EXTREMITY INJURIES IN NEW ZEALAND

WATKIN WARD, A.1, MYLES, J.2, BELCHER, S.2, WHATMAN, C.3

1 AUCKLAND UNIVERSITY OF TECHNOLOGY, AUCKLAND, NEW ZEALAND; 2 WAIKATO INSTITUTE OF TECHNOLOGY, HAMILTON, NEW ZEALAND; 3 SPORTS PERFORMANCE RESEARCH INSTITUTE NZ, AUCKLAND UNIVERSITY OF TECHNOLOGY

INTRODUCTION: Field hockey (hockey) is a popular team sport worldwide. Its physiological demands pose injury risks which may vary by demographics such as sex, age, and competition level. Research indicates the lower extremity (LE) is the most common injury site in hockey [1]. According to national insurance (Accident Compensation Corporation [ACC]) data in New Zealand (NZ), hockey ranks fifth for team sport injury claims [2]. National, multi-year reviews to understand injury epidemiology and inform injury prevention programmes (IPPs) have been conducted in other popular sports including netball, football, and rugby [3, 4, 5]. Given hockey's popularity in NZ and the significant ACC injury claims, similar initiatives are warranted. An understanding of injury types, rates, costs and trends will help inform future injury prevention strategies. Therefore, this study aimed to review ACC LE injury claims in youth hockey players from 2013-2023.

METHODS: Youth hockey injury data was extracted from ACC and reported by injury site and monthly injury count for the top three LE body sites per year to determine seasonal patterns over the 10-year period between 2013/14-2022/23. Age groups were defined as intermediate school age (10-14yrs) and high-school age (15-19yrs), representing the different schooling levels of play. Monthly injury counts and participation data from Hockey NZ were used to calculate monthly injury rates per 1000 affiliated players. Injury costs per year are also reported. A Shewhart control chart was used to identify seasonal changes and patterns within each year.

RESULTS: The highest average injury rate was for hip/upper leg/thigh injuries in females (15-19yr, 35.8/1000; 10-14yr, 26.2/1000), followed by knee injuries in females (15-19yr, 31.3/1000; 10-14yr, 25.9/1000). In both male age groups, the highest injury rate was also for hip/upper leg/thigh injuries (15-19yr, 29.13/1000; 10-14yr, 17.13/1000), followed by ankle injuries in the 15-19yr group (22.18/1000) and knee injuries in the 10-14yr group (15.95/1000). The highest mean cost/year was for knee injuries in females (15-19yr NZ\$343,885; 10-14yr NZ\$120,042). Most injury counts decreased over the 10-year period (15-19yr range -35.9% to +0.6%; 10-14yr range -45.6% to -27.0%). Consistent injury peaks were seen in May/June near the start of the season, and August/September around annual tournaments, except for 2020 and 2021 during the Covid-19 pandemic.

CONCLUSION: The most common injuries in youth hockey involve the hip/upper leg/thigh and knee. Injuries were more common in females than males and in 15-19yr compared to 10-14yr age groups. The majority of hockey LE injuries decreased between 2013-2023. Seasonal data across both age groups shows that high intensity periods can lead to higher injury rates. These findings could inform future IPP design to help reduce LE injuries in youth hockey.

SPORTS INJURIES AT THE SPECIAL OLYMPICS NIPPON NATIONAL WINTER GAMES 2024

SOMEYA, Y., SHIOTA, Y., USHIO, K., SAKAMITSU, T., TOGASHI, I., SOMEYA, S., TERAURA, H., WADA, T., TAKAZAWA, Y.

JUNTENDO UNIVERSITY

INTRODUCTION: Studying sports injuries and illness are crucial to their prevention and plays a vital role in the continuation and promotion of sports activities. However, few studies of sports injury have been conducted at sporting events for para-sports athletes, especially those with intellectual disabilities. A clear understanding of the difference between sports injuries and illness in athletes with intellectual disabilities and those without is important for prevention and medical sup-

port of injuries and illness in these athletes. The objective of this study was to clarify the incidence and characteristics of sports injuries and illness during the Special Olympics Nippon National Winter Games 2024.

METHODS: Four hundred and eighty-five athletes with intellectual disabilities (male: 378 [77.3%], female: 107 [22.7%]) and 26 unified partners, who are teammates without intellectual disability, (male: 17 [65.4%], female: 9 [34.6%]) who participated in the Special Olympics Nippon National Winter Games 2024 were included in the study. The sports included alpine skiing, snowboarding, cross-country skiing, figure skating, short track skating, floorball, and floor hockey. The number of injuries and illnesses and incidence (injuries/1000 athlete exposure [AE]) were investigated over the period. Additionally, location, mode of onset, mechanism, etc. were classified according to the definitions recommended by the International Olympic Committee. These analyses were categorized according to athletes and unified partners.

RESULTS: A total of 10 injuries occurred during the games period (6 days), there were no illnesses. All injuries occurred in athletes with intellectual disabilities, not in unified partners. The incidence in athletes with intellectual disabilities was 10.6/1000 AEs. In terms of the location and mechanism of injury, 70% of the injuries occurred in the lower extremity and were non-contact injuries. There were two time-loss injuries, both of which were serious and required surgery. On the other hand, the majority of injuries did not involve time loss and included complaints where the mechanism of injury or clinical findings were unclear.

CONCLUSION: At the Special Olympics Nippon National Winter Games 2024, sports injuries occurred only among athletes with intellectual disabilities. The characteristics of winter sports injuries in athletes with intellectual disabilities showed a high incidence in the lower extremities. Injuries ranged from severe to minor or unspecified complaints, requiring medical support to meet a wide range of needs.

GAIT CHARACTERISATIONS IN ADOLESCENT IDIOPATHIC SCOLIOSIS PATIENTS WITH RIGO A

LIAO, B., WANG, D., ZHANG, X.

GUANGZHOU SPORT UNIVERSITY

INTRODUCTION: Adolescent idiopathic scoliosis (AIS) is one of the most common spinal deformities, with a prevalence of 1% to 3%. AIS disrupts the biomechanics of the lower limbs, leading to altered gait patterns. These abnormal gait characteristics may, in turn, increase asymmetric loading on the spine, potentially contributing to the progression of AIS. Previous studies have demonstrated that patients with Rigo type A scoliosis exhibit significant imbalances in spinal coronal parameters. However, the specific gait characteristics associated with this condition have rarely been reported. This study aimed to compare the gait characteristics and trunk stress patterns between Rigo type A AIS patients and healthy controls. The findings may provide valuable insights for clinical interventions.

METHODS: A cross-sectional design was employed in this study. The study protocol was registered with the Chinese Clinical Trial Registry (Registration Number: ChCTR1800018310) and approved by the Human Subject Committee of Guangzhou Sport University (Approval Number: 2023LCLL-10).

Ten AIS patients (aged 10–16 years) and an equal number of age- and sex-matched healthy adolescents (control group) were recruited. A 3D motion capture system was used to analyze the spatiotemporal parameters of gait in both groups. First, the German Zebris FDM gait analysis system was utilized to collect gait parameters at normal walking speed. Second, the Vicon motion capture system, combined with an AMTI force platform, was employed to analyze dynamic gait parameters at a constant speed and calculate trunk forces using inverse dynamics. Each participant was measured three times, and the average values were used for statistical analysis.

All experimental data were processed and analyzed using SPSS 26.0 software. Independent samples t-tests were applied to data conforming to a normal distribution, while non-parametric rank-sum tests were used for data that did not meet normality assumptions. Statistical results are presented as mean $\pm$ standard deviation.

RESULTS: Compared to the control group, AIS patients exhibited a longer double stance phase ($25.43 \pm 1.77\%$ vs. $22.98 \pm 2.90\%$). Additionally, in AIS patients, the vertical force on the trunk reached its maximum during the early phase of the right stance in the gait cycle.

CONCLUSION: Compared to healthy controls, AIS patients in this study demonstrated a greater proportion of double stance phases during gait cycles, suggesting that they may compensate for reduced stability by increasing double stance time. Furthermore, the maximum vertical force on the trunk occurred during the early phase of the right stance, which may be associated with the right-sided coronal imbalance typically observed in right thoracic curves. These findings highlight the potential relationship between gait adaptations and spinal asymmetry in AIS patients.

SURVEILLANCE OF UNIVERSITY AMERICAN FOOTBALL TEAM INJURIES OVER THREE YEARS

IZUMI, S., SUGENO, R., NOSE, T., MIMURA, Y.

HOSEI UNIVERSITY

INTRODUCTION: The purpose of this study was to conduct an injury survey of a total of 317 male university students enrolled in American football clubs at universities in one of the two major leagues in Japan from 2021 to 2023.

METHODS: Method of recording injury investigation records. All injuries were diagnosed by the team physician and reported by the student trainer using an electronic medical record. Injury incidence was calculated using units of 1000 Athlete-Exposures (1000 AE) and 95% confidence intervals (95% CI) were obtained. Other factors such as the cause of the injury, the location of the injury, the type of injury, and the severity of the injury were also tabulated.

RESULTS: In 2021, the club had 111 members, 9 games, 156 practices, and an injury rate of 5.2/1000AE [3.6-7.6]; in 2022, the club had 102 members, 13 games, 152 practices, and an injury rate of 5.8/1000AE [4.4-7.3]. In 2023, there were 104 members, 12 games, 176 practices, and 4.8/1000AE [3.5-6.1]; in 2021, contusion and meniscus tears were the most common, both at 16.5/1000AE; in 2022, dislocation was the In 2023, cartilage injury was the most common with 36.9/1000AE, followed by dislocation with 10.3/1000AE.

CONCLUSION: Although the number of injuries and disabilities has increased over the three-year period 2021-2023, the injury rate has decreased; the injury rate is higher in Contact than in No contact. Injuries to the upper and lower limbs have remained constant. On the other hand, injuries and disabilities in the head and neck and trunk/back areas varied from year to year. In terms of injury type, the incidence of injuries occurring in games was high, with bruises, dislocations, meniscus tears, cartilage injuries, and arthritis being the most common types of injuries

EVALUATING THE PRECISION AND UTILITY OF HRMAX PREDICTION FORMULAS: A SYSTEMATIC REVIEW AND META-ANALYSIS

CHEN, Y., LEI, S.M., CHOI, S.M.

UNIVERSITY OF MACAU

INTRODUCTION: Accurate estimation of maximum heart rate (HRmax) is essential for safe exercise prescriptions and cardiovascular risk assessment [1]. Widely adopted formulas (e.g., Fox [220-age], Tanaka [208-0.7×age]) may over- or underestimate true HRmax, especially in older or clinical populations [2]. This review and meta-analysis aimed to clarify potential bias in these formulas among both healthy and special cohorts (e.g., older adults, athletes, cardiac patients) and to examine subgroups (e.g., age, fitness, medication) that could influence HRmax prediction accuracy.

METHODS: This review was registered in PROSPERO (CRD42024607429). A comprehensive literature search was conducted in PubMed, Web of Science, Scopus, SPORTDiscus, Medline up to March 2024. Search terms for maximal heart rate ("HRmax," "maximum heart rate"), prediction equations ("heart rate prediction," "HRmax equation," "220-age," "Tanaka formula"), and populations ("adults," "elderly") were combined using Boolean operators ("AND"/"OR") and database-specific indexing. Only cross-sectional studies enrolling adults (≥18 y) or older adults (≥60/65 y), examining commonly used HRmax formulas (e.g., Fox, Tanaka, Gellish) and directly measuring HRmax (e.g., treadmill, ergometer) were included. Three reviewers independently screened records, extracted data, and assessed methodological quality (Newcastle-Ottawa Scale). A random-effects meta-analysis estimated the pooled mean difference (predicted vs. measured HRmax) with 95% confidence intervals, and subgroup analyses addressed age group, sex, cardiac status, athletic status, and formula type.

RESULTS: A total of 60 cross-sectional studies met the inclusion criteria, of which 23 provided mean ± SD ± n data for meta-analysis, and 37 were assessed narratively. Among these 60, 3 developed new HRmax equations, 47 validated existing models, and 10 incremented established formulas. Methodological quality was moderate in most studies, often due to limited confounder control (e.g., training status, β-blocker use). The meta-analysis indicated a systematic overestimation of measured HRmax in adults (18–59 y) (MD: +4.85 bpm, 95% CI: 2.96–6.74) and older adults (≥60/65 y) (+10.89 bpm, 7.84–13.94), with Fox showing greater bias (+7.43 bpm) than Tanaka (+1.94 bpm). Despite high heterogeneity ($I^2 > 75\%$), excluding lower-quality studies still yielded similar outcomes. Qualitatively assessed articles, especially involving athletes or older participants with comorbidities, reinforced overestimation trends, underscoring the need for population-specific refinements.

CONCLUSION: Commonly used HRmax prediction formulas systematically overestimate measured HRmax, particularly in older or specialized populations. Developing refined or population-specific models may enhance exercise prescription accuracy and cardiovascular risk stratification. Further research should validate adjustments for age, sex, and fitness level, thereby optimizing HRmax prediction across diverse populations.

IMPACT OF PATIENT POSITIONING HEIGHTS ON RESCUER MUSCLE FATIGUE DURING CHEST COMPRESSIONS IN CARDIO-PULMONARY RESUSCITATION: PRELIMINARY RESULTS

ALEIXO, P., BHUDARALLY, M., MORGADO, J., GUERRA, J., FEBRA, C., ABRANTES, J., PEREIRA, H., ATALAIA, T.

MOVLAB/UNIVERSIDADE LUSÓFONA DE HUMANIDADES E TECNOLOGIAS

INTRODUCTION: Current adult cardiopulmonary resuscitation guidelines do not provide specific recommendations regarding the patient positioning height (e.g., ground level or elevated surfaces).1-2 However, previous research suggests the patient positioning height may impact rescuer muscle fatigue and, consequently, the quality of chest compressions (CC).3 Moreover, biomechanical advantages have been observed when rescuers are allowed to select the patient positioning height.4 Despite these findings, further investigation is required to address this topic comprehensively. The median frequency (MDF) is a parameter commonly used in electromyography (EMG) analysis, especially for studying muscle fatigue (its value tends to decrease when a muscle is fatigued).5-6 Thus, this preliminary study aimed to compare rescuer muscle fatigue across different patient positioning heights.

METHODS: In this randomized crossover trial (one week between different scenarios), 7 participants (mean age: 46.6 ± 9.0 years; 2 men) with a minimum of 5 years of experience in cardiopulmonary resuscitation were recruited. Each participant performed CC under four different patient positioning heights (scenarios): 1) on the ground; 2) on a bed at 75 cm (like the most common hospital bed height); 3) on a bed at 42 cm (the lowest height of electronic hospital beds); 4) on a bed at self-selected height (mean: 60 cm). CC were performed on the manikin's left side, with the rescuers right hand on its ster-

num, following 5 cycles of 2-minute CC (each separated by a 2-minute pause). The MDF values for both left and right portions of the trapezius superior (TS) and lumbar erector spinae (ES) were obtained from surface EMG (Biosignalplux; 1000 Hz), according to literature.⁶ Wilcoxon test was used to compare the four different scenarios, during 5 CC cycles.

RESULTS: In most cycles, CC performed on the ground yielded higher MDF values of the ES compared to self-selected and 42 cm heights ($p < 0.05$). In some cycles, CC performed standing at 80 cm also yielded higher MDF values compared to the other two CC standing scenarios ($p < 0.05$). Regarding TS, the CC performed on the ground also yielded higher MDF values compared to the other three CC standing scenarios ($p < 0.05$).

CONCLUSION: Performing CC on the ground appears to result in lower TS fatigue. In contrast, performing CC in a standing position, with the patient positioned at lower heights, appears to induce higher ES fatigue. Given the small sample size, further research is necessary to validate these findings. These findings will be crucial for refining future cardiopulmonary resuscitation guidelines and optimizing exercise programs aimed at enhancing CC performance.

ASSOCIATIONS BETWEEN HAMSTRING STRAIN INJURY AND EXCENTRIC HAMSTRING MUSCLE STRENGTH IN ELITE MALE SOCCER PLAYERS

SHIOZAWA, J., HITOSHI, A., MORIO, H., IKEDA, H., ISHIJIMA, M., TAKAZAWA, Y.

JUNTENDO UNIVERSITY

INTRODUCTION: Hamstring strain injuries (HSI) are a common problem in football, accounting for 12% of all injuries in high-level professional players, and recurrence rates have not decreased in recent years. These data suggest that our understanding of HSI and the risk of re-injury is incomplete. Many risk factors for HSI have been reported, such as older age, previous HSI and muscle fatigue. In recent years, eccentric hamstring imbalances, low eccentric strength and torque have been highlighted as new risk factors for HSI in many athletes. However, it has remained unclear whether eccentric hamstring imbalances, low eccentric strength and torque are associated with a previous occurrence of HSI in football players. The aim of this study was to investigate the relationship between the occurrence of HSI and eccentric hamstring strength in Japanese male soccer players.

METHODS: A total of 119 elite male football players (mean age 25.5 ± 3.5 years) from one team underwent eccentric strength testing during the preseason (2020-2024). Players with a history of HSI were assigned to group H (mean age 25.8 ± 3.3 years) and those without a history of HSI to group NH (mean age 25.5 ± 3.5 years). Eccentric hamstring strength was measured using the NordBord (VALD Performance, Albion, Australia). From these measurements, maximum force (N), torque (N·m), and imbalances for each leg (%) were calculated. All data were analyzed using SPSS Statistics software version 21.0 (IBM, Armonk, NY). p -value < 0.05 was considered statistically significant.

RESULTS: The number of players with a history of HSI was thirty-six (30.3%: group H) and those without a history of HSI was eighty-three (69.7%: group NH). There were no significant differences in baseline characteristics such as age, weight, height and body mass index (BMI) between the two groups. No significant differences were observed between group H (dominant leg: 309 ± 64 N, non-dominant leg: 299 ± 63 N) and group NH (dominant leg: 308 ± 61 N, non-dominant leg: 291 ± 60 N) in the maximum force of eccentric hamstring strength ($p = 0.821$, $p = 0.821$) and torque between group H (dominant leg: 134 ± 27 N·m, non-dominant leg: 130 ± 26 N·m) and group NH (dominant leg: 137 ± 28 N·m, non-dominant leg: 130 ± 28 N·m), respectively ($p = 0.810$, $p = 0.958$). In addition, the eccentric hamstring force imbalances for each leg were not significantly different between the two groups (group H: 6.2 ± 6.4 , group NH: 7.4 ± 7.7) ($p = 0.387$).

CONCLUSION: The history of HSI among elite male soccer players in Japan was approximately thirty percent. There was no association between a history of HSI and eccentric hamstring strength.

PREVALENCE OF LOW ENERGY AVAILABILITY AND NUTRITIONAL INTAKE DURING OFF-SEASON IN JAPANESE ADOLESCENT WATER POLO PLAYERS

KOMORI, Y., IWAMOTO, M., NAKAGI, N., KAWASHIMA, N.

KYOTO KOKA WOMENS UNIVERSITY

INTRODUCTION: The International Olympic Committee (2014, 2023) introduced the concept of relative energy deficiency in sports (RED-S), a clinical syndrome resulting from low energy availability (EA). Insufficient energy intake can lead to issues with growth and development, metabolism, mental health, cardiovascular health, and bone health, ultimately impairing athletic performance.

The Japan Sports Association (2021) issued the "Guidelines for Sports Activities in the Developmental Period," highlighting the importance of psychological and social factors, adequate nutrition, and sports injury prevention.

Nutritional guidelines emphasise that sufficient energy intake and a well-balanced diet are essential for physical growth. Additionally, studies suggest that adequate daily energy intake is essential for preventing RED-S in adolescent athletes. However, research on energy availability in this population remains limited.

This study evaluates nutritional intake, training volume, and the occurrence of low EA (<30 kcal/kg FFM) in Japanese adolescent water polo players. The findings aim to contribute to the promotion of a healthy sporting life during early growth and development.

METHODS: Twenty-five elementary and junior high school water polo players (aged 8-15years) from clubs in Kyoto Prefecture, Japan, participated in this study. This study was conducted during the off-season to assess nutritional intake and energy availability when training demands may differ from the competitive season. The primary measurements included nutritional intake, training volume, body composition, and bone density. Nutritional intake was assessed using the brief-type self-administered diet history questionnaire for 15-year-olds (BDHQ-15y), and dairy energy intake was calculated. Exercise energy expenditure (EEE) was determined from a 7-day training record.

Participants were categorised into three groups for comparison: low, sub-optimal, and optimal EA according to the established definition of EA.

RESULTS: The mean EA was 64.8 ± 36.9 kcal/kg FFM. The prevalence of low, sub-optimal, and optimal EA was observed in 29.1%, 16.7%, and 62.5% of the players.

The corresponding EA values for these groups were 23.5 ± 3.9 , 40.6 ± 5.2 , and 87.3 ± 27.4 kcal/kg FFM, respectively. The low and sub-optimal EA groups had lower EA than the optimal EA group ($F(2) = 38.1$, $p = 0.006$, $p < 0.001$ and $p = 0.03$). Similarly, energy intake in the low EA and sub-optimal EA groups was lower compared to the optimal EA group ($F(2) = 15.5$, $p = 0.01$, $p < 0.001$ and $p = 0.04$). EEE also tended to be higher in the low EA group.

CONCLUSION: These findings indicate that 29% of the players had low energy availability and low energy intake. This group also tended to have a higher training volume.

In conclusion, these results highlight the need for a dietary intake improvement plan, particularly to enhance energy and nutrient intake during the developmental period.

THE STUDY OF INJURIES AND INITIAL FIRST AID FOR BASKETBALL ATHLETES IN THE 3 × 3 BASKETBALL CHAMPIONSHIP OF THAILAND 2024

CHANTASORN, N., NEELAPAIJI, N., NHUSAWI, K., KAESMAN, I.

SILPAKORN UNIVERSITY

INTRODUCTION: The objectives of this study are to investigate the causes of injuries, the body parts that affected, and the nature of injuries sustained by 3x3 basketball athletes of Thailand.

METHODS: The sample group used in this study comprised 272 basketball athletes who participated in the 3 × 3 Basketball Championship of Thailand in 2024. The Taro Yamane (1973) formula was used to determine the sample size. The research instrument employed in this study was a questionnaire on the study of injuries and initial first aid. Content validity was assessed by calculating the Item-Objective Congruence (IOC) index, which ranged from 0.67 to 1.00. $(R=1.0)$. The statistical methods used for data analysis included frequency, percentage, mean, and standard deviation.

RESULTS: 1) Causes of Injuries, and Nature of Injuries of Basketball Athletes – the most common causes of injuries due to external factors. Substandard shoes and poor playing surface conditions were the leading causes, accounting for 28.60% of cases. Causes of injuries due to internal factors primarily involved a lack of warm-up, which contributed to 28.10% of injuries. Regarding Body Parts affected, head injuries were the most commonly found at the eyebrow (30.59%), while lower back injuries were the most frequent for the trunk (43.57%). Injuries to the upper limbs predominantly affected the fingers (35.75%), whereas the lower limbs were most commonly injured at the ankle (41.88%). In terms of the Nature of Injuries, skin injuries were mostly abrasions (47.81%), while muscle injuries were primarily cramps (57.10%). Joint and ligament injuries were mostly sprains (96.81%), and fractures were the most common type of bone injury (70%). The severity of injuries was mostly minor, allowing athletes to continue training and competing the next day (65.07%). The ongoing injuries due to training were mostly reported by athletes (90.44%). 2) Survey of Initial First Aid Approaches for Basketball Athletes – regarding first aid approaches within the first 24 hours after injury Providers of first aid were mostly the athletes themselves (44.05%). First aid method used was predominantly with cold compresses (48.84%)

CONCLUSION: The study concluded that the most common cause of injuries among basketball athletes in the 3 × 3 Basketball Championship of Thailand was the lack of warm-up. The most frequently injured body part was the ankle, followed by the knee. The most common type of injury was cramps, while the severity of injuries was mostly classified as minor, allowing athletes to continue their training and competition. The predominant first aid method within 24 hours after injury was rest. Most athletes self-administering treatment with cold compresses was the most common method. The majority of treatment durations to recovery ranged from 7 to 13 days. The main source of first aid knowledge was from sports coaches. The findings of this study will serve as a guideline for coaches and athletes to plan injury prevention strategies in future competitions.

LOW AWARENESS AMONG COACHES AS A RISK FACTOR FOR THE WIDESPREAD PREVALENCE OF RED-S AMONG ELITE ENDURANCE ATHLETES

KAPRALOVA, E., VOLEL, B., BEZUGLOV, E., CHYOGIN, S., BUTOVSKIY, M.

SECHENOV UNIVERSITY

INTRODUCTION: The widespread prevalence of Relative Energy Deficiency in Sport (RED-S) represents one of the most pressing challenges in global sports, negatively impacting multiple dimensions of athletic performance. These include elevated injury rates, detrimental impacts on reproductive health, and compromised mental well-being. Consequently, it is imperative to ensure sufficient awareness and understanding of RED-S among professionals who work directly with athletes, particularly coaches and sports physicians. Prior research has indicated that coaches' knowledge regarding the prevalence and implications of this syndrome is inadequate, highlighting a potential significant concern [1]. The objective of this study was to assess the level of awareness of RED-S among coaches who train elite athletes in short-track speed skating and track and field.

METHODS: The study involved a total of 100 coaches (mean age 43.41 ± 12.68 years, mean coaching experience 18.65 ± 12.58 years) from track and field ($n=73$) and short-track speed skating ($n=27$). 19% coaches were currently working with high-level athletes (including medalists and participants of Olympic Games and medalists of European Championships) at the time of the survey, while 81% coaches worked with lower level athletes. All participants completed an online questionnaire in real time, based on the questionnaire used in the study by Kroshus et al. [2].

RESULTS: Among all participants, 61% of coaches answered "no" to the question "Have you heard of Relative Energy Deficiency in Sport (RED-S)?" while only 39% answered "yes." There was no statistically significant difference in RED-S awareness between speed skating and track and field coaches (40.7% and 38.4%, respectively; $p > 0.05$), indicating similarly low levels of awareness across both disciplines. Additionally, coaches currently working with elite athletes demonstrated higher awareness than those working with lower-level athletes (47.4% vs. 37%; $p < 0.05$). Among the coaches who were aware of RED-S, 51.3% considered their knowledge insufficient (low and very low), and all of them believed it was extremely important to implement educational initiatives on RED-S syndrome.

CONCLUSION: The study revealed extremely low awareness of RED-S among both coaches working with elite athletes and those working with lower-level athletes. This highlights the need for the implementation of educational programs detailing the diagnosis, treatment, and prevention of RED-S syndrome in practice.

ANALYSIS OF THE IMPACT OF MUSCLE DEFICIENCY ON BALANCE ABILITY AND WALKING IN THE ELDERLY

CHEN, W., LI, T.F., CHIU, W.H.

CHANG GUNG UNIVERSITY OF SCIENCE AND TECHNOLOGY

INTRODUCTION: Muscle deficiency, a condition commonly associated with aging, is characterized by the progressive loss of muscle mass, strength, and function, collectively referred to as sarcopenia. This degenerative process has been shown to substantially impair postural stability and locomotor ability in older adults, thereby increasing the risk of falls, mobility limitations, and loss of independence. Given that ambulation is a fundamental component of daily living in the elderly population, any decline in walking ability can have profound implications for overall health and quality of life. Falls, often resulting in a cascade of medical interventions, represent a major concern for aging individuals. Since balance dysfunction is a key contributor to fall risk, understanding the relationship between muscle deficiency, balance impairment, and gait alterations is of critical importance. Therefore, this study aims to analyze the effects of muscle deficiency on balance control and walking performance in the elderly.

METHODS: This study recruited elderly individuals diagnosed with sarcopenia ($n = 16$) as the sarcopenia group and age-matched healthy elderly individuals ($n = 17$) as the control group, all of whom participated voluntarily. Static balance and gait performance were assessed using plantar pressure measurement systems. Descriptive statistical analysis was conducted to summarize the characteristics of both groups. An independent sample t-test was employed to evaluate differences in balance capacity and gait parameters between the sarcopenia and control groups. Additionally, a paired sample t-test was used to examine intra-group differences in balance performance under open-eye versus closed-eye conditions, as well as gait parameters under self-selected comfortable versus maximum walking speeds.

RESULTS: Regarding balance, the sarcopenia group exhibited a significantly larger COP sway area (4.95 ± 1.82 cm² vs. 2.84 ± 1.12 cm², $p < .05$) and higher COP movement speed of the center of pressure during open-eye standing balance compared to the control group (1.64 ± 0.66 cm/sec vs. 1.27 ± 0.35 cm/sec, $p < .05$). However, no significant differences were observed between the two groups in closed-eye standing balance performance. Regarding gait, no significant differences were found between the sarcopenia and control groups in gait parameters during self-selected comfortable walking. However, during maximum-speed walking, the sarcopenia group demonstrated significantly shorter stride length (99.48 ± 14.30 cm vs. 116.31 ± 14.17 cm, $p < .05$), lower cadence (114.63 ± 12.61 step/min vs. 126.58 ± 16.63 step/min, $p < .05$), and reduced gait speed (0.95 ± 0.18 m/sec vs. 1.22 ± 0.15 m/sec, $p < .05$), compared to the control group ($p < .05$), while foot angles and step width did not differ significantly between the groups.

CONCLUSION: Elderly individuals with sarcopenia exhibit significantly impaired open-eye balance and maximal-speed gait performance compared to their healthy counterparts. To effectively distinguish between sarcopenic and healthy elderly individuals, open-eye standing balance assessment and maximum-speed walking tests are recommended as more sensitive detection methods.

RUNNING OFF THE BEATEN PATH: A REVIEW OF INJURIES IN TRAIL RUNNING

POCECCO, E., DIELS, S., WOLKENHAAR, E., JAÉN-CARRILLO, D.

UNIVERSITY OF INNSBRUCK

INTRODUCTION: Trail running events take place in natural environments, mostly off-road, and vary in distance as well as vertical gain. Considering its increasing popularity, evidence-based information on trail running related injury (RRI) epidemiology is fundamental in identifying risk factors and hence suggesting preventive strategies for safer practice. Thus, the aim of this study was to summarize the existing literature on injury frequency, characteristics, and risk factors in trail running.

METHODS: A literature search was performed electronically in PubMed from inception to February 12th, 2025, using the terms "(injury OR epidemiol*) AND (trail running OR mountain running)" or running-related terms. From 576 identified records (including duplicates), 12 fulfilled the inclusion criteria for the current review.

RESULTS: Frequency of injury. The incidence of RRIs, including illnesses, during training in the year before a race varies between 28.2% and 71.7% [1,2,3], probably influenced by recall bias. Reported RRIs during single races range from 25% to 56.5% [4,5], according to different definitions of injury.

Injury type. Musculoskeletal trauma is the most commonly reported injury type (17.4%-56%) [2,4,5,6], and usually occurs in training. During races, a higher incidence of dermatologic injuries, such as blisters or lacerations (33%), has been reported [5].

Injury location. The lower leg (15.3%-94%), especially the knee (9.1%-33.2%) and ankle, is the most common location of RRIs [3,5,7,8].

Risk factors. Viljoen et al. [1] reported that being male and having a history of RRIs increased the odds for RRI, while a higher number of running sessions or increasing distance covered lowered the odds of RRIs. However, there is no general consensus on the latter relationships so that protective factors are still not well defined. On the other hand, bone stress injuries are more frequent among older women [9].

CONCLUSION: This review presents the latest knowledge on RRIs. These vary considerably in incidence, mostly affect the musculoskeletal system followed by the skin, are typically localized at the lower leg, and are overall more common among men as well as athletes with injury history.

These results could be the basis for the implementation of evidence-based preventative measures, which are crucial for injury management and performance enhancement. The present findings highlight the need for a deeper understanding of injury mechanisms and potential protective factors as well as the importance of tailoring training plans to reduce injury risks [1,6,8]. Additionally, injury prevention efforts should be reinforced through educational programs for athletes and coaches, providing evidence-based guidance on risk factors, prevention strategies, and early treatment options for RRIs.

Statistics and Analyses

INTERPLAY OF PHYSICAL ACTIVITY, SLEEP QUALITY, AND CHRONOTYPE IN UNIVERSITY STUDENTS' ACADEMIC PERFORMANCE

HADDAD, M., ABBES, Z., ALSHAER, A., MOUSTAFA, A., ABDELSALAM, A.G.

QATAR UNIVERSITY

INTRODUCTION: Physical activity, sleep quality, and chronotype are critical factors that influence cognitive function and academic performance. While physical activity is widely recognized for its physical health benefits, its role in enhancing academic outcomes, particularly in physically active student populations, remains underexplored. This study aims to assess the combined effects of physical activity, sleep quality, and chronotype on academic performance in a cohort of

university physical education students, offering new insights into how these factors contribute to success in physically demanding academic programs.

METHODS: A total of 58 undergraduate students from the Department of Physical Education at Qatar University participated in this study. Participants completed the International Physical Activity Questionnaire (IPAQ) to assess physical activity levels, the Pittsburgh Sleep Quality Index (PSQI) to evaluate sleep quality, and the Morningness-Eveningness Questionnaire (MEQ) to determine chronotype. Academic performance was measured through participants' GPA. Statistical analyses were conducted using IBM SPSS Statistics, Version 29, including Pearson's correlation and multiple regression analyses. Normality was assessed using the Shapiro-Wilk and Kolmogorov-Smirnov tests.

RESULTS: The analysis revealed significant interactions between sleep quality, physical activity, chronotype, and academic performance. A moderate negative correlation was found between sleep quality (PSQI) and GPA ($r = -0.37$), with students experiencing poorer sleep quality ($PSQI > 5$) showing a lower average GPA (2.90) compared to those with better sleep quality ($PSQI \leq 5$), who had a higher GPA (3.26). Although no significant direct correlation was observed between total physical activity (MET-minutes/week) and GPA, students with moderately evening chronotypes reported the highest levels of physical activity (3792 MET-minutes/week). Regarding academic performance, definitely evening-type students had the highest GPA (3.57), while moderately morning-type students had the lowest GPA (2.71). Additionally, sleep quality was associated with chronotype, as evening-type students reported the best sleep quality ($PSQI = 5.00$), further highlighting the role of chronotype and sleep in academic success.

CONCLUSION: This study underscores the importance of chronotype and sleep quality in shaping academic performance, with evening-type students demonstrating both higher physical activity levels and better academic outcomes. Although physical activity did not directly predict GPA, the interaction between physical activity and circadian preferences suggests that aligning physical activity with one's natural chronotype may have beneficial effects on both cognitive and physical performance. These findings highlight the need to consider the combined effects of physical activity, sleep, and chronotype in promoting academic success among students in physically demanding programs.

ANALYSIS OF THE TECHNICAL ELEMENTS OF THE ESTONIAN MENS VOLLEYBALL TEAM AT THE 2023 EUROPEAN CHAMPIONSHIP FINALS.

STAMM, R., STAMM, M., RESIK, K.

INSTITUTE OF HEALTH SCIENCES AND SPORTS

INTRODUCTION: Analysing teams' proficiency about different technical elements at competitions leads to valuable information, which allows coaches to understand the weak and strong sides of the players and change the training plans and methods, which ultimately contributes to the advancement of the team. (Drikos et al., 2022)

The aim of the thesis was to compare the performance indicators of different technical elements in matches won and lost, and to determine their effect on the games result. The specific aims were compare serving indicators, serving reception indicators, attack indicators and blocking indicators in won and lost sets. The study involved the Estonian men's volleyball team. Five matches were analysed from the 2023 final tournament, comprising eighteen sets, of which four were won and fourteen were lost.

METHODS: Data were collected through video observations, where the author recorded serving, serving reception, attack and blocking performances, which were evaluated based on the Data Volley 4. For data processing was used Microsoft Excel. Students t-test in Jamovi was used for comparing data and evaluating relationships.

RESULTS: No significant differences were found between losing sets and winning sets in serving and serve reception performance. Differences were found in attack performance ratings and effectiveness averages between winning and losing sets. Differences were also found in blocking performance rating and effectiveness averages between winning and losing sets.

CONCLUSION: In conclusion one can say that the games what we lost were lost mainly because of our weaker block and attack because these elements were performed statistically significantly weaker in lost sets than in the sets that estonians won. The conclusions drawn from the study could be helpful for coaches in improving the technical elements of the game, helping them understand which technical aspects may be crucial from the perspective of match outcomes and how to improve or optimize them.

Drikos, S., Barzouka, K., Balasas, D., & Sotiropoulos, K. (2022). Effect of quality of opposition on game performance indicators in elite male volleyball. *International Journal of Sports Science & Coaching*, 17(1), 169-177.

HAS COVID-19 INFLUENCED THE PERFORMANCE OF TOP-CLASS ATHLETES IN THE OLYMPIC DISTANCE OF THE ITU WORLD TRIATHLON CHAMPIONSHIP?

GARCÍA-GONZÁLEZ, P., GONZÁLEZ-JURADO, J.A.

PABLO DE OLAVIDE UNIVERSITY

INTRODUCTION: World Championships are attractive to the scientific community and have been investigated in a wide range of sports. The World Triathlon Series (WTS) is the top championship for triathlon in Olympic distance (OD). Sex differences in triathlon performance have been found to depend on discipline and distance, as previous studies have shown (Lepers, 2019). Lepers & Stapley (2010) have asserted that the sex performance gap is narrower in the Olympic distance

when compared to other larger distances. The influence of COVID-pandemic on triathlon is not yet clear. The aim of the present study is to provide a comprehensive analysis of the effect of COVID-19 pandemic on performance in the WTS focusing on male and female categories.

METHODS: The dataset for this study was obtained from the ITU World Triathlon Series (WTS) website (<http://wts.triathlon.org/>). Individual discipline times and overall times from 2018 and 2022 were collected for analysis, excluding 2020 due to the COVID-19 outbreak. The total number included athletes in this study was 1,628 subjects (874 males and 754 females). The mean age of subjects overall was 27.00 for males and 27.59 for females. The Students t-test for independent samples comparing sex was used for normal variables, whereas the Mann-Whitney U-test was used for non-normal variables.

RESULTS: The analysis displayed several significant changes in performance after the COVID-19 pandemic. For men, all the variables changed with a p value lower than 0.001. All variables except for swimming and first transition performance showed better performance values. For women, all variables significantly changed after the COVID-19 pandemic. Swimming, cycling and final performance improved (p values 0.033; <0.001; <0.001 respectively) whereas the running performance decreased (p value 0.003). When examining the relative changes between sexes, four out of six studied variables showed significant differences, being the cycling and the final performance the most significant (p values <0.001). Additionally, the two other variables (swimming and first transition performance), showed a smaller difference (p values <0.05).

CONCLUSION: These results suggest that triathletes from both sexes participating in the Olympic Distance of the WTS were able to not only maintain but also improve their final performance level despite the COVID-19 pandemic, except for the swimming performance. The reason may be because access to swimming pools during the lockdown may have been more complicated than cycling or running training. These findings also highlight the importance of considering specific variables, distances, and sex when assessing the impact of the pandemic on multi-sport performance.

QUANTIFYING MOTOR MOVEMENT DIFFICULTY USING ITEM RESPONSE THEORY: A CASE STUDY OF STRADDLE VAULTING IN THIRD- AND FOURTH-GRADE ELEMENTARY SCHOOL STUDENTS

SANO, T., UEDA, K., KOKUDO, S.

CHUKYO UNIVERSITY

INTRODUCTION: In motor learning, setting appropriate tasks based on an individuals ability is crucial. Overly difficult tasks may lead to a sense of powerlessness and increase the risk of unexpected injuries, while overly easy tasks may decrease motivation. Quantifying motor movement difficulty provides valuable information for designing progressive movement tasks tailored to individual abilities. This study aimed to quantify the difficulty of individual movements that constitute the straddle vault in third- and fourth-grade elementary school students.

METHODS: This study involved 538 children (263 boys and 275 girls) from five elementary schools in Japan. Their straddle vault movements were recorded from both the left and front sides. The movements were evaluated and scored using the observational evaluation criterion (30 items) [1]. After confirming item unidimensionality through factor analysis, item difficulty values (b) were estimated using item response theory (IRT). Additionally, differential item functioning (DIF) was analyzed to assess whether difficulty levels varied by grade.

RESULTS: The IRT analysis revealed that item difficulty values for taking off from a stable run-up (b=-4.952 to -1.833) and shifting weight forward (b=-0.610 to -0.048) indicated that these were low-difficulty movements. The movements required for a bouncy take-off (b=0.131 to 0.360) and stable landing (b=0.012 to 0.816) were of medium difficulty. DIF analysis revealed that third graders found four landing movements—looking at the landing position, closing the legs, flexing the lower limbs, and stopping firmly—more difficult than fourth graders. The movements of turning rotation (b=1.026 to 1.309) and aggressive landing (b=1.152 to 1.806) were highly difficult. The dynamic take-off movements were extremely difficult (b=2.432 to 3.824). Based on this information, a sequence diagram of movements was created, considering both movement timing and difficulty levels.

CONCLUSION: The movements for a stable run-up and weight shift are of low difficulty, making them suitable for early learning stages. The bouncy take-off and stable landing are of medium difficulty, with landing being harder for third graders than for fourth graders. Turning back and aggressive landing are high-difficulty movements that should be learned as skill levels progress. The dynamic take-off is highly difficult and may not need to be mastered by third or fourth graders. Developing a teaching program that considers movement difficulty and verifying its effectiveness will be essential.

DECLARATIVE KNOWLEDGE TEST ON RIGGING IN SAILING COMPETITIONS: CREATING TESTS BY KNOWLEDGE LEVEL

AOYAGI, O., SAKAGUCHI, H., IMAGURA, K.

FUKUOKA UNIVERSITY, JAPAN UNIVERSITY OF ECONOMICS

INTRODUCTION: In sailing, the ability to make decisions in various situations is essential. Decision-making is not simply based on that alone but is also based on a wealth of declarative knowledge. Therefore, the possession of declarative

knowledge is also important as a basis for decision-making. So, we created a knowledge test that asked about the importance of rigging in sailing competitions. However, if there were to be a large number of questions, then for those with a lot of knowledge, the easy questions would be tedious and redundant, while for those with less knowledge, the difficult questions would be too difficult and stressful. Therefore, it was desirable to create a test with a small number of items of varying difficulty that are appropriate to each person's ability.

METHODS: A test consisting of 40 questions on the names of ship riggings was given to 174 people who had participated in a nationwide competition for the general public and a nationwide competition for high school students in Japan. Obtained data were applied to the one-, two- and three-parameter item response models, and we then obtained the item parameters, individual ability parameters θ , and information functions that indicated the accuracy of θ corresponding to the models.

RESULTS: After calculating the BIC for each model, we found that the BIC for the 1-parameter model was 5827; that for the 2-parameter model was 5736; and that for the 3-parameter model was 5747, i.e., that for the 2-parameter model was the lowest, so we adopted the 2-parameter model. The difficulty parameters obtained were mostly around -0.5, gradually decreasing in the negative direction, and the positive parameters were fewer than the negative ones. The discrimination parameter was mostly around 2.0, and while the shape was unimodal, it was relatively even. θ , which indicates the amount of knowledge an individual has, was symmetrically distributed around 0, ranging from -2 to 2. The relatively difficult test items included "Catamaran (difficulty = 3.406, discrimination = 0.221)," "Stern (0.740, 0.843)," "Transom (0.557, 2.030)," and "Halyard (0.099, 1.615), the moderately difficult test items, "Rudder (-1.387, 3.623)," "Bow (-1.449, 2.983)," and "Reach Ribbon (-1.464, 2.636)," and the less difficult test items, "Beam (-4.307, 0.542)," "Abeam (-4.307, 0.542)," "Centerboard (-4.226, 0.362)," and "Raffing (-3.012, 1.087)." Taking into account the difficulty parameter(b), we considered the high ability range to be $\theta=0.0$ to -1.0, the moderate one to be -1.0 to -2.0, and the low one to be -2.0 to -3.0 and set the amount of information to $I=9.0$, which corresponds to a reliability coefficient of 0.9 in classical test theory.

CONCLUSION: As a result, in the high range, 15 items with b of -0.915 or more were required, and in the medium range, 11 items with b of -1.618 to -1.106 were required. However, even when using the 23 items with a low range of $b=-0.971$ or less, it was not possible to cover the lowest part of the range.

ASSESSMENT OF THE DEFENSIVE TRIANGULAR FORMATION IN FOOTBALL

ISHIZAKI, S., SANAKA, Y., YAMAMOTO, D., MURAI, S.

SHIBAURA INSTITUTE OF TECHNOLOGY

INTRODUCTION: Advancements in information technology have facilitated real-time data acquisition during soccer matches and its application in tactical analysis. Measurement of the defensive triangular area can aid in quantifying the probability of scoring and conceding goals. However, data on the defensive triangular area near the penalty area (PA) are limited. Therefore, in this study, we aimed to investigate the defensive triangular areas under different attacking patterns near PA.

METHODS: Twenty matches from the 2023 J-League Division 2 were analyzed and only those without any player dismissal were selected. Match footage was reviewed to identify the instances of defensive success and failure near PA. Attacking patterns were classified into five categories: (A) Passes within PA, (B) passes from outside to inside PA, (C) dribbling within PA, (D) dribbling from outside PA, and (E) shots taken within PA.

Defensive triangle was defined as the area formed by the three nearest defensive players in front of the ball holder at the final moment. Positional coordinates of the defensive players were extracted using a semi-automatic tracking system (Iseyama et al., 2015). Defensive triangular areas were calculated from the XY coordinates and classified based on the attacking patterns (A-E).

RESULTS: Defensive triangular areas were analyzed and classified according to the attacking patterns. In all attacking patterns, the defensive triangular area was significantly smaller during successful defense than during failure ($p<0.05$). Notably, the defensive triangular area during successful defense was the smallest in C ($16.8\pm9.6\text{m}^2$). No significant difference in the defensive triangular area was observed between C and A ($21.2\pm5.7\text{m}^2$); however, the defensive triangular area was significantly smaller in C than in B ($35.8\pm4.6\text{m}^2$), D ($26.3\pm5.9\text{m}^2$), and E ($20.9\pm5.7\text{m}^2$). The defensive triangular area was the largest in B, being significantly larger than those in the other attacking patterns. These findings suggest that defensive players position themselves widely when defending crosses.

During defensive failures, the defensive triangular area was the smallest in A ($37.2\pm3.1\text{m}^2$). No significant difference in the defensive triangular area was observed between A and E ($39.2\pm16.2\text{m}^2$); however, the defensive triangular area was significantly smaller in A than in B ($57.2\pm12.4\text{m}^2$), C ($50.9\pm8.0\text{m}^2$), and D ($43.5\pm5.8\text{m}^2$) ($p<0.05$). These findings highlight the importance of defensive compactness in preventing goal-scoring opportunities.

CONCLUSION: This study analyzed the defensive triangular areas under different attacking patterns near PA and showed that successful defense is associated with a significantly small triangular defensive area. Our findings suggest the defensive triangular area as a valuable metric to determine the defensive effectiveness near PA.

A TEST OF DECLARATIVE KNOWLEDGE OF SAILING THEORY IN SAILING COMPETITIONS

SAKAGUCHI, H., AOYAGI, O., IMAMURA, K.

JAPAN UNIVERSITY OF ECONOMICS

INTRODUCTION: In sailing, the ability to make decisions and judgments that should be performed in a split second under various conditions is required, but these judgments are not made based solely on this ability, and a wealth of declarative and procedural knowledge is needed as a foundation. Therefore, in this study, we created a knowledge test that asked about important sailing theory in sailing competitions. We used the item response theory to estimate ability because the number of correct answers and ability are not necessarily linear. In particular, we proposed a simple method with a correspondence table with the number of correct answers, in which complex calculations were not required.

METHODS: A test consisting of 28 questions about sailing theory was conducted on 174 people who had participated in prefectural and nationwide tournaments in Japan and who had agreed to the aims of this research. We applied one-, two-, and three-parameter models in the item response theory to the data, which had been converted so that the correct answers were scored 1 and the incorrect ones 0, and we selected the model with the best fit using BIC and then obtained the item parameters and individual ability parameters corresponding to that model.

RESULTS: After calculating the BIC for each model, the BIC for the one-parameter model was the lowest, at 4674, while that for the two-parameter model was 4691, and that for the three-parameter model was 4685. These results allowed us to select the three-parameter model. The values of the individual ability θ obtained were generally within the range of ± 2.0 and were symmetrical around 0, with the most distribution of values mainly between $\theta = -0.3$ and $\theta = 0.7$. The difficulty parameter, which indicates the difficulty of the test items, was the lowest for "Close-hauled angle" at -5.543 (standard error = 1.012), followed by "Heel" at -3.115 (0.347); "Tacking" at -2.726 (0.302); and "Jibing" at -2.643 (0.294), which were relatively low in difficulty. On the other hand, "Sail shape wrinkle" was the most difficult, with a difficulty parameter of 2.805 (0.311), followed by "Outhaul" with 1.621 (0.222), then "St. bend wrinkle" with 1.302 (0.209), and subsequently "Cunningham" with 0.951 (0.198), and "Side-jibe instructions" with 0.822 (0.195), which were relatively difficult items. These difficulty parameters were the most frequent between $\theta = -1$ and $\theta = 0$ and were almost evenly distributed, but there was a slight skew towards lower difficulty. In addition, the information function, which indicates the accuracy of the θ estimation, showed a maximum value of 4.8 around $\theta = -0.7$, indicating that the θ value in this area was estimated to have the highest accuracy. This corresponded to a reliability coefficient of 0.83 in classical test theory.

CONCLUSION: Finally, we proposed a converting table corresponding to the number of correct answers and θ values one-to-one by having calculated it in advance, which should allow us to calculate θ values conveniently.

VENTILATORY THRESHOLD POWER PREDICTION MODEL FOR FUNCTIONAL THRESHOLD POWER TESTING IN RECREATIONAL TRIATHLETES

LI, T., HSU, W.1, LIN, Y.2

NATIONAL TAIWAN UNIVERSITY OF SCIENCE AND TECHNOLOGY

INTRODUCTION: Previous studies often use training zones to develop training prescriptions, with the three-zone, two-threshold model based on ventilatory thresholds (VT1 and VT2) being the gold standard for setting exercise intensity[1-3]. However, measuring ventilatory thresholds requires expensive equipment and trained personnel[4]. Therefore, this study aims to develop a pedaling power prediction model for ventilatory thresholds using the more accessible Functional Threshold Power (FTP) test, providing a simple and fast method for recreational triathletes in Taiwan to adjust their training prescriptions.

METHODS: This study recruited 22 recreational triathletes (13 males, 9 females) who completed an FTP and cycling-graded exercise tests on separate days. Physiological parameters (e.g., heart rate, power, core temperature) were measured during the FTP test, while ventilatory threshold (VT) and their corresponding power outputs were determined from the graded exercise test. Stepwise multiple linear regression was used to develop pedaling power prediction models for different VT.

RESULTS: The results showed that in the prediction model for VT1 power, the maximum heart rate reserve (MaxHRR) during the 20-minute FTP stage was the primary predictor, explaining 90.8% of the total variance in VT1_Power (W), with an adjusted R^2 of 89.6%, indicating a high predictive ability. The prediction equation was $VT1\_Power (W) = 993.192 - 8.956 \times MaxHRR$. For the VT2 power prediction model, FTP value and the average core temperature (AvgCoretemp) during the 20-minute FTP stage were the key predictors, explaining 93.5% of the total variance in VT2_Power (W), with an adjusted R^2 of 91.6%, demonstrating an excellent predictive ability. The prediction equation was $VT2\_Power (W) = 2931.049 + 0.772 \times FTP - 74.519 \times AvgCoretemp$. However, previous studies on ventilatory threshold prediction using multiple linear regression models incorporating multiple indicators remain limited, with most research relying on single-variable correlation models[5].

CONCLUSION: Indicators from the widely used FTP test can accurately predict ventilatory threshold power. The high accuracy of the prediction models suggests that FTP testing can effectively replace traditional cycling-graded exercise tests, providing valuable guidance for athlete training. This offers a practical alternative for recreational triathletes and supports using FTP testing in sports science.

Training and Testing

THE VALIDITY OF THE ITALIAN TALK TEST FOR MEASURING EXERCISE INTENSITY IN HEALTHY ADULTS

FESTINO, E., PAPALE, O., DI ROCCO, F., DE MAIO, M., FOSTER, C., CORTIS, C., FUSCO, A.

UNIVERSITY OF CASSINO AND LAZIO MERIDIONALE

INTRODUCTION: Talk Test (TT) is a simple method for measuring exercise intensity and estimating the ventilatory threshold (VT). It has been validated and used in several languages, such as Spanish and English, but no validation is available in Italian. Therefore, this study aimed to validate the Italian version of the TT (ITT) as a method for exercise prescription in the adult population.

METHODS: 14 healthy participants (24.6 ± 2.9 yrs) performed two testing sessions: one submaximal incremental treadmill exercise test (SITE) during which each individuals' ventilatory threshold (VT) was assessed via respiratory gas analysis, and one ITT following the same protocol. The SITE involved 3-min warm-up at 1% slope, followed by a 1 km/h speed increase every 2 minutes. In the last 30s of each stage, heart rate (HR), Rating of Perceived Exertion (RPE, Borg CR10 scale), and speed (km/h) were recorded. In the ITT, participants read aloud the Italian version of the Olympic Oath and were asked, "Can you speak comfortably?" with three possible responses: yes, not sure, or no. The last "yes" stage was considered the last positive (LP), the first "not sure" stage the equivocal (EQ), and the first "no" stage the negative (NEG). To investigate concurrent validity, Pearson's correlation coefficient (r) was used to assess ($p < 0.05$) the relationship between HR, RPE, and speed at LP, EQ, and NEG during the ITT and the corresponding variables at VT recorded during SITE. Bland-Altman plots and 95% limits of agreement (LoA) were used to evaluate the level of agreement between HR, RPE, and speed variables from the ITT and SITE.

RESULTS: EQ (HR= 167.6 ± 11.6 bpm; Speed= 8.9 ± 2 km/h; RPE= 3.6 ± 0.9 AU) and VT (HR= 166.5 ± 9.6 bpm; Speed= 9.2 ± 2.4 km/h; RPE= 2.8 ± 0.9 AU) showed a very good to excellent correlation, with significant relationships for HR ($r=0.78$, $p < 0.001$) and speed ($r=0.97$, $p < 0.001$).

For RPE, a moderate correlation ($r=0.55$, $p=0.040$) was observed between LP (2.5 ± 0.9 AU) and VT. Bland-Altman plots indicated good agreement between EQ and VT, with mean bias of 1.14 bpm for HR (LoA ranging from -12.97 to 15.25 bpm), and -0.29 km/h for speed (LoA ranging from -1.48 to 0.91 km/h) values. Bland-Altman plots supported the significant relationship between LP and VT, where the mean bias was of -0.25 AU for RPE (LoA ranging from -1.87 to 1.37 AU) values.

CONCLUSION: The EQ stage of the ITT is a practical and valid surrogate for VT in exercise prescription for healthy Italian adults. When participants were unsure about speaking comfortably, they exercised at an intensity measured by HR and speed comparable to VT. The discrepancy in RPE results, where RPE at VT aligns more closely with LP intensity, may be due to a timing mismatch. While HR and speed increase at the start of each stage, RPE is recorded at the end, reflecting accumulated effort. This lag in perceived exertion may explain its misalignment with the other physiological variables.

KINEMATIC ANALYSIS OF FOREHAND STROKES IN SENIOR ELEMENTARY TABLE TENNIS PLAYERS

TSENG, G., LIU, C.C., CHEN, P.C., LIN, Y.J., HUANG, B.W.

KAOHSIUNG CHANG GUNG MEMORIAL HOSPITAL

INTRODUCTION: Table tennis is one of the ten most popular sports globally, ranking seventh with 850 million fans as reported by Sports Show in 2020. The forehand stroke is a fundamental skill in table tennis, critical for generating ball speed during impact with the racket. It is also a relatively simple technique for beginners to master in introductory training. By incorporating scientific methods, this study aims to enhance the quality and efficiency of training for table tennis players.

METHODS: Four senior elementary school table tennis players (mean age: 11.5 ± 0.25 years, mean height: 144.3 ± 3.03 cm) were engaged for evaluation. Each participant performed six forehand movements, divided into two stance types: (1) Standing with feet shoulder-width apart and straight, (2) Standing with knees bent and feet positioned forward and backward. For each stance, players executed three hitting methods: (1) Hand moving while the body remained still, (2) Body moving while the hand remained still, (3) Hand and body moving together. Each action involved hitting the ball 10 times, resulting in a total of 240 forehand hits.

We assessed various parameters, including swing time, racket horizontal displacement, bat face angle, elbow joint angle changes, and hitting accuracy. Kinematic measurements were conducted using Kinovea motion analysis software. Statis-

tical analysis was performed with SPSS 22.0, using Pearson correlation analysis to explore relationships among parameters such as ball speed, bat face angle, racket horizontal displacement, swing time, and elbow joint angle across different hitting movements. Statistical significance was set at $P < 0.05$.

RESULTS: The research demonstrates significant correlations between hand length, forearm length, shoulder width, and ball speed ($P < 0.05$). Additionally, when standing with knees bent and feet positioned in a forward-backward stance, participants exhibited a shorter racket swing time, greater horizontal displacement of the racket, faster ball speed, and higher hit scores.

CONCLUSION: This pilot study revealed that optimizing swing time, racket horizontal displacement, bat face angle, and elbow joint angle can improve the quality of forehand strokes in table tennis. These findings provide valuable insights for coaches and players, offering a scientific basis to enhance training methods.

EXPLORING THE LINK BETWEEN LANDING TECHNIQUE AND INJURY RISK IN ADOLESCENT FEMALE SOCCER PLAYERS: A LESS SCORE ANALYSIS

PARPA, K., PALUDO, C.A., MOUBARAK, M., MICHAELIDES, M.

ULCLAN UNIVERSITY OF CYPRUS

INTRODUCTION: The Landing Error Scoring System (LESS) is a clinical assessment tool commonly used to evaluate landing techniques and movement patterns associated with injury risk. This study aimed to investigate the link between LESS score and injury occurrence in female adolescent soccer players.

METHODS: Seventeen adolescent female soccer players (age 15.47 ± 0.72 years, weight 57.81 ± 7.93 kg, height 159.99 ± 5.26 cm) participating in the girls U-18 Championship were recruited for the study. The landing technique of the players was evaluated using the LESS score (0-19 errors score), with video recordings captured from frontal and sagittal views using the KINOVEA software. The assessment was conducted prior to the pre-season preparation period, and the players were monitored throughout the season. During the season, the medical personnel were instructed to report any injuries sustained during official games or training sessions that resulted in the players' inability to continue participating. Only non-contact injuries that were clinically diagnosed and resulted in an absence from training or competition for at least seven days were included. For the statistical analysis, the players were divided into two groups for comparison: those who sustained injuries throughout the season and those who remained injury-free.

RESULTS: Results indicated that 35.29% of the players sustained a non-contact injury during the season. Furthermore, the independent samples t-test demonstrated that the injured players ($n = 6$) had significantly higher LESS score compared to the non-injured players ($n = 11$) (injured: 8.17 ± 1.17 ; non-injured: 5.36 ± 1.29 , $p < 0.01$).

CONCLUSION: These findings indicate that injured female soccer players demonstrated poorer landing mechanics compared to the non-injured group, as reflected by higher LESS scores assessed prior to injury. Although the reliability of screening tests in identifying individuals at increased risk for sports injuries is debatable, these tests can still offer valuable insights. When used in combination, screening tools such as the LESS score could enhance the ability to identify high-risk female soccer players by detecting errors in landing mechanics and movement patterns.

ASYMMETRY OF CHANGE OF DIRECTION PERFORMANCE IN SHUFFLE MOVEMENT AND 505 TEST AMONG COLLEGE BASKETBALL PLAYERS

PENG, W., MENGDE, L.

BEIJING SPORT UNIVERSITY

INTRODUCTION: examine the difference and asymmetry in change of direction in shuffle movement (CoDS) performance among basketball players

METHODS: assess the correlation and directional agreement between asymmetry scores of CoDS, 505, and single leg jump tests. Forty-two college basketball players performed three trials of the CoDS, 505, single leg countermovement jumps, lateral jumps, broad jumps, and drop jumps tests for each leg, with the best performance used for the final analysis.

RESULTS: The dominant (D) limb was defined as the side that performs better, while the non-dominant (ND) limb is the opposite. Asymmetry scores were calculated using the formula: $(D - ND) / D \times 100\%$. Significant differences were found in CoDS ($ES = 0.49$, $p < 0.01$) and 505 ($ES = 0.34$, $p < 0.01$) performance between D and ND limbs. There was no significant correlation between the asymmetry scores in CoDS and 505 ($p > 0.05$). The Kappa coefficients between CoDS, 505 and single leg jump tests showed poor to slight agreement (Kappa range from -0.07 to 0.22) regarding asymmetry direction.

CONCLUSION: These results suggest that practitioners should specialize in assessing CoD asymmetry in both forward-backward and lateral movement performance.

THE DEVELOPMENT OF THE PSOAS MAJOR MUSCLE IN THREE POSITIONS OF CHEERLEADER

SUGIYAMA, K., WATANABE, A., UMEDA, T., HIRASAWA, H., TACHIBANA, M., HOJO, T.

DOSHISHA UNIVERSITY

INTRODUCTION: In cheerleading, the technical demands of high performances increase the risk of injuries. To prevent injuries in cheerleading, proper posture and core stability are required (Goto. 2001). Especially in top position (TP), main-

taining their posture in unstable conditions such as stunts and pyramids is needed. Therefore, top position requires greater core muscle strength than base (BP) and spot positions (SP) for balance during performances. Among the core muscles, the psoas major muscle is especially important, as it connects the torso to the lower limbs, playing a central role in stabilizing posture and enhancing performance (Andersson. 1997). Also, it has been reported that there is a correlation indicating that a larger cross-sectional area of the psoas major muscle is associated with reduced anterior-posterior sway of the center of gravity (Ozawa. 2006). From this, it can be inferred that TP, which particularly requires more postural stability in their performance than other positions, may have more developed psoas major muscle compared to other positions. The purpose of this study was to evaluate the differences in core muscle development among three positions in cheerleaders with cross-sectional area (CSA) of the psoas major muscles.

METHODS: The study involved 32 female cheerleaders aged 18 to 22 from a competitive university team (9 TP, 15 BP, and 8 SP). We measured height, weight, BMI, and muscle mass. MRI imaging at the L4-L5 intervertebral space was used to measure the psoas major muscle CSA and spinel CSA and calculate the psoas major muscle-to-spinel ratio (ps-R). An independent t-tests with Bonferroni correction were applied to compare the three positions: TP, BP and SP. Additionally, independent t-tests were applied to compare between two groups: TP and the others (BP and SP: BSP).

RESULTS: Height was significantly taller in SP than in TP and BP, and BSP was also significantly taller than in TP. Weight and BMI were significantly lighter and lower in TP than in BP and SP. Muscle mass was significantly greater in BP and SP than in TP. No significant differences in the ps-R were observed among the three positions. However, the ps-R was significantly higher in TP than in BSP.

CONCLUSION: Results of this study shows that TP is smaller in height, lighter in weight, and has higher ps-R than the other positions. The high ps-R in TP suggests that necessity of the psoas major muscle is higher in TP than the other positions for balance and stability, and the necessity induces the development of the psoas major muscle in TP which has high risk of serious injuries caused by falling.

This study highlights the importance of the psoas major muscle especially in TP, preventing injury and improving performance. Therefore, positive training of core muscle should be essential in TP.

THE PROFILE OF HIP ROTATION RANGE OF MOTION AND BATTING PERFORMANCE IN COLLEGIATE BASEBALL PLAYERS

CHANG, H., CHIU, C.W., CHEN, C.L.

NATIONAL TAIWAN SPORT UNIVERSITY

INTRODUCTION: A restricted hip rotational range of motion (ROM) may impede the efficient transfer of energy from the lower limbs to the trunk and upper extremities during throwing or hitting, thereby increasing the risk of hip, groin, or lower back injuries. Maintaining adequate hip joint mobility is crucial for baseball players to optimize performance and reduce injury risk. This study aimed to assess the bilateral hip rotational ROM, evaluate hitting performance, and analyze the correlation between hip rotational ROM and hitting performance among collegiate baseball players.

METHODS: Forty-three collegiate baseball players from Taiwan (mean height: 178.2 ± 5.7 cm, mean weight: 79.2 ± 9.5 kg, mean age: 17.3 ± 0.7 years) participated in this study. Hip internal and external rotation range of motion (ROM) for both the leading and axial legs was measured in a seated position using an electronic goniometer application integrated into a mobile phone. On the same day, hitting performance—specifically bat speed and peak hand speed—was assessed using a Blast baseball swing analyzer sensor attached to the butt end of the bat. Each player completed five repetitions of tee-batting. A non-parametric Wilcoxon signed-rank test was conducted to compare differences in hip internal and external rotation ROM between the leading and axial legs, while Spearman's rho correlation coefficient was used to examine the relationship between hip rotational ROM and hitting performance.

RESULTS: The hip internal rotation ROM of the players exhibited a trend of being slightly greater in the lead leg ($31.8 \pm 9.8^\circ$) compared to the pivot leg ($29.5 \pm 8.8^\circ$). However, the difference was not statistically significant ($p = .172$). Conversely, the hip external rotation ROM showed a trend of being slightly lower in the lead leg ($27.0 \pm 8.7^\circ$) compared to the pivot leg ($28.8 \pm 8.7^\circ$), with no statistically significant difference observed ($p = .288$). The bat speed was 65.7 ± 5.7 km/hr, with a maximum hand speed of 19.1 ± 1.9 km/hr. Further analysis revealed a moderate negative correlation between the external rotation ROM of both the lead and pivot legs and bat speed ($\rho = -0.427$ and -0.401 , $p < .05$).

CONCLUSION: In collegiate baseball players, the external rotation ROM of both the lead and pivot legs have a greater influence on bat speed during hitting.

EFFECT OF CORE TRAINING ON STRIKING VELOCITY AND FUNCTIONAL PERFORMANCE IN TEENAGE TABLE TENNIS PLAYERS

LU, Y., TU, M.H., CHANG, C.Y., CHAN, K.H.

SOOCHOW UNIVERSITY

INTRODUCTION: Table tennis is a sport that demands agility, coordination, reaction time and strength. Striking the ball relies on both lower and upper limb strength. Improving core muscle stability through targeted core training can significantly enhance various functional performances, which may further increase ball velocity and enhance table tennis performance. However, previous studies have not specifically examined the effects of a core training program on functional ability and striking velocity in youth table tennis players. Therefore, the aim of this study was to investigate the effects of a 5-week core training program on forehand stroke velocity and the functional performance of dynamic balance, agility, and core endurance in teenage table tennis players.

METHODS: Thirty teenage table tennis players (age range: 13–17 years) were recruited for the study. Participants underwent functional performance tests of the star excursion balance test (SEBT), agility T-test, and 1-minute sit-up. Additionally, their forehand stroke velocity in table tennis was measured. Participants were divided into experimental and control groups based on their forehand stroke velocity, with 15 players in each group. All participants completed 12 sessions of regular training over six days per week. After completing their morning specialized training, participants in the experimental group additionally performed a core training program lasting 30–40 minutes, three times per week for five weeks. Functional performance and striking velocity tests were conducted again two days after the five-week experimental period. Data were analyzed using a mixed-design two-way ANOVA to examine differences in dependent variables between the groups and time points.

RESULTS: Following five weeks of training, the 1-minute sit-up test performance in the experimental group improved significantly compared to the pre-training ($p < .05$) and was also significantly higher than that of the control group ($p < .05$). The agility T-test performance in the control group declined significantly post-training and was also significantly worse than that of the experimental group ($p < .05$). Moreover, the SEBT performance of the non-holding racket side support leg in the experimental group improved significantly after training compared to pre-training ($p < .05$), whereas no significant difference was observed in the control group. On the other hand, the SEBT performance of the holding racket side support leg and forehand stroke velocity in table tennis showed no significant difference between pre-training and post-training in both groups.

CONCLUSION: Engaging in a progressive core training program three times per week for five weeks enhances dynamic balance and abdominal muscular endurance in teenage table tennis players but has no significant effect on forehand stroke velocity.

IS MUSCLE OXYGENATION ASSOCIATED WITH HAEMATOLOGICAL STATUS IN ELITE FEMALE SPEED SKATERS?

MALCZEWSKA-LENCZOWSKA, J., KLUSIEWICZ, A., REBIS, K., GRANDA, D., KOWALSKI, T., SURALA, O., SZCZEPANSKA, B.
INSTITUTE OF SPORT- NATIONAL RESEARCH INSTITUTE

INTRODUCTION: Changes in the muscle tissue oxygenation, metabolism and haemodynamics in response to exercise remain understudied [1]. Additionally, the relationship between the body's haematological status and tissue oxygenation remains relatively unexplored, with inconclusive findings [2,3]. The aim of this study was to analyze the relationship between the amount of haemoglobin in the body - assessed by blood count indices and by carbon monoxide (CO) rebreathing method - and near-infrared spectroscopy (NIRS) indices at rest, during a 2-minute time trial, and post-exercise recovery.

METHODS: Fourteen, healthy, elite female speed skaters (aged 20.5 ± 3.8 years) performed a 2-min time trial (TT) on Watt-bike Air trainer, simulating a 1,500 m race effort on ice, during which the average and maximum power (P_{mean} , P_{max}), as well as blood lactate concentration at 3 minute after exercise, were measured. Haematology status was assessed with two methods: blood morphology and total haemoglobin mass (tHbmass). Blood morphology parameters i.e haemoglobin concentration ([Hb]), hematocrit (Hct) and red blood cells (RBC) were assessed using haematology analyser (Sysmex 100X). tHbmass, plasma volume (PV), blood volume (BV) and red cell volume (RCV) were determined using CO rebreathing method. Local oxygenation (SmO_2) was measured during exercise and recovery using NIRS with the Moxy device in the vastus lateralis. The following oxygenation parameters were measured: $SmO_{2baseline}$, SmO_{2min} , SmO_{2max} , ΔSmO_2 , half-time of local muscle re-oxygenation and local haemoglobin concentration (tHblocal). Pearson's correlation was applied to explore the association between all variables.

RESULTS: The haematological status assessed both by blood morphology parameters ([Hb], Hct, RBC) and by parameters of CO rebreathing method's (tHbmass, EV, PV and BV) was not associated with any indicators of muscle oxygenation and with tHblocal during the entire observation period. tHbmass, RCV and BV ($p < 0.001$) were positively associated only with relative value of P_{mean} achieved during 2-minute TT.

CONCLUSION: The results indicate that regardless of used assessment method, haematological indices do not affect muscle oxygenation at rest, during exercise and post-exercise recovery. This suggests that tHblocal may reflect local blood flow in the microvascular system rather than overall haematological status. When evaluating exercise capacity, total haemoglobin mass and intravascular volume indices appear to be more relevant than commonly used blood count parameters.

ANALYSIS OF PHYSICAL STRENGTH FACTORS THAT CAN PREDICT THE COMPETITIVE PERFORMANCE OF JAPANESE FEMALE TENNIS PLAYERS

KOYA, N., KITAMURA, T.
DAIDO UNIVERSITY

INTRODUCTION: Technical skills are the predominant factors in tennis [1]; therefore, players spend significant time on the court for technical training with a racket. Notably, devoting exactly the same amount of time to on-court technical training

as to physical training without a racket is difficult. However, as the competition level increases, players often realize the importance of physical strength and fitness [1, 2, 3]. Because higher physical strength is required for a higher competition level, clarifying the extent of the difference between domestic and global levels would be practically useful as a developmental training indicator. Research on differences in physical strength depending on the competition level is still in the developmental stage; therefore, attempting to quantify these factors is important for designing training programs in tennis. Therefore, the aim of this study was to assess physical strength factors that serve as guidelines for competing in world-class tennis and examine the physical strength indicators in Japanese female tennis players. Male players have been assessed previously; therefore, differences between male and female players were assessed.

METHODS: In this study, 71 female tennis players performed six physical strength tests (5 m sprint, t-test, 505-agility test, vertical jump (VJ), medicine ball throw (MBT), and shuttle run [converted to VO2max]). The Japan Tennis Association ranking points per one tournament (JTA/1T) were used as indicators of tennis competition levels. Pearson's product-moment correlation coefficient was used to assess the association between ranking and physical strength. Principal component analysis (PCA) was performed on the physical strength variables and PCA1 was used as a comprehensive index of physical strength. Multiple regression analysis was performed with JTA/1T as the dependent variable and each physical strength test item as the independent variable to identify the physical strength items that affected the ranking. Based on these results, a regression formula was constructed to predict the rankings. Statistical significance was set at $P < 0.05$.

RESULTS: Multiple regression analysis was performed on 71 female tennis players, and a significant regression equation was observed using shuttle run (VO2max), the 505-agility test, and MBT as independent variables to predict rankings ($Y = -7201.472 - 329.548x_1 + 5024.562x_2 + 527.064x_3$ (x_1 : VO2max, x_2 : 505 agility test, x_3 : MBT), $F = 4.625$, $p = 0.005$). The contribution rate of this equation was 17.2% ($r = 0.414$); indicating that 17.2% of the rankings can be explained by the shuttle run (VO2max), the 505-agility test, and MBT.

CONCLUSION: The novel finding of this study was that in Japanese female tennis players aiming to become world-class players, physical strength factors are related to shuttle run (VO2max), the 505-agility test, and MBT. Furthermore, these indicators can be used to identify talent among junior players.

COMPARISON BETWEEN CROSS-SECTIONAL AND LONGITUDINAL DATA FOR CHANGES IN ANTHROPOMETRIC AND PERFORMANCE MEASURES FROM 11 TO 17 YEARS OLD IN JAPANESE MALE SPEED SKATERS

KUMAGAWA, D., IMAWAKA, T., NOSAKA, K.

KOKUSHIKAN UNIVERSITY

INTRODUCTION: Investigating longitudinal changes in physical fitness, motor skills, and athletic performance of children is important to understand whether they are positively responding to training, and achieving their goals (1). While longitudinal data can provide growth and developmental changes in individuals, obtaining such data takes time and effort, thus conducting longitudinal studies is a challenge. On the other hand, cross-sectional studies make it easier to collect large samples in a relatively short period of time, but the rate of change derived from the cross-sectional data may not represent longitudinal individual changes. In fact, it has been shown that differences in growth changes exist between the two types of data, suggesting that cross-sectional data may over- or underestimate growth and development, especially during adolescence (2). This may be due to how the two data sets are compared, and how the data were collected (3). The present study compared the cross-sectional (CS) and longitudinal (LT) data collected over the same period for junior speed skaters in the same region for their changes in anthropometric and performance measures.

METHODS: Male speed skaters aged from 11 to 17 years old, who had belonged to a same speed skating club in Japan were used in the present study. The CS data consisted of 404 male skaters of 11 ($n=60$), 12 ($n=67$), 13 ($n=73$), 14 ($n=69$), 15 ($n=53$), 16 ($n=40$) and 17 years ($n=42$) taken between 2004 and 2019. The LT data followed 11 male skaters for six consecutive years (11 to 17 y) in the period. Outcome measures included height, body mass, body mass index (BMI), lower limb circumference, lower limb muscle thicknesses (MT), peak power during 10-s maximal bicycle pedaling (MANP), peak skating velocity on a sliding board (PSV), and average ice-skating speed in 500-m calculated from individual time in each year (SP500). Importantly, the same investigator took the measures of MT, MANP and PSV. A two-way ANOVA was used to compare changes in the outcome measures over 6 years (11 to 17 y) between the CS and LT data.

RESULTS: The average values of the outcome measures were not different ($p=0.795-0.999$) between the CS and LT data at any age (e.g., BMI: 21.7 ± 2.0 vs 22.3 ± 2.3 kg/m²; thigh anterior MT: 60.5 ± 5.1 vs 60.5 ± 4.5 mm; MANP: 1022 ± 141 vs 1026 ± 164 W; PSV: 3.21 ± 0.25 vs 3.11 ± 0.21 m/s; SP500: 12.5 ± 0.4 vs 12.5 ± 0.4 m/s at 17 years). Changes in the measures from 11 to 17 years were not different ($p=0.750-0.998$) between the CS and LT data.

CONCLUSION: The results showed that changes in the anthropometric and performance measures over the 6 years were similar in the CS and LT data. This suggests that longitudinal development of individuals can be predicted well by cross-sectional data obtained for junior athletes.

IMPACT OF INTENSE GLYCOLYTIC EFFORTS ON ANAEROBIC POWER AND LACTATE LEVELS IN ELITE VS. SUB-ELITE 400-METER SPRINTERS

MASTALERZ, A., JOHNE, M., MRÓZ, A., BOJARCZUK, A., STASTNY, P., PETR, M., KOLINGER, D., PISZ, A., VOSTATKOVA, P., MACULEWICZ, E.

UNIVERSITY OF PHYSICAL EDUCATION IN WARSAW

INTRODUCTION: To improve anaerobic performance, coaches and athletes focus on speed endurance training. Successful 400-m performance requires a fast start, followed by a relative decrease in velocity during the final 100 meters. Blood lactate (LA) levels are commonly used to evaluate anaerobic metabolism, exercise intensity, lactate threshold, and recovery, offering valuable insights into metabolic demands during various physical activities. Post-exercise lactate concentration is particularly informative about the workload and its impact on recovery. This study aims to investigate the differences in lactate concentration following maximal anaerobic efforts in a group of 400-m sprinters, further categorized based on performance levels.

METHODS: One hundred thirty male runners were divided into two groups: elite ($n = 66$, body mass = 73.4 ± 7.8 kg, height = 182.1 ± 6.2 cm, age = 20.8 ± 4.0 years) and sub-elite ($n = 64$, body mass = 72.0 ± 7.1 kg, height = 182.1 ± 5.2 cm, age = 20.8 ± 4.0 years). Elite athletes had a 400-m sprint time below 50 seconds, while sub-elite athletes had a personal best above 50 seconds. Power output during countermovement (CMJ) and sequential squat jumps (SSJ) was measured in two sets after a warm-up. This was followed by two intermittent 30-second Wingate tests. Lactate concentration was measured at eight time points.

RESULTS: Maximal power (P_{max}) was significantly higher in the elite group for both Wingate and jump tests (CMJ, SSJ). P_{max} in the second Wingate test was lower in both groups and not significantly different ($p = 0.140$). Elite sprinters had higher lactate (LA) concentrations at most time points, except at rest and post-warm-up. After the first Wingate test, LA accumulation was 9% higher in the elite group up to 6 minutes post-exercise. The sub-elite group showed higher LA clearance at 9 and 12 minutes. At 20 minutes, LA concentration in both groups was similar to the 1st minute. Peak lactate (LA_{max}) occurred at 3 minutes post-Wingate for 40% of both groups, while 32% of elite and 38% of sub-elite reached LA_{max} at 6 minutes. The timing of LA_{max} did not differ between groups. LA kinetics during accumulation (1-3 minutes) and clearance (9-20 minutes) were similar in both groups, with no significant differences between 3-9 minutes.

CONCLUSION: Elite athletes demonstrate higher maximum power and greater lactate concentration following Wingate tests, which can likely be attributed to their adaptation to anaerobic metabolism dominance and the recruitment of fast-twitch muscle fibers during prolonged sprints. This adaptation, along with a more aggressive running strategy, sets them apart from their less experienced sub-elite counterparts. Despite these differences, the kinetics of LA accumulation and clearance were comparable between the two groups. Furthermore, the 400-meter running time was significantly correlated with the rate of LA accumulation from the 1st to the 3rd minute post-effort, but showed no relationship with the rate of LA clearance.

JUMPING ABILITY IN YOUTH AND PROFESSIONAL FOOTBALL PLAYERS

MICHAELIDES, M., PARPA, K.

UCLAN CYPRUS

INTRODUCTION: This study aimed to compare jumping performance between youth and professional football players while investigating potential differences based on playing positions. A total of 96 male athletes participated: 52 professionals and 44 youth players. Jumping assessments included the squat jump (SJ), countermovement jump (CMJ), and eccentric utilization ratio (EUR).

METHODS: Jumping assessments included the squat jump (SJ), countermovement jump (CMJ), and eccentric utilisation ratio (EUR), measured using a Fusion Sport JumpMat (Fusion Sport®, Brisbane, Australia).

RESULTS: Demographic characteristics (mean $\pm$ SD) for professional and youth players respectively were as follows: body fat (7-site) $10.50 \pm 3.88\%$ vs $9.24 \pm 3.28\%$; age 27.37 ± 5.57 years vs 16.20 ± 0.80 years; height 179.78 ± 6.72 cm vs 175.97 ± 5.84 cm; body mass 77.12 ± 6.54 kg vs 66.98 ± 6.19 kg. Professional players demonstrated significantly higher SJ (39.62 ± 3.83 cm) and CMJ (42.52 ± 3.85 cm) compared to youth players (SJ: 33.68 ± 4.72 cm; CMJ: 36.86 ± 4.73 cm; $p < 0.05$). Among professionals, wingers showed superior SJ and CMJ values compared to other positions, while no significant position-based differences were found in youth athletes.

CONCLUSION: Interestingly, the EUR was lower in professionals (1.07) than in youth players (1.10), indicating that youth players relied more on elastic energy during jumps. This observation aligns with prior findings suggesting that younger athletes often compensate for lower muscular strength by leveraging tendon elasticity during dynamic movements. These results underscore the importance of position-specific jump training for professional players and highlight the need to focus on strength development in youth players to enhance explosive performance.

MODE-SPECIFIC RESPONSES DURING TRACK AND TREADMILL RUNNING IN ELITE DISTANCE RUNNERS

SUZUKI, Y., TAKEI, N., SAEKI, T.

TOKYO KEIZAI UNIVERSITY

INTRODUCTION: The translation of laboratory-based assessments to field training prescription represents a critical challenge in endurance sports, particularly at intensities typical of contemporary high-level training. Previous research has

focused primarily on recreational runners at moderate intensities, leaving a significant knowledge gap regarding mode-specific responses in elite athletes training at substantially higher intensities. This study investigated the physiological and biomechanical differences between track and treadmill running using a protocol specifically designed to reflect contemporary training practices.

METHODS: Nine elite male distance runners (5000m season best: 13:47 +/- 0:12, 10,000m season best: 27:58 +/- 0:11) completed identical six-stage protocols on track (300m outdoor) and treadmill (0% gradient) in a randomized crossover design. Each stage comprised 1,200m at velocities progressing from 3:30 to 2:40 min/km, with standardized pacing for track trials. Blood lactate concentration, heart rate, and RPE were measured after each stage. Spatiotemporal parameters were analyzed using high-speed video at 240 Hz during the final 10s of each quarter of the stage. All testing was conducted under standardized environmental conditions with 48h between trials.

RESULTS: Track running elicited progressively higher blood lactate responses compared to treadmill running, with the difference becoming most pronounced at the highest intensity (stage 6: 12.1 +/- 0.6 vs. 8.4 +/- 0.8 mmol/L, $P < 0.001$). This metabolic divergence manifested in significantly lower running velocities at fixed blood lactate concentrations during track running (4 mmol/L: 316.2 +/- 8.4 vs. 328.5 +/- 7.8 m/min, $P = 0.008$; 6 mmol/L: 342.3 +/- 9.1 vs. 356.7 +/- 8.5 m/min, $P = 0.012$). Track running velocities at these thresholds showed remarkably strong correlations with 10,000m season best times (4 mmol/L: $r = -0.950$, $P < 0.001$; 6 mmol/L: $r = -0.973$, $P < 0.001$), while treadmill correlations were substantially weaker (4 mmol/L: $r = -0.703$, $P = 0.054$; 6 mmol/L: $r = -0.695$, $P = 0.061$). Biomechanically, track running exhibited consistently longer stride lengths ($P = 0.008$) and distinct ground contact time patterns at higher intensities ($P = 0.039$), despite similar step frequencies.

CONCLUSION: This study reveals systematic mode-specific differences in metabolic and mechanical responses at training-relevant intensities in elite runners. The strong correlation between track-based measurements and competition performance, coupled with the substantial underestimation of metabolic demand in laboratory assessments, suggests the need for mode-specific adjustments in training intensity prescriptions. These findings have direct implications for optimizing the precision of training prescription in high-performance endurance training.

PHYSIOLOGICAL CHARACTERISTICS OF CROSSFIT TRAINING: COMPARISON WITH TRADITIONAL CIRCUIT TRAINING

OHARA, Y., FERNANDO, H.I., IOANNIS, G.C.

NATIONAL INSTITUTE OF TECHNOLOGY, MATSUE COLLEGE

INTRODUCTION: In sports coaching and physical education, the time available for improving physical fitness is limited due to the various tasks involved in learning sports skills and understanding tactics. Therefore, we focused on CrossFit training (CFT). CrossFit training is a high intensity training methodology where athletes perform a variety of training exercises without rest periods in between sets or exercises. In this study, we compared the physiological load of CFT with that of a traditional circuit training (TCT).

METHODS: High school and college age male students who regularly participated in recreational sports were included in this study. The exercise protocol consisted of 10 squats, 10 burpee jumps, 10 sit-ups, and 10 push-ups in which the subjects performed them in two variations: CFT-style (no rest between exercises and sets) and TCT (including a 15-second rest period). To be able to accurately quantify the training volume and necessary time spent performing these exercise modalities we examined and compared two conditions: test 1) a comparison with unified time (CFT vs. TCT, total volume in 4 min) and test 2) a comparison with unified number of sets to be performed (CFT vs. TCT, 3 total sets in both modalities). In the experiment, the cardiovascular system, metabolic system, and muscle activity levels were quantified using a heart rate monitor (H10, Polar), a blood lactate meter (Lactatepro2, Arkray), and electromyography (Free EMG, BTS). The muscles tested were the triceps brachii (TB), rectus abdominis (RA), and rectus femoris (RF).

RESULTS: In test 1, the mean heart rate during CFT was 88.9% HRmax, post-exercise blood lactate concentration was 15.0 mmol/L, and muscle activity level was 66.2% EMGmvc in the TB, 43.0% EMGmvc in the RA, and 45.6% EMGmvc in the RF. The mean heart rate during TCT was 77.9% HRmax, post-exercise blood lactate concentration was 10.7 mmol/L, and muscle activity levels were 74.9% EMGmvc for TB, 48.5% EMGmvc for RA, and 56.8% EMGmvc for RF. In test 2, mean heart rate during CFT was 91.4% HRmax, post-exercise blood lactate concentration was 15.2 mmol/L, and muscle activity levels were 55.9% EMGmvc for TB, 51.3% EMGmvc for RA, and 55.9% EMGmvc for RF. The mean heart rate during TCT was 87.4% HRmax, post-exercise blood lactate concentration was 16.7 mmol/L, and muscle activity levels were 60.8% EMGmvc for TB, 55.3% EMGmvc for RA, and 48.2% EMGmvc for RF.

CONCLUSION: The results of this study showed that CFT had a greater physiological load on the cardiovascular system than TCT when the time was standardized (Test 1), and CFT had a greater physiological load on the cardiovascular system than TCT when the number of sets was standardized (Test 2). These results suggest that CFT is a training method that can produce a higher physiological load in the cardiovascular system in less time than the TCT, which can potentially provide instructors with a variety of options to train their athletes more effectively in a shorter amount of time per session in the future.

EXAMINING THE RELATIONSHIP BETWEEN TRUNK FLEXIBILITY AND ISOKINETIC HIP STRENGTH PARAMETERS USING WEARABLE TECHNOLOGICAL SYSTEMS

ACAR, S., ÖLMEZ, C.
ORDU UNIVERSITY

INTRODUCTION: The relationship between strength and flexibility is complex. Increased joint flexibility has been shown to enhance muscle power output [1]; however, an excessive focus on muscle strength without adequate flexibility training may elevate the risk of injury [2]. Therefore, the precise assessment of flexibility and strength parameters using reliable measurement systems is essential for injury prevention. This study investigates the relationships between isokinetic hip strength parameters—including force, power, and movement analysis metrics—and multidimensional trunk flexibility measures.

METHODS: This study involved 22 female subjects. Hip strength, peak torque (PT) attainment time, and angles were assessed using the Cybex (Humac Norm) isokinetic dynamometer (CSMI, Stoughton, MA).

Participants flexibility was evaluated using the MyoMotion system (Noraxon, USA). The system utilized five strategically placed sensors to measure lumbar flexion (LMB FLX), lumbar extension (LMB EXT), lumbar lateral (LMB LTR), and lumbar axial (LMB AXI) movements, as well as thoracic flexion (THR FLX), thoracic extension (THR EXT), thoracic lateral (THR LTR), thoracic axial (THR AXI), hip flexion (HFLX), and hip abduction (H ABD) range of motion.

RESULTS: A moderate and statistically significant relationship was observed between participants FLX PT and LMB EXT ($r=0.546$; $p<0.01$), LMB LTR ($r=0.535$; $p<0.05$), LMB AXI ($r=0.454$; $p<0.05$), and H ABD ($r=0.443$; $p<0.05$) flexibility levels.

Additionally, the PT attainment angle during HFLX movement exhibited a similarly significant correlation with LMB LTR ($r=0.438$; $p<0.05$) and H ABD ($r=0.448$; $p<0.05$) flexibility. A moderate significant relationship was also identified between the PT attainment time during HFLX movement and H ABD flexibility ($r=0.431$; $p<0.05$).

In contrast, no statistically significant relationships were found between HFLX strength and other flexibility parameters or between HEXT strength and any of the flexibility measures ($p>0.05$).

CONCLUSION: The findings indicate that increased flexibility does not negatively impact PT production in HFLX and EXT; rather, it supports FLX strength. However, LMB LTR and H ABD flexibility were found to increase the PT attainment angle, while H ABD flexibility also prolonged the time to reach PT. These results suggest that LMB LTR and H ABD flexibility levels should be carefully considered in training and performance assessments, particularly in sports requiring explosive strength.

A BASIC STUDY ON THE IMPROVEMENT OF ATHLETIC PERFORMANCE OF FOOTBALL PLAYERS WITH CEREBRAL PALSY

FUKUSHI, N., LEE, W.2, MIYAMORI, T.3, MOMOI, Y.3
1 KEIO UNIVERSITY.; 2 SENSU UNIVERSITY.; 3 JUNTENDO UNIVERSITY.

INTRODUCTION: Cerebral palsy football (CP football) is a sport created for individuals with relatively mild cerebral palsy and was adopted as an official event at the Paralympic Games since 1984 in New York. Unfortunately, after the 2016 Rio de Janeiro Games, it was dropped as an official sport. However, attempts are being made to popularize it worldwide to make it an official Paralympic sport. Recently, parallel with the World Championships, regional international competitions, such as the European, National, and Asia-Oceania Championships, have been held. However, there is no information on objective accumulation of data by teams using scientific methods to strengthen and nurture their players. Therefore, there has been no continuous effort or handover for the strategic, medium- and long-term planning for strengthening. Therefore, the Japanese CP football community has called for strengthening cooperation with universities and other research institutions to enhance scientific support (Football Science, 2023). Therefore, this study aimed to obtain basic data to help improve the competitiveness of CP football players. Here, we report the results of physical fitness tests conducted on male candidate national team players in CP football.

METHODS: The participants were 11 male Japanese national team 2024 CP football candidates (24.9 ± 4.93 years). The physical fitness test items were 30-m running (10- and 20-m transit time), 5-m x 3 shuttle run, vertical jump, standing broad jump, bounding, and Yo-Yo intermittent recovery test level 1 (YYIR1). Each measurement was performed in accordance with previous studies (Japan Football Association, 2005; Bangsbo and Mohr, 2015; MEXT, 1999; Ariga et al., 2016).

RESULTS: The mean and standard deviation of each fitness test result are as follows; 10-m transit time was 1.98 ± 0.1 s, 20-m transit time was 3.4 ± 0.17 s, 30-m transit time was 4.74 ± 0.23 s, 5-m x 3 shuttle run was 4.46 ± 0.21 s, vertical jump was 47.09 ± 6.11 cm, standing broad jump was 1.88 ± 0.25 m, bounding was 9.64 ± 0.86 m, and YYIR1 was 956.36 ± 361.53 m.

CONCLUSION: The study results revealed the physical fitness characteristics of male Japanese national football team candidates with CP, which remained unclear. Additionally, these results were compared with those of the U-20 Japan National Team (Japan Football Association, 2021) and All-Japan University Selected Team (Japan University Football Association, 2024), all of which showed low values. Therefore, improvement in the physical aspect (physical performance) required for soccer performance is an essential future enhancement measure for Japanese men's national team CP football players.

LACTATE RESPONSE IN ACROBATIC ROCK AND ROLL: THE EFFECT OF AN 8-WEEK TRAINING PROGRAM

CHLAPCOVÁ, A., KALCOKOVÁ, J., KYSELOVICOVÁ, O.

COMENIUS UNIVERSITY - FACULTY OF PHYSICAL EDUCATION AND SPORT

INTRODUCTION: Sport dances are high intensity, intermittent activities that alternate explosive and slow movements, requiring dancers to have specialized skills, a strong aerobic base, and high lactate tolerance [1-3]. Dance engages multiple energy systems with metabolic demands varying according to discipline, intensity, choreography, and length of the routine [4]. The study compares changes in blood lactate levels (La) after the modified competitive routine (CR) of acrobatic rock and roll (ARnR) dancers at the end of the preparatory phase (PP) and the beginning of the competitive phase (CP).

METHODS: The research sample included 8 ARnR dancers from the small formation ladies category (17.10 ± 4.69 years; 54.73 ± 6.61 kg; 162.50 ± 4.28 cm). Dancers had to complete minimum 22 of 27 training units (80%). La was measured using a Lactate Scout device. Measurements were taken at four time points: at rest, immediately after the ARnR CR at 5, 10 and 20 minutes post-exercise. The first measurement (t0) was performed in the final of the PP, the second measurement (t1) after 4 weeks as an interim assessment, and the last measurement (t2) in the initial CP. Repeated measures ANOVA was used to detect changes between treatments, and partial eta-squared was calculated to express the practical effect size. Significant effects were followed by Bonferroni post hoc procedures with Cohens d effect size. Significance was established at $p < 0.05$.

RESULTS: The dancers reached a maximum La of 12.69 ± 2.65 mmol/l (t0), 13.36 ± 1.90 mmol/l (t1) and 18.06 ± 4.39 mmol/l (t2). The difference between all measurements (t0, t1, t2) was statistically significant with a large effect ($F(2) = 6.945$; $p = 0.028$; $\eta^2 p = 0.499$). A significant increase in maximum La was observed after the modified CR in CP vs. PP ($p = 0.040$; $d = 0.899$). The La gradient of dancers decreased by 2.69 ± 2.65 mmol/l (t0), 4.83 ± 2.13 mmol/l (t1) and 10.44 ± 5.14 mmol/l (t2). Statistically significant differences with large effects were found between t0 and t2 ($p = 0.005$; $d = 1.411$). The difference between all measurements was statistically significant with a large effect ($F(2) = 11.204$; $p = 0.008$; $\eta^2 p = 0.615$).

CONCLUSION: The significant increase in maximum La during the CP indicates the effectiveness of specific training focused on resistance to La, with intensified training leading to beneficial adaptations in La tolerance. La gradient values showed a statistically significant difference with a large effect size between measurements. A decreased La gradient is crucial for maintaining performance during prolonged exercise and minimizing fatigue. These findings suggest that the dancers adapted to higher levels of La, enabling their organism to tolerate acidosis. **Acknowledgements:** This work was supported by the Scientific Grant Agency of the Ministry of Education, Research, Development and Youth of the Slovak Republic and the Slovak Academy of Sciences (Nos. 1/0712/24 and 1/0512/25).

COMPARISON OF FULL SQUAT MOVEMENT VELOCITY BETWEEN SMITH MACHINE AND FREE WEIGHTS ACROSS DIFFERENT LOADS IN WOMEN

TSOUKOS, A., BOGDANIS, G.C.

UNIVERSITY OF ATHENS

INTRODUCTION: The load-velocity relationship is fundamental in velocity-based training for accurate and effective load determination [1]. Strength and conditioning coaches commonly utilize both free weights (FW) and Smith machine (SM) to enhance strength and power [2]. However, the mechanical constraints of each method differ, with FW requiring greater stabilization, whereas SM provides a guided bar path, potentially altering neuromuscular activation and movement velocity [3]. While previous studies have highlighted these biomechanical differences, it remains unclear whether velocity differences persist across various loads. This study compares movement velocity in the full squat exercise performed with FW and SM across various loads, assessing their agreement and interchangeability.

METHODS: Eleven women performed a one-RM maximum assessment in the full squat exercise under two conditions (FW and SM) in a randomized order one week apart. Mean velocity (MV) was recorded using a linear position encoder (Tendo Unit). The load-velocity relationships were modeled using linear regression, and velocity values were compared across conditions at eight relative loads (30%-100%). Statistical analyses included a two-way repeated measures ANOVA (2 conditions x 8 loads), Cohens' d effect sizes, Pearson's correlations, typical error (TE) and Bland Altman plots to assess agreement.

RESULTS: The two-way ANOVA (Condition x Load) showed a significant main effect for load ($p < 0.01$; $\eta^2 = 0.97$). Tukey's post hoc tests indicated that MV differed across all loads ($p < 0.001$). No significant main effect was found between FW and SM ($p = 0.35$; $\eta^2 = 0.08$, pairwise Cohen's $d = 0.03$ - 0.12). Pearson correlations of the individual data showed very strong agreement between FW and SM from 30% to 80% of 1-RM ($r = 0.88$ - 0.97). However, at 90% and 100% of 1-RM, the correlations were moderate (0.74 and 0.63 respectively). The typical error of velocity differences was low (0.02-0.025 m/s) at moderate loads (50-80%) and slightly higher at the extremes of the load-velocity relationship (0.03-0.04 m/s). Finally, the Bland-Altman plots demonstrated that the differences in MV between FW and SM were within the 95% limits of agreement, with no values falling outside the limits, suggesting excellent agreement between the two conditions across all loads.

CONCLUSION: These findings indicate that both SM and FW yield comparable MV measurements during the full squat exercise in women making them interchangeable in velocity-based training. The consistency of the results across loads implies that either method can be used with confidence for training prescription, providing flexibility for strength and conditioning coaches in selecting the most appropriate equipment.

KOTOV 1916: AN INSIGHT INTO THE ORIGIN OF TRAINING PERIODIZATION.

BARTOLOMEI, S., MAMMADOVA, G., MANNO, R., HOFFMAN, J.R., HAFF, G.G., MERNI, F.

UNIVERSITY OF BOLOGNA

INTRODUCTION: The debate on the origins of the discipline of training periodization is still ongoing. The text "Olympic Sport", published by B. A. Kotov in 1916, was the first known book to focus on training methods and strategies for performance development. The manuscript is also considered the first to consider training organization and periodization. In addition, Kotov was the only author to cover these topics in Russia before the Soviet Bolshevik Revolution of October 1917.

METHODS: Recently, our research group had the opportunity to translate from Russian language and work on the original text published in 1916 in Russian 1, 2, and on the manuscript published with the pseudonym of "Boko" in 1913 for the journal "Russky Sport"3.

RESULTS: The analysis of Kotov's manuscripts offers an insight into periodization and training at the beginning of the 20th century. The knowledge of the historical events and of the evolution of sport allow this manuscript to be contextualized and to understand the author's attempt to promote a different approach to athletic training. Relevant breakthroughs were included in this manuscript, such as the use of training programs to organize long training periods, the prescription of submaximal training loads based on perceived effort and the use of specific preparation phases. In addition, the text contains one of the first notations of the concept of overtraining.

CONCLUSION: Considering its novelty, "Olympic Sport" represents a revolutionary book and the author can be considered as a fundamental contributor to the development of the discipline of the training theory and a starting point of modern periodization.

THE ASSOCIATION BETWEEN WALKING PARAMETERS AND MAXIMAL OXYGEN UPTAKE DURING THE UKK WALK TEST IN JAPANESE ADULTS

ADACHI, T., ADACHI, H., FUJITA, K., MARUTANI, Y., YOKOYAMA, T.

OSAKA UNIVERSITY OF HEALTH AND SPORT SCIENCES

INTRODUCTION: The UKK Walk Test (UKKWT) is an endurance test developed in Finland, but its validity for Japanese adults has not yet been established. This study aimed to investigate the relationship between walking parameters and maximal oxygen uptake ($\text{VO}_{2\text{max}}$) during the UKKWT in Japanese adults and to assess the influence of walking characteristics on $\text{VO}_{2\text{max}}$ estimation.

METHODS: A total of 102 healthy adults (48 men, 54 women) aged 20–73 years participated in this study. $\text{VO}_{2\text{max}}$ was measured using a treadmill protocol following the method of Laukkanen et al., with breath-by-breath gas analysis performed using the Aero Monitor AE-310S. Heart rate was continuously recorded using a Polar H10 and a Polar M430. The UKKWT was conducted at 80% of heart rate reserve (HRR) according to the UKK Walk Test Tester's Guide. Walking parameters, including stride length (SL), stride frequency (SF), and stride length as a percentage of height (%SL), were derived from cadence data obtained via the accelerometer in the Polar M430.

RESULTS: $\text{VO}_{2\text{max}}$ was 41.99 ± 6.64 ml/kg/min in men and 32.38 ± 5.56 ml/kg/min in women. Walking speed was 120.9 ± 7.5 m/min in men and 108.9 ± 7.5 m/min in women. SL, SF, and %SL were 0.887 ± 0.048 m, 136.5 ± 6.3 steps/min, and $52.3 \pm 2.8\%$ in men, and 0.801 ± 0.052 m, 136.2 ± 6.7 steps/min, and $51.0 \pm 2.7\%$ in women, respectively.

Correlation analysis revealed significant positive correlations between $\text{VO}_{2\text{max}}$ and all walking parameters in men ($r = 0.41$ – 0.72 , $p < 0.01$). SF was not significantly correlated with $\text{VO}_{2\text{max}}$ in women, whereas SL and %SL exhibited significant positive correlations ($r = 0.55$, 0.61 , $p < 0.001$). Age was negatively correlated with $\text{VO}_{2\text{max}}$ (men: $r = -0.56$, women: $r = -0.51$) and walking speed (men: $r = -0.59$, women: $r = -0.39$, $p < 0.01$).

CONCLUSION: The results of this study indicate that $\text{VO}_{2\text{max}}$ is significantly associated with walking speed, SL, and %SL, with SL having the most significant effect on $\text{VO}_{2\text{max}}$. SF was also a significant determinant of $\text{VO}_{2\text{max}}$ in men, whereas no significant association was observed in women. These findings suggest that men increase walking speed by adjusting both SL and SF, whereas women depend primarily on SL.

Additionally, the negative correlation between age and both $\text{VO}_{2\text{max}}$ and walking speed suggests that age-related declines in walking ability may be due to reductions in SL.

The results of this study demonstrate that the UKKWTs walking parameters impact the estimation of $\text{VO}_{2\text{max}}$, with SL and %SL being critical parameters. Future development of a Japanese version of the UKK Walk Test should consider gender—and age-related differences in walking patterns.

VALIDITY OF SPORT-SPECIFIC AEROBIC AND ANAEROBIC TESTS IN PREDICTING THE TIME-MOTION PROFILE IN INTERNATIONAL TAEKWONDO MATCHES

APOLLARO, G., PANASCÌ, M., FRANCHINI, E., MORGANTI, G., FALCÓ, C., RUGGERI, P., FAELLI, E.

UNIVERSITY OF GENOA

INTRODUCTION: The Frequency Speed of Kick Test (FSKT) and the Progressive Specific Taekwondo Test (PSTT) are among the most used sport-specific tests in taekwondo. The FSKT is divided into two versions to assess anaerobic power (FSKT10s) and capacity (FSKTMult) in intermittent mode, while the PSTT allows the determination of both aerobic capacity and power indicators in continuous mode. Although these two tests are widely studied, the relationship between them needs further investigation and their criterion predictive validity has not been established, despite the fundamental importance of this tests' property in practice. Therefore, this study aimed to: i) investigate the relationship between sport-specific anaerobic (FSKT10s and FSKTMult) and aerobic (PSTT) performance; ii) evaluate the validity of the above sport-specific anaerobic and aerobic tests in predicting the time-motion profile in international matches.

METHODS: Sixteen taekwondo black belt athletes (8 males and 8 females; 17 ± 3 years; 12 ± 1 hours training/week) took part in this study. Athletes conducted three distinct experimental sessions. On the first day, the FSKT10s and FSKTMult were performed. After 24 hours, athletes executed the PSTT. Heart rate (HR) was measured, during the FSKTMult and the PSTT, using a HR monitor strap. In the following 1–3 weeks, athletes participated in an official international competition recognized by World Taekwondo. Videos of each athlete's first combat of the day were obtained for the time-motion analysis. All athletes were studied individually, using Kinovea software, and consequently thirty-two performance (tested athlete and respective opponent) were analyzed.

RESULTS: FSKT10s and FSKTMult performance were significantly correlated (Spearman's $\rho = 0.545\text{--}0.759$, $p < 0.05$) with aerobic power indicators of the PSTT. Moreover, FSKTMult performance were significantly correlated ($\rho = -0.606\text{--}0.555$, $p < 0.05$) with aerobic capacity indicators of the PSTT. No significant relationship emerged between anaerobic ($\rho = -0.442\text{--}0.396$, $p > 0.05$) and aerobic ($\rho = -0.462\text{--}0.462$, $p > 0.05$) physical fitness variables and time-motion indexes. All time-motion indexes were significantly correlated ($\rho = 0.756\text{--}1.000$, $p < 0.001$) and they did not differ ($p = 0.498\text{--}1.000$) between the tested athletes and their opponents during international matches.

CONCLUSION: Our results support the assumption that the typical intermittent activity of taekwondo involves high demands on both anaerobic and aerobic metabolism. The specific rhythm of the first official combat of the day, generated by the technical-tactical dynamics between the two interacting opponents, could explain the inability to predict time and frequency spent in the different kinds of actions performed from the anaerobic and aerobic physical fitness variables. However, the athletes' conditioning level would play a key role in supporting the high attack/skipping ratio ($\sim 1:1.3$) of the match.

COMPARISON OF DIFFERENT METHODS FOR ASSESSING SKELETAL MUSCLE MASS: ACCURACY AND APPLICABILITY

SAMPIERI, A., FERRARI, F., CASONATO, E., POLENCIG, D., LISTA, G., CANCIAN, A., CAMPA, F., PAOLI, A.

UNIVERSITY OF PADUA, ITALY

INTRODUCTION: Skeletal muscle mass (SMM) is a key parameter in body composition assessment. Although it can be estimated with high accuracy through imaging techniques, simpler and more cost-effective alternative methods have been developed over the years. This study aimed to evaluate the agreement between anthropometric and bioelectrical-based procedures and Dual-Energy X-Ray Absorptiometry (DXA) in estimating SMM in male and female individuals.

METHODS: A total of 39 males and 27 females (age 34.4 ± 17.9 years, BMI 24 ± 3.1 kg/m²) underwent DXA scans, anthropometric measurements, and bioelectrical impedance analysis (BIA) using five different BIA devices (i.e., AKERN_BIVA_PRO, Tanita_MC780/980, Inbody_570, Technogym Health, Inbody 270). Anthropometric measurements were applied in the Lee equation, while only for the AKERN device that allowed the measurement of raw bioelectrical properties, the Janssen equation was utilized. For DXA-based SMM estimation, the McCarthy equation was used: $\text{SMM (kg)} = \text{appendicular lean soft mass} \times 1.12 - 0.63$.

RESULTS: The analysis of variance for repeated measures showed a significant ($p < 0.01$) effect within subjects measured by different devices for SMM prediction. Post-hoc tests identified significant differences ($p < 0.05$ in all cases), with the lowest values obtained from DXA (25.6 ± 7.3 kg). Bland-Altman analysis was performed comparing DXA with the alternative procedures, yielding the following results: (Anthropometry: mean difference of 1.3, 95% limits of agreement ranging from -6.6 to 9.3; AKERN: mean difference of 2.6, 95% limits of agreement ranging from -1.5 to 6.6; Technogym_Health: mean difference of 6.2, 95% limits of agreement ranging from -11.7 to 24.1; Inbody_570: mean difference of 6.3, 95% limits of agreement ranging from -11.8 to 24.3; Inbody_270: mean difference of 6.0, 95% limits of agreement ranging from -12.3 to 24.2).

CONCLUSION: A general lack of agreement has been identified among methods in the estimation of SMM. Considering the need to develop new predictive equations specific to different populations, only doubly indirect methods that allow the measurement of raw parameters can be used for the development of new regression models. Conversely, the updating of methods that directly provide body composition estimates without allowing the measurement of raw values will be limited for researchers and primarily the responsibility of manufacturers.

DIVERGENT BLOOD LACTATE RESPONSES IN REPEATED SPRINTS VERSUS MAXIMAL AEROBIC SPEED TEST: A COMPARISON BETWEEN MIDDLE-DISTANCE RUNNERS AND SPRINTERS

PARADISIS, G., BELECHRIS, N.P., ZACHAROYIANNIS, E., PETRAKI, D.P., DIAKOSTEFANIS, S., BOGDANIS, G.C.

NATIONAL & KAPODISTRIAN UNIVERSITY OF ATHENS

INTRODUCTION: Blood lactate accumulation and clearance play a crucial role in repeated sprint performance, particularly in athletes with varying aerobic capacities. This study aimed to examine the effects of repeated sprints, aerobic capacity and anaerobic speed reserve (ASR) on blood lactate responses.

METHODS: Twelve athletes (Sprinters (SPR): 400 m sprint time: 50.46 ± 1.02 s and Middle-Distance runners (MDR): 800 m time: 114.00 ± 3.95 s) participated in the study. Maximum oxygen uptake ($\text{VO}_{2\text{max}}$), velocity at $\text{VO}_{2\text{max}}$ ($v\text{VO}_{2\text{max}}$) and velocity at respiratory threshold ($v\text{VT}$) were assessed on a treadmill using the Bruce Protocol, and ASR was calculated from $v\text{VO}_{2\text{max}}$ and peak running speed during a 40 m sprint. Two protocols were additionally used, one for lactate accumulation (LA) and one for lactate clearance (LC). In the LA protocol, athletes performed 10 X 60 m sprints with 30 s recovery, with lactate measured at baseline and after the 2nd, 4th, 6th, 8th, and (when possible) 10th sprint. In the LC protocol, athletes ran on a track at their $v\text{VO}_{2\text{max}}$ until volitional fatigue, after which they completed 4 X 60 m sprints, with 2 min recovery, with lactate assessments after each effort. Two-way repeated measures ANOVAs (group x time) were used to compare blood lactate responses, while a MANOVA followed by univariate analyses compared the aerobic variables between groups.

RESULTS: The MANOVA demonstrated a significant group effect (Pillai's trace = 0.917, $F(4,7) = 19.38$, $p < 0.001$), with univariate analyses confirming that $\text{VO}_{2\text{max}}$ ($F = 25.19$, $p < 0.001$, MDR: 64.1 ± 3.9 vs. SPR: 54.6 ± 2.6 mL/kg/min), $v\text{VO}_{2\text{max}}$ ($F(1,10) = 84.40$, $p < 0.001$, MDR: 20.2 ± 0.9 vs. SPR: 16.4 ± 0.5 km/h), $v\text{VT}$ ($F = 54.50$, $p < 0.001$, MDR: 16.1 ± 1.0 vs. SPR: 12.7 ± 0.6), and ASR ($F(1,10) = 48.71$, $p < 0.001$, MDR: 13.54 ± 1.4 km/h vs. SPR: 19.04 ± 2.2) differed significantly between groups. For the LA protocol, ANOVA revealed a significant interaction ($F(4,51) = 4.07$, $p = 0.006$), with pairwise comparisons indicating no group differences at baseline ($p = 0.96$, MDR: 1.15 ± 0.26 vs. SPR: 1.07 ± 0.24 mmol) but significant differences from the 2nd (MDR: 3.87 ± 0.84 vs. SPR: 7.25 ± 2.46 mmol) through 8th (MDR: 10.6 ± 2.53 vs. SPR: 17.87 ± 4.32 mmol) sprints (p ranging from 0.0436 to 0.0001). In the LC protocol, a significant main effect on sprint number was observed ($F(5,59) = 47.34$, $p < 0.001$), yet neither the group effect ($p = 0.143$) nor the interaction ($p = 0.689$) was significant, suggesting comparable lactate clearance between groups. Blood lactate values were similar in the two groups after the high-intensity aerobic running (MDR: 22.17 ± 2.32 vs. SPR: 22.2 ± 3.96 mmol), as well as after the last sprint (MDR: 11.45 ± 5.2 vs. SPR: 15.1 ± 5.83 mmol).

CONCLUSION: These findings indicate that while SPR and MDR display different responses with SPR accumulating more lactate during repeated sprints, their abilities to clear lactate following high-intensity aerobic exertion are comparable.

THE IMPACT OF ATTENTIONAL FOCUS STRATEGIES ON BIOMECHANICAL AND NEUROMUSCULAR RESPONSES DURING ECCENTRIC FLYWHEEL SQUATS: A RANDOMIZED CROSSOVER STUDY

NIE, R., KONG, J.

北京体育学院

INTRODUCTION: Internal focus (IF) and external focus (EF) influences motor performance through distinct cognitive mechanisms. While EF generally enhances movement efficiency, IF can disrupt performance but may optimize muscle activation in certain contexts. Eccentric flywheel training, known for its high mechanical tension and neuromuscular adaptations, is widely used to enhance athletic performance. However, no study has explored how attentional focus strategies modulate biomechanical and neuromuscular responses during eccentric flywheel exercises. This study addresses this gap by examining the effects of IF and EF on ground reaction force and muscle activation during eccentric flywheel squats, providing new insights into optimizing performance and rehabilitation.

METHODS: 28 healthy males (aged 18–25) with over 1 year of resistance training experience participated in this randomized, counterbalanced crossover study. 3 AF conditions were tested during eccentric flywheel squats: EF, IF and Control (CO). Ground reaction force (GRF) and surface electromyography (sEMG) of 7 lower limb muscles were measured. GRF peak and mean values were recorded for eccentric and concentric phases, while sEMG signals were normalized to maximal voluntary contractions. Repeated measures ANOVA or Friedman tests were used for statistical analysis, with significance set at $p < 0.05$.

RESULTS: Average and peak amplitudes (A.A. and P.A.) of the gluteus maximus, rectus femoris, biceps femoris, semitendinosus, medial gastrocnemius, lateral gastrocnemius, and tibialis anterior were analyzed across conditions. EF resulted in the highest mean (M.) and peak (P.) concentric (C.) and M. eccentric (E.) forces (M.C.=107.65[102.13,115.64];M.E.=87.84[79.58,96.85]; P.C.=128.81[112.26,137.06]; P.E.=103.91[90.33,116.50]), followed by IF(M.C.=90.18[79.45,94.92];M.E.=78.66[70.36,84.11]; P.C.=106.53[94.00,112.14];P.E.=96.38[84.50,101.13]) and CO (M.C.=96.07[75.70,110.82]; M.E.=87.10[75.00,99.80];P.C.=111.06[87.05,112.57]; P.E.=106.93[90.75,120.02]), $p < 0.001$, $p < 0.001$, $p < 0.001$, $p = 0.008$. EF also showed superior muscle activation efficiency, particularly in the gluteus maximus (P.A.A.=0.001, PP.A.=0.002) and biceps femoris (P.A.A.=0.01, PP.A.=0.025). In contrast, IF enhanced rectus femoris (P.A.A.=0.019, PP.A.=0.36) and semitendinosus P.A.A.=0.004, PP.A.=0.001) activation compared to CO. These findings suggest EF optimizes force production and movement efficiency during eccentric flywheel squats.

CONCLUSION: EF enhances force production and movement efficiency during eccentric flywheel squats compared to IF and CO. IF demonstrates benefits for specific muscle activations, such as the rectus femoris and semitendinosus. These

findings suggest that EF is more effective for optimizing overall performance, while IF may be useful for targeted muscle engagement. Integrating attentional focus strategies with eccentric flywheel training could enhance athletic performance and rehabilitation outcomes.

A COMPARISON OF THE RECOVERY RESPONSES FOLLOWING ISOMETRIC AND VARIABLE RESISTANCE EXERCISE IN TRAINED MEN

ROSACI, G., MERNI, F., BARTOLOMEI, S.

UNIVERSITÀ DI BOLOGNA

INTRODUCTION: Despite isometric exercise performed at long muscle length (LML), short muscle length (SML) and variable resistance exercise (VAR) represent effective methods to achieve neuromuscular and morphological adaptations [1,2], no studies to date investigated the recovery responses of the pectoral muscles following these training methods. Thus, the aim of the present study was to compare acute effects, muscle damage and the recovery responses following LML, SML and VAR exercise sessions involving the pectoral muscles in resistance trained men.

METHODS: Twelve trained men (age: 25.3 ± 4.1 years; height: 177.6 ± 7.3 cm; body mass: 81.6 ± 10.1 ; training experience: 6.7 ± 3.7 ; 1RM bench press: 108.5 ± 21.6 kg) performed a LML, SML and VAR exercise protocol in random order, with a 10-day washout between them. Participants were assessed prior to each protocol, 15 minutes (P-15min), 24 hours (P-24h) and 48 hours (P-48h) post-exercise for muscle architecture (muscle thickness [PECMT] and echo-intensity [PECEI]), and performance (peak isometric force [PF], power at bench press throw [BTP]) and muscle soreness. Blood samples were also collected at BL and at P-24h and Creatine Phosphokinase (CPK) was measured.

RESULTS: A longer time to recover the initial PECMT ($p = 0.003$) was registered in VAR, compared to LML and SML. This parameter returned to baseline at P-48h following VAR, and in correspondence of P-24h following LML and SML protocols. Similar recovery responses between the protocols were detected for PECEI ($p = 0.369$), PF ($p > 0.319$), BPT ($p = 0.614$) and muscle soreness ($p = 0.115$). The PECEI, PF and BPT parameters returned to BL within 24 h following all the protocols while muscle soreness was still present at P-48h without differences between the protocols. In addition, all the exercise protocols resulted in similar ($p = 0.727$) elevations of CPK (382.64 ± 172.95).

CONCLUSION: Results of the present investigation indicated that upper body isometric exercises performed at LML and SML and VAR exercise may result in muscle damage. The metabolic stimulus and the presence of eccentric phases in VAR protocol only, may have delayed the return to baseline registered for muscle architecture compared to both LML and SML protocols. A recovery period of 24-48h was required to dissipate performance reductions and partially muscle soreness following both isometric and VAR exercise protocols for the upper body muscles.

THE INFLUENCE OF MATURITY STATUS ON THE REACTIVE STRENGTH INDEX AND MAXIMAL SPRINTING SPEED IN YOUTH FEMALE VOLLEYBALL PLAYERS AGED 8–15 YEARS

LEHNERT, M., KREJČÍ, J.1, HANZLÍKOVÁ, I.1, SYLVESTER, R.2

1 PALACKÝ UNIVERSITY, FACULTY OF PHYSICAL CULTURE, CZECH REPUBLIC; 2 UNIVERSITY OF MANITOBA, CANADA

INTRODUCTION: Understanding changes in physical fitness during maturation is essential for developing appropriate sport performance and injury management strategies [1]. Many researchers have characterized various physical fitness parameters of youth athletic and non-athletic populations depending on chronological age. Fewer studies have considered the influence of maturation on physical fitness and performance, and those have yielded ambiguous results [1,2,3]. This study investigated the influence of maturity status on the Reactive Strength Index (RSI) and sprinting speed in youth female volleyball players. The hypothesis of the study was that maturity status would influence the RSI and sprinting speed in youth female volleyball players.

METHODS: This observational cross-sectional study included 54 female volleyball players aged 8 to 15 years. The biological maturity of the players was predicted as the offset from peak height velocity (PHV) using the sex appropriate equation of Mirwald [4]. Subsequently, players were classified into three categories: pre-PHV (offset < -1 year), circa-PHV (offset in range -1 to $+1$ year) or post-PHV (offset $> +1$ year). The RSI was determined during a drop jump test using a height of 30 cm. In the 20 m sprint test, maximal speed was measured. Values between maturity offset categories were compared using one-way ANOVA with Fisher's post-hoc tests.

RESULTS: RSI in circa-PHV (0.91 ± 0.25 m/s) was significantly higher compared to pre-PHV (0.66 ± 0.17 m/s, $p = 0.012$) but not significantly different from post-PHV (1.03 ± 0.29 m/s, $p = 0.20$). Maximal sprinting speed in circa-PHV (6.27 ± 0.61 m/s) was significantly different from both pre-PHV (5.56 ± 0.38 m/s, $p < 0.001$) and post-PHV (6.76 ± 0.47 m/s, $p = 0.005$).

CONCLUSION: Our findings in female youth volleyball players support those studies research indicating gradual improvement in reactive strength and maximum speed in youth female athletes during maturation. Given that some studies have not confirmed this trend, there is a need for longitudinal research, including studies that consider the specificities of training load in individual sports.

RELIABILITY AND VALIDITY OF THE RESPIRATORY THRESHOLD METHOD

AS, H., PEKER, A., YILDIZTEPE, E., OZKAYA, O.

FACULTY OF SPORTS SCIENCES, EGE UNIVERSITY

INTRODUCTION: Traditional methods for determining exercise thresholds, such as the gas exchange threshold (GET) and the respiratory compensation point (RCP), have limitations, as they rely on identifying breakpoints in progressively increasing values along the x- and y-axis during an incremental exercise test (1). In 2021, a novel method was proposed that reinterprets these thresholds (RT1 and RT2) using the ratio of minute ventilation (VE) to end-tidal CO₂ partial pressure (PET-CO₂) during incremental exercise (VE/PETCO₂-W) (2). However, the reliability and validity of this method have not yet been fully established. The aim of this study was to assess the test-retest reliability and comprehensive validity of the VE/PETCO₂-W method.

METHODS: Male participants who engaged in at least 150 minutes of exercise per week were recruited for both the reliability study (n = 42; age: 26 ± 7 years; height: 183 ± 8 cm; mass: 74 ± 13 kg; peak VO₂ (VO₂peak): 52 ± 10 mL·min⁻¹·kg⁻¹) and the validity study (n = 143; age: 26 ± 8 years; height: 182 ± 8 cm; mass: 73 ± 13 kg; VO₂peak: 52 ± 10 mL·min⁻¹·kg⁻¹). All participants completed two ramp tests (30 W·min⁻¹) on separate days to assess reliability. For the validity analysis, participants were classified based on VO₂peak as physically active (<45 mL·min⁻¹·kg⁻¹, n = 44), trained (45-55 mL·min⁻¹·kg⁻¹, n = 51), or well-trained (>55 mL·min⁻¹·kg⁻¹, n = 48). GET and RCP were identified using piecewise regression in the VCO₂-VO₂ and VE-VCO₂ relationships, respectively, while RT1 and RT2 were derived from the VE/PETCO₂-W relationship.

RESULTS: Results indicated that RT1 (3.0 ± 1.0 vs. 3.0 ± 1.0 W·kg⁻¹) and RT2 (3.8 ± 1.0 vs. 3.8 ± 1.0 W·kg⁻¹) demonstrated high reliability (intraclass correlation coefficient > 0.99; standard error of measurement < 3%; limits of agreement (LoA): -0.23 W·kg⁻¹ to 0.22 W·kg⁻¹). In terms of validity, RT1 and RT2 (2.9 ± 1.0 and 3.7 ± 1.1 W·kg⁻¹) showed strong agreement (Pearson r > 0.99; standard error of the estimate < 3%) with GET and RCP (2.9 ± 1.0 and 3.8 ± 1.1 W·kg⁻¹) and accurately predicted these thresholds (effect size (ES) < 0.16; LoA: -0.12 W·kg⁻¹ to 0.12 W·kg⁻¹). Furthermore, RT1 and RT2 effectively distinguished between the physically active (28 ± 3 and 37 ± 3 mL·min⁻¹·kg⁻¹), trained (34 ± 5 and 45 ± 4 mL·min⁻¹·kg⁻¹) and well-trained (41 ± 6 and 66 ± 12 mL·min⁻¹·kg⁻¹) groups (ES > 1.4).

CONCLUSION: In conclusion, the VE/PETCO₂-W method is a reliable and valid tool for determining exercise thresholds and classifying aerobic endurance profiles. These findings highlight the potential of the VE/PETCO₂-W method to enhance individualised exercise prescription and performance assessment.

EFFECTS OF COMBINED STRENGTH TRAINING ON BODY COMPOSITION AND VERTICAL JUMP IN ADOLESCENT FEMALE VOLLEYBALL PLAYERS

RODRIGUEZ, K., TREJO, M., PINEDA, A., GUILLEN, D., LARA, C., RAMOS, A., CHAVEZ, I.

AUTONOUOMUS UNIVERSITY OF BAJA CALIFORNIA

INTRODUCTION: The skill of the vertical jump is vital to success in volleyball, it is used in serving, setting, spiking and blocking. For this, it is necessary to have the ability to generate power in a short period (1). There are different types of training to increase the strength and power of the vertical jump, some of them are weight training (WT), plyometric training (PT), electrostimulation training, training based on technique and games, and training combined (CT). The combined training is that system where two types of training are combined during the same training session or week. This method also it is known as complex training, which aims to develop and increase the linear power of athletes (2). Research has reported significant improvements in speed, strength, power and agility in subjects participating in a combined training protocol (WT + PT), compared with subjects participating in these training protocols separately (3).

METHODS: Objective.- Determine the effects of a 9-week Combined Strength Training on the vertical jump in female adolescent volleyball players.

A total of 8 teenage volleyball players (age: 16.4±0.12) at an amateur level participated in a personalized training program with a duration of nine weeks, that consists of two training sessions per week that combined strength training (weights) with plyometric training in a single exercise session, assessing body composition by bioimpedance and vertical jump with force platform (countermovement jump, blocking jump and attack jump) at baseline and after the exercise intervention. Statistical significance was p < 0.05.

RESULTS: At the end of the training, significant improvements were obtained in the height (BVJ from 26.3±3.9 cm to 30.1±3.78 cm, CMJ from 26.9±4cm to 28.3±4.7 cm), flight time in seconds (BVJ from 0.46±0.03 to 0.49±0.03, CMJ from 0.46±0.03 to 0.5±0.03 and the SPJ from 0.5±0.03 to 0.52±0.04.) and power in kgm/s (BVJ from 634±87.3 to 682±88.4, CMJ from 644.8±93 to 692.8±90.1 and the SPJ from 689.6±96.4 to 737.3±87.1); General body composition did not show any significant difference.

CONCLUSION: A 9-weeks CT improved the vertical jump in female adolescent volleyball players, increasing the vertical covered distance, flight time and muscle power of the athletes. A small increment on lower limbs muscle mass seems to explain these functional adaptations, although, neural activity and technique may also be involved.

TRAINING LOAD VARIATIONS IN FEMALE COLLEGIATE RHYTHMIC GYMNASTS: INSIGHTS FROM SESSION-RPE MONITORING

SHIMIZU, K., HOSHIKAWA, Y.²

1. KEIO UNIVERSITY 2. JAPAN WOMENS COLLEGE OF PHYSICAL EDUCATION

INTRODUCTION: Rhythmic gymnastics (RG) is an aesthetic sport that requires a fusion of beauty and advanced technique, and athletes need flexibility, a sense of balance, precision of movement, and artistic ability. During competition preparation, routine repetitions "run-throughs" and weight management often lead to increased physiological and psychological stress in RG athletes. The session-RPE (sRPE) method has been widely used for evaluating internal load (ITL), yet its application in collegiate RG athletes, who must balance academics and sports, remains unclear. This study aimed to monitor ITL variations during competition preparation period using sRPE method in association with body composition and menstrual cycle in female RG athletes.

METHODS: Seven RG athletes in individual events were monitored for 17 weeks leading up to the All-Japan Championships. Athletes recorded their training duration, sRPE, and ITL daily, and ACWR, Monotony, and Strain were calculated weekly. Additionally, body composition was measured by the InBody system every three weeks. The relationship between weight fluctuations, menstrual cycle, and ITL was analyzed.

RESULTS: Training load fluctuated throughout the competition preparation period, with a notable increase observed during the training camp in Week 6, where ITL peaked at 13,860 AU and ACWR reached 1.93. A similar trend was also observed in Week 16, just before the All-Japan Championships, with ITL and Monotony levels rising to 10,011AU and 1.7. A significant correlation was confirmed between training duration and sRPE, although the relationship was weak ($r=0.24-0.58$) and varied between individuals. Regarding weight management, participants who lost more than 3% of their body mass exhibited higher sRPE. In contrast, no significant differences in sRPE were observed between menstrual and non-menstrual phases, although sRPE were slightly higher during menstrual phase.

CONCLUSION: This study found that training load in collegiate RG athletes spikes during competition prep, especially in off-academic training camps with intensive "run-throughs." These workload surges may increase fatigue and injury risk, highlighting the need for gradual load adjustments. A weak correlation between training duration and sRPE suggests that longer sessions may elevate perceived exertion, but assessing training content and intensity is also crucial for effective load management. Pre-competition weight loss may further increase ITL, emphasizing the importance of sustainable weight management. While menstrual cycle effects on sRPE were unclear, individual differences should be considered. These findings support sRPE as a valuable tool for monitoring training load in time-constrained RG athletes.

EXPLORING THE RELATIONSHIP BETWEEN HAND GRIP STRENGTH AND ANTHROPOMETRIC CHARACTERISTICS IN COLLEGIATE LACROSSE PLAYERS

TAMULEVICIUS, N., KHERANI, N., RIDDELL, S., HOUSTON, F.

THE UNIVERSITY OF TAMPA

INTRODUCTION: Lacrosse is a dynamic sport where players' positions are influenced by grip strength (1, 2). This study analyzes the relationship between Hand Grip Strength (HGS) and various anthropometric measures, including body composition (BMI), limb lengths (arm and forearm length), and hand size in collegiate lacrosse players.

METHODS: A total of 48 participants (22 males and 26 females, age 20.2 ± 1.47 years) were assessed in a single session. Hand grip strength was measured using a handheld dynamometer. Height and weight measurements were recorded to calculate BMI. Limb lengths such as arm and forearm lengths were also documented. Hand size was assessed using a measuring tape.

RESULTS: Correlation analysis revealed a strong positive relationship between HGS and both arm length and forearm length ($r = 0.625$, $p < 0.001$; $r = 0.508$, $p < 0.001$ respectively), while moderate correlations were noted for BMI ($r = 0.491$, $p < 0.001$). In contrast, hand size weakly correlated with HGS ($r = 0.279$, $p = 0.055$). Linear regression analysis showed that these four factors together explained 55.6% of the variance in HGS.

CONCLUSION: These findings emphasize the importance of considering the anthropometric characteristics of lacrosse players for training regimens in this sport. Understanding how these factors impact grip strength can help coaches tailor training programs to enhance performance and reduce injury risk among athletes.

SWEAT LACTATE RESPONSE DURING CLASSICAL ROLLER SKIING AT INTENSITY ZONE 4

YAMAMOTO, N.¹, KASHIWAGI, Y.², HIRANO, T.⁵, TAKENOYA, F.³, SHINTAKU, Y.⁴, WADA, T.⁵

1 JAPANESE RED CROSS HOKKAIDO COLLEGE OF NURSING, 2 SENSU UNIV., 3 HOSHI UNIV., 4 WAKAYAMA PROFESSIONAL UNIV. OF REHABILITATION, 5 KOKUSHIKAN UNIV.

INTRODUCTION: Roller ski training is an effective summer conditioning program for improving cross-country skiing performance. Monitoring metabolic responses during training is crucial, and blood lactate concentration serves as a key marker of exercise intensity. However, limited research has investigated lactate behavior during roller skiing, particularly in classical technique at high intensities. Recently, a non-invasive, real-time method for monitoring sweat lactate has been developed. This study aimed to analyze sweat lactate dynamics in junior cross-country skiers during classical roller skiing at high intensity (Zone 4).

METHODS: Five junior cross-country skiers (2 males: 15–18 years, height: 170–175 cm, weight: 52–60 kg; 3 females: 15–17 years, height: 153–162 cm, weight: 41–55 kg) participated in this study. A sweat lactate sensor was affixed to the left upper arm and secured with a bandage, with data transmitted to a wearable device. Heart rate was recorded using the bipolar induction method, and distance and speed were measured via GPS. The training protocol included two 5-minute bouts of classical roller skiing at intensity Zone 4 (80–90% HRmax), with a 2-minute rest interval. Sweat lactate responses were analyzed throughout the session.

RESULTS: The skiers covered a total distance of 6.37 ± 0.12 km at an average speed of 8.09 ± 0.72 km/h. Heart rate ranged from 166–197 bpm in the first Zone 4 bout, dropped to 137–155 bpm during the rest interval, and increased to 178–201 bpm in the second Zone 4 bout. Sweat lactate levels were 3.0–4.0 μA in the first Zone 4 session, 2.6–4.0 μA during the rest period, and 3.5–5.8 μA in the second Zone 4 session.

CONCLUSION: The progressive increase in sweat lactate suggests rising metabolic demand. Individual variations were noted, particularly between male and female athletes, indicating potential sex-based differences in metabolic response. These findings highlight the potential of sweat lactate as a non-invasive biomarker for monitoring training intensity in roller skiing. The observed fluctuations in heart rate, speed, and pacing align with metabolic stress markers. Further studies with larger sample sizes are needed to establish more definitive trends.

Sweat lactate concentrations increased during high-intensity classical roller skiing, reflecting metabolic stress. These findings support the feasibility of sweat lactate monitoring as a non-invasive tool for assessing training intensity in endurance sports.

THE INFLUENCE OF REPRESENTATION ON POSTURAL CONTROL

MURAYAMA, T.

NIIGATA-UNIVERSITY

INTRODUCTION: We have analyzed the mechanisms of postural control during movement, focusing on factors such as plantar pressure distribution and hip joint strategies. Our objective was to quantify postural control during walking movements in gradient transition tasks, particularly by examining center-of-gravity movement trajectories.

In this study, we used a custom-made adjustable slope device. Participants performed stepping movements while experiencing slope changes imposed under instructor-guided gradient transition tasks, allowing us to examine postural control patterns. Participants received prior information about slope changes, leading to the hypothesis that they would respond predictively by adjusting their posture based on spatial mental representations. However, discussions on the applicability of this approach in actual exercise instruction settings remained insufficient.

Therefore, this study aimed to investigate whether gait analysis incorporating image processing could serve as an effective assessment method in exercise instruction settings. Additionally, we report on how quantitatively capturing participants' adaptation to the changing slope and providing them with feedback can assist in instructional guidance.

METHODS: The study involved four healthy university students (both male and female). A treadmill was used to create a setting where the slope gradually increased. Participants walked on the treadmill while experiencing gradual slope changes. Their vision was obstructed with an eye mask during walking.

Two trials were conducted:

- Trial 1: Slope set to 0°
- Trial 2: Slope set to 10°

Each trial consisted of a 30-second measurement period, which was divided into three phases:

- Phase 1: First 10 seconds
- Phase 2: Middle 10 seconds
- Phase 3: Final 10 seconds

The walking movements under changing conditions were recorded using video analysis.

RESULTS: The influence of mental representation on walking under treadmill slope changes was observed. In Trial 1, no significant posture changes were detected. However, in Trial 2, clear postural changes were identified.

A one-way repeated measures ANOVA confirmed significant posture changes in Trial 2 across the three phases. Motion capture analysis showed posture changes at different body points:

- Acromion (shoulder joint): Postural changes were observed across all phases.
- Knee joint: Postural changes were observed across all phases.
- Heel: Postural changes were observed across all phases.

CONCLUSION: This study aimed to investigate predictive postural control based on human sensory information. Such predictive postural control is carried out by utilizing mental representations of body and environmental information.

The findings highlight the importance of examining how inaccurate mental representations or the absence of predictive postural control affect human movement and posture. These results contribute to a deeper understanding of the role of mental representations in human sensory and motor functions and may aid in the development of methods for treating sensory and movement disorders.

GWAS APPROACH TO IDENTIFYING CANDIDATE GENES FOR THE ELITE ATHLETIC PHENOTYPE IN LITHUANIAN POPULATION

ANIKEVICIUTE, G., VAIŠNORE, R., GINEVICIENE, V., URNIKYTE, A.

VILNIUS UNIVERSITY

INTRODUCTION: A comprehensive understanding of the genetic factors influencing elite athletic performance is a key to optimizing training strategies and integrating precision-based approaches in sports medicine. This pilot genome-wide association study (GWAS) aimed to identify genetic markers associated with physical performance phenotype of Lithuanian elite athletes.

METHODS: The study included 96 Lithuanian elite athletes (55 males, 41 females participating in endurance and sprint/power sports) and 424 non-athlete controls (healthy unrelated 211 males, 213 females). Each elite athlete underwent anthropometric and functional assessment of physical performance (grip strength, vertical jump and stair climbing test and maximal oxygen consumption - VO₂max). Whole-genome genotyping was performed using Illumina Infinium OmniExpress-24 and Global Screening Array-48 Kits. Chi-squared tests and logistic regression analysis of case/control data were performed using PLINK-1.9 to evaluate the genetic association between 77607 single nucleotide polymorphisms (SNPs) and athletic traits.

RESULTS: Endurance athletes exhibit significantly higher VO₂max values compared with the sprint/power athletes ($p < 0.05$), whereas sprint/power athletes demonstrate greater explosive muscle anaerobic power in a single repetition, a higher muscle mass percentage, elevated body mass index (BMI), and increased right- and left-hand grip strength. GWAS results did not reveal any statistically significant associations between SNPs and elite athlete status or phenotypic characteristics ($p > 5 \times 10^{-8}$). Nonetheless, eight SNPs demonstrated suggestive significance for elite athlete status ($p < 5 \times 10^{-5}$), including three intergenic variants (rs10957507, rs9453403, rs4359550), three intronic variants (rs12485289, rs16873417, rs1347756), one non-coding transcript exon variant (rs2001078) and one missense variant (rs3213445, CPT1B:c.196A>T (p.Ile66Phe)). The CPT1B gene encodes carnitine palmitoyltransferase 1B, a key enzyme in the β -oxidation of long-chain fatty acids within muscle mitochondria—a fundamental aerobic metabolic pathway essential for energy production during endurance-based activities.

CONCLUSION: Phenotypic analysis confirmed expected physiological differences between elite endurance and sprint/power athletes, reinforcing the importance of muscle metabolism, aerobic capacity, and anaerobic power in athletic specialization. However, further investigations with larger cohorts are required to validate suggestive genetic markers and their implications for performance optimization in elite Lithuanian athletes.

RELIABILITY AND CRITERION VALIDITY OF THE CONCEPT 2 SKIERG™ TO ASSESS 1-KM ON-SNOW, TIME TRIAL PERFORMANCE – A CASE STUDY.

SPENCER, M., WORN, R., OBRIEN, B.

1 UNIVERSITY OF AGDER, DEPARTMENT OF SPORT SCIENCE AND PHYSICAL EDUCATION, NORWAY

INTRODUCTION: Cross-country skiing is a physically demanding sport, requiring whole body strength and power and high and sustained aerobic energy turnover. However, standardised testing for cross country skiing performance can be challenging due to unpredictable snow conditions. Specificity of an exercise test to actual field performance is an important concept in sport performance assessment. The Concept 2 SkiErg™ ergometer has been developed to simulate on-snow double poling performance. However, the test-retest error (reliability) and capability of the Concept 2 SkiErg™ to discern genuine intervention effect from random error and the criterion validity to assess on-field snow performance has not been reported. Therefore, this study's objective is to determine Concept 2 SkiErg™ reliability and criterion validity to assess on-snow performance.

METHODS: Ten members, 5 males and 5 females of a national cross-country ski team participated in this study (20.4±3.8 yrs, 179.8±9.7 cm, 70.0±10.5 kg). Informed consent was provided during an on-snow training camp held over 4 days at an elevation of 1200 metres. Athletes completed two 1-km Concept 2 SkiErg™ tests in a temperature-controlled room (18°C) in random, counter-balanced sequence. On a separate day, athletes completed a 1-km maximal flat terrain (±5 m altitude change) effort time trial on-snow using the classical double poling technique. Athletes used their own equipment and ski waxing products and procedures were standardized. All on-snow testing was completed within a 45-min period and environmental conditions were stable (air temperature 12±1°C; no precipitation and high visibility). Athletes wore an accelerometer and GPS unit (MinimaxX, Catapult, Australia) to record poling cadence and completion time was recorded. Reliability of Concept 2 SkiErg™ test was determined and reported as typical error and coefficient of variation. The average of the two Concept 2 SkiErg™ trials was compared to the 1-km time trial on the snow time trial to determine the Concept 2 SkiErg™ validity.

RESULTS: There was a strong positive correlation between the Concept 2 SkiErg™ and the on-snow test time trial (mean $r = .99$), although on-snow performance was significantly slower than performance on the Concept 2 SkiErg™ (254.1±38.6 v 235.9±24.5 s). The typical error was 6.95 s (coefficient of variation = 2.5%). The reliability assessment of the Concept 2 SkiErg™ showed a typical error of 3.75 s (1.5 %, $r = 0.98$). There was a significant decrease in time from test 1 to test 2 (238.3±26.1 v 233.4±23.9 s).

CONCLUSION: The findings of our case study suggest that the Concept 2 SkiErg™ performance has strong criterion validity despite a slight bias for faster times than on-snow performance, suggesting that it can be used as a tool to assess cross

country skiing performance indoors. Furthermore, the Concept 2 SkiErg™ is a very reliable test and should have sufficiently sensitivity to detect genuine and meaningful changes in performance.

A NEW REACTIVE STRENGTH INDEX FOR TRACK AND FIELD SPRINTING: DIFFERENCES BETWEEN AGE GROUPS.

CIACCI, S., AVENA, G., PIAZZA, N., ZANOTTI, S., CORATELLA, G., BARTOLOMEI, S.

UNIVERSITY OF BOLOGNA

INTRODUCTION: The Reactive Strength Index (RSI) represents a commonly accepted measurement of the reactive strength, defined as the ability to perform fast stretch-shortening cycles (SSC). Track and field sprinting requires a fast SSC, especially during the maximum velocity phase. The RSI is usually assessed as the ratio between jump height (JH) and contact time (CT) in specific vertical jumps, but some studies suggest that an RSI calculated by a horizontal jump test may be a better predictor of sprint performance [1]. These studies, however, present some methodological limitations in the calculation of the RSI, such as the use of non-standardized horizontal jumps. Therefore, the aim of the present study was to assess a new RSI (RSI RUN) based on CT and stride length (SL) measured in sprint running and then to correlate this index with sprint performance.

METHODS: One hundred and five athletes, divided in three groups based on age (Group 1 [G1] elite and sub elite athletes [n=16, age 23.9 ± 3.6 y], Group 2 [G2] junior sprinters [n=22, 15.5 ± 0.6 y] and Group 3 [G3] youth athletes [n= 67, 12.6 ± 1.2 y]), performed a Vertical Stiffness test (VJ, 6 stiffed leg jumps) and a 60-m sprint. Subsequent analysis considered the best RSI for VJ (RSIVJ), calculated as JH divided by CT, and the RSI for the sprint (RSIRUN), calculated as the average SL divided by the average CT of five steps performed at top speed.

RESULTS: A nearly perfect significant correlation was detected between RSI RUN and sprint performance in G1 and G2 ($r=0.945$ and 0.923 , respectively) and a very large correlation was detected in G3 ($r=0.754$). No significant correlations were observed between RSIVJ and max speed in the three group. Combining the three groups, RSIRUN showed a nearly perfect correlation with performance ($r=0.902$). In addition, RSIVJ showed a moderate correlation with performance ($r=0.481$).

CONCLUSION: The new horizontal-based RSIRUN showed a greater correlation with sprint performance in athletes of different age compared to vertical-based RSI. On the contrary, RSIVJ calculated by the stiffness test, was moderately correlated with max speed when the whole sample was considered, but not when each group was separately analyzed. In conclusion, the RSIRUN is a better predictor of sprint performance than the stiffness test and the calculation of this parameter may help coaches and sport scientists to assess the characteristics of the athletes, to identify talents and to monitor the influences of training on CT and SL.

EFFECTS OF ISOMETRIC AND ISOTONIC COMPLEX TRAINING ON STRENGTH AND VERTICAL JUMP PERFORMANCE IN FOLK DANCERS

KIRKAYA, I., ILANBEY, S.

YOZGAT BOZOK UNIVERSITY

INTRODUCTION: The implementation of isometric and isotonic complex training in folk dancers can significantly enhance their performance through mechanisms such as post-activation potentiation (PAP). PAP refers to the phenomenon where the force exerted by a muscle increases following a prior contraction, which can be particularly beneficial in dance, where explosive movements are frequently required. This training approach not only improves strength and power but also aids in injury prevention, a critical aspect for dancers who are prone to musculoskeletal injuries due to the physical demands of their art. This study aims to investigate the effects of isotonic and isometric complex training on the muscular strength and jumping abilities of folk dancers.

METHODS: The study groups were randomly formed as isometric complex training (ICTG) and isotonic complex training (ISCTG) groups. 43 male folk dancers participated in the study voluntarily. ICTG=age:20,14 $\pm$ 1.35years; body weight:74,7 $\pm$ 6.03kg; body height:177.58 $\pm$ 1.08cm, N=23; ISCTG=age:20,02 $\pm$ 1.55years; body weight:73.81 $\pm$ 9.87kg; body height:174.5 $\pm$ 6.13cm, N=20. Participants participated in complex exercise sessions determined 3 days a week for 4 weeks before their routine folk dance training. ICTG group completed the mid-thigh pull exercise 3x10s, and the ISCTG completed the back squat exercise 3x3 with 1RM 90%. As a pre-test and post-test, counter movement jump, squat jump, back squat and isometric mid-thigh pull values were evaluated. Mixed design anova was used to test the time x group interaction.

RESULTS: According to the pre-post test results, time x group interactions were found as follows; Counter movement jump height= (η^2 :0.032; p :0.248), squat jump height= (η^2 :0.016; p :0.424), back squat 1RM= (η^2 :0.382; p :0.04). isometric mid-thigh pull= (η^2 :0.166; p :0.007), percentage of improvement in each training session= (η^2 :0.118; p :0.024), respectively.

CONCLUSION: The findings of this study suggest that both isometric and isotonic complex training can enhance muscular strength and performance in folk dancers, particularly in movements requiring maximal force production.

PHASE-SPECIFIC MUSCLE ACTIVATION IN ONE STRIDE CYCLE DURING A SIMULATED 400 M SPRINT TREADMILL

KAJIWARA, W., UDA, S., HORIMOTO, R., OKADA, T., EGUCHI, F., NAKANO, H., MIYAMOTO, N., TAKEDA, M.

DOSHISHA UNIVERSITY

INTRODUCTION: This study aimed to analyze the changes in phase-specific muscle activity in one stride cycle during simulated a 400 m sprint running on a treadmill.

METHODS: Two male track and field athletes (A: 35 years, 180 cm, 68 kg; B: 24 years, 177 cm, 70 kg) participated in this experiment. Muscle activity was measured while running on a treadmill. The treadmill speed gradually increased to 25 km/h over 10 seconds at a 0 % incline, and then the 400 m sprint started the moment this speed (25 km/h) was reached. The treadmill speed was adjusted in increments of 0.1 km/h according to the subjects position on the treadmill or their intention, maximizing their 400m performance. After completing 400 m, the speed was reduced.

Kinematic data were collected using a marker-based motion capture system (sampling rate 100 Hz, BTS Bioengineering, SMART-DX EVO, Italy). Based on the method of Aurélien et al. (2021), the following gait events were identified: initial contact (IC), Mid-stance (Mid), Toe-off (TO), and maximum knee flexion (MKF). The stride cycle was divided into four phases: Braking (IC to Mid), Propulsion (Mid to TO), Recovery (TO to MKF), and Pre-activation (MKF to the next IC). EMG signals were recorded from eight muscles of the right leg: gastrocnemius (GAS), soleus (SOL), tibialis anterior (TIB), biceps femoris (BF), vastus lateralis (VL), rectus femoris (RF), tensor fasciae latae (TFL), and gluteus maximus (GMax) (sampling rate 1000 Hz, BTS Bioengineering, FREEMG, Italy). The root mean square (RMS) values were calculated for the entire stride cycle and for each phase duration.

RESULTS: The 400 m sprint times were 54.0 seconds for participants A and 60.0 seconds for participants B. The maximum speeds reached were 27.8 km/h for A and 25 km/h for B. Post-sprint blood lactate levels were 16.8 mmol/L for A and 16.6 mmol/L for B. Participants A showed a decrease in RMS values of the GAS and SOL during the Braking phase as the running distance increased. Additionally, most muscles exhibited an increasing trend in muscle activity during the Pre-activation phase. For participants B, the TIB decreased during the Braking phase, while it increased during the Propulsion phase as the running distance increased. Additionally, the BF showed an increase in RMS values during the Pre-activation phase. Participant B showed increased muscle activity during both the Propulsion and Pre-activation phases.

CONCLUSION: The results of this study suggest that muscle activity during a 400 m sprint changes with the increase in running distance, depending on the phase of the stride cycle. Future research should increase the number of subjects to enhance the reliability of the data.

CONSTRUCT VALIDITY OF TWO NEW RPE SCALES TO ASSESS PSYCHOLOGICAL AND PHYSICAL LOADS IN ÉLITE SOCCER ATHLETES DURING TRAINING AND COMPETITIONS

NIGRO, F., BENEDETTI, L., DI MICHELE, R., MARCORA, S.M.

UNIVERSITY OF BOLOGNA

INTRODUCTION: Recently, two new rating scales of perceived exertion (RPE) have been developed and validated: the Mental RPE (M-RPE), designed to assess the psychological load experienced by athletes during training and competition, and the Physical RPE (P-RPE), aimed at evaluating the subjective physical load (1, 2). This study aims to assess the construct validity of the P-RPE and M-RPE scales in a field setting by examining whether they can effectively differentiate between training sessions with varying physical and mental loads.

METHODS: Four youth teams of elite soccer players ($n = 38$ U20, $n = 45$ U18, $n = 38$ U17, $n = 18$ U16) were monitored for two consecutive competitive seasons 2023/2024 and 2024/2025) for a total of 337 training sessions and 89 matches (7934 total records). Athletes completed RPE assessments (Overall, Physical, and Mental) 30 minutes after each training session or competition. The linear mixed model analysis compared P-RPE and M-RPE scores across different sessions categorized using the match day (MD) minus days formula. Session type was included in the model as a fixed effect, while players were included as random effects to consider the intra-individual variability. Separate models were created for each RPE scale as the dependent variable. The P-RPE values were compared between the most intense training session of the week, usually the MD-3, and the pre-match session in which the players are not overloaded before the match. For the M-RPE values, the MD-3 was compared with the recovery session performed by the players on the first day after the match, the MD-5.

RESULTS: The analysis of variance (ANOVA) from the linear mixed model revealed a significant main effect of session type for the P-RPE, $F(1, 64.20) = 139.006$, $p < .001$. Thus, post hoc analysis between the specified contrast was run and a significant difference ($p < .001$) was found between MD-1 and MD-3 training sessions for the P-RPE scale. Similarly, a significant main effect of session type was found in the ANOVA from the linear mixed model for the M-RPE scale, $F(5, 83.98) = 31.622$, $p < .001$. Post hoc comparisons revealed a trend toward statistical significance ($p = .059$) for M-RPE scores between MD-5 and MD-3 training sessions.

CONCLUSION: Accordingly with literature (1), in the present study P-RPE scale effectively discriminates between training sessions with different physical loads in elite soccer players. Regarding M-RPE scale, while the findings were not statistically significant, they approached significance and suggested a potential effect to differentiate between training sessions

with varying mental demands. The present research highlighted the utility of differentiated RPE-based scales for monitoring both physical and mental training loads, though further research is needed.

INFLUENCE OF TESTING PROTOCOL ON THE RELATIONSHIP BETWEEN PHYSIOLOGICAL VARIABLES AND PERFORMANCE IN MOUNTAIN RUNNING

RODRÍGUEZ-MARROYO, J., RODRÍGUEZ-MEDINA, J., GUTIÉRREZ-ARROYO, J., GARCÍA-HERAS, F., CARBALLO-LEYENDA, B.
UNIVERSIDAD DE LEÓN

INTRODUCTION: The assessment of aerobic capacity is crucial in mountain running performance. However, the most appropriate testing protocol for evaluating athletes remains unclear. This study aimed to analyze whether the type of protocol used for physiological assessment (flat vs. slope) influences its relationship with race performance in mountain runners.

METHODS: Twenty-eight amateur mountain runners (39.9 ± 6.6 years) who competed in a mountain race of two different distances (26 km and 42 km) underwent physiological assessments in two laboratory sessions. They performed incremental tests to exhaustion and submaximal running economy tests under two conditions: flat (1% gradient) and slope (10% gradient). VO_2max , ventilatory thresholds, heart rate, running economy, and perceived exertion were recorded. Additionally, anthropometric measurements and jump tests were conducted to assess leg stiffness and lower limb strength. Statistical analyses examined the correlation between race performance (finish time) and physiological variables obtained from each protocol.

RESULTS: Significant correlations were found between race performance and VO_2max ($r = -0.68$, $p < 0.05$), ventilatory thresholds ($r = -0.71$, $p < 0.05$), and running economy ($r = -0.54$, $p < 0.05$). The slope protocol was more sensitive in distinguishing performance levels, particularly in the 42 km race, where VO_2max measured in the slope test showed a stronger relationship with race time ($r = -0.75$, $p < 0.01$) compared to the flat test ($r = -0.62$, $p < 0.05$). Additionally, running economy assessed in the slope protocol correlated more strongly with performance ($r = -0.54$, $p < 0.05$) than in the flat protocol, suggesting greater specificity for mountain running demands. However, both protocols provided reliable physiological markers for training prescription.

CONCLUSION: The slope protocol proved to be a more suitable method for assessing aerobic capacity in mountain runners, as it showed stronger relationships with race performance, particularly in long-distance events. These findings suggest that using a gradient-based protocol may enhance the precision of physiological evaluations and training recommendations in mountain running.

TECHNICAL TESTS IN YOUNG FEMALE HANDBALL ATHLETES: VALIDITY AND RELIABILITY ANALYSIS

BASSA, E., LOLA, A., AMANATIDOU, Z., STAVROPOULOU, G., PAPAVASILEIOU, A., HATZIMANOUIL, D.
ARISTOTLE UNIVERSITY OF THESSALONIKI

INTRODUCTION: The accuracy and consistency of technical skill tests form a significant aspect of research methodology in young athletes' evaluation. This study aimed to evaluate in female adolescent handball athletes the validity and reliability of three technical handball tests: - passing-receiving, dribbling, and shooting accuracy - using expert judgment and statistical analysis.

METHODS: A total of 15 female handball athletes (age: 13.84 ± 0.64 y) participated in the study. The study assessed the validity and reliability of three technical handball tests (Sullivan, 2011): passing – receiving (as many successful passes as possible against the wall from 2m distance within a 30-second timeframe), dribbling (time during a 15-meter slalom) and shooting accuracy (10 shots on goal from the penalty line, evaluated with different points depending on the target area). Descriptive statistics were used to analyze the characteristics of the sample. Logical validity was ensured by working with an experienced handball coach to examine if the tests accurately measured performance. The content validity of the technical tests was assessed by three handball experts who evaluated the test structure and scoring procedures (7-point scale). Reliability was assessed using Pearson correlation and intra-rater reliability analysis of data collected in two assessments a week apart. All statistical analyses were performed in R using JASP software and the level of significance was set at $\alpha = 0.05$.

RESULTS: The requirements for logical validity have been met. The high average scores given by the experts (passing: 5.37 ± 0.66 , dribbling: 5.28 ± 0.77 , shooting: 5.35 ± 0.63) indicated strong content validity. Reliability was assessed using Pearson correlation coefficients and intraclass correlation coefficients (ICCs), both of which showed excellent consistency. Passing - receiving showed a correlation of $r = .961$ ($p < .001$) and an ICC of 0.945, dribbling showed almost perfect reliability with $r = .991$ ($p < .001$) and an ICC of 0.989, and shooting accuracy showed strong reliability with $r = .936$ ($p < .001$) and an ICC of 0.935.

CONCLUSION: The study demonstrated strong validity and reliability for the three technical handball tests, passing - receiving, dribbling and shooting accuracy in adolescent female handball players. These findings suggest that the assessment tools examined are robust and suitable for the reliable assessment of performance in young female handball players.

EFFECT OF GPS-DERIVED FOOTBALL MATCH ACCELERATIONS AND DECELERATIONS ON JUMP HEIGHT AND LEG STIFFNESS IN YOUTH FEMALE ACADEMY ATHLETES

DEIGHAN, M., HODUN, M., DE STE CROIX, M., HUGHES, J.

UNIVERSITY OF GLOUCESTERSHIRE

INTRODUCTION: Increased ACL injury risk in female youth football (1) may be linked to exercise-induced fatigue (2). Studies have found negative changes in knee neuromuscular control in response to simulated match-play in adult (3) and youth (4) female footballers. Biomechanical studies suggest ACL risk factors include changes of direction (CoDs) involving deceleration and acceleration efforts (5) with 80-100 CoDs occurring per match (6). Due to limited data on the topic, the study aimed to analyse neuromuscular response to match-play in U16 female footballers.

METHODS: Twenty-eight U16 female footballers completed 95 player-sessions of ≥ 75 of 80 minutes in a match. Relative accelerations and decelerations (ACCEL and DECEL, n/min) were determined by GPS analysis (GPSports HPU system). Players completed neuromuscular response (NMR) testing pre- and post-match involving mean-of-3 countermovement jump height (CMJ) (7) and relative leg stiffness (LS) using submaximal hopping (SmartJump, Fusion Sport) (8). Paired t-tests compared pre- and post-match responses. NMRs were converted into a z-score (z-score = participant test score – group mean score)/SD, and differences (post – pre) were calculated. Pearson's correlation analysed the relationship between Z-score difference of NMRs with ACCEL and DECEL, respectively.

RESULTS: There was no significant change ($p > 0.05$) in CMJ from pre-match (27.9 ± 3.4 cm) to post-match (27.6 ± 3.8 cm). LS was significantly lower post-match (30.6 ± 10.1) vs. pre-match (35.4 ± 9.2), ($p < 0.001$, $d = 0.49$). A small negative correlation was found between CMJ z-score difference and DECEL ($r = -0.231$, $p < 0.05$), but not ACCEL. No significant correlation was found between LS z-score difference and either ACCEL or DECEL.

CONCLUSION: Results showing a decrease in LS post-match align with previous research on simulated matches in female youth football (4), suggesting a negative alteration in lower limb neuromuscular control from repetitive stretch-shortening cycle loading (9). However, changes in LS were not shown to be related to ACCEL or DECEL, suggesting LS is altered by match-play without effect from specific high-intensity efforts. A negative correlation between changes in CMJ and DECEL may be related to the energy costs of decelerations (10) and subsequent decrease in jump height which may indicate a reduction in neuromuscular performance (11). This study shows negative neuromuscular response due to match-play, warranting further study of ACL injury risk in female youth football.

THE DIFFERENCE AND CORRELATION BETWEEN FUNCTIONAL THRESHOLD POWER AND VENTILATORY THRESHOLD POWER IN RECREATIONAL TRIATHLETES

LI, T.1, HSU, W.1, LIN, Y.2

NATIONAL TAIWAN UNIVERSITY OF SCIENCE AND TECHNOLOGY

INTRODUCTION: The relationship between Functional Threshold Power (FTP) and the metabolic threshold defined in graded exercise test is an essential topic in sports science. However, existing research is limited and contradictory, possibly due to differences in study populations and fitness levels. Some researchers suggest FTP is a good indicator of the anaerobic threshold and is valuable for training and performance monitoring (1). However, further validation is needed regarding the factors influencing FTP and its comparability to the ventilatory threshold (VT1 and VT2). This study aims to explore the differences and correlations between FTP and pedaling power at the ventilatory threshold in recreational triathletes in Taiwan.

METHODS: This study recruited 22 recreational triathletes (13 males, 9 females) and conducted FTP and cycling-graded exercise tests on separate days to calculate FTP value and determine the ventilatory threshold and corresponding power. All power data were normalized by body weight. The Shapiro-Wilk test was used to assess the normality of the data. If the data followed a normal distribution, the Pearson correlation test was employed; if not, the Spearman correlation test was used. The difference in pedaling power was performed using the Kruskal-Wallis H test with Dunn's post-hoc test.

RESULTS: In the overall and male groups, the relative power output at FTP (All: 2.56 ± 0.49 W/kg; Male: 2.67 ± 0.49 W/kg) was significantly higher than at VT1 (All: 1.61 ± 0.29 W/kg, $p < 0.001$; Male: 1.55 ± 0.34 W/kg, $p = 0.014$) and lower than at

VT2 (All: 3.42 ± 0.51 W/kg, $p = 0.005$; Male: 3.56 ± 0.45 W/kg, $p = 0.039$). In the female group, FTP (Female: 2.42 ± 0.47 W/kg) was higher than VT1 (Female: 1.68 ± 0.22 W/kg, $p = 0.044$), but no significant difference was found between FTP and VT2 (Female: 3.25 ± 0.53 W/kg, $p = 0.119$). Additionally, FTP and VT1 showed no significant correlation, while a strong correlation was found between FTP and VT2 (All: $\gamma = 0.788$; Male: $\gamma = 0.755$; Female: $\gamma = 0.795$). These findings align with previous studies on elite athletes, where FTP and VT1 showed similar relationships, but no significant difference was observed between FTP and VT2 [2]. This suggests that FTP may underestimate VT2 in the overall and male groups but may better represent VT2 in female athletes.

CONCLUSION: It is suggested that the training level of participants is a key factor influencing the differences between FTP and the ventilatory threshold. The recreational male athletes FTP values may significantly underestimate the VT2, though this may not be the case for female athletes. Therefore, caution is required when applying FTP values to avoid misjudging an athletes true capacity.

EFFECTS OF MENTAL FATIGUE ON 400-M FRONT-CRAWL SWIMMING PERFORMANCE IN ELITE ATHLETES

ALVES ARAUJO DE LIMA JUNIOR, D., CAPORASO, G., CORTESI, M., MARCORA, S.
UNIVERSITÀ DI BOLOGNA

INTRODUCTION: This study aimed to investigate the effects of mental fatigue on 400-meter front-crawl swimming performance in elite athletes.

METHODS: Ten elite swimmers (FINA points = 725 ± 74) participated in a crossover, randomized, and counterbalanced study design. The study consisted of three experimental visits over three weeks. Participants were familiarized with the testing instruments and procedures during the first visit. In the second and third visits, swimmers underwent two experimental conditions in a randomized order: control (CON) and mental fatigue (MF). Following the intervention, participants performed a 400-meter front-crawl maximal effort test. Mental fatigue was assessed using the Brunel Mood Scale (BRUMS), physiological and psychological parameters, including heart rate (HR), lactate (La), and rating of perceived exertion (RPE), were evaluated during the assessments.

RESULTS: Manipulation Check

- **BRUMS-Fatigue:** A significant interaction was found ($X^2(1,18) = 5.60$, $p = 0.018$). Fatigue significantly increased following the MF intervention [PRE = 9.7 (8.3 to 11.1) a.u.; POST = 12.1 (9.7 to 14.6) a.u.; CI95%diff = -2.43 (-4.03 to -0.82); $p = 0.018$], while the CON condition remained unchanged [PRE = 9.0 (5.8 to 12.1) a.u.; POST = 0.35 (-0.76 to 1.46) a.u.; CI95%diff = -10.20 (-12.50 to -7.95); $p = 1.00$].

400-Meter Performance

- **Performance:** A significant condition effect was observed ($X^2(1,9) = 117.14$, $p < 0.001$). Participants performed better in the CON condition than in the MF condition [CON = 277.0 (270.0 to 283.0) s; MF = 288.0 (281.0 to 294.0) s; CI95%diff = 10.89 (8.92 to 12.86); $p < 0.001$].
- **RPE:** An interaction effect was observed ($X^2(1,27) = 48.29$, $p < 0.001$). RPE values were higher in the MF condition during pre-measurements [CON = 8.56 (8.12 to 9.00) a.u.; MF = 10.45 (9.97 to 10.93) a.u.; CI95%diff = -9.68 (-10.32 to -9.03); $p = 0.001$]. Post-measurement RPE values were similar between conditions [CON = 18.24 (17.48 to 18.99) a.u.; MF = 18.54 (17.95 to 19.22) a.u.; CI95%diff = -0.30 (-1.10 to 0.50); $p = 0.465$].
- **Heart Rate:** No interaction was found ($X^2(1,18) = 0.422$, $p = 0.516$).
- **Lactate (La):** Significant interaction was observed ($X^2(1,18) = 36.2$, $p = 0.001$). Post-measurement La levels were higher in the CON condition compared to the MF condition [CON = 10.24 (9.16 to 11.32) mmol/L; MF = 9.02 (7.93 to 10.10) mmol/L; CI95%diff = 1.22 (0.81 to 1.63); $p < 0.001$].

CONCLUSION: The findings demonstrate that mental fatigue significantly impairs 400-meter front-crawl swimming performance in elite athletes. The MF condition led to increased perceived fatigue, higher RPE values, and reduced performance compared to the CON condition. These results highlight the importance of managing mental fatigue in elite swimmers to optimize performance. Future research should explore strategies to mitigate the negative effects of mental fatigue in competitive swimming.

CORRELATION BETWEEN PHASE ANGLE AND STRENGTH PERFORMANCE IN HIGH-LEVEL SPRINT RUNNERS.

LAZARI, E., VIRGILIO, M.L., SANTOS, G., DANGELO, R., BUENO, T., RAMOS DE LAZARI, M.
UNIVERSIDADE ESTADUAL DE CAMPINAS

INTRODUCTION: In high-performance sports, monitoring body composition is important to develop athletes and improve performance. Body composition-BC can be estimated using several methods, including adipometry, bioelectrical

impedance-BIA, dual-energy X-ray absorptiometry-DXA. Specifically in relation to BIA, it has been used in this context, due to its easy application, time, and reduced costs. The assessment includes four parameters: resistance, reactance, impedance, and phase angle, which estimate body composition through equations. The phase angle-PA is a parameter obtained from the relationship between resistance-R and reactance-Xc measurements, and has been related as an important marker of cellular and muscle integrity, in addition occurrence of some diseases. The objective of the present study is to associate, in high-performance athletes, muscle strength parameters, through one maximum repetition-1MR tests, PA values and body fat percentage-BF obtained by BIA.

METHODS: Athletics sprinters participated in national and international competitions, with results corresponding to 88.42% of the world records of their events, were selected to participate in a tetrapolar bioimpedance tests-50kHz to obtain PA, percentage of BF and skeletal muscle mass, in addition tests of 1MR in the bench press and half squat. From these tests, the mean and standard deviation of all values were obtained and the Graphpad Prism v. 8.0.1 was used to obtain the correlation between the measures.

RESULTS: 11 athletes (men=7, women=4), aged 23.00 ± 3.95 , were evaluated. The mean PA obtained was $8.19^\circ \pm 1.08$, a study [1] with similar population found a higher mean value than the untrained population. The moderate strong negative correlation between PA and BF percentage $r = -0.71$ indicates that individuals with lower fat percentage tend to have higher PA values. The moderate positive relationship between PA and skeletal muscle mass $r = 0.61$ suggests that higher values of this parameter are associated with a greater amount of muscle mass, an essential factor for sports performance. The results found regarding muscle strength and BC, PA proved to be an important indicator in the sports context. In addition, the relationship between PA and muscle strength was significant. A strong positive correlation was observed with the load lifted in the bench press $r = 0.81$ and moderate strong correlation with the half squat $r = 0.64$. Indicates that athletes with higher PA perform better in maximum strength and muscle power.

CONCLUSION: Phase angle monitoring can be a useful tool in monitoring the evolution of training, helping to optimize body composition and improve sports performance. Its use can be relevant for sports that require strength and power, as in the case of speed tests in athletics, proving to be an important marker in the periodization of sports training.

MONITORING TRAINING LOAD IN YOUNG FEMALE TABLE TENNIS PLAYERS DURING THE PRE-COMPETITION PERIOD

BELLI, T., RODRIGUES, C.S., GAMA, M.C.T.

SCHOOL OF PHYSICAL EDUCATION, UNIVERSITY OF CAMPINAS

INTRODUCTION: Muscle fatigue can impair velocity, accuracy, and motor control in racket sports [1]. Managing fatigue is crucial for injury prevention and optimal training adaptations [2]. Higher training volumes enhance performance and strength, but they also increase injury risk [3]. Most research focuses on male athletes, yet young women exhibit distinct physiological, psychological, and maturational responses affecting training loads [4]. This study aimed to characterize the training model of young female Brazilian table tennis elite players during pre-competition period, and examine associations between external and internal loads, performance, and maturation.

METHODS: Seven female players participated in the study (16.4 ± 1.8 years; 53.2 ± 6.9 kg; 156.1 ± 8.8 cm; 3.0 ± 1.1 maturity offset), all selected to compete in the Brazilian Table Tennis National Youth Team (U15 and U19). The following procedures were performed: 1. anthropometric and maturation assessments [5]; 2. a sport-specific test to obtain performance variables [6]; and 3. completing a questionnaire for monitoring and diagnosing external and internal loads during the training week. Internal load was calculated using the Rate of Perceived Exertion (RPE) scale, which was also used to calculate monotony and strain [7]. Pearson's correlation coefficient was used to analyze associations between external and internal training loads, performance parameters, and maturation indicators. Significance was set at $P < 0.05$. Data are presented in mean $\pm$ SD.

RESULTS: Performance variables were 44.5 ± 4.3 for ball velocity (km/h); 46.6 ± 9.9 for error (%); 24.0 ± 4.4 for consistency (%); 28.8 ± 14.5 accuracy (%); 37.0 ± 10.6 accuracy score and 15.3 ± 4.3 for the performance index. External loads were 18 ± 7 in weekly training volume/h and 5 ± 1.7 in weekly training frequency/days. Internal loads were 4.2 ± 1.2 for average weekly RPE; 5895.5 ± 4397.1 for strain and 1.7 ± 0.4 for monotony. Weekly frequency showed positive product-moment correlations related to consistency (%) ($R = 0.79$, $p = 0.03$); accuracy (%) ($R = 0.76$, $p = 0.04$); accuracy score ($R = 0.80$, $p = 0.03$) and performance index ($R = 0.84$, $p = 0.01$). Moreover, it was inversely related to error (%) ($R = -0.79$, $p = 0.03$). Weekly volume correlated with monotony ($R = 0.77$, $p = 0.04$) and maturation ($R = 0.82$, $p = 0.02$); strain was also related to maturation ($R = 0.78$, $p = 0.03$).

CONCLUSION: Training frequency correlated to performance while volume correlated to monotony, suggesting that more frequent, shorter training may be optimal for this population. Moreover, maturation seemed to be a key factor to monitor, as it correlates with internal and external load parameters. Triangulating monitoring parameters is essential for coaches. Additionally, maturation in young female athletes affects body development and hormonal changes, impacting performance and recovery.

MUSCULAR ENDURANCE AND SPRINT INTERVAL SWIMMING TRAINING ADAPTATIONS FOLLOWING CONCURRENT TRAINING

TOUBEKIS, A., ARSONIADIS, G., BOTONIS, P.

NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS

INTRODUCTION: A session of dryland muscular endurance training (ME) deteriorates sprint interval swimming performance (SIT) [1]. However, applying ME sessions concurrent to SIT for a period of several weeks may facilitate adaptations and reverse the previously induced swimming performance impairment. It remains unclear whether different dryland training characteristics (i.e. ME or maximum strength: MS) concurrent with SIT will induce adaptive responses facilitating acute performance maintenance and long-term performance improvement. The present study examined the effects of different dryland training characteristics on SIT performance before and after a 6-week concurrent ME and SIT training period.

METHODS: Eight competitive swimmers (15.9 ± 2.0 years) participated in concurrent dryland ME training (2 sets x 20 repetitions @55% of one repetition maximum: 1RM) applying three exercises: bench press, seated pulley rowing, and half squat 20 min before SIT (2 sets x 4 x 50 m and 1 x 100 m swimming sprints), three times per week during a 6-week period. Before (T1) and after (T2) the training period all swimmers completed three experimental conditions: i) Muscular endurance (ME, @55% of 1RM), ii) MS, @90% of 1RM, and iii) control (CON, no dryland). Twenty minutes following ME, MS, and CON, swimmers performed a 10 s tethered swimming sprint, 4x50 m and 1x100 m front crawl sprints. Performance time, blood lactate (BL), stroke rate (SR), and stroke length (SL) were measured during 4x50 m and 100 m. Hand grip strength (HG) and shoulder isometric extension (ISO) were measured after each session.

RESULTS: Performance time in 4 x 50 m and 100 m was decreased (indicating improvement) in all conditions at T2 compared to T1 (4x50 m: 2.5-4.1%, 100 m: 4.3-4.4%, $p=0.01$). Performance decrements in the 2nd, 3rd, and 4th repetitions of 4x50 m were similar in all conditions before and after the 6-week training period ($p=0.03$). At T2, ISO was increased in MS and ME conditions compared to CON ($p=0.03$), while TF was increased in all conditions ($p=0.01$). BL was higher in ME session compared to CON in T1 but not in T2 (T1: $5. \pm 3.2$ vs. T2: 4.1 ± 1.9 , $p=0.04$). SR, and SL were similar between conditions before and after the 6-week period.

CONCLUSION: Applying dryland endurance training (ME) concurrent to SIT may improve performance following a 6-week training period. Moreover, ME sessions attenuated metabolic perturbation within a training unit preceding SIT at T2 following six weeks of concurrent ME and SIT training. This may be attributed to specific adaptations occurred over the six-week training period.

TIME-COURSE CHANGES IN CONTRACTILE PROPERTIES OF KNEE EXTENSOR MUSCLES FOLLOWING ECCENTRIC EXERCISE ASSESSED BY TENSIO MYOGRAPHY.

HIRATSUKA, K.1, YOKOZAWA, S.2, HATASHIMA, K.3, KUMAGAWA, D.3, TANAKA, S.3

HACHINOHE GAKUIN UNIVERSITY

INTRODUCTION: Fatigue influences athletic performance and can also increase the risk of injury in sports, and most of the methods to evaluate it require an additional voluntary effort. Recently, tensiomyography (TMG) has received attention as a non-invasive assessment of muscle contractile properties. TMG is independent of motivation or volitional effort. For this reason, TMG has been investigated as a means to assess muscle contractile properties after fatigue. However, previous studies have not clarified the time-course changes in the contractile properties of the knee extensor muscles after eccentric exercise (ECC). Therefore, this study aimed to investigate the early and recovery-phase changes in the contractile properties of the knee extensor muscles following ECC using TMG.

METHODS: Fourteen healthy males (mean $\pm$ standard deviation [SD] age: 21.1 ± 0.8 years; height: 173.1 ± 6.9 cm; weight: 72.1 ± 6.4 kg) participated in this study. Participants performed five sets of 20 maximal eccentric contractions of the knee extensor muscles. The contractile properties of the rectus femoris (RF), vastus medialis (VM), and vastus lateralis (VL) were assessed using TMG. Maximal voluntary isometric contraction (MVC) torque and muscle contractile properties (TMG parameters: maximum displacement [Dm] and velocity of deformation [Vd]) were assessed before, immediately and 1-4 days after exercise.

RESULTS: MVC torque decreased immediately ($-21.4 \pm 9.1\%$, $p < 0.05$) and 1 day ($-19.5 \pm 9.1\%$, $p < 0.05$) after exercise, but returned to baseline at 2-day post-exercise. Dm in RF decreased immediately after exercise and remained lower than the baseline at 1 day ($-21.6 \pm 18.0\%$, $p < 0.05$), 2 day ($-19.2 \pm 9.1\%$, $p < 0.05$), 4 day ($-10.5 \pm 11.3\%$, $p < 0.05$) after exercise. Vd in RF decreased ($p < 0.05$) $-20.3 \pm 13.7\%$ from 211.2 ± 33.7 mm/s (baseline) to 166.6 ± 28.1 mm/s (immediately after exercise) and remained lower than the baseline ($p < 0.05$) for 4 days after exercise. Dm and Vd of VM were significantly decreased 1 day (Dm: $-20.9 \pm 17.5\%$, Vd: $-23.4 \pm 16.7\%$, $p < 0.05$) of after exercise, but returned to baseline 3 days of after exercise. Dm and Vd of VL were significantly decreased immediately (Dm: $-19.5 \pm 15.1\%$, Vd: $-18.0 \pm 15.9\%$, $p < 0.05$), 1 day (Dm: $-22.1 \pm 11.8\%$, Vd: $-24.8 \pm 12.5\%$, $p < 0.05$) and 2 days (Dm: $-12.6 \pm 11.4\%$, Vd: $-14.1 \pm 11.2\%$, $p < 0.05$) after exercise compared to baseline.

CONCLUSION: In conclusion, the TMG parameters of the knee extensor muscle (RF, VM and VL) after eccentric exercise showed different changes over time. These results are particularly important to understand how TMG parameters are modified with the type of muscle and indicate that TMG can be highly sensitive in detecting fatigue-induced changes and its recovery.

CONCURRENT DRYLAND MAXIMUM STRENGTH AND SPRINT SWIMMING TRAINING: ADAPTIVE RESPONSE FOLLOWING A 6-WEEK TRAINING PERIOD

ARSONIADIS, G., TOUBEKIS, A., BOTONIS, P.

NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS

INTRODUCTION: Applying dryland maximum strength training (MS) concurrent to sprint interval swimming training (SIT) is well-accepted by competitive swimmers. It has been seen that a MS followed by SIT order does not acutely impair swimming performance [1]. Moreover, the concurrent application of MS with high-intensity training can enhance swimmers' performance after a period of training [2]. It is unclear whether such improvement in performance, following a period of training, is facilitated by adaptation to a dryland training specific modality. Swimmers are likely getting adapted to the dryland training specific characteristics they regularly apply concurrent to swimming training (i.e. maximum strength or muscular endurance concurrent to SIT). The present study examined the effects of various dryland training characteristics on SIT performance before and after a 6-week concurrent MS and SIT training period.

METHODS: Eight competitive swimmers (17.0 ± 2.6 years) participated in concurrent MS and SIT training consisted of 3 sets x 4 repetitions @90% of one repetition maximum (1RM) applying three exercises: bench press, seated pulley rowing, and half squat 20 min before SIT (2 sets x 4 x 50 m and 1 x 100 m swimming sprints), three times per week during a 6-week period. Before (T1) and after (T2) the training period all swimmers completed three experimental conditions: i) Muscular endurance (ME, @55% of 1RM), ii) MS, @90% of 1RM, and iii) control (CON, no dryland session). Twenty minutes following ME, MS, and CON, swimmers performed a 10 s tethered swimming sprint, 4x50 m and 1x100 m front crawl sprints. Performance time, decrement score (DS), blood lactate (BL), stroke rate (SR), and stroke length (SL) were measured during the 4x50 m and 100 m sprints. Hand grip strength (HG) and shoulder isometric extension (ISO) were measured after each session.

RESULTS: Performance time in 4 x 50 m and DS were similar between ME, MS, and CON ($p=0.68-0.88$) in T1 and T2 ($p=0.07$), whereas performance time improved in the 100 m for all conditions (ME, T1: 72.5 ± 5.6 vs. T2: 70.0 ± 4.7 s; MS, T1: 72.6 ± 6.2 vs. T2: 69.7 ± 4.3 s; CON, T1: 72.2 ± 5.3 vs. T2: 69.2 ± 5.2 s, $p=0.01$). HG and ISO were increased in all conditions after the 6-week period ($p=0.01$). TF increased in all conditions ($p=0.01$), while swimmers managed to increase TF to a higher extent in MS compared to CON ($3.2 \pm 2.4\%$) in T2 compared to T1 ($p=0.01$). BL, SR, and SL were similar between conditions before and after the 6-week period.

CONCLUSION: A concurrent application of MS and SIT may increase specific in-water force. This finding suggests a potential enhancement in muscle activation following MS training relative to the absence of dryland training in the CON condition. Such improvements may be attributed to neuromuscular adaptations induced by the 6-week concurrent training program.

THE EFFECTS OF FATIGUE ON REACTION SPEED IN BASKETBALL: VISUAL STIMULI RESPONSE IN COGNITIVE TESTS OF DIFFERENT COMPLEXITY

OCIC, M., BON, I., DUKARIC, V.

UNIVERSITY OF ZAGREB FACULTY OF KINESIOLOGY

INTRODUCTION: Basketball is a clear example of open skill sport where changes of direction are often performed, and the player is required to continuously respond to various stimuli from the environment. Reactive agility is one of the key factors of a basketball players performance, therefore unhindered scanning of information must be at a high level, considering that the player is simultaneously handling the ball while also moving on the court. The role of cognitive components related to decision-making during the game, which also include visual scanning, anticipation and recognition of certain patterns, is increasing, and nowadays more attention is given in the training process to tasks that require its involvement. To determine player's level of reactive agility, the applied testing protocols must contain some external stimuli that will then "load" the player's visual system and visual scanning abilities in general, as well as anticipation and decision-making abilities. Fatigue, especially as the game progresses, further challenge this process by potentially impairing visual scanning, decision-making, and reaction speed, highlighting the need for training and testing protocols that account for its effects. The main aim of this research is to determine whether a fatigue affects player performance in a reactive agility test at three levels of complexity.

METHODS: The sample of participants consists of Faculty of Kinesiology students who have successfully finished the mandatory course of Basketball. For testing purposes in this research, three variations of a cognitive reaction agility test were performed using Witty SEM system (Microgate). As a fatigue protocol, 300 meters shuttle run test was carried out.

RESULTS: A mixed model ANOVA was performed, and a statistically significant difference was determined between the various levels of test complexity, but there was no statistically significant difference between the test results depending on whether it was conducted under the influence of fatigue ($p > 0.05$). Results indicated that, regardless of whether players were fatigued, in the second and third variation (higher complexity levels) of the test the participants had issues with recognizing the correct stimuli, which in turn resulted in a slower reaction. In the first variation (lower complexity) of the test the results were significantly faster when compared to other two variations ($p < 0.01$).

CONCLUSION: Although no significant differences were found in test results before and after physiological load, indicating that fatigue did not negatively impact players performance, it is essential to emphasize the importance of such assessments in the training process. The development of decision-making ability is crucial for player performance, and incorpo-

rating cognitive tests can provide valuable insights for optimizing training strategies. It is possible that the application of a more specific fatigue protocol would have yielded different results, highlighting the need for further research.
